Flag-transitive 4-\((v, k, 5)\) designs and \(PSL(2, q)\) groups

Huili Dong*

College of Mathematics and Information Science, Henan Normal University, Xinxiang, Henan 453007, P. R. China

Abstract This paper is a contribution to the classification of flag-transitive 4-(\(v, k, \lambda\)) designs. Let \(D\) be a nontrivial 4-(\(q + 1, k, 5\)) design with the automorphism simple group \(G = PSL(2, q)\) acting flag-transitively. Then up to isomorphism \(D\) is a unique 4-(9, 8, 5) design with \(G_B = E_8 \rtimes C_7\) or a unique 4-(24, 8, 5) design with \(G_B = D_8\).

Keywords Design, flag-transitive, projective linear group

MSC(2000) Subject Classification 05B05, 05B25, 20B25

1 Introduction

A \(t-(v, k, \lambda)\) design \(D\) is an incidence structure \((\mathcal{P}, \mathcal{B})\) where \(\mathcal{P}\) is a set of \(v\) points and \(\mathcal{B}\) is a collection of \(b\) distinct \(k\)-subsets of \(\mathcal{P}\) (blocks) such that any \(t\) distinct points of \(\mathcal{P}\) are incident with exactly \(\lambda\) blocks. The design \(D\) is called nontrivial if \(t < k < v\). Two designs \(D_1\) and \(D_2\) are called isomorphism if there exists a bijection from \(D_1\) onto \(D_2\) which maps points onto points and blocks onto blocks preserving the incidence relation.

An automorphism of \(D = (\mathcal{P}, \mathcal{B})\) is a permutation of \(\mathcal{P}\) that also permutes \(\mathcal{B}\) and preserves the incidence relation. An automorphism group \(G\) of a design \(D\) is a group consisting of some automorphisms of \(D\). A flag of \(D\) is an incident pair \((\alpha, B)\) with \(\alpha \in B\). We call a design \(D\) point-primitive if \(G\) acts primitively on \(\mathcal{P}\), block-transitive if it acts transitively on \(\mathcal{B}\), flag-transitive if it acts transitively on the set of flags. Let \(G_B\) be the setwise stabilizer of a block \(B \in \mathcal{B}\). It is easily known that \(G\) acts flag-transitively on \(D\) if and only if \(G\) acts block-transitively on \(D\) and \(G_B\) acts transitively on \(B\).

The simple group $PSL(2, q)$ as an automorphism group of a design is of interest. For flag-transitive 2-designs, many results have been got. In 1986, Delandtsheer\[1\] classified finite linear spaces. In 2016, Alavi, Bayat and Daneshkhah\[2\] gave a complete classification of symmetric designs with the socle of the automorphism group is two dimensional special projective linear groups. In 2018, Zhan and Zhou\[3\] determined all nonsymmetric designs with $(v, \lambda) = 1$. In 2019, Zhan, Ding and Bai\[4\] gave a classification of flag-transitive 2-$(v, 4, \lambda)$ designs. For 3-designs, there are also many results given in[5, 6, 7, 8]. After Dai and Li\[9, 10\] classified flag-transitive 4-designs with $\lambda = 3$ or 4, we continue this work, and get the following results:

**Theorem 1.1.** Let $G = PSL(2, q)$ be a simple group acting flag-transitively on a nontrivial 4-$(q+1, k, 5)$ design $D$. Then up to isomorphism $D$ is a unique 4-$(9, 8, 5)$ design with $G_B = E_8 \rtimes C_7$ or a unique 4-$(24, 8, 5)$ design with $G_B = D_8$.

2 Preliminaries

The following lemmas are about the subgroups of $PSL(2, q)$, which are listed in [11, 12], where $N_l$ denotes the number of orbits of length $l$.

**Lemma 2.1.** Let $U$ be the cyclic group of order $c$ with $c \mid \frac{q+1}{n}$. Then
(i) if $c \mid \frac{q+1}{n}$, then $N_c = \frac{q+1}{c}$;
(ii) if $c \mid \frac{q-1}{n}$, then $N_1 = 2$, $N_c = \frac{q-1}{c}$.

**Lemma 2.2.** Let $U$ be the dihedral group of order $2c$ with $c \mid \frac{q+1}{n}$. Then
(i) for $q \equiv 1 \pmod{4}$, we have
(a) if $c \mid \frac{q+1}{2}$, then $N_c = 2$, and $N_{2c} = \frac{q+1-2c}{2c}$;
(b) if $c \mid \frac{q-1}{2}$, then $N_2 = 1$, $N_c = 2$, and $N_{2c} = \frac{q-1-2c}{2c}$, unless $c = 2$,

(ii) for $q \equiv 3 \pmod{4}$, we have
(a) if $c \mid \frac{q+1}{2}$, then $N_{2c} = \frac{q+1}{2c}$;
(b) if $c \mid \frac{q-1}{2}$, then $N_2 = 1$, $N_{2c} = \frac{q-1}{2c}$.

(iii) for $q \equiv 0 \pmod{2}$, we have
(a) if $c \mid (q+1)$, then $N_c = 1$, $N_{2c} = \frac{q+1-2c}{2c}$;
(b) if $c \mid (q-1)$, then $N_2 = 1$, $N_c = 1$, and $N_{2c} = \frac{q-1-c}{2c}$.

**Lemma 2.3.** Let $U$ be the elementary Abelian group of order $q_0 \mid q$. Then $N_1 = 1$, $N_{q_0} = \frac{q}{q_0}$.

**Lemma 2.4.** Let $U$ be a semi-direct product of the elementary Abelian subgroup of order $q_0 \mid q$ and the cyclic subgroup of order $c$, where $c \mid (q_0-1)$ and $c \mid (q-1)$. Then $N_1 = 1$, $N_{q_0} = 1$, $N_{c_{q_0}} = \frac{q-1}{c_{q_0}}$. 
Lemma 2.5. Let $U$ be $\text{PSL}(2,q_0)$ and $q_0^m = q$, $m \geq 1$. Then $N_{q_0+1} = 1$, $N_{q_0(q_0-1)} = 1$ if $m$ is even, and all other orbits are regular.

Lemma 2.6. Let $U$ be $\text{PGL}(2,q_0)$ and $q_0^m = q$, $m > 1$ even. Then $N_{q_0+1} = 1$, $N_{q_0(q_0-1)} = 1$, and all other orbits are regular.

Lemma 2.7. Let $U$ be isomorphic to $A_4$. Then

(i) for $q \equiv 1(\mod 4)$, we have
   (a) if $3 \mid \frac{q+1}{2}$, then $N_6 = 1$ and $N_{12} = \frac{q-5}{12}$;
   (b) if $3 \mid \frac{q-1}{2}$, then $N_4 = 2$, $N_6 = 1$, and $N_{12} = \frac{q-13}{12}$;
   (c) if $3 \mid q$, then $N_4 = 1$, $N_6 = 1$, and $N_{12} = \frac{q-9}{12}$.

(ii) for $q \equiv 3(\mod 4)$, we have
   (a) if $3 \mid \frac{q+1}{2}$, then $N_{12} = \frac{q+1}{12}$;
   (b) if $3 \mid \frac{q-1}{2}$, then $N_4 = 2$ and $N_{12} = \frac{q-7}{12}$;
   (c) if $3 \mid q$, then $N_4 = 1$ and $N_{12} = \frac{q-3}{12}$.

(iii) for $q = 2^f$, $f \equiv 0(\mod 2)$, then $N_1 = 1$, $N_4 = 1$, and $N_{12} = \frac{q-4}{12}$.

Lemma 2.8. Let $U$ be isomorphic to $S_4$. Then

(i) for $q \equiv 1(\mod 8)$, we have
   (a) if $3 \mid \frac{q+1}{2}$, then $N_6 = 1$, $N_{12} = 1$, and $N_{24} = \frac{q-17}{24}$;
   (b) if $3 \mid \frac{q-1}{2}$, then $N_6 = 1$, $N_8 = 1$, $N_{12} = 1$, and $N_{24} = \frac{q-25}{24}$;
   (c) if $3 \mid q$, then $N_4 = 1$, $N_6 = 1$, and $N_{24} = \frac{q-9}{24}$.

(ii) for $q \equiv -1(\mod 8)$, we have
   (a) if $3 \mid \frac{q+1}{2}$, then $N_{24} = \frac{q+1}{24}$;
   (b) if $3 \mid \frac{q-1}{2}$, then $N_8 = 1$ and $N_{24} = \frac{q-7}{24}$.

Lemma 2.9. Let $U$ be isomorphic to $A_5$. Then

(i) for $q \equiv 1(\mod 4)$, we have
   (a) if $q = 5^f$, $f \equiv 1(\mod 2)$, then $N_6 = 1$ and $N_{60} = \frac{q-5}{60}$;
   (b) if $q = 5^f$, $f \equiv 0(\mod 2)$, then $N_6 = 1$, $N_{20} = 1$, and $N_{60} = \frac{q-25}{60}$;
   (c) if $15 \mid \frac{q+1}{2}$, then $N_{30} = 1$ and $N_{60} = \frac{q-29}{60}$;
   (d) if $3 \mid \frac{q+1}{2}$ and $5 \mid \frac{q-1}{2}$, then $N_{12} = 1$, $N_{30} = 1$, and $N_{60} = \frac{q-41}{60}$;
   (e) if $3 \mid \frac{q-1}{2}$ and $5 \mid \frac{q+1}{2}$, then $N_{20} = 1$, $N_{30} = 1$, and $N_{60} = \frac{q-49}{60}$;
   (f) if $15 \mid \frac{q+1}{2}$, then $N_{12} = 1$, $N_{20} = 1$, $N_{30} = 1$, and $N_{60} = \frac{q-61}{60}$;
   (g) if $3 \mid q$ and $5 \mid \frac{q+1}{2}$, then $N_{10} = 1$ and $N_{60} = \frac{q-9}{60}$;
   (h) if $3 \mid q$ and $5 \mid \frac{q-1}{2}$, then $N_{10} = 1$, $N_{12} = 1$, and $N_{60} = \frac{q-21}{60}$.

(ii) for $q \equiv 3(\mod 4)$, we have
   (a) if $15 \mid \frac{q+1}{2}$, then $N_{60} = \frac{q+1}{60}$;
   (b) if $3 \mid \frac{q+1}{2}$ and $5 \mid \frac{q-1}{2}$, then $N_{12} = 1$ and $N_{60} = \frac{q-11}{60}$;
   (c) if $3 \mid \frac{q-1}{2}$ and $5 \mid \frac{q+1}{2}$, then $N_{20} = 1$ and $N_{60} = \frac{q-19}{60}$;
   (d) if $15 \mid \frac{q-1}{2}$, then $N_{12} = 1$, $N_{20} = 1$, and $N_{60} = \frac{q-31}{60}$.
Next we give some useful results. The notations $n$ and $G_{xB}$ denote $\gcd(2,q-1)$ and $G_x \cap G_B$ respectively, where $x \in B$.

**Lemma 2.10.** Let $\mathcal{D}$ be a 4-$(q+1,k,5)$ design, $G = PSL(2,q)$ be a flag-transitive automorphism group of $\mathcal{D}$. Then

(i) $k \mid (5n(q-2)|G_{xB}|+6);$  
(ii) $q = \frac{(k-1)(k-2)(k-3)}{5n(G_{xB})} + 2;$  
(iii) $k \mid \gcd(\frac{4i^2-1}{n},5n(q-2)|G_{xB}|+6).$

**Proof.** Since $G$ acts flag-transitively, then by [13] $G$ is also 2-transitive, therefore, $G$ is point-primitive. Thus $|G| = |G_{xB}|[(x,B)]^G = |G_{xB}|bk.$ And by [14], $b = \frac{\lambda(n-1)(n-2)(n-3)}{n[n(n-1)](k-2)(k-3)},$ we get $b = \frac{|G|}{|G_{xB}|} = \frac{4i^2-1}{n[G_{xB}]}. Then 5n(q-2)|G_{xB}| = (k-1)(k-2)(k-3) = k(k^2 - 6k + 11) - 6$. Obviously (i) and (ii) hold. Note that $k \mid |G_B|$ and $|G_{xB}| \mid |G|$, (iii) holds.

## 3 Proof of Theorem 1.1

In this section, we assume that $\mathcal{D}$ is a nontrivial flag-transitive 4-$(q+1,k,5)$ design, $G = PSL(2,q)$ is an automorphism group of $\mathcal{D}$, where $q = p^f \geq 4$ and $p$ is a prime. Since the design is nontrivial, we always assume that $4 < k < q + 1$.

**Lemma 3.1.** Assume that $|G_{xB}| > 2$, then $(k,|G_{xB}|,q) = (8,7,8)$ or (13,12,13).

**Proof.** Let $|G_{xB}| > 2$, then $k = \frac{|G_B|}{|G_{xB}|} < \frac{|G_B|}{2}$. Examining the list of subgroups of $PSL(2,q)$ with their orbits on the projective line by Lemmas 2.1-2.9, we have to consider the following cases:

Let $G_B$ be conjugate to a semi-direct product of the elementary Abelian subgroup of order $q_0 \mid q$ and the cyclic subgroup of order $c$, where $c \mid (q_0-1)$ and $c \mid (q-1)$. Then $k = q_0$ and $|G_{xB}| = \frac{|G_B|}{c} = c.$ Since $k \mid q$, by Lemma 2.10(i), $k \mid \gcd(5n(q-2)|G_{xB}|+6,q),$ that is, $k \mid \gcd(5nq|G_{xB}|+6,q).$ Thus, $k \leq 10n|G_{xB}| - 6$, therefore, $\frac{k-1}{10n} < \frac{k+6}{10n} \leq |G_{xB}|.$ From $|G_{xB}|$ | (k-1), we let $|G_{xB}| = \frac{k-1}{i}$, where $i = 1, 2, \cdots, 10n-1$. Then from $k \mid (\frac{10n(k-1)}{i} - 6)$, we get $k \mid (10n + 6i).$ Note that $k$ is a prime power and $k > \max(4,2i+1)$, for every value of $i$, we get possible parameters of $(n,i,k)$ are (1,1,8), (1,1,16), (1,9,32), (1,9,64), (2,1,13), (2,3,19), (2,4,11), (2,5,25), (2,7,31), (2,9,37), (2,11,43), (2,13,49), (2,17,61) or (2,19,67). Now from Lemma 2.10(ii) $q = \frac{(k-1)(k-2)(k-3)}{5n(G_{xB})} + 2$, we get $(i,k,|G_{xB}|,q) = (1,8,7,8)$ or (1,13,12,13).
Let $G_B$ be conjugate to $PSL(2,q_0)$ and $q_0^m = q$, $m \geq 1$. Then $k = q_0 + 1$ or $q_0(q_0 - 1)$ if $m$ is even. If $k = q_0 + 1$, then $|G_{xB}| = \frac{q_0(q_0-1)}{2}$. By Lemma 2.10(ii), we get $q_0^m - 2 = \frac{q_0-2}{5}$. However, there is no such $q_0 > 3$ satisfying the equation. If $k = q_0(q_0 - 1)$, then $|G_{xB}| = \frac{q_0+1}{2}$. By Lemma 2.10(i) $k \mid (5(q_0+1)(q_0^m - 2) + 6)$, that is, $q_0(q_0 - 1) \mid (5q_0(q_0^m - 1) + 5q_0(q_0^{m-1} - 1) - 4)$. Thus, $k \mid 4$, a contradiction.

Let $G_B$ be conjugate to $PGL(2,q_0)$ and $q_0^m = q$, $m > 1$ even. Then $k = q_0 + 1$ or $q_0(q_0 - 1)$. If $k = q_0 + 1$, then $|G_{xB}| = q_0^2(q_0 - 1)$ and $q_0^m - 2 = \frac{q_0-2}{5n}$. However, this is impossible. If $k = q_0(q_0 - 1)$, then $|G_{xB}| = q_0 + 1$ and $k \mid (5n(q_0 + 1)(q_0^m - 2) + 6)$, that is, $q_0(q_0 - 1) \mid (5nq_0(q_0^m - 1) + 5nq_0(q_0^{m-1} - 1) - 10n + 6)$. Thus $k \mid (10n - 6)$. However, this is also impossible.

Let $G_B$ be conjugate to $S_4$. Then $k = 6$ or 8. If $k = 6$, then $q - 2 = \frac{3}{n}$. We get $(n,q) = (1,5)$. However, this is contrary with $q \equiv 1 \pmod{8}$. If $k = 8$, then $q - 2 = \frac{14}{n}$. We get $(n,q) = (1,16), (2,9)$. However, this is contrary with $3 \mid 2^n - 1$.

Let $G_B$ be conjugate to $A_5$. Then $k = 6, 10, 12$ or 20. By Lemma 2.10(ii), $5n(q - 2)|G_{xB}| = (k - 1)(k - 2)(k - 3)$, this is impossible.

**Lemma 3.2.** Assume that $|G_{xB}| \leq 2$, then $(k, |G_{xB}|, q) = (8, 1, 23)$ or $(12, 1, 101)$.

**Proof.** Assume that $|G_{xB}| \leq 2$. By Lemma 2.1(iii) $k \mid gcd(q(q^2 - 1), 5n(q - 2)|G_{xB}| + 6)$.

Assume that $|G_{xB}| = 1$. If $q$ is even, then $k \mid gcd(q(q^2 - 1), 5q - 4)$, we get $k \mid 36$. Thus $k = 6, 9, 12, 18$ or 36. However, there is no even prime power $q$ satisfying $q = \frac{(k - 1)(k - 2)(k - 3)}{10} + 2$. If $q$ is odd, then $k \mid gcd(q(q^2 - 1), 10q - 14)$, we get $k \mid 2^3 \cdot 3 \cdot 7$. The values of $(k,q)$ satisfying $q = \frac{(k - 1)(k - 2)(k - 3)}{10} + 2$ are $(8, 23)$ or $(12, 101)$. By Lemmas 2.1-2.9, $G_B$ is conjugate to the dihedral group $D_8$ or $A_4$ respectively.

Assume that $|G_{xB}| = 2$. If $q$ is even, then $k \mid gcd(q(q^2 - 1), 10q - 14)$, therefore, $k \mid 6$. Thus $(k,q, |G_{xB}|) = (6,8,12)$. Then by Lemmas 2.1-2.9, this is impossible. If $q$ is odd, then $k \mid gcd(\frac{2(q^2 - 1)}{2}, 20q - 34)$, therefore, $k \mid 2 \cdot 7 \cdot 17 \cdot 27$. However, there is no odd prime power satisfying $q = \frac{(k - 1)(k - 2)(k - 3)}{10} + 2$.

**Lemma 3.3.** Up to isomorphism $D$ is a unique 4-(9,8,5) design with $G_B = E_8 \times C_7$ or a unique 4-(24,8,5) design with $G_B = D_8$.

**Proof.** Assume that $(k, |G_{xB}|, q) = (8, 7, 8)$, then by Lemma 3.1, $G_B$ is conjugate to a semi-direct product of the elementary Abelian subgroup of order 8 and the cyclic subgroup of order 7, denoted by $E_8 \times C_7$. 

5
Using the computer algebra system MAGMA\textsuperscript{13}, the command PrimitiveGroup(9,8) leads to the primitive permutation representation of the group $G = PSL(2,8)$ acting on the set $\Omega = \{1,2,\ldots,9\}$. The command Generators(G) returns the generators of the group $G$ as follows: $g_1 = (1,2,3,4,5,6,7)$, $g_2 = (1,8)(2,4)(3,7)(5,6)$, $g_3 = (2,7)(3,6)(4,5)(8,9)$. By employing the command Subgroups(G:OrderEqual:=56), we have that $G$ has only one conjugacy class of subgroups of order 56, denoted by $L$ as a representative. The command Orbits(L) shows that the two orbit of $L$ acting on the set $\Omega$ are $\Omega_1 = \{8\}$ and $\Omega_2 = \{1,2,3,4,5,6,7,9\}$. Note that $k$ is one orbit length of $L$. Take $B = \Omega_2$ as a possible basic block of a design. The command Design<4,9|B> where $D = B^G$ returns a 4-(9,8,5) design $D_1$. Clearly, $D_1$ is also flag-transitive.

Now we deal with the remaining three parameters. First we rule out $(k,|G_x:B|,q) = (13,12,13)$ or $(12,1,101)$. For the former, using the MAGMA command, we easily get that the primitive permutation representation of the group $G = PSL(2,13)$ acting on the set $\Omega = \{1,2,\ldots,14\}$ and $G$ has no conjugacy class of subgroups of order 156. For the latter, $G$ has only one conjugacy classes of subgroups of order 12 and the possible lengths of all orbits of $G_B$ acting on $\Omega$ are 6 and $12^3$, where the notation $a^b$ means that the degree $a$ appears $b$ times. There are 8 possible basic blocks $B_0$ of designs. However, these structures are not 4-design.

Now we consider $(k,|G_x:B|,q) = (8,1,23)$. By Lemma 3.2, $G_B$ is conjugate to the dihedral group $D_8$. The command PrimitiveGroup(24,1) returns the primitive permutation representation of the group $G$ acting on the set $\Omega = \{1,2,\ldots,24\}$. The generators of the group $G$ are listed as follows:

$g_1 = (1,8)(2,10)(3,16)(4,24)(5,15)(6,21)(7,23)(9,20)(11,22)(12,14)(13,18)(17,19)$,

$g_2 = (1,19,24,6)(2,13,22,20)(3,12,23,5)(4,17,8,21)(7,14,16,15)(9,11,18,10)$,

The same as before, $G$ has only one conjugacy class of subgroups of order 8 and all the orbits of $G_B$ acting on the set $\Omega$ are listed as follows:

$\Omega_1 = \{1,4,6,8,17,19,21,24\}$,

$\Omega_2 = \{2,9,10,11,13,18,20,22\}$,

$\Omega_3 = \{3,5,7,12,14,15,16,23\}$.

First take $B_0 = \Omega_1$ as a possible basic block of a design. However, the structure is not 4-design. Now take $B_0 = \Omega_2$ or $\Omega_3$ as a possible basic block of a design, then we construct two flag-transitive 4-(24,8,5) design $D_1$ and $D_2$. By\textsuperscript{16}, the GAP-command IsIsomorphicBlockDesign($D_1$, $D_2$) shows that both designs are isomorphic.

This completes the proof of Theorem 1.1.
