The parity-preserving $U_A(1) \times U_a(1)$ massive QED$_3$ is ultraviolet finiteness – exhibits vanishing β-functions, associated to the gauge coupling constants (electric and chiral charges) and the Chern-Simons mass parameter, and all the anomalous dimensions of the fields – as well as is parity and gauge anomaly free at all orders in perturbation theory. The proof is independent of any regularization scheme and it is based on the quantum action principle in combination with general theorems of perturbative quantum field theory by adopting the Becchi-Rouet-Stora algebraic renormalization method.

I. INTRODUCTION

The quantum electrodynamics in three space-time dimensions (QED$_3$) has attracted attention since the seminal works by Deser, Jackiw, Templeton and Schonfeld [1] in view of a possible theoretical foundation for condensed matter phenomena, such as high-$T_c$ superconductivity, quantum Hall effect and, more recently, graphene and topological insulators. The massive and the massless QED$_3$ can exhibit interesting and subtle properties, namely superrenormalizability, parity violation, topological gauge fields, anyons and the presence of infrared divergences. Since then, the planar quantum electrodynamics has been widely studied in many physical configurations, namely, small (perturbative) and large (non perturbative) gauge transformations, Abelian and non-Abelian gauge groups, fermions families, odd and even under parity, compact space-times, space-times with boundaries, curved space-times, discrete (lattice) space-times, external fields and finite temperatures.

The massless $U(1)$ QED$_3$ is ultraviolet and infrared perturbatively finite, infrared and parity anomaly free at all orders [2], despite some statements found out in the literature that still support that parity could be broken even perturbatively, called parity anomaly, which has already been discarded [2, 3]. The massive $U(1)$ QED$_3$ can be odd (odd fermion families number) or even (even fermion families number) under parity symmetry. The parity-even massive $U(1)$ QED$_3$ exhibits vanishing gauge coupling β-function, vanishing anomalous dimensions of all the fields, and besides that, is infrared and parity anomaly free at all orders in perturbation theory [4].

The proposed issue is to show that the parity-even $U_A(1) \times U_a(1)$ massive QED$_3$ [5] exhibits ultraviolet finiteness – vanishing β-functions of both gauge couplings and anomalous dimensions of all the fields – and is parity anomaly free at all orders in perturbation theory. The proof is done by using the BRS (Becchi-Rouet-Stora) algebraic renormalization method in the framework of Bogoliubov-Parasiuk-Hepp-Zimmermann (BPHZ) subtraction scheme, which is based on general theorems of perturbative quantum field theory [6–10], thus independent of any regularization scheme. Accordingly, the action of the model and its symmetries, the gauge-fixing and the antifields action are established in Section II. The issue of the extension of parity-even $U_A(1) \times U_a(1)$ massive QED$_3$ in the tree-approximation to all orders in perturbation theory – its perturbative quantization – is organized according to two independent parts. First, in Section III, it is analysed the stability of the classical action – for the quantum theory, the stability corresponds to the fact that the radiative corrections can be reabsorbed by a redefinition of the initial parameters of the theory. Second, in Section IV, it is computed all possible anomalies through an analysis of the Wess-Zumino consistency condition, furthermore, it is checked if the possible breakings induced by radiative corrections can be fine-tuned by a suitable choice of local non-invariant counterterms. Section V is left to the final comments and conclusions.

II. THE MODEL AND ITS SYMMETRIES

The $U_A(1) \times U_u(1)$ gauge invariant action for the parity-preserving massive QED$_3$ (the mass-gap graphene-like planar quantum electrodynamics [5]) is:

$$\Sigma_{\text{inv}} = \int d^3x \left\{ -\frac{1}{4} F_{\mu \nu}^a F_{\mu \nu} + \frac{1}{4} f_{\mu \nu}^{\pm} f_{\mu \nu}^{\pm} + \mu \epsilon^{\mu \nu \rho} A_\mu \partial_\rho a_\nu + i \bar{\psi}_- D \psi_+ + i \bar{\psi}_+ D \psi_- - m (\bar{\psi}_+ \psi_- - \bar{\psi}_- \psi_+) \right\},$$

(1)

where $D \psi_{\pm} = (\partial + i e A) \psi_{\pm}$, the coupling constants $e$ (electric charge) and $g$ (chiral charge) are dimensionful with mass dimension $\frac{1}{2}$, and, $m$ and $\mu$ are mass parameters with mass dimension 1. The field strengths, $F_{\mu \nu} = \partial_{\mu} A_{\nu} - \partial_{\nu} A_{\mu}$ and $f_{\mu \nu}^{\pm} = \partial_{\mu} a_{\nu} - \partial_{\nu} a_{\mu}$, are the associated to the electromagnetic field ($A_\mu$) and the chiral gauge field ($a_\mu$), respectively. The Dirac spinors $\psi_+$ and $\psi_-$ are two kinds of fermions where the ± subscripts are related to their spin sign [11], and the gamma matrices are $\gamma^\mu = (\sigma_z, -i\sigma_x, i\sigma_y)$.

The action (1) was built up assuming invariance under parity, fixed posteriorly, and the gauge-invariant ghosts (a parity-even gauge-fixing action has been added. However, in order to follow the BRS procedure [7], two sorts of transformations as follows:

$$\delta \psi_+ (x) = i [\theta (x) + \omega (x)] \psi_+ (x), \quad \delta \psi_- (x) = i [\theta (x) - \omega (x)] \psi_- (x),$$

$$\delta \bar{\psi}_+ (x) = -i [\theta (x) + \omega (x)] \bar{\psi}_+ (x), \quad \delta \bar{\psi}_- (x) = -i [\theta (x) - \omega (x)] \bar{\psi}_- (x),$$

$$\delta A_\mu (x) = -\frac{1}{e} \partial_\mu \theta (x), \quad \delta a_\mu (x) = \left(-\frac{1}{g} \partial_\mu \omega (x)\right),$$

(2)

from which the BRS field transformations shall be defined. In view of a forthcoming quantization of the model (1), a parity-even gauge-fixing action has been added. However, in order to follow the BRS procedure [7], two sorts of ghosts ($c$ and $\xi$), antighosts ($\bar{c}$ and $\bar{\xi}$) and Lautrup-Nakanishi fields ($b$ and $\pi$) [12], the latter ($b$ and $\pi$) playing the role of the Lagrange multiplier fields for the gauge condition, have to be introduced. The gauge-fixing action, presented bellow, belongs to the class of linear covariant gauges discussed by ’t Hooft [13]:

$$\Sigma_{\text{gf}} = \int d^3x \left\{ b \epsilon^{\mu \nu} A_\mu + \frac{\alpha}{2} b^2 + \bar{c} \square c + \pi \partial^\mu a_\mu + \frac{\beta}{2} \pi^2 + \bar{\xi} \square \xi \right\}.$$

(3)

Hereafter, the BRS transformations of the quantum fields are now defined by:

$$s \psi_+ = i (c + \xi) \psi_+, \quad s \bar{\psi}_+ = -i (c + \xi) \bar{\psi}_+;$$

$$s \psi_- = i (c - \xi) \psi_-, \quad s \bar{\psi}_- = -i (c - \xi) \bar{\psi}_-;$$

$$s A_\mu = -\frac{1}{e} \partial_\mu c, \quad s c = 0; \quad s a_\mu = -\frac{1}{g} \partial_\mu \xi, \quad s \xi = 0;$$

$$s \bar{c} = \frac{b}{e}, \quad s b = 0; \quad s \bar{\xi} = \frac{\pi}{g}, \quad s \pi = 0.$$  

(4)

Together with the parity-even action term, $\Sigma_{\text{inv}} + \Sigma_{\text{gf}}$, another parity-even action, $\Sigma_{\text{ext}}$, is introduced. There, the nonlinear BRS transformations are coupled to the antifields (BRS invariant external fields) in order to control at the quantum level the renormalization of those transformations:

$$\Sigma_{\text{ext}} = \int d^3x \left\{ i \bar{c}_+ c_+ \psi_+ - i \bar{c}_- c_- \psi_- + i c_+ \bar{\psi}_+ \Omega_+ - i c_- \bar{\psi}_- \Omega_- \right\},$$

(5)

where $c_+ = c + \xi$ and $c_- = c - \xi$. It should be pointed out that in spite of the Faddeev-Popov ghosts be massless, consequently serious infrared divergences could be stemmed from radiative corrections, they are free fields, they decouple, thus no Lowenstein-Zimmermann mass term [10] has to be introduced for them. Now, the complete classical action to be perturbatively quantized reads

$$\Gamma^{(0)} = \Sigma_{\text{inv}} + \Sigma_{\text{gf}} + \Sigma_{\text{ext}}.$$  

(6)

The propagators are the key ingredient on spectral consistency and unitarity analyses at tree-level of the model$^1$, as well as in the determination of ultraviolet and infrared dimensions of the fields. The tree-level propagators can be

---

$^1$ The issues about unitarity, spectral consistency and two-particle scattering potentials have been discussed in [14].
Finally, from the action of the antifields (\(\Sigma_{\text{fixed}}\)) it follows that:

\[\Delta_{\phi\psi}^+(k) = i \frac{k - m}{k^2 - m^2}, \quad \Delta_{\phi\psi}^-(k) = i \frac{k + m}{k^2 - m^2},\]  
\[\Delta_{\alpha\alpha}^{\alpha\alpha}(k) = -i \left\{ \frac{1}{k^2 - \mu^2} \left( \eta^{\alpha\alpha} - \frac{k^{\alpha} k^{\alpha}}{k^2} \right) + \frac{\alpha}{k^2} \frac{k^{\alpha} k^{\alpha}}{k^2} \right\},\]  
\[\Delta_{\alpha\alpha}(k) = \Delta_{\alpha\alpha}(k) = \frac{k^{\alpha}}{k^2},\]  
\[\Delta_{\pi\pi}(k) = \Delta_{\pi\pi}(k) = -i \frac{1}{k^2},\]  
\[\Delta_{bb}(k) = \Delta_{bb}(k) = 0 .\]

Additionally, in order to establish the ultraviolet (UV) and infrared (IR) dimensions of any fields, \(X\) and \(Y\), the UV and IR asymptotical behaviour of their propagator \(\Delta_{XY}(k)\), \(d_{XY}\) and \(r_{XY}\), respectively, are written as:

\[d_{XY} = \overline{\text{deg}_k} \Delta_{XY}(k) \quad \text{and} \quad r_{XY} = \text{deg}_k \Delta_{XY}(k),\]

where the upper degree \(\overline{\text{deg}_k}\) gives the asymptotic power for \(k \to \infty\) whereas the lower degree \(\text{deg}_k\) gives the asymptotic power for \(k \to 0\). The UV \((d)\) and IR \((r)\) dimensions of the fields, \(X\) and \(Y\), are chosen to fulfill the following inequalities:

\[d_X + d_Y \geq 3 + d_{XY} \quad \text{and} \quad r_X + r_Y \leq 3 + r_{XY} .\]

At this moment, it shall be called into attention that the non decoupled propagators \((7)–(9)\) carrying physical degrees of freedom are all massive, so there were no infrared divergences that would arisen during the ultraviolet subtractions in BPHZ method.

In order to fix the UV dimensions of the spinor fields, \(\psi^+\) and \(\psi^-\), and the vector fields, \(A_\mu\) and \(a_\mu\), use has been made of the propagators \((7)–(9)\) together with the conditions \((15)\), that results:

\[d_{++} = -1 \Rightarrow 2d_+ \geq 2 \Rightarrow d_+ = 1 ; \quad d_{--} = -1 \Rightarrow 2d_- \geq 2 \Rightarrow d_- = 1 ;\]  
\[d_{AA} = -2 \Rightarrow 2d_A \geq 1 \Rightarrow d_A = \frac{1}{2} ; \quad d_{aa} = -2 \Rightarrow 2d_a \geq 1 \Rightarrow d_a = \frac{1}{2} .\]

From the propagators \((11)\) and the conditions \((15)\) and \((17)\), the UV dimensions of the Lautrup-Nakanishi fields, \(b\) and \(\pi\), can be fixed as:

\[d_{bb} = -1 \Rightarrow d_B + d_b \geq 2 \Rightarrow d_b = \frac{3}{2} ; \quad d_{\pi\pi} = -1 \Rightarrow d_\pi + d_\pi \geq 2 \Rightarrow d_\pi = \frac{3}{2} .\]

By considering the propagators \((12)\), the UV dimensions of the Faddeev-Popov ghosts, \(c\) and \(\xi\), and antighosts, \(\bar{\tau}\) and \(\bar{\xi}\), are constrained by:

\[d_{cc} = -2 \Rightarrow d_c + d_c \geq 1 ; \quad d_{\bar{\xi}\xi} = -2 \Rightarrow d_\xi + d_\xi \geq 1 .\]

Furthermore, assuming that the BRS operator \((s)\) is dimensionless and knowing that the coupling constants \(e\) and \(g\) have mass dimension \(\frac{1}{2}\), from the conditions \((19)\), the UV dimensions of the Faddeev-Popov ghosts and antighosts result:

\[d_c = 0 \quad \text{and} \quad d_\xi = 1 ; \quad d_\xi = 0 \quad \text{and} \quad d_\xi = 1 .\]

Finally, from the action of the antifields \((\Sigma_{\text{ext}})\) together with the UV dimensions of all the quantum fields previously fixed, it follows that:

\[d_{\Omega_+} = 2 \quad \text{and} \quad d_{\Omega_-} = 2 .\]
TABLE I: The UV dimension \(d\), ghost number (\(\Phi\)) and Grassmann parity (\(GP\)).

Briefly, the UV dimension \(d\), the ghost number (\(\Phi\)) and the Grassmann parity (\(GP\)) of all the fields are gathered in Table I. The statistics is defined in such a way that, the half integer spin fields with even ghost number, as well as, the integer spin fields with odd ghost number anticommute among themselves. Meanwhile, the other fields commute with the formers and also among themselves.

The BRS invariance of the action \(\Gamma^{(0)}\) (6) is expressed in a functional way by the Slavnov-Taylor identity

\[
S(\Gamma^{(0)}) = 0 , \tag{22}
\]

where the Slavnov-Taylor operator \(S\) is defined, acting on an arbitrary functional \(F\), by

\[
S(F) = \int d^3x \left\{ -\frac{1}{e} \frac{\partial \mu c}{\partial A^\mu} - \frac{1}{g} \frac{\partial \mu \xi}{\partial \psi} + \frac{\pi \delta \psi}{\partial \Omega^+} + \frac{\delta \psi}{\partial \psi^+} - \frac{\delta \psi}{\partial \psi^-} + \frac{\delta \psi}{\partial \Omega^-} \right\} . \tag{23}
\]

and the corresponding linearized Slavnov-Taylor operator is written as

\[
S_F = \int d^3x \left\{ -\frac{1}{e} \frac{\partial \mu c}{\partial A^\mu} + \frac{\delta \psi}{\partial \psi^+} - \frac{\delta \psi}{\partial \psi^-} + \frac{\delta \psi}{\partial \Omega^-} \right\} . \tag{24}
\]

Thenceforward, the following nilpotency identities hold:

\[
S_F S(F) = 0 , \quad \forall F , \tag{25}
\]

\[
S_F S_F = 0 \quad \text{if} \quad S(F) = 0 . \tag{26}
\]

In particular, the linearized Slavnov-Taylor operator \(S_{\Gamma^{(0)}}\) is nilpotent, namely \(S_{\Gamma^{(0)}}^2 = 0\), due to the fact that the action \(\Gamma^{(0)}\) (6) obeys the Slavnov-Taylor identity (22). Moreover, the operation of \(S_{\Gamma^{(0)}}\) upon the fields and the external sources (antifields) is given by

\[
S_{\Gamma^{(0)}}(\phi) = s\phi , \quad \phi = \{ \psi^+, \psi^-, \bar{\psi}^+, \bar{\psi}^-, A_\mu , a_\mu , b, c, \pi , \xi \} ; \quad S_{\Gamma^{(0)}}(A^\mu) = \frac{\delta \Gamma^{(0)}}{\delta A^\mu} , \quad S_{\Gamma^{(0)}}(\Omega^\mu) = \frac{\delta \Gamma^{(0)}}{\delta \Omega^\mu} , \quad S_{\Gamma^{(0)}}(\Omega^\pm) = - \frac{\delta \Gamma^{(0)}}{\delta \psi^\pm} , \quad S_{\Gamma^{(0)}}(\bar{\psi}^\pm) = - \frac{\delta \Gamma^{(0)}}{\delta \bar{\psi}^\pm} . \tag{27}
\]

In addition to the Slavnov-Taylor identity (22), the classical action \(\Gamma^{(0)}\) satisfies the following gauge conditions, antighost equations and ghost equations:

\[
\frac{\delta \Gamma^{(0)}}{\delta b} = \partial^\mu A_\mu + ab , \quad -i \frac{\delta \Gamma^{(0)}}{\delta c} = i \bar{\psi}^+ + \bar{\psi}^- + \bar{\psi}^+ , \quad \frac{\delta \Gamma^{(0)}}{\delta \pi} = \partial^\mu a_\mu + ab , \quad -i \frac{\delta \Gamma^{(0)}}{\delta \xi} = i \bar{\psi}^+ + \bar{\psi}^- + \bar{\psi}^+ , \quad \frac{\delta \Gamma^{(0)}}{\delta \bar{\psi}^+} = \bar{\psi}^- . \tag{28}
\]

Furthermore, the action \(\Gamma^{(0)}\) (6) is invariant under the two rigid symmetries associated to \(U_A(1) \times U_a(1)\):

\[
W_r^{\psi} \Gamma^{(0)} = 0 \quad \text{and} \quad W_r^{\psi} \Gamma^{(0)} = 0 , \tag{30}
\]

where the Ward operators, \(W_r^{\psi}\) and \(W_r^{\psi}\), read

\[
W_r^{\psi} = \int d^3x \left\{ \psi^+ \frac{\delta}{\delta \psi^+} - \psi^- \frac{\delta}{\delta \psi^-} + \Omega^+ \frac{\delta}{\delta \Omega^+} \right\} , \tag{31}
\]

\[
W_r^{\psi} = \int d^3x \left\{ \psi^+ \frac{\delta}{\delta \psi^+} - \psi^- \frac{\delta}{\delta \psi^-} + \Omega^+ \frac{\delta}{\delta \Omega^+} \right\} . \tag{32}
\]
The $U_A(1) \times U_1(1)$ gauge invariant action $\Gamma^{(0)} (6)$ being even under the parity transformation $(P)$ fixes its action upon the fields and external sources:

$$
\psi_+ \stackrel{P}{\longrightarrow} \psi_P^+ = -i\gamma^1 \psi_-, \quad \psi_- \stackrel{P}{\longrightarrow} \psi_P^- = -i\gamma^1 \psi_+ , \\
\Omega_+ \stackrel{P}{\longrightarrow} \Omega_P^+ = -i\gamma^1 \psi_-, \quad \Omega_- \stackrel{P}{\longrightarrow} \Omega_P^- = -i\gamma^1 \psi_+ , \\
A_\mu \stackrel{P}{\longrightarrow} A_\mu_P = (A_0, -A_1, A_2) ; \quad \phi \stackrel{P}{\longrightarrow} \phi_P = \phi , \quad \phi = \{ b, c, \tau \} ; \\
a_\mu \stackrel{P}{\longrightarrow} a_\mu_P = (-a_0, a_1, -a_2) ; \quad \chi \stackrel{P}{\longrightarrow} \chi_P = -\chi , \quad \chi = \{ \pi, \xi, \overline{\xi} \} .
$$

### III. THE STABILITY CONDITION: IN SEARCH FOR COUNTERTERMS

The stability condition, i.e. the multiplicative renormalizability, is ensured if perturbative quantum corrections do not produce local counterterms corresponding to renormalization of parameters which are not already present in the classical theory, therefore thus those radiative corrections can be reabsorbed order by order through redefinitions of the initial physical quantities – fields, coupling constants and masses – of the theory. Consequently, in order to verify if the classical action $\Gamma^{(0)} (6)$ is stable under radiative corrections, it is perturbed by an arbitrary integrated local functional (counterterm) $\Sigma^c$, namely $\Gamma^c = \Gamma^{(0)} + \varepsilon \Sigma^c$, such that $\varepsilon$ is an infinitesimal parameter and the counterterm action $\Sigma^c$ has the same quantum numbers as the tree-level action $\Gamma^{(0)} (6)$. Provided that the deformed action $\Gamma^c$ satisfies all the conditions fulfilled by the classical action $\Gamma^{(0)} (6)$, this leads to the counterterm $\Sigma^c$ be subjected to the following set of constraints:

$$
\mathcal{S}_{\text{rig}} \Sigma^c = 0 ;
$$

$$
W_{\text{rig}} \Sigma^c = 0 , \quad W_{\text{rig}}^g \Sigma^c = 0 ;
$$

$$
\frac{\delta \Sigma^c}{\delta b} = \frac{\delta \Sigma^c}{\delta c} = \frac{\delta \Sigma^c}{\delta \xi} = 0 , \quad \frac{\delta \Sigma^c}{\delta \pi} = \frac{\delta \Sigma^c}{\delta \xi} = 0 ;
$$

$$
\frac{\delta \Sigma^c}{\delta \Omega_+} = \frac{\delta \Sigma^c}{\delta \Omega_-} = 0 , \quad \frac{\delta \Sigma^c}{\delta \Omega_-} = \frac{\delta \Sigma^c}{\delta \Omega_+} = 0 .
$$

At this point, it should be emphasized that, as far as rigid gauge invariance is concerned, since the symmetry group $U_A(1) \times U_1(1)$ is a non-semisimple Lie group, in principle rigid invariance could be broken at the quantum level, in other words, rigid symmetry might be anomalous. Nevertheless, none of both abelian factors are spontaneously broken as well as the conditions displayed in (30), $W_{\text{rig}} \Gamma^{(0)} = 0$ and $W_{\text{rig}}^g \Gamma^{(0)} = 0$, express indeed the conservation of the electric $(e)$ and the chiral $(g)$ charges, therefore the conditions exhibited in (35), $W_{\text{rig}} \Sigma^c = 0$ and $W_{\text{rig}}^g \Sigma^c = 0$, are still valid [15, 16].

The most general Lorentz invariant and vanishing ghost number field polynomial ($\Sigma^c$) fulfilling the conditions (34)–(37) with ultraviolet dimension bounded by $d \leq 3$, reads:

$$
\Sigma^c = \int d^3 x \big\{ \alpha_i \overline{\psi}_+ \slashed{D} \psi_+ + \alpha_2 \overline{\psi}_- \slashed{D} \psi_- + \alpha_3 \overline{\psi}_+ \psi_+ + \alpha_4 \overline{\psi}_- \psi_- + \alpha_5 F_{\mu\nu} F^{\mu\nu} + \alpha_6 f^{\mu\nu} f_{\mu\nu} + \alpha_7 \varepsilon^{\mu\nu\rho\sigma} A_\mu \partial_\rho a_\sigma \big\} ,
$$

where $\alpha_i (i = 1, \ldots, 7)$ are at first arbitrary parameters. However, there are other restrictions owing to superrenormalizability and parity invariance. Since all quantum fields are massive no infrared divergences arise from the ultraviolet subtractions in the Bogoliubov-Parasiuk-Hepp-Zimmermann (BPHZ) renormalization procedure, thereby there is no need to use the Lowenstein-Zimmermann subtraction scheme [10] – which explicitly breaks parity in three space-time dimensions [2, 4] while the infrared divergences are subtracted – in order to subtract those infrared divergences. In this way, as a by-product the BPHZ method is an available parity-preserving subtraction procedure guaranteeing that at each loop order the counterterm ($\Sigma^c$) shall be parity-even. Concerning the model superrenormalizability, the coupling-constant-dependent power-counting formula [17]:

$$
\delta(\gamma) = 3 - \sum_{\Phi} d_\Phi N_\Phi - \frac{1}{2} N_e - \frac{1}{2} N_g ,
$$

is defined for the UV degree of divergence ($\delta(\gamma)$) of a 1-particle irreducible Feynman graph ($\gamma$) where $N_\Phi$ is the number of external lines of $\gamma$ corresponding to the field $\Phi$, $d_\Phi$ is the UV dimension of $\Phi$ (see Table I), and $N_e$ and $N_g$ are the powers of the coupling constants $e$ and $g$, respectively, in the integral corresponding to the diagram $\gamma$. Thanks to fact that counterterms are generated by loop graphs, they are at least of order two in the coupling constants, namely,
where the Slavnov-Taylor breaking $\Delta$ is an integrated local Lorentz invariant functional, with ghost number equal to 1 and UV dimension bounded by $d \leq \frac{5}{2}$.

Taking into consideration the Slavnov-Taylor quantum identity (46), the nilpotency identity (25) applied to the quantum vertex functional, i.e., $S_\Gamma S(\Gamma) = 0$, and the equation $S_\Gamma = S_{\Gamma(0)} + \mathcal{O}(\hbar)$ obtained from (24) and (45), this all together implies the following consistency condition for the quantum breaking $\Delta$:

$$S_{\Gamma(0)} \Delta = 0$$

$$\psi^2, \ g^2 \text{ or } e^g.$$ Accordingly, the effective UV dimension of the counterterm (\Sigma) is bounded by $d \leq 2$, implying that, $\alpha_1 = \alpha_2 = \alpha_5 = \alpha_6 = 0$. Furthermore, since a parity-even subtraction scheme is available thus the counterterm has to be parity invariant, resulting that $\alpha_3 = -\alpha_4 = \alpha$, and the counterterm expressed by

$$\Sigma^e = \int d^3 x \left\{ \alpha (\bar{\psi} \gamma_+ \psi_+ - \bar{\psi} \gamma_- \psi_-) + \alpha \tau \epsilon^{\mu \rho \nu} A_\mu \partial_\rho a_\nu \right\} = z_m m \frac{\partial}{\partial m} \Gamma^{(0)} + z_\mu \frac{\partial}{\partial \mu} \Gamma^{(0)} ,$$

(40)

where $z_m = -\frac{\alpha}{m}$ and $z_\mu = \frac{\alpha}{\mu}$ are arbitrary parameters to be fixed, order by order in perturbation theory, by the normalization conditions:

$$\Gamma^e_{\bar{\psi}_+ \psi_+}(p) \Big|_{p^2 = m^2} = 0 \text{ or } \Gamma^e_{\bar{\psi}_- \psi_-}(p) \Big|_{p^2 = m^2} = 0 \text{ and } \int \frac{i}{6} \epsilon^{\mu \rho \nu} \frac{\partial}{\partial p_\rho} \Gamma^{\mu \rho \nu}_{Aa}(p) \bigg|_{p^2 = \kappa^2} = \mu ,$$

(41)

with $\kappa$ being an energy scale. The counterterm (40) shows that, \textit{a priori}, only the mass parameters $m$ and $\mu$ can get radiative corrections. This means that, at all orders in $\hbar$, the $\beta$-functions associated to the gauge coupling constants, $e$ and $g$, are vanishing, $\beta_e = 0$ and $\beta_g = 0$, respectively, as well as the anomalous dimensions ($\gamma$) of the fields.

In time, a subtle property of the Chern-Simons piece of action in $\Gamma^{(0)} (6)$:

$$\Sigma_{CS} = \mu \int d^3 x \epsilon^{\mu \rho \nu} A_\mu \partial_\rho a_\nu ,$$

(42)

shall be put in evidence. The Chern-Simons action $\Sigma_{CS}$ (42) is not BRS local invariant, thus its invariance under BRS transformations is up to a surface term, \textit{i.e.} total derivative,

$$s \Sigma_{CS} = s \left\{ \mu \int d^3 x \epsilon^{\mu \rho \nu} A_\mu \partial_\rho a_\nu \right\} = -\frac{\mu}{c} \int d^3 x \epsilon^{\mu \rho \nu} \partial_\mu (c \partial_\rho a_\nu) ,$$

(43)

indicating that at quantum level the $\beta$-function associated to the Chern-Simons mass parameter ($\mu$) vanishes, $\beta_\mu = 0$ [17, 18]. In summary, the counterterm finally reads

$$\Sigma^e = \int d^3 x \left\{ \alpha (\bar{\psi} \gamma_+ \psi_+ - \bar{\psi} \gamma_- \psi_-) \right\} = z_m m \frac{\partial}{\partial m} \Gamma^{(0)} ,$$

(44)

yielding that all $\beta$-functions associated to the gauge coupling constants ($e$ and $g$) and the Chern-Simons mass parameter ($\mu$), and all anomalous dimensions ($\gamma$) of the fields, are vanishing, excepting the $\beta$-function corresponding to the fermions mass parameter ($m$). As an ultimate result, it can be concluded that the parity-even $UA(1) \times U_s(1)$ massive QED$_3$ [5] is ultraviolet finiteness at all orders in perturbation theory, provided no gauge anomalies emerge jeopardizing its unitarity. The issue of gauge anomalies is hereafter analyzed by means of the Slavnov-Taylor identity behavior at the quantum level.

IV. THE UNITARITY CONDITION: IN SEARCH FOR ANOMALIES

In view of the fact that the stability condition does not assure the extension of the theory to the quantum level, it still remains to show the inexistence of gauge anomalies and also the parity anomaly, once the latter is sometimes claimed in the literature as a typical anomaly of three dimensional space-times.

The quantum vertex functional ($\Gamma$) coincides with the classical action ($\Gamma^{(0)}$) at zeroth-order in $\hbar$,

$$\Gamma = \Gamma^{(0)} + \mathcal{O}(\hbar) ,$$

(45)

shall fulfill the same conditions (28)–(30) of the classical action.

According to the Quantum Action Principle [6], the Slavnov-Taylor identity (22) acquires a quantum breaking:

$$S(\Gamma) = \Delta \cdot \Gamma = \Delta + \mathcal{O}(\hbar \Delta) ,$$

(46)

where the Slavnov-Taylor breaking $\Delta$ is an integrated local Lorentz invariant functional, with ghost number equal to 1 and UV dimension bounded by $d \leq \frac{5}{2}$.
Moreover, in addition to (47), calling into question the Slavnov-Taylor identity (22), the gauge, antighost and ghost equations (28)–(29), so as the rigid conditions (30), it is verified that the Slavnov-Taylor quantum breaking (Δ) also satisfies the constraints:

\[
\frac{\delta \Delta}{\delta b} = \int d^3 x \frac{\delta \Delta}{\delta c} = W_{\text{rig}}^c \Delta = 0 \quad \text{and} \quad \frac{\delta \Delta}{\delta \xi} = \int d^3 x \frac{\delta \Delta}{\delta \xi} = W_{\text{rig}}^g \Delta = 0 .
\] (48)

The Wess-Zumino consistency condition (47) is indeed a cohomology problem in the sector of ghost number one. Consequently, its solution can always be written as a sum of a trivial cocycle \(S_{\Gamma(0)} \hat{\Delta}(0)\), where \(\hat{\Delta}(0)\) has ghost number zero, and of nontrivial elements \(\hat{\Delta}^{(1)}\) lying in the cohomology of \(S_{\Gamma(0)}\) (24) in the sector of ghost number one:

\[
\Delta^{(1)} = \hat{\Delta}^{(1)} + S_{\Gamma(0)} \hat{\Delta}^{(0)} ,
\] (49)

reminding that the Slavnov-Taylor quantum breaking \(\Delta^{(1)}\) (49) has to satisfy the conditions imposed by (47) and (48). It should be highlighted that the trivial cocycle \(S_{\Gamma(0)} \hat{\Delta}(0)\) can be absorbed order by order into the vertex functional \(\Gamma\), namely \(S_{\Gamma(0)} (\Gamma - \hat{\Delta}(0)) = \Delta^{(1)} + O(h\Delta^{(1)})\), as a noninvariant integrated local counterterm, \(-\hat{\Delta}(0)\). The linearized Slavnov-Taylor operator \(S_{\Gamma(0)}\) (24) in combination with the Slavnov-Taylor quantum identity (46) results that the breaking \(\Delta^{(1)}\) exhibits UV dimension bounded by \(d \leq \frac{3}{2}\). Nevertheless, being an effect of radiative corrections, the insertion \(\Delta^{(1)}\) possesses a factor, \(c^2\), \(g^2\) or \(eg\), at least, hence its effective UV dimension turns out to be bounded by \(d \leq \frac{3}{2}\).

Now, it has been verified that, as displayed in (48), from the antighost equations (28)–(29), the quantum breaking \(\Delta^{(1)}\) (49) fulfill the constraints:

\[
\int d^3 x \frac{\delta \Delta^{(1)}}{\delta c} = 0 \quad \text{and} \quad \int d^3 x \frac{\delta \Delta^{(1)}}{\delta \xi} = 0 ,
\] (50)

then it follows that \(\Delta^{(1)}\) reads

\[
\Delta^{(1)} = \int d^3 x \left( \mathcal{K}_\mu^{(0)} \partial^\mu c + \mathcal{X}_\mu^{(0)} \partial^\mu \xi \right) ,
\] (51)

where \(\mathcal{K}_\mu^{(0)}\) and \(\mathcal{X}_\mu^{(0)}\) are rank-1 tensors with zero ghost number and UV dimension bounded by \(d \leq \frac{3}{2}\). Beyond that, the breaking \(\Delta^{(1)}\) may be split into two pieces, one even and another odd under parity, thus \(\mathcal{K}_\mu^{(0)}\) and \(\mathcal{X}_\mu^{(0)}\) can be written as

\[
\mathcal{K}_\mu^{(0)} = \sum_{i=1}^{\nu} v_{k,i} V_{\mu}^{(i)} + \sum_{i=1}^{\nu} p_{k,i} P_{\mu}^{(i)} \quad \text{and} \quad \mathcal{X}_\mu^{(0)} = \sum_{i=1}^{\nu} v_{x,i} \Upsilon_{\mu}^{(i)} + \sum_{i=1}^{\nu} p_{x,i} \Upsilon_{\mu}^{(i)} ,
\] (52)

with \(v_{k,i}, p_{k,i}, v_{x,i}, p_{x,i}\) being fixed coefficients to be further determined. Moreover, \(V_{\mu}^{(i)}\) and \(\Upsilon_{\mu}^{(i)}\) are defined as vectors, while \(P_{\mu}^{(i)}\) and \(\Upsilon_{\mu}^{(i)}\) as pseudo-vectors, in such a way that \(V_{\mu}^{(i)} \partial^\mu c\) and \(\Upsilon_{\mu}^{(i)} \partial^\mu \xi\) are parity-even, whereas \(P_{\mu}^{(i)} \partial^\mu c\) and \(\Upsilon_{\mu}^{(i)} \partial^\mu \xi\) are parity-odd, since \(\partial^\mu c\) is a vector and \(\partial^\mu \xi\) a pseudo-vector. Taking into consideration that \(\mathcal{K}_\mu^{(0)}\) and \(\mathcal{X}_\mu^{(0)}\) have their UV dimensions given by \(d \leq \frac{3}{2}\) and \(\Delta^{(1)}\) must fulfill the conditions (47) and (48), it is verified that even though there are \(P_{\mu}^{(i)}\) and \(\Upsilon_{\mu}^{(i)}\) surviving all of these constraints, namely, \(P_{\mu}^{(i)} \epsilon_{\mu\rho\nu} \partial^\rho A^\nu\) and \(\Upsilon_{\mu}^{(i)} = \epsilon_{\mu\rho\nu} \partial^\rho a^\nu\), their contributions in \(\Delta^{(1)}\) (51) are all ruled out by partial integration, therefore effectively for the anomaly analysis purposes, \(\{P_{\mu}^{(i)}\} = 0\) and \(\{\Upsilon_{\mu}^{(i)}\} = 0\), thereby leaving only the parity invariant part (\(\Delta_{\text{even}}^{(1)}\)) of the Slavnov-Taylor quantum breaking \(\Delta^{(1)}\) (51):

\[
\Delta_{\text{even}}^{(1)} = \int d^3 x \left( \sum_{i=1}^{\nu} v_{k,i} V_{\mu}^{(i)} \partial^\mu c + \sum_{i=1}^{\nu} p_{x,i} \Upsilon_{\mu}^{(i)} \partial^\mu \xi \right) ,
\] (53)

ending the proof that parity is not broken at the quantum level, there is no parity anomaly at all.

It still remains to verify if the parity-even breaking \(\Delta_{\text{even}}^{(1)}\) (53) is a genuine gauge anomaly or just a trivial cocycle that could be reabsorbed into the quantum action as noninvariant counterterms. However, it lacks to find the candidates for \(V_{\mu}\) (vector) and \(\Upsilon_{\mu}\) (pseudo-vector) with UV dimensions given by \(d \leq \frac{3}{2}\) provided that \(\Delta_{\text{even}}^{(1)}\) (53) satisfies the constraints (47) and (48). So, they read as follows:

\[
V_{\mu}^{(1)} = A_\mu A^\nu A_\nu , \quad \mathcal{V}_{\mu}^{(1)} = A_\mu a^\nu A_\nu , \quad \mathcal{V}_{\mu}^{(2)} = A_\mu a^\nu a_\nu , \quad \Upsilon_{\mu}^{(1)} = a_\mu a^\nu A_\nu , \quad \Upsilon_{\mu}^{(2)} = a_\mu A^\nu A_\nu , \quad \Upsilon_{\mu}^{(3)} = a_\mu A^\nu A_\mu ,
\] (54)
as a consequence the quantum breaking $\Delta^{(1)}_{\text{even}}$ (53) becomes expressed by

$$
\Delta^{(1)}_{\text{even}} = \int d^3x \left\{ v_{k,1} A_\mu A^\nu A_\nu \partial^\mu c + v_{k,2} A_\mu a^\nu A_\nu \partial^\mu c + v_{k,3} A_\mu a^\nu a_\nu \partial^\mu c +
+ p_{x,1} a_\mu a^\nu A_\nu \partial^\mu c + p_{x,2} a_\mu A^\nu A_\nu \partial^\mu c + p_{x,3} A_\mu A^\nu A_\nu \partial^\mu c \right\} .
$$

(55)

At this moment, from the Wess-Zumino consistency condition (47), whether a gauge anomaly owing to radiative corrections exists or not shall be proved by analyzing the breaking $\Delta^{(1)}_{\text{even}}$ (55), consequently if it could be written unambiguously as a trivial cocycle $S_{\Gamma(0)} \tilde{\Delta}^{(0)}$, with $\tilde{\Delta}^{(0)}$ being a zero ghost number integrated local monomials, the noninvariant counterterms, there is no gauge anomaly and the unitarity is guaranteed, otherwise, if there is at least one nontrivial element $\tilde{\Delta}^{(1)}$ belonging to the cohomology of $S_{\Gamma(0)}$ (24) in the sector of ghost number one, the gauge symmetry is anomalous and unitarity is definitely jeopardized. In order to give the sequel on the issue of gauge anomaly, it can be straightforwardly verified that:

$$
S_{\Gamma(0)} \tilde{\Delta}^{(0)1} = S_{\Gamma(0)} \int d^3x A^\mu A_\mu A^\nu A_\nu = -\frac{4}{e} \int d^3x A_\mu A^\nu A_\nu \partial^\mu c ,
$$

(56)

$$
S_{\Gamma(0)} \tilde{\Delta}^{(0)2} = S_{\Gamma(0)} \int d^3x a^\mu a_\mu a^\nu a_\nu = -\frac{4}{g} \int d^3x a_\mu a^\nu a_\nu \partial^\mu \xi ,
$$

(57)

$$
S_{\Gamma(0)} \tilde{\Delta}^{(0)3} = S_{\Gamma(0)} \int d^3x A^\mu A_\mu a^\nu a_\nu = \frac{2}{e} \int d^3x A_\mu a^\nu a_\nu \partial^\mu c - \frac{2}{g} \int d^3x a_\mu A^\nu A_\nu \partial^\mu c ,
$$

(58)

$$
S_{\Gamma(0)} \tilde{\Delta}^{(0)4} = S_{\Gamma(0)} \int d^3x A^\nu A_\nu a^\mu a_\mu = \frac{2}{e} \int d^3x A_\mu a^\nu a_\nu \partial^\mu c - \frac{2}{g} \int d^3x a_\mu A^\nu A_\nu \partial^\mu c .
$$

(59)

Besides that, by taking into consideration the four trivial cocycles above (56)–(59), it follows that the quantum breaking (53) might be rewritten as:

$$
\Delta^{(1)}_{\text{even}} = S_{\Gamma(0)} \left\{ \lambda_1 \tilde{\Delta}^{(0)1} + \lambda_2 \tilde{\Delta}^{(0)2} + \lambda_3 \tilde{\Delta}^{(0)3} + \lambda_4 \tilde{\Delta}^{(0)4} \right\}
$$

$$
= S_{\Gamma(0)} \left\{ \lambda_1 \int d^3x A^\mu A_\mu A^\nu A_\nu + \lambda_2 \int d^3x a^\mu a_\mu a^\nu a_\nu + \lambda_3 \int d^3x A^\mu A_\mu a^\nu a_\nu + \lambda_4 \int d^3x A^\mu A_\mu a^\nu a_\nu \right\}
$$

$$
= \int d^3x \left\{ -\frac{4}{e} \lambda_1 A_\mu A^\nu A_\nu \partial^\mu c - \frac{2}{e} \lambda_3 A_\mu a^\nu a_\nu \partial^\mu c - \frac{2}{e} \lambda_4 A_\mu a^\nu a_\nu \partial^\mu c +
+ \frac{4}{g} \lambda_2 a_\mu a^\nu a_\nu \partial^\mu \xi - \frac{2}{g} \lambda_3 a_\mu A^\nu A_\nu \partial^\mu \xi + \frac{2}{g} \lambda_4 a_\mu A^\nu A_\nu \partial^\mu \xi \right\} ,
$$

(60)

where it can be checked that

$$
v_{k,1} = -\frac{4}{e} \lambda_1 , \quad v_{k,2} = -\frac{2}{e} \lambda_3 , \quad v_{k,3} = -\frac{2}{e} \lambda_4 , \quad p_{x,1} = \frac{4}{g} \lambda_2 , \quad p_{x,2} = -\frac{2}{g} \lambda_3 , \quad p_{x,3} = -\frac{2}{g} \lambda_4 ,
$$

(61)

thus finally demonstrating that the quantum breaking $\Delta^{(1)}_{\text{even}}$ (53) is actually a trivial cocycle $S_{\Gamma(0)} \tilde{\Delta}^{(0)}$:

$$
\Delta^{(1)}_{\text{even}} = S_{\Gamma(0)} \tilde{\Delta}^{(0)} = S_{\Gamma(0)} \left\{ \lambda_1 \tilde{\Delta}^{(0)1} + \lambda_2 \tilde{\Delta}^{(0)2} + \lambda_3 \tilde{\Delta}^{(0)3} + \lambda_4 \tilde{\Delta}^{(0)4} \right\} .
$$

(62)

Therefore, as a final result, the integrated local monomials $\tilde{\Delta}^{(0)1}$, $\tilde{\Delta}^{(0)2}$, $\tilde{\Delta}^{(0)3}$ and $\tilde{\Delta}^{(0)4}$ can be absorbed as noninvariant counterterms order by order into the quantum action, e.g., at n-order in $h$:

$$
S_{\Gamma(0)} (\Gamma - h^n \tilde{\Delta}^{(0)}) \equiv S_{\Gamma(0)} \left( \Gamma - h^n \lambda_1 \tilde{\Delta}^{(0)1} - h^n \lambda_2 \tilde{\Delta}^{(0)2} - h^n \lambda_3 \tilde{\Delta}^{(0)3} - h^n \lambda_4 \tilde{\Delta}^{(0)4} \right) = 0 h^n + \mathcal{O}(h^{n+1}) ,
$$

(63)

which concludes the proof on the absence of gauge anomaly, meaning that the $U_A(1) \times U_A(1)$ local symmetry is not anomalous at the quantum level.

In summary, the last result (63), about the Wess-Zumino condition, combined with the previous one (44), the stability condition analysis, completes the proof of vanishing $\beta$-functions associated to the gauge coupling constants ($e$ and $g$) and the Chern-Simons mass parameter ($\mu$), and all anomalous dimensions ($\gamma$) of the fields, as well as the absence of parity and gauge anomaly at all orders in perturbation theory. Finally, as a by-product, it can also be deduced that the parity-even $U_A(1) \times U_A(1)$ massive QED$_3$ [5] is ultraviolet finiteness.
V. CONCLUSION

In conclusion, the parity-even $U_A(1) \times U_a(1)$ massive QED$_3$ [5] is parity and gauge anomaly free at all orders in perturbation theory. Beyond that, it exhibits vanishing $\beta$-functions associated to the gauge coupling constants ($e$ and $g$) and the Chern-Simons mass parameter ($\mu$), and all the anomalous dimensions ($\gamma$) of the fields as well. The proof is independent of any regularization scheme or any particular diagrammatic calculation, it is based on the quantum action principle in combination with general theorems of perturbative quantum field theory by adopting the BRS (Becchi-Rouet-Stora) algebraic renormalization method in the framework of BPHZ (Bogoliubov-Parasiuk-Hepp-Zimmermann) subtraction scheme [6–10]. As a final comment, once the quantum perturbative physical consistency of the mass-gap graphene-like planar quantum electrodynamics has been proven from the results demonstrated here together with those presented in [5], it should be newsworthy to deepen its analysis so as to apply in graphene-like electronic systems [19].
