SCHUR MULTIPLIERS OF SPECIAL $p$-GROUPS OF RANK 2

SUMANA HATUI

Abstract. Let $G$ be a special $p$-group with center of order $p^2$. Berkovich and Janko asked to find the Schur multiplier of $G$ in [1, Problem 2027]. In this article we answer this question by explicitly computing the Schur multiplier of these groups.

1. Introduction

Let $G$ be a finite $p$-group and $d(G)$ denotes the cardinality of minimal generating set of $G$. The commutator subgroup and center of $G$ are denoted by $G'$ and $Z(G)$ respectively. By $ES_p^k(p^n)$, we denote the extraspecial $p$-group of order $p^n$ of exponent $p^k$, $k = 1, 2$ and by $\mathbb{Z}_p^{(k)}$, we denote the elementary abelian $p$-group of rank $k$ for $k \geq 1$. For a prime $p$, $G^p$ denotes the group generated by the set $\{g^p \mid g \in G\}$. A finite $p$-group $G$ is called special $p$-group of rank $k$ if $G' = Z(G)$ is an elementary abelian $p$-group of order $p^k$ such that $G' = G/G'$ is elementary abelian. A group $G$ is called capable group if there exists a group $H$ such that $G \cong H/Z(H)$. The epicenter of a group $G$ is denoted by $Z^*(G)$, which is the smallest central subgroup $K$ of $G$ such that $G/K$ is capable.

The Schur multiplier of a group $G$, denoted by $M(G)$, is the second integral homology group $H_2(G, \mathbb{Z})$ which was introduced by Schur in 1904 in his fundamental work on projective representation of groups. There has been a great importance in understanding the Schur multipliers of finite $p$-groups in recent past. Here we are interested to compute Schur multiplier of special $p$-groups of rank 2. The special $p$-groups of minimum rank are the extraspecial $p$-groups and their Schur multiplier was studied in [3]. The Schur multiplier of special $p$-groups having maximum rank was studied in [12]. In this article we determine the Schur multiplier of special $p$-groups of rank 2 and that answered the question which was asked by Berkovich and Janko in [1, Problem 2027].

Recall that, there are two extraspecial $p$-groups of order 8 up to isomorphism, both are of exponent 4, one is quaternion group $Q_8$ which has trivial Schur multiplier and another is dihedral group $D_8$ which has Schur multiplier of order 2 (see [8, Theorem 3.3.6]).

We state our main results now. The following result describes the Schur multiplier of $G$ when $G^p = G' \cong \mathbb{Z}_p \times \mathbb{Z}_p$.

Theorem 1.1. Let $G$ be a special $p$-group of rank 2 with $d = d(G)$ and $G^p = G'$. Then the following assertions hold:

(a) Either $Z^*(G) = Z(G)$ or $G$ is capable.
(b) $M(G)$ is elementary abelian of order $p^\frac{1}{2}d(d-1)-2$ if and only if $Z^*(G) = Z(G)$.
(c) $M(G)$ is of order $p^\frac{1}{2}d(d-1)-1$ of exponent at most $p^2$ if and only if $G$ is capable.
(d) For every central subgroup $Z$ of order $p$, $G/Z$ is isomorphic to $ES_p^1(p^{2m+1}) \times \mathbb{Z}_p^{(d-2m)}$ ($m \geq 2$), $ES_p^2(p^3) \times \mathbb{Z}_p^{(d-2)}$ or $Q_8 \times \mathbb{Z}_2^{(d-2)}$.

By [4, Proposition 3] and Theorem 1.1 we have the immediate corollary.

Corollary 1.2. If $G$ is a special $p$-group of rank 2 of order $p^n$ ($n \geq 8$) with $G^p = G'$, then $M(G)$ is elementary abelian of order $p^\frac{1}{2}(n-2)(n-3)-2$.
The following result describes the Schur multiplier of \( G \) when \( G^p \) is cyclic of prime order.

**Theorem 1.3.** If \( G \) is a special \( p \)-group of rank 2 with \( d = d(G) \) and \( G^p \cong \mathbb{Z}_p \), then the following assertions hold:

(a) \( G \) is not capable and either \( Z^*(G) = Z(G) \) or \( Z^*(G) = G^p \).

(b) \( M(G) \) is elementary abelian.

(c) The following are equivalent:

(i) \( M(G) \) is of order \( \frac{1}{2}d(d-1) - 2 \).

(ii) \( Z^*(G) = Z(G) \).

(iii) \( G/G \) is spanned by all \( G/G \) such that \( G/G \) is of order \( 2 \).

(d) The following are equivalent:

(i) \( M(G) \) is of order \( \frac{1}{2}d(d-1) \).

(ii) \( Z^*(G) = G^p \).

(iii) \( G/G \cong ES_p(p^{2m+1}) \times \mathbb{Z}_p^{(d-2m)}, m \geq 2 \).

Now we are left with only one case when \( G^p \) is trivial and in this case the Schur multiplier of \( G \) is studied in the following result.

**Theorem 1.4.** If \( G \) is a special \( p \)-group of rank 2 with \( d = d(G) \) and \( G^p = 1, \) \( p \) odd, then the following assertions hold:

(a) \( M(G) \) is elementary abelian.

(b) \( p^\frac{1}{2}d(d-1) - 2 \leq |M(G)| \leq p^\frac{1}{2}d(d-1) + 3 \).

(c) \( G \) is capable if and only if \( G \) is isomorphic to one of the following groups:

(i) \( \Phi_4(1^5) = \langle \alpha, \alpha_1, \alpha_2, \beta_1, \beta_2 \mid [\alpha, \alpha] = \beta_i, \alpha^p = \beta_i^p = 1 (i = 1, 2) \rangle \).

(ii) \( \Phi_{12}(1^6) = ES_p(p^3) \times ES_p(p^3) \).

(iii) \( \Phi_{13}(1^6) = \langle \alpha, \alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2 \mid [\alpha, \alpha_1] = \beta_i, [\alpha_2, \alpha_3] = \beta_1, [\alpha_2, \alpha_3] = \beta_1, \alpha^p = \beta_i^p = 1 (i = 1, 2) \rangle \).

(iv) \( \Phi_{15}(1^6) = \langle \alpha, \alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2 \mid [\alpha, \alpha_1] = \beta_i, [\alpha_2, \alpha_3] = \beta_1, [\alpha_2, \alpha_3] = \beta_1, \alpha^p = \beta_i^p = 1 (i = 1, 2) \rangle \).

(v) \( T = \{x_1, \ldots, x_5, c_1, c_2 \mid [x_2, x_1] = [x_5, x_3] = c_1, [x_3, x_1] = [x_5, x_4] = c_2, x_i^p = \alpha_i^p = \beta_i^p = 1, 1 \leq i \leq 5 \} \).

(d) \( |M(G)| = p^\frac{1}{2}d(d-1) + 3 \) if and only if \( G \) is isomorphic to \( \Phi_4(1^5) \).

(e) \( |M(G)| = p^\frac{1}{2}d(d-1) + 2 \) if and only if \( G \) is isomorphic to \( \Phi_{12}(1^5), \Phi_{13}(1^6), \) or \( \Phi_{15}(1^6) \).

(f) \( |M(G)| = p^\frac{1}{2}d(d-1) - 1 \) if and only if \( G \) is isomorphic to \( T \).

(g) \( M(G) \) is of order \( p^\frac{1}{2}d(d-1) - 2 \) if and only if \( Z^*(G) = Z(G) \). In this case, \( G/Z \cong ES_p(p^{2m+1}) \times \mathbb{Z}_p^{(d-2m)}, m \geq 2 \), for every central subgroup \( Z \) of order \( p \).

(h) \( M(G) \) is of order \( p^\frac{1}{2}d(d-1) \) if and only if \( Z^*(G) \cong \mathbb{Z}_p \). In this case, \( G/Z^*(G) \cong ES_p(p^3) \times \mathbb{Z}_p^{(d-2)} \).

The following result is for \( p = 2 \).

**Theorem 1.5.** Let \( G \) be a special 2-group of rank 2. Then \( G^2 = G' \) holds.

2. Preliminaries

For a finite group \( G \) of class 2 with \( G/G' \) elementary abelian, the following construction is given in [3]. We consider \( G/G' \) and \( G' \) as vector spaces over \( \mathbb{F}_p \), which we denote by \( V, W \) respectively. The bilinear map \((-,-) : V \times V \to W \) is defined by

\[
(v_1, v_2) = [g_1, g_2]
\]

for \( v_1, v_2 \in V \) such that \( v_i = g_i G', i \in \{1, 2\} \) for some \( g_1, g_2 \in G \). Let \( X_1 \) be the subspace of \( V \otimes W \) spanned by all

\[
v_1 \otimes (v_2, v_3) + v_2 \otimes (v_3, v_1) + v_3 \otimes (v_1, v_2)
\]
for \( v_1, v_2, v_3 \in V \). Consider a map \( f : V \to W \) given by
\[
f(gG') = g^p
\]
for \( g \in G \). Let \( X_2 \) be the subspace spanned by all \( v \otimes f(v), v \in V \), and take
\[
X := X_1 + X_2.
\]
Now consider a homomorphism \( \sigma : V \otimes V \to (V \otimes W)/X \) given by
\[
\sigma(v_1 \otimes v_2) = (v_1 \otimes f(v_2) + (\partial^2_2) v_2 \otimes (v_1, v_2)) + X.
\]
Then there exists an abelian group \( M^* \) with a subgroup \( N \) isomorphic to \((V \otimes W)/X\), such that
\[
1 \to N \to M^* \xrightarrow{\xi} V \otimes V \to 1
\]
is exact and
\[
\sigma\xi(\alpha) = \alpha^p \text{ for } \alpha \in M^*.
\]
Now we consider a homomorphism \( \rho : V \otimes V \to W \) given by
\[
\rho(v_1 \otimes v_2) = (v_1, v_2)
\]
for all \( v_1, v_2 \in V \). Notice that \( \rho \) is an epimorphism. We let \( M \) be the subgroup of \( M^* \) containing \( N \) such that \( M/N \cong \text{Ker } \rho \). We use this notation throughout the paper without further reference.

With the above setting, we have

**Theorem 2.1.** ([3] Theorem 3.1) \( M(G) \cong M \).

**Note:** It is easy to observe that \( X_1 \) is generated by the set
\[
\{ \bar{x}_1 \otimes [x_2, x_3] + \bar{x}_2 \otimes [x_3, x_1] + \bar{x}_3 \otimes [x_1, x_2] \mid x_1, x_2, x_3 \in S \},
\]
where \( S \) is a set of generators of \( G \) and \( \bar{x} \) is the image of \( x \) in \( G/G' \).

Suppose \( G \) has a free presentation \( F/R \). Let \( Z = S/R \) be a central subgroup of \( G \). Then the map from \((F/F') \times (S/R) \) to \((F'/R)/[F, R] \) defined by \((x F' R, s R) \mapsto [x, s][F, R] \) is a well-defined bilinear map and induces a homomorphism \( \lambda_Z : (G/G') \otimes Z \to M(G) \), called the Ganea map.

**Theorem 2.2** ([3]). Let \( Z \) be a central subgroup of a finite group \( G \). Then the following sequence is exact
\[
(G/G') \otimes Z \xrightarrow{\lambda_Z} M(G) \xrightarrow{\alpha} M(G/Z) \to G'/R \otimes Z \to 1.
\]

**Theorem 2.3** ([3]). Let \( Z \) be a central subgroup of a finite group \( G \). Then \( Z \subseteq Z^*(G) \) if and only if \((G/G') \otimes Z = \text{Ker } \lambda_Z \).

By [3 Corollary 3.2.4], we have \( X = \text{Ker } \lambda_{Z(G)} \). Hence by Theorem 2.3 we have the following result:

**Lemma 2.4.** Let \( Z \) be a central subgroup of a group \( G \) of nilpotency class 2. Then \( Z \subseteq Z^*(G) \) if and only if \((G/G') \otimes Z \) is contained in \( X \).

Let \( v_1, v_2, \ldots, v_d \) be the generators of \( V \) such that \( \{ f(v_1), f(v_2), \ldots, f(v_r) \} \) is a basis of \( G^p \). Then the set
\[
\{ v_i \otimes f(v_i), v_i \otimes f(v_i), (v_i \otimes f(v_i) + v_j \otimes f(v_i)) \mid 1 \leq i < j \leq r, (r + 1) \leq l \leq d \}
\]
forms a basis of \( X_2 \), from which the following result follows.

**Proposition 2.5** (Proposition 3.3 of [3]). Let \( G \) be a special \( p \)-group with \( d = d(G) \) and \( G^p \) of order \( r \). Then \( |X_2| = p^{rd - \frac{1}{2} r(r-1)} \).
By Theorem 2.8 we have

\[(2.1) \quad \frac{|M(G)|}{|\text{Im} \lambda|} = \frac{|M(G/Z)|}{|G'|}.
\]

As \(X = \text{Ker} \lambda_{Z(G)}\), so \(|\text{Im} \lambda_{Z(G)}| = \frac{p^d}{|X|}\). Hence, by (2.1), taking \(Z = Z(G)\), we have

\[(2.2) \quad |M(G)| = p^{d(d-1)} \frac{p^d}{|X|}.
\]

Now we recall the following results which will be used in the proof of the main results.

**Theorem 2.6** (Main Theorem of [9]). Let \(G\) be a \(p\)-group of order \(p^n\). Then \(|M(G)| = p^{\frac{1}{2}(n-1)(n-2)+1}\) if and only if \(G \cong ES_p(p^3) \times \mathbb{Z}_p^{(n-3)}\).

**Theorem 2.7** (Theorem 21 of [10]). Let \(G\) be a \(p\)-group of order \(p^n\). Then \(|M(G)| = p^{\frac{1}{2}(n-1)(n-2)}\) if and only if \(G\) is isomorphic to one of the following groups.

(i) \(G \cong \mathbb{Z}_{p^2} \times \mathbb{Z}_p^{(n-2)}\),
(ii) \(G \cong D_8 \times \mathbb{Z}_2^{(n-3)}\),
(iii) \(G \cong \mathbb{Z}_p^d \times \mathbb{Z}_p (p \neq 2)\).

**Theorem 2.8** (Theorem 11 of [11]). Let \(G\) be a group of order \(p^n\) such that \(G/G'\) is elementary abelian of order \(p^{n-1}\). Then \(|M(G)| = p^{\frac{1}{2}(n-1)(n-2)-1}\) if and only if \(G\) is isomorphic to one of the following groups.

(i) \(ES_p(p^3) \times \mathbb{Z}_p^{(n-3)}\),
(ii) \(Q_8 \times \mathbb{Z}_2^{(n-3)}\),
(iii) \(ES(p^{2m+1}) \times \mathbb{Z}_p^{(n-2m-1)} (m \geq 2)\).

### 3. Proofs

In this section we prove our main results.

**Proof of Theorem 2.1**: Consider \(G^p = G' \cong \mathbb{Z}_p \times \mathbb{Z}_p\). Now by Proposition 2.3 \(|X_2| = p^{2d-1}\). Let \(v_1, v_2 \in V\) such that \(\{f(v_1), f(v_2)\}\) is a basis of \(W\). Observe that \(X_2\) is generated by the set

\(\{v_i \otimes f(v_i), v_j \otimes f(v_i), (v_1 \otimes f(v_2) + v_2 \otimes f(v_1)) \mid i = 1, 2 \text{ and } 3 \leq j \leq d\}\).

Hence \(p^{2d} \geq |X| \geq p^{2d-1}\) and by (2.2),

\(p^{d(d-1)-2} \leq |M(G)| \leq p^{d(d-1)-1}\).

(a) Observe that \(|X| = p^{2d}\), i.e., the set \(\{v_1 \otimes f(v_2), v_2 \otimes f(v_1)\}\) is contained in \(X\) if and only if \(Z^*(G) = Z(G)\), follows by Lemma 2.1. Another possibility is \(|X| = p^{2d-1}\), i.e., \(X_1 \subseteq X_2\) if and only if \(v_1 \otimes f(v_2), v_2 \otimes f(v_1)\) are not in \(X\). Hence, by Lemma 2.1 \(Z^*(G) = 1\). So \(G\) is capable.

(b) By (2.2), \(|X| = p^{2d}\) if and only if

\(|M(G)| = p^{d(d-1)-2}\).

By Theorem 2.3 and Theorem 2.2, taking \(Z = Z(G)\), we see that \(M(G)\) embeds in \(M(G/Z(G))\) which is elementary abelian. So in this case \(M(G)\) is elementary abelian.

(c) For \(x \in M(G), x^p \in (V \otimes W)/X\) and \(V \otimes W/X\) is elementary abelian, so \(x^{p^2} = 1\). By (2.2), \(X_1 \subseteq X_2\) i.e., \(|X| = p^{2d-1}\) if and only if, by (2.2),

\(|M(G)| = p^{d(d-1)-1}\).

Hence, by Lemma 2.1 \(Z^*(G) = 1\). So \(G\) is capable. Converse follows from (b).
(d) Observe that, in both the cases \(|M(G/Z)| = p^{d(d-1)-1}\), follows from (2.1), taking \(Z\) a central subgroup of order \(p\). Therefore by Theorem 2.8,
\[
G/Z \cong ES_p(p^{2m+1}) \times Z_p^{(d-2m)}, \quad (m \geq 2), ES_p(p^3) \times Z_p^{(d-2)} \text{ or } Q_8 \times Z_2^{(d-2)}.
\]
\[
\Box
\]

Proof of Theorem 1.3: (a) Assume \(G_p\) is cyclic of order \(p\). Now by Proposition 2.3, \(|X_2| = p^d\). Let \(v_1 \in V\) such that \(G_p = \langle f(v_1) \rangle\). Observe that \(X_2\) is generated by the set
\[
M' := \{v_i \otimes f(v_1), \ 1 \leq i \leq d\}.
\]
Hence by Lemma 2.3 \(G_p \subseteq Z^*(G)\). Hence \(G\) is not capable with \(Z^*(G) = G_p\) or \(Z^*(G) = Z(G)\).

Using Theorem 2.8 and taking \(Z = G_p\) in (2.1), we have
\[
(3.1) \quad |M(G)| = \frac{|M(G/G_p)|}{p}
\]
Now let \(v_1, v_2 \in V\) such that \((v_1, v_2) \in G' \setminus G_p\). Then the set
\[
N' := \{v_i \otimes (v_1, v_2) + v_1 \otimes (v_2, v_i) + v_2 \otimes (v_i, v_1) \mid 3 \leq i \leq d\}
\]
is linearly independent in \(X_1\), so \(|X_1| \geq p^d-2\). The set \(M' \cup N'\) is linearly independent in \(X\) and \(M' \cap N' = \emptyset\). Thus
\[
p^2d \geq |X| \geq p^{2d-2}.
\]
Hence by (2.2),
\[
p^{d(d-1)-2} \leq |M(G)| \leq p^{d(d-1)}.
\]
(c) Now similarly, as described in the proof of Theorem 1.1, we have \(Z^*(G) = Z(G)\) if and only if \(|M(G)| = p^{d(d-1)-2}\) i.e., by (3.1),
\[
|M(G/G_p)| = p^{d(d-1)-1},
\]
which happens if and only if
\[
G/G_p \cong ES_p(p^{2m+1}) \times Z_p^{(d-2m)}, \quad m \geq 2,
\]
follows from Theorem 2.8.

(d) By Theorem 2.7 it follows that there is no \(G/G_p\) such that
\[
|M(G/G_p)| = p^{d(d-1)}.
\]
Thus by (5.1), \(|M(G)|\) cannot be of order \(p^{d(d-1)-1}\). Hence \(|M(G)| = p^{d(d-1)}\) if and only if \(Z^*(G) = G_p\). By (5.1),
\[
|M(G/G_p)| = p^{d(d-1)+1},
\]
which happens if and only if
\[
G/G_p \cong ES_p(p^3) \times Z_p^{(d-2)},
\]
follows by Theorem 2.6.

(b) By (c) and (d) it follows that \(p\) must be odd. The group \(G/G_p\) is of exponent \(p\) and \(p\) odd, so the homomorphism \(\sigma\), described in Section 2, is trivial map and therefore, \(\sigma(x) = x^p = 1\) for \(x \in M(G/G_p)\). Thus \(M(G/G_p)\) is elementary abelian. Since \(G_p \subseteq Z^*(G)\), by Theorem 2.3 and Theorem 2.2 \(M(G)\) embeds in \(M(G/G_p)\). Therefore, \(M(G)\) is also elementary abelian. The proof is complete now.

Proof of Theorem 1.4: (a) Since \(p\) is odd and \(G_p = 1\), the homomorphism \(\sigma\) described in Section 2 is the trivial map and therefore \(\sigma(x) = x^p = 1\). Thus, \(M(G)\) is elementary abelian.
Let \( z, z' \) be the generators of \( \mathbb{Z}(G) \) and \( x_1, x_2, \ldots, x_d \) be the generators of \( G \) such that \( [x_1, x_2] \in \langle z \rangle \) is non-trivial. Then the set
\[
A := \{ x_1 \otimes [x_1, x_2] + x_1 \otimes [x_2, x_3] + x_2 \otimes [x_1, x_3] \mid 3 \leq i \leq d \}
\]
consists of \( d - 2 \) linearly independent elements of \( X_1 \).

Now if for some \( x_k \in \{ 3, 4, \ldots, d \}, [x_1, x_k] \in \langle z' \rangle \) is non-trivial, then the set
\[
B := \{ x_1 \otimes [x_1, x_k] + x_1 \otimes [x_k, x_1] + x_k \otimes [x_1, x_1] \mid 3 \leq i \leq d, i \neq k \}
\]
consists of \( d - 3 \) linearly independent elements of \( X_1 \). Thus, \( A \cup B \) consists of \( (2d - 5) \) linearly independent elements of \( X_1 \).

If \( 1 \neq [x_2, x_k] \in \langle z' \rangle \), for some \( k \in \{ 3, 4, \ldots, d \} \), then a similar conclusion holds. Suppose then that \( [x_1, x_k] \) and \( [x_2, x_k] \) are all trivial or in \( \langle z \rangle \) for all \( k \in \{ 3, 4, \ldots, d \} \). Say, \( [x_3, x_4] \in \langle \{ \} \rangle \) in this case
\[
B_1 := \{ x_1 \otimes [x_3, x_4] + x_3 \otimes [x_4, x_1] + x_4 \otimes [x_1, x_3] \mid 1 \leq i \leq d, i \neq 3, 4 \}
\]
consists of \( d - 2 \) independent elements of \( X_1 \). Thus, \( A \cup B_1 \) consists of \( 2d - 4 \) linearly independent elements of \( X_1 \).

Hence in both cases, \( 2d \geq |X| = |X_1| \geq p^{2d-5} \) holds. By (2.2), it follows that,
\[
p^{d(d-1)-2} \leq |M(G)| \leq p^{d(d-1)+3},
\]
which proves (b).

Now if \( G \) is not capable, then by (2.1) and [9, Main Theorem] we have
\[
p^{d(d-1)-2} \leq |M(G)| = \frac{|M(G/Z)|}{p} \leq p^{d(d-1)} \text{ for } Z \subseteq Z^*(G), Z \cong \mathbb{Z}_p.
\]

By Theorem 2.7, there is no \( G \) and central subgroup \( Z \) such that \( |M(G/Z)| = p^{d(d-1)} \).

Hence
\[
(3.2) \quad |M(G)| = p^{d(d-1)-2} \text{ or } p^{d(d-1)-1}, \text{ if } G \text{ is not capable.}
\]

Assume then that \( G \) is capable. By [3, Proposition 3], \( p^5 \leq |G| \leq p^7 \), with \( p \) odd. If \( |G| = p^5 \), then looking through the list of groups given in [7], it follows that \( G \cong \Phi(15) \).

Since \( |X| = p \), it follows by (2.2) that \( |M(G)| = p^6 = p^{d(d-1)+3} \).

If \( |G| = p^6 \), then looking through the list of groups given in [7], it follows that \( G \cong \Phi(12)(1^6), \Phi(13)(1^6) \) or \( \Phi(15)(1^6) \). Since \( |X| = p^4 \), it follows by (2.2) that \( |M(G)| = p^6 = p^{d(d-1)+2} \).

Now consider groups of order \( p^7 \) of exponent \( p \). By [6], it follows that there is only one capable group
\[
G = \langle x_1, \ldots, x_5, c_1, c_2 \mid [x_2, x_1] = [x_5, x_3] = c_1, [x_3, x_1] = [x_5, x_4] = c_2, x_1^p = c_1^p = 1,
\]
up to isomorphism. By (2.2), \( |M(G)| = p^9 = p^{d(d-1)-1} \).

Now (e), (d), (e), (f) follow by (3.2).

(g) Now by (2.1) we have that \( Z^*(G) \cong \mathbb{Z}(G) \) if and only if \( |M(G)| = p^{d(d-1)-2} \), taking \( Z = \mathbb{Z}(G) \). Hence by (2.3), we have that for every central subgroup \( Z \) of order \( p \), \( |M(G/Z)| = p^{d(d-1)-1} \), thus
\[
G/Z \cong ES_p(p^{2m+1}) \times \mathbb{Z}_p^{d(d-1)}, \quad m \geq 2,
\]
follows from Theorem 2.8.

(h) Suppose \( Z^*(G) \cong \mathbb{Z}_p \). By (3.2) and (g), it follows that \( |M(G)| = p^{d(d-1)} \).

Conversely suppose \( |M(G)| = p^{d(d-1)} \). From the previous cases it follows that \( G \) is not capable since \( Z^*(G) \cong \mathbb{Z}_p \).
In this case, we have
\[ |M(G)| = \frac{|M(G/Z^*(G))|}{p}. \]

By Theorem 2.6, it follows that \(|M(G/Z^*(G))| = p^{\frac{d}{2}(d-1)+1}\) if and only if
\[ G/Z^*(G) \cong ES_p(p^3) \times \mathbb{Z}_p^{(d-2)}. \]

The proof is complete now. \(\square\)

**Proof of Theorem 1.5:** By Theorem 1.3, it follows that there is no special 2-group of rank 2 with \(G^2 \cong \mathbb{Z}_2\).

Assume that \(p = 2\). As in the proof of Theorem 1.4, we conclude that
\[ p^{\frac{d}{2}(d-1)+2} \leq |M(G)| \leq p^{\frac{d}{2}(d-1)+3}. \]

Let \(Z\) be a central subgroup of order 2. If \(G\) is not capable then by (2.1),
\[ 2^{\frac{d}{2}(d-1)+2} \leq |M(G)| = \frac{|M(G/Z)|}{2} \leq 2^{\frac{d}{2}(d-1)} \text{ for } Z \subseteq Z^*(G). \]

By Theorem 2.6, 2.7 and 2.8, there is no group \(G\) and central subgroup \(Z\) such that \(G/Z\) of exponent 2 and \(2^{\frac{d}{2}(d-1)+1} \leq |M(G/Z)| \leq 2^{\frac{d}{2}(d-1)+1}\). Hence \(G\) must be capable and \(|M(G/Z)| \leq 2^{\frac{d}{2}(d-1)-2}\).

Suppose \(|M(G)| = 2^{\frac{d}{2}(d-1)+2+k}\), 0 \(\leq k \leq 5\). Then by (2.2), \(|\text{Ker} \lambda_{Z(G)}| = |X| = 2^{2d-k}\).

Hence 1 \(\leq |\text{Im} \lambda_Z| = 2^m \leq 2^k\). By (2.1), it follows that
\[ 2^{\frac{d}{2}(d-1)+2+k-m} = \frac{|M(G)|}{|\text{Im} \lambda_Z|} = \frac{|M(G/Z)|}{2} \leq 2^{\frac{d}{2}(d-1)+3}. \]

Hence \(k - m \leq -1\), which is not possible. So there is no special 2-group of rank 2 with \(G^2 = 1\). The proof is complete now. \(\square\)
