ON ORLICZ-JENSEN-HERMITE-HADAMARD INEQUALITIES AND THEIR APPLICATIONS IN CONVEX GEOMETRY

BERNARDO GONZÁLEZ MERINO

Abstract. In this paper we show some Orlicz-Jensen-Hermite-Hadamard inequality and a reverse to that inequality. This establishes, in particular, one of the first multidimensional Hermite-Hadamard inequality in this generality. We then show several consequences of those inequalities.

Using the direct version of the inequality above, we derive a Milman-Pajor-Spingarn type inequality, which in some sense, improves the previous versions. Moreover, as a particular case we answer a question posed by Francisco Santos on upper bounds of the volume of a convex body in terms of the volume of one of its central sections. Using the reverse version, we derive a generalization of the Rogers-Shephard inequality for the volume of sections and projections of convex bodies.

Finally, we also derive some new tight Grünbaum type inequalities, choosing a different center than in the corresponding inequalities of Makai-Martini, Fradelizi, and Stephen-Yaskin. These new inequalities will help in quantifying the improvement of the new volumetric inequalities derived before.

The classical Jensen’s inequality [J] states that if \((X, \Sigma, \mu)\) is a probability space, then for any concave \(f : \mathbb{R} \to \mathbb{R}\) and any \(\mu\)-integrable function \(g : X \to \mathbb{R}\), we have that

\[
\int_X f(g(x))d\mu(x) \leq f \left( \int_X g(x)d\mu(x) \right),
\]

and moreover, equality holds if and only if either \(f\) is affine or \(g\) is independent of \(x\).

Let \(K^n\) (resp. \(K^n_0\)) be the set of \(n\)-dimensional compact, convex (resp. 0-symmetric) sets. For any set \(K \in K^n\), we denote by \(|K|\) the volume (or Lebesgue measure) of \(K\) computed in its affine hull \(\text{aff}(K)\), i.e., the smallest affine subspace containing \(K\). Let \(\|x\| = \sqrt{x_1^2 + \cdots + x_n^2}\) be the Euclidean norm of \(x = (x_1, \ldots, x_n) \in \mathbb{R}^n\), let \(B_n^2 = \{x \in \mathbb{R}^n : \|x\| \leq 1\}\) be the Euclidean unit ball of \(\mathbb{R}^n\), and let \(\omega_n = |B_n^2|\) be its

1
volume. The center of mass of $K \in \mathcal{K}^n$ is the point

$$x_K = \frac{1}{|K|} \int_K x \, dx.$$ 

A well-known consequence of Jensen’s inequality is the following Hermite-Hadamard inequality: for any $C \in \mathcal{K}^n$ and $f : C \to \mathbb{R}$ concave, then

$$\frac{1}{|C|} \int_C f(x) \, dx \leq f(x_C),$$

with equality sign if and only if $f$ is affine. It was named after Hermite 1881 and Hadamard 1893 proved independently (1) in the 1-dimensional case. See [DP] (and [CalCar] or [St]) and the references on it for other historical considerations and a comprehensive and complete view of this type of inequalities.

Let $\mathcal{L}_i^n$ be the set of $i$-dimensional linear subspaces in $\mathbb{R}^n$. For $K \in \mathcal{K}^n$ and $H \in \mathcal{L}_i^n$, let $P_H K$ be the orthogonal projection of $K$ onto $H$. Moreover, let $e_1, \ldots, e_n$ be the vectors of the canonical basis of $\mathbb{R}^n$. For every $A \subset \mathbb{R}^n$, let $\text{lin}(A)$ be the linear hull of $A$, and let $A^\perp$ be the orthogonal subspace to $A$, and let $\partial A$ be the boundary of $A$.

In 2017 during the conference Convex, Discrete and Integral Geometry Francisco Santos asked the following question: for every $K \in \mathcal{K}^n$ such that $P_{\text{lin}(e_1)} K = [-e_1, e_1]$, what is the smallest $c_n > 0$ such that

$$|K| \leq c_n |K \cap e_1^\perp|.$$ 

One of our aims is to compute this constant $c_n$. The same inequality is derived in [IVS, Lemma 5.2] where it is used to bound the volume of empty lattice 4-simplices in terms of volumes of 3-lattice polytopes. Notice that for every $K \in \mathcal{K}^n$ and $H \in \mathcal{L}_i^n$, Fubini’s theorem implies that

$$|K| \leq |P_H K| \max_{x \in H^\perp} |K \cap (x + H^\perp)|.$$ 

There exist special subspaces for which the inequality above strengthens. In this regard Spingarn [S] and later Milman and Pajor [MP] proved that if $K \in \mathcal{K}^n$ and $H \in \mathcal{L}_i^n$, then

$$|K| \leq |P_H K| |K \cap (x_K + H^\perp)|.$$ 

It is even known the worst deviation between the maximal volume section and the one passing through the centroid of $K$ (cf. [Fr],[MM], and further extensions in [SY]). Surprisingly enough, a consequence of Jensen’s inequality (1) shows that (cf. Theorem 3.2 below) for every $K \in \mathcal{K}^n$ and $H \in \mathcal{L}_{n-1}^n$ then

$$|K| \leq |P_H K| |K \cap (x_{P_H K} + H^\perp)|,$$

and this choice can be sometimes better than (2) (cf. Remarks 3.3 and 4.5). In this regard, we prove the following result, extending the inequality above when $K \in \mathcal{K}_0^n$.
and answering to the question posed at the beginning. The result below can be sometimes better than (2) (cf. Remark [3,3]) up to a linear factor in the dimension of the subspace.

**Theorem 1.1.** Let \( K \in \mathcal{K}^n \) and \( H \in \mathcal{L}_n^i \) be such that \( P_H K = -P_H K \). Then

\[
|K| \leq \frac{2^{n-i}}{n-i+1} |P_H K||K \cap H^\perp|.
\]

If we assume w.l.o.g. that \( H = \mathbb{R}^i \times \{0\}^{n-i} \), there is equality above if and only if there exist \( B_0 \in \mathbb{R}^{(n-i) \times i} \) and \( u \in \mathbb{R}^i \) such that \( K \cap (x + H^\perp) = (x, B_0 x) + \lambda_x K \cap H^\perp \), where

\[
\lambda_x = \frac{\langle u, x \rangle + |K \cap H^\perp|^{1 \over n-i}}{|K \cap H^\perp|^{1 \over n-i}},
\]

for every \( x \in P_H K \). If in addition \( i \leq n - 2 \), then there exist \( (x_0, 0) \in \mathbb{R}^i \times \mathbb{R}^{n-i} \) and \( K_0 \in \mathcal{K}_{i-1} \) such that \( P_H K = [(-x_0, 0), (x_0, 0)] + (\{0\} \times K_0 \times \{0\}^{n-i}) \) and that

\[
|K \cap (x + H^\perp)| = \left( 1 + \frac{\langle (x_0, 0), x \rangle}{\|x_0\|^2} \right) |K \cap H^\perp|,
\]

for every \( x \in P_H K \).

At the core of the proof of Theorem 1.1 rests a generalization of (1), which is the main result of the paper. We call it an *Orlicz-Jensen-Hermite-Hadamard inequality*, due to the similarities with the Orlicz-Brunn-Minkowski inequality [X JL]. In a sense, in this paper we highlight the intimate relation between Hermite-Hadamard inequalities and some Rogers-Shephard and Milman-Pajor type inequalities.

**Theorem 1.2.** Let \( C \in \mathcal{K}_{0}^n \), let \( f : C \to [0, \infty) \) be concave, and let \( \phi : [0, \infty) \to [0, \infty) \) be convex, non-decreasing be such that \( \phi(0) = 0 \) and \( \lim_{t \to \infty} \phi(t) = \infty \). Then

\[
\frac{1}{|C|} \int_C \phi(f(x)) dx \leq \frac{1}{2} \int_{-1}^1 \phi(f(0)(1 + t)) dt.
\]

If \( \phi \) is strictly convex and strictly monotonic, equality holds if and only after applying a suitable rotation then there exist \( C_0 \in \mathcal{K}_{0\cdot1}^{n-1} \) and \( x_0 \in \mathbb{R}^n \) with \( (x_0)_1 > 0 \) such that \( C = [-x_0, x_0] + (\{0\} \times C_0) \)

and such that \( f \) is an affine function with \( f(-x_0 + x) = 0 \), for every \( x \in \{0\} \times \mathbb{R}^{n-1} \).

Notice that the constant \( \int_{-1}^1 \phi(f(0)(1 + t)) dt / 2 \) in Theorem 1.2 is typically larger than 1, as in the case \( \phi(t) = t^m \), \( m \in \mathbb{N} \) (cf. Corollary [2,2]). One can generally obtain a similar inequality with constant 1 at the cost of choosing a worse center. Milman
and Pajor (see [MP]) proved that if \( f : \mathbb{R}^n \to [0, \infty) \) is an integrable log-concave function (i.e. \( \log(f) \) is concave), and \( \mu : \mathbb{R}^n \to [0, \infty) \) is a probability measure, then
\[
\int_{\mathbb{R}^n} f(x) d\mu(x) \leq f \left( \int_{\mathbb{R}^n} \frac{f(x)}{\int_{\mathbb{R}^n} f(z) d\mu(z)} d\mu(x) \right),
\]
and equality holds if and only if \( f(x) \) is independent of \( x \). A direct consequence of this result is the following Hermite-Hadamard inequality: for any \( C \in K^n \), \( f : C \to [0, \infty) \) concave, and \( m \in \mathbb{N} \), then
\[
\frac{1}{|C|} \int_C f(x)^m dx \leq f(x_f)^m,
\]
where \( x_f = \int_C x \frac{f(x)^m}{\int_{\mathbb{R}^n} f(z)^m dz} dx \) (\( f^m \) is log-concave if \( f \) is concave). Notice that the point \( x_f \) depends on \( f \) and does not coincide in general with \( x_C \) (cf. Corollary 2.2).

We find reverse inequalities to (1) in the literature (see for instance [Sch]) even integrated with respect to more general measures (cf. [AHRYZ, Cor. 3.1]). Here we give a reverse inequality in the sense of Theorem 1.2. Notice that for every \( A \subset \mathbb{R}^n \), we let \( \text{conv}(A) \) be the convex hull of \( A \). Moreover, for every function \( f : A \to \mathbb{R} \), \( A \subset \mathbb{R}^n \), we let \( G(f) = \{(x, f(x)) : x \in A\} \) be the graph of \( f \).

**Theorem 1.3.** Let \( C \in K^n \) with \( 0 \in C \), let \( f : C \to [0, \infty) \) be a concave function and let \( \phi : [0, \infty) \to [0, \infty) \) be convex, strictly increasing function with \( \phi(0) = 0 \) and \( \lim_{t \to \infty} \phi(t) = \infty \). Then
\[
\int_0^{\phi(f(0))} \left( 1 - \frac{\phi^{-1}(t)}{f(0)} \right)^n dt \leq \frac{1}{|C|} \int_C \phi(f(x)) dx.
\]
Moreover, equality holds if and only if \( G(f) = \text{conv}((C \times \{0\}) \cup \{(0, f(0))\}) \).

As a consequence of Theorem 1.3 we will derive (cf. Section 3) the well-known reverse inequality to (2) due to Rogers and Shephard [RS58]. It states that for every \( K \in K^n \) with \( 0 \in K \), and \( H \in L^n \), then
\[
|P_H K||K \cap H^\perp| \leq \binom{n}{i}|K|.
\]
One of the consequences of Rogers and Shephard inequality (5) states that for any \( K, C \in K^n \), then
\[
|K + C||K \cap (-C)| \leq \binom{2m}{n}|K||C|,
\]
\( \text{cf. [RS58], and see [AGJV, AJV]} \) for its equality cases. This inequality is considered as the reverse inequality to the so-called Brunn-Minkowski inequality, which states that for any \( K, C \in K^n \) and \( \lambda \in [0, 1] \), then
\[
|(1 - \lambda)K + \lambda C|^{\frac{1}{n}} \geq (1 - \lambda)|K|^{\frac{1}{n}} + \lambda|C|^{\frac{1}{n}},
\]
and equality holds if and only if $K$ and $C$ are dilates, or if they are lower dimensional, then they must be contained in parallel hyperplanes.

We split the proofs of the results into three sections. In Section 2 we proof all the functional inequalities, i.e. Theorems 1.2 and 1.3. Afterwards in Section 3 we show some applications, in particular, some volumetric inequalities solving in particular the question posed above. In Section 4 we prove some Grünbaum type inequalities for a compact convex set $K$ and a subspace passing through the centroid of an orthogonal projection of $K$. With these results, we will quantify the improvements of the results in Section 3 compared to previously known results.

2. Proof of the Orlicz-Jensen-Hermite-Hadamard type inequalities

Let us start this section by remembering that the Schwarz symmetrization of $K \in K^n$ with respect to $\text{lin}(u)$, $u \in \mathbb{R}^n \setminus \{0\}$, is the set

$$\sigma_u(K) = \bigcup_{t \in \mathbb{R}} (tu + r_t(B_2^n \cap u^\perp)),$$

where $r_t \geq 0$ is such that $|K \cap (tu + u^\perp)| = r_t^{n-1}\omega_{n-1}$. It is well-known that $\sigma_u(K) \in K^n$ and that $|\sigma_u(K)| = |K|$ (cf. [Gru, Section 9.3] or [Sch] for more details). For every $K \in K^n$ and $x \in \mathbb{R}^n \setminus \{0\}$, the support function of $K$ at $x$ is defined by $h(K, x) = \sup\{\langle x, y \rangle : y \in K\}$.

Proof of Theorem 1.2. Since $f$ is concave and non-negative in $C$, then let $g : C \to [0, \infty)$ be an affine function such that $g(0) = f(0)$ and $g(x) \geq f(x)$ for every $x \in C$.

Since $\phi$ is non-decreasing, then

$$(7) \quad \int_C \phi(f(x))dx \leq \int_C \phi(g(x))dx.$$  

Now let $H := \text{aff}(G(g))$, where $G(g) = \{(x, g(x)) : C \times \mathbb{R}\}$ is the graph of $g$, and observe that $H$ is an affine hyperplane in $\mathbb{R}^{n+1}$. Let us furthermore observe that since $H \cap (g(0)e_{n+1} + \text{lin}(\{e_1, \ldots, e_n\})) \neq \emptyset$ then $\dim(H \cap (g(0)e_{n+1} + \text{lin}(\{e_1, \ldots, e_n\}))) \geq n - 1$, and thus we let $L \in \mathcal{L}_{n-1}^n$ be such that $g(0)e_{n+1} + (L \times \{0\}) \subset H \cap (g(0)e_{n+1} + \text{lin}(\{e_1, \ldots, e_n\})).$

After a suitable rotation, we can assume that $L = \text{lin}(\{e_2, \ldots, e_n\})$, that $h(C, e_1) = t_0 > 0$, and that

$$(t_0, (x_0)_2, \ldots, (x_0)_n, g(0) + \delta) \in G(g),$$
for some \((t_0, (x_0)_2, \ldots, (x_0)_n) \in C\) and some \(\delta \geq 0\). Since \(C\) is 0-symmetric and \(g\) is affine, thus \((-t_0, -(x_0)_2, \ldots, -(x_0)_n, g(0) - \delta) \in G(g)\) too. Observe that \(g(0) - \delta \geq f((-t_0, -(x_0)_2, \ldots, -(x_0)_n)) \geq 0\), i.e., \(\delta \leq g(0)\).

Observe also that \(g\) gets constant value on each affine subspace \(M_t = \{(t, x_2, \ldots, x_n) \in C\}, t \in [-t_0, t_0]\). Hence, if \((t, x_2, \ldots, x_n) \in C\), let

\[
g(t, x_2, \ldots, x_n) = g(0) + \frac{t}{t_0} \delta.
\]

Using Fubini’s formula we have that

\[
\int_C \phi(g(x)) dx = \int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t}{t_0} \delta \right) |M_t| dt.
\]

Let us consider now \(C' := \sigma_{e_1}(C)\). If we denote by \(M'_t := \{(t, x_2, \ldots, x_n) \in C'\}\) for every \(t \in [-t_0, t_0]\), then

\[
|M_t| = |M'_t| \quad \text{for every } t \in [-t_0, t_0]
\]

and in particular \(|C| = |C'|\). Moreover, we also have that \(g(t, x_2, \ldots, x_n) = g(0) + \frac{t}{t_0} \delta\) for every \((t, x_2, \ldots, x_n) \in M'_t\). Therefore

\[
\int_C \phi(g(x)) dx = \int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t}{t_0} \delta \right) |M'_t| dt.
\]

We now define the cylinders

\[
R_t := (-te_1 + M'_t) + [-t_0e_1, t_0e_1] \quad \text{for every } t \in [0, t_0].
\]

Since \(C'\) is 0-symmetric and convex, then \(R_{t_0} \subseteq C' \subseteq R_0\). Moreover, \((R_t)_t\) is a continuously decreasing family, and thus there exists \(t^* \in [0, t_0]\) such that \(|R_{t^*}| = |C'|\).

Let \(R := R_{t^*}\) and let \(M''_t := \{(t, x_2, \ldots, x_n) \in R\} \quad \text{for } t \in [-t_0, t_0]\). Let us observe that since \(R\) and \(C'\) are 0-symmetric and \(M'_t\) and \(M''_t\) are \((n - 1)\)-Euclidean balls centered at \(te_1\) then

\[
M'_t \subseteq M''_t \quad \text{if } |t| \in [t^*, t_0] \quad \text{and} \quad M''_t \subseteq M'_t \quad \text{if } |t| \in [0, t^*].
\]

We also observe that \(|C'| = |R|\) implies that \(|C' \setminus R| = |R \setminus C'|\). Let us furthermore denote by

\[
M^*_t := M'_t \cap M''_t \quad \text{and} \quad M^{**}_t := (M'_t \setminus M''_t) \cup (M''_t \setminus M'_t).
\]

Then

\[
\int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t}{t_0} \delta \right) |M'_t| dt
\]

\[
= \int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t}{t_0} \delta \right) |M^*_t| dt + \int_{-t^*}^{t^*} \phi \left( g(0) + \frac{t}{t_0} \delta \right) |M^{**}_t| dt.
\]

\[(8)\]
We start bounding from above the simpler left integral in (8), whose domain of integration is \( C' \cap R \). Since \( \phi \) is a convex function, then \( \delta \to \phi(g(0) + (t/t_0)\delta) \) is convex too, from which we see that

\[
\int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t\delta}{t_0} \right) |M_t^*|dt = \int_{0}^{t_0} \left( \phi \left( g(0) + \frac{t}{t_0}\delta \right) + \phi \left( g(0) - \frac{t}{t_0}\delta \right) \right) |M_t^*|dt \leq \int_{0}^{t_0} \left( \phi \left( g(0) + \frac{t}{t_0}g(0) \right) + \phi \left( g(0) - \frac{t}{t_0}g(0) \right) \right) |M_t^*|dt = \int_{-t_0}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^*|dt.
\]

Now we focus in bounding from above the right integral in (8), whose domain is \((C' \setminus R) \cup (R \setminus C')\), partially using ideas from above. Using again that \( \phi \) is convex, then \( \delta \to \phi(g(0) + (t/t_0)\delta) \) is convex too, and thus

\[
\int_{-t^*}^{t^*} \left( g(0) + \frac{t\delta}{t_0} \right) |M_t^{**}|dt = \int_{0}^{t^*} \left( \phi \left( g(0) + \frac{t}{t_0}\delta \right) + \phi \left( g(0) - \frac{t}{t_0}\delta \right) \right) |M_t^{**}|dt \leq \int_{0}^{t^*} \left( \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t}{t_0} \right) \right) \right) |M_t^{**}|dt.
\]

Once more since \( \phi \) is convex then \( t \to \phi(g(0)(1 + t/t_0)) \) is convex too, and thus

\[
\int_{0}^{t^*} \left( \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t}{t_0} \right) \right) \right) |M_t^{**}|dt \leq \left( \phi \left( g(0) \left( 1 + \frac{t^*}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t^*}{t_0} \right) \right) \right) \int_{0}^{t^*} |M_t^{**}|dt = \left( \phi \left( g(0) \left( 1 + \frac{t^*}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t^*}{t_0} \right) \right) \right) \frac{|C' \setminus R|}{2} = \left( \phi \left( g(0) \left( 1 + \frac{t^*}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t^*}{t_0} \right) \right) \right) \int_{t^*}^{t_0} |M_t^{**}|dt \leq \int_{t^*}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) + \phi \left( g(0) \left( 1 - \frac{t}{t_0} \right) \right) |M_t^{**}|dt = \int_{t^*}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^{**}|dt + \int_{-t_0}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^*|dt.
\]
These two upper bounds prove from (8) that
\[
\int_C \phi(g(x))dx = \int_{-t_0}^{t_0} \phi \left( g(0) + \frac{t\delta}{t_0} \right) |M_t|dt \\
\leq \int_{-t_0}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^*|dt + \int_{-t_0}^{-t_0^*} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^*|dt \\
+ \int_{t_0^*}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) |M_t^*|dt = \int_R \phi(g_0(x))dx,
\]
where \( g_0(x) \) is an affine function with \( g_0(0) = g(0) \) and \( g_0(-t_0, x_2, \ldots, x_n) = 0 \) for every \((x_2, \ldots, x_n) \in \mathbb{R}^{n-1}\). Again by Fubini we now get that
\[
\int_R \phi(g_0(x))dx = \int_{-t_0}^{t_0} \phi \left( g(0) \left( 1 + \frac{t}{t_0} \right) \right) \frac{|R|}{2t_0^*}dt = \frac{1}{2} \int_{-1}^{1} \phi(g(0)(1+s))ds|R| \\
= \frac{1}{2} \int_{-1}^{1} \phi(f(0)(1+s))ds|C|,
\]
concluding the proof of the inequality.

For the equality case, let us suppose that \( \phi \) is strictly convex and strictly increasing, we must have equality in all inequalities above. Equality in (7) together with the strict monotonicity of \( \phi \) implies that \( f \) must be an affine function. Equalities in (10) together with the strict convexity of \( \phi \) force that \( |M_t^*| = 0 \) for every \( t \in [0, t_0] \), i.e., \( C' \) has to fulfill
\[
|C' \cap (t, x_2, \ldots, x_n)| = |R \cap (t, x_2, \ldots, x_n)| = c
\]
for every \( t \in [-t_0, t_0] \) and some constant \( c > 0 \). Since \( C' = \sigma_e C \), hence we also have that
\[
|C \cap (t, x_2, \ldots, x_n)| = |C' \cap (t, x_2, \ldots, x_n)| = c,
\]
and thus the equality case of Brunn-Minkowski inequality (6) implies that \( C \cap (t, x_2, \ldots, x_n) \) is a translation of the same \((n-1)\)-dimensional set for every \( t \in [-t_0, t_0] \). This is equivalent to the fact that
\[
C = [-x_0, x_0] + (\{0\} \times C_0),
\]
where \( x_0 = (t_0, (x_0)_2, \ldots, (x_0)_n) \) and \( C_0 \in \mathcal{K}_0^{n-1} \). Finally, equality in (9) forces that \( \delta = f(0) \), i.e., that \( g(-t_0, x_2, \ldots, x_n) = 0 \) for every \((x_2, \ldots, x_n) \in \mathbb{R}^{n-1}\), which concludes the equality case.

\[\square\]

**Remark 2.1.** Notice that for any \( C_0 \in \mathcal{K}_0^n \) then
\[
C = [-e_1, e_1] \times C_0 \quad \text{and} \quad f(x) = \langle x, e_1 \rangle - 1
\]
attain equality in Theorem 1.3 for every convex, non-decreasing function \( \phi : [0, \infty) \rightarrow [0, \infty) \) with \( \phi(0) = 0 \) and \( \lim_{t \rightarrow \infty} \phi(t) = \infty \).
Our first corollary follows from applying Theorem 1.2 to $\phi(t) = t^\alpha$. In the next section we will use it to give new estimates of the volume of a convex body in terms of the volumes of some of its sections and projections.

**Corollary 2.2.** Let $C \in \mathcal{K}_0^n$, let $f : C \rightarrow [0, \infty)$ be concave, and let $\alpha \geq 1$. Then
\[
\frac{1}{|C|} \int_C f(x)^\alpha dx \leq \frac{2^\alpha}{\alpha + 1} f(0)^\alpha.
\]
Equality holds if $f$ is affine and if moreover $\alpha > 1$, if and only if $C$ is a generalized cylinder $C = [-x_0, x_0] + \{0\} \times C_0$, for some $C_0 \in \mathcal{K}^{n-1}$ with $(x_0)_1 > 0$, and such that $f(-x_0 + x) = 0$ for every $x \in \mathbb{R}^n$ with $x_1 = 0$.

Yet another corollary to Theorem 1.2 is when we apply it to $\phi(t) = e^t - 1$.

**Corollary 2.3.** Let $C \in \mathcal{K}_0^n$ and let $f : C \rightarrow [0, \infty)$ be concave. Then
\[
\frac{1}{|C|} \int_C e^{f(x)} dx \leq \frac{e^{2f(0)} - 1}{2f(0)}.
\]
Equality holds if and only if $C$ is a generalized cylinder $C = [-x_0, x_0] + \{0\} \times C_0$, for some $C_0 \in \mathcal{K}^{n-1}$ with $(x_0)_1 > 0$, and $f$ is an affine function such that $f(-x_0 + x) = 0$ for every $x \in \mathbb{R}^n$ with $x_1 = 0$.

**Proof of Theorem 1.3.** Since $f$ is a non-negative concave function, then the function $g : C \rightarrow [0, \infty)$ whose graph is the truncated cone with base at $C \times \{0\}$ and apex at $(0, f(0)) \in \mathbb{R}^n \times \mathbb{R}$ fulfills $g(x) \leq f(x)$ for every $x \in C$ and $g(0) = f(0)$. Since $\phi$ is increasing, then $\phi(g(x)) \leq \phi(f(x))$ for every $x \in C$ and thus
\[
\int_C \phi(f(x)) dx \geq \int_C \phi(g(x)) dx.
\]
Let us observe that if $(x_0, 0) \in \partial C \times \{0\}$, for any $s \in [0, 1]$ then
\[
g((1 - s)(0, \ldots, 0) + s(x_0, 0)) = g(0)(1 - s).
\]
This means that for every $t \in [0, 1]$, then
\[
\{x \in \mathbb{R}^n : \phi(g(x)) \geq t\} = \left(1 - \frac{\phi^{-1}(t)}{f(0)}\right) C.
\]
Observe that $\phi^{-1}$ is well-defined and continuous as $\phi$ is strictly increasing and continuous on its interior as it is convex too. Thus
\[
\int_C \phi(g(x)) dx = \int_0^{\phi(0)} \left|\{x \in \mathbb{R}^n : \phi(g(x)) \geq t\}\right| dt
\]
\[
= \int_0^{\phi(0)} \left(1 - \frac{\phi^{-1}(t)}{f(0)}\right) C dt
\]
\[
= |C| \int_0^{\phi(f(0))} \left(1 - \frac{\phi^{-1}(t)}{f(0)}\right)^n dt,
\]
which concludes the proof.

Since \( \phi \) is strictly increasing, there is equality above if and only if \( f(x) \) coincides with \( g(x) \), therefore concluding the equality case. \( \square \)

A direct consequence of Theorem 1.3 is the following result.

**Corollary 2.4.** Let \( C \in K^n \) with \( 0 \in C \), let \( f : C \to [0, \infty) \) be a concave function, and let \( m \in \mathbb{N} \). Then

\[
\left( \frac{n + m}{n} \right)^{-1} f(0)^m \leq \frac{1}{|C|} \int_C f(x)^m dx.
\]

Moreover, equality holds if and only if \( G(f) = \text{conv}((C \times \{0\}) \cup (0, f(0))) \)

**Proof.** Applying Theorem 1.3 to \( \phi(t) = t^m \), we see that

\[
\frac{1}{|C|} \int_C f(x)^m dx \geq \int_0^{f(0)^m} \left( 1 - \frac{t^{\frac{1}{m}}}{f(0)} \right)^n dt \]

\[
= f(0)^m \int_0^1 \left( 1 - t^{\frac{1}{m}} \right)^n dt \]

\[
= f(0)^m m \int_0^1 (1 - r)^n r^m dr = \left( \frac{n + m}{n} \right)^{-1} f(0)^m,
\]

concluding the proof.

The equality holds the same way as in Theorem 1.3. \( \square \)

### 3. Estimating sizes of convex sets by their marginals

We start this section by proving Theorem 1.1 as a consequence of Corollary 2.2.

**Proof of Theorem 1.1.** By Fubini’s formula, we have that

\[
|K| = \int_{P_H K} |K \cap (x + H^\perp)| dx.
\]

By Brunn-Minkowski inequality (6) then

\[
f : H \to [0, \infty) \quad \text{where} \quad f(x) := |K \cap (x + H^\perp)|^{\frac{1}{n-i}}
\]

is a concave function. Assuming that \( H = \mathbb{R}^i \times \{0\}^{n-i} \), then Corollary 2.2 implies that

\[
\int_{P_H K} f(x)^{n-i} dx \leq \frac{2^{n-i}}{n - i + 1} |P_H K| f(0)^{n-i}
\]

\[
= \frac{2^{n-i}}{n - i + 1} |P_H K| |K \cap H^\perp|,
\]

concluding the result.
For the equality case, we must have equality in Corollary 2.2 where \( f(x) = |K \cap (x + H^\perp)|^{1/n} \), \( C = P_H K \), and \( \alpha = n - i \). Hence, first of all, \( f(x) \) must be an affine function. We hence can write
\[
f(x) = f(0) + \langle u, x \rangle,
\]
for some \( u \in \mathbb{R}^i \). This means in particular that
\[
|K \cap ((1 - \lambda)x + \lambda y)|^{\frac{1}{n-1}} = f((1 - \lambda)x + \lambda y) = f(0) + \langle u, (1 - \lambda)x + \lambda y \rangle
\]
\[
= (1 - \lambda)(f(0) + \langle u, x \rangle) + \lambda (f(0) + \langle u, y \rangle)
\]
\[
= (1 - \lambda)|K \cap (x + H^\perp)|^{\frac{1}{n-1}} + \lambda |K \cap (y + H^\perp)|^{\frac{1}{n-1}}.
\]
Hence, using Brunn-Minkowski equality case 6, we have that \( K \cap (x + H^\perp) \) are dilates, of volume
\[
|K \cap (x + H^\perp)|^{\frac{1}{n-1}} = \langle u, x \rangle + |K \cap H^\perp|^{\frac{1}{n-1}}.
\]
Since \( K \) is convex, then there exists a matrix \( B \in \mathbb{R}^{n \times n} \) of the form
\[
B = \begin{pmatrix}
I_i & 0 \\
B_0 & 0
\end{pmatrix},
\]
where \( B_0 \in \mathbb{R}^{(n-i) \times i} \) and \( I_i \) is the identity matrix of \( \mathbb{R}^{i \times i} \), such that
\[
K \cap (x + H^\perp) = (x, B_0 x) + \lambda_x (K \cap H^\perp),
\]
with
\[
\lambda_x = \frac{|K \cap (x + H^\perp)|^{\frac{1}{n-1}}}{|K \cap H^\perp|^{\frac{1}{n-1}}} = \frac{\langle u, x \rangle + |K \cap H^\perp|^{\frac{1}{n-1}}}{|K \cap H^\perp|^{\frac{1}{n-1}}}.
\]
Second, if \( \alpha = n - i \geq 2 \), i.e. \( i \leq n - 2 \), then we moreover have that there exist \( K_0 \in K^{i-1} \) and \( x_0 \in \mathbb{R}^i \) such that \( P_H K = [-x_0, x_0] + (\{0\} \times K_0) \). Moreover, we must have also that
\[
f((-x_0, x_{i+1}, \ldots, x_n) = 0 \quad \text{for every } (-x_0, x_{i+1}, \ldots, x_n) \in \mathbb{R}^n,
\]
i.e., that \( |K \cap ((-x_0, x_{i+1}, \ldots, x_n) + H^\perp)| = 0 \). Once more since \( f \) is affine, this means that
\[
u = \frac{|K \cap H^\perp|^{\frac{1}{n-1}}}{\|x_0\|^2} x_0,
\]
i.e., that
\[
|K \cap (x + H^\perp)|^{\frac{1}{n-1}} = \frac{|K \cap H^\perp|^{\frac{1}{n-1}}}{\|x_0\|^2} \langle x_0, x \rangle + |K \cap H^\perp|^{\frac{1}{n-1}},
\]
thus concluding the equality case. \( \square \)
Remark 3.1. For any $C_0 \in K_{0}^{i-1}$, $C_1 \in K_n^{i}$, the set

$$C = \{(t, x_2, \ldots, x_n) : t \in [-1, 1], (x_2, \ldots, x_i) \in C_0, (x_{i+1}, \ldots, x_n) \in (1 + t)C_1\}$$

together with the subspace $H = \text{lin}\{e_1, \ldots, e_i\}$ achieves equality in Theorem 1.1.

We now properly state (1) along with the characterization of its equality cases. Notice that here we do not require $K$ to be 0-symmetric.

Theorem 3.2. Let $K \in K^n$ and $H \in L_{n-1}^n$. Then

$$|K| \leq |P_HK||K \cap (x_{P_HK} + H^\perp)|.$$  

If we assume w.l.o.g. that $H = \mathbb{R}^{n-1} \times \{0\}$ and that $x_{P_HK} = \{0\}$, there is equality above if and only if there exist $B_0 \in \mathbb{R}^{1 \times n-1}$ and $u \in \mathbb{R}^{n-1}$ such that $K \cap (x + H^\perp) = (x, B_0x) + \lambda_x K \cap H^\perp$, where

$$\lambda_x = \frac{\langle u, x \rangle + |K \cap H^\perp|}{|K \cap H^\perp|},$$

for every $x \in P_HK$.

Proof. Let us consider the function

$$f : P_HK \to [0, \infty) \quad \text{with} \quad f(x) = |K \cap (x + H^\perp)|$$

which by Brunn-Minkowski inequality (6), is a concave function. Hence, using Fubini’s formula and (1) we directly obtain that

$$|K| = \int_{P_HK} f(x) dx \leq |P_HK||f(x_{P_HK})| = |P_HK||K \cap (x_{P_HK} + H^\perp)|,$$

as desired.

The equality case follows as the equality case of Theorem 1.1.

We now give two interesting observations out of Theorem 3.2.

Remark 3.3. Let us observe that Theorem 3.2 sometimes gives a tighter inequality than (2). Indeed, if we consider the cone $K \in K^3$ with apex at $(0, 0, \sqrt{3})$ and basis $B_2^2 \times \{0\}$, and consider $H = \text{lin}\{e_1, e_3\}$, it is straightforward to check that

$$x_K = \left(0, 0, \frac{\pi}{4}\right) \quad \text{and} \quad x_{P_HK} = (0, 0, 1),$$

and thus, that

$$\frac{|K|}{|P_HK||K \cap (x_K + H^\perp)|} < \frac{|K|}{|P_HK||K \cap (x_{P_HK} + H^\perp)|} < 1.$$

One can combine two of those inequalities to show that any point in the line segment determined by two good choices of points (as in (2)), is again a good choice.
Remark 3.4. If for some $K \in \mathcal{K}^n$ and $H \in \mathcal{L}_i^a$ there exist points $x_0, x_1 \in K$ such that
\begin{equation}
\frac{|K|}{|P_H K|} \leq |K \cap (x_j + H^\perp)|, \quad \text{for } j = 0, 1,
\end{equation}
then, for every $\lambda \in [0, 1]$, the Brunn-Minkowski inequality (6) gives that
\begin{equation*}
|K \cap ((1 - \lambda)x_0 + \lambda x_1 + H^\perp)| \\
\geq \left( (1 - \lambda)|K \cap (x_0 + H^\perp)| \frac{1}{n-i} + \lambda|K \cap (x_1 + H^\perp)| \frac{1}{n-i} \right)^{n-i} \\
\geq \frac{|K|}{|P_H K|},
\end{equation*}
i.e., all points $(1 - \lambda)x_0 + \lambda x_1$ also fulfills the inequality (11), $\lambda \in [0, 1]$. In particular, from Theorem 3.2 and (2) with $i = n - 1$, we obtain that $c_\lambda = (1 - \lambda)x_K + \lambda x_{P_H K}$ gives also an inequality of the same type.

We finish this section by proving (5) as a direct consequence of Corollary 2.4.

Proof of (5). Let us observe that Brunn-Minkowski inequality (6) implies that $f : P_H K \to [0, \infty)$ with $f(x) = |K \cap (x + H^\perp)| \frac{1}{n-i}$ is a concave function. Therefore Fubini’s formula and Corollary 2.4 imply that
\begin{align*}
|K| &= \int_{P_H K} |K \cap (x + H^\perp)| \, dx = \int_{P_H K} f(x)^{n-i} \, dx \\
&\geq \binom{n}{i-1} |P_H K| f(0)^{n-i} \\
&= \binom{n}{i-1} |P_H K| |K \cap H^\perp|,
\end{align*}
proving the inequality.

The equality case follows immediately as in the equality case of Theorem 1.1. □

4. GRÜNBAUM TYPE INEQUALITIES THROUGH CENTROID OF PROJECTIONS

As observed above, replacing in (2) $x_K$ by $x_{P_H K}$ gives sometimes a better choice. To see this, remember that if $K \in \mathcal{K}^n$ with $x_K = 0$ and $H \in \mathcal{L}_i^a$, then Fradelizi [Fr] (earlier Makai and Martini [MM] in the case $i = 1$) proved that
\begin{equation}
\max_{x \in H} |K \cap (x + H^\perp)| \leq \left( \frac{n + 1}{n - i + 1} \right)^{n-i} |K \cap H^\perp|.
\end{equation}
However, if we translate $K$ such that $x_{P_H K} = 0$, then we obtain a much tighter estimate (cf. (2) and Theorem 1.1). For any $A \subset \mathbb{R}^n$ we denote by $\text{relbd}(A)$ the relative boundary of $A$. 
Theorem 4.1. Let $K \in \mathcal{K}^n$ and let $H \in \mathcal{L}_i^n$ be such that $P_H K = -P_H K$. Then
$$\max_{x \in H} |K \cap (x + H^\perp)| \leq 2^{n-i}|K \cap H^\perp|.$$ Moreover, equality holds if and only if there exists $u \in \partial K \cap H$, $v \in H^\perp$, $a, b \in \mathbb{R}$, such that $|K \cap (u + H^\perp)| = \max_{x \in H} |K \cap (x + H^\perp)|$ and
$$K \cap (tu + H^\perp) = (a + bt)v + \frac{1 + t}{2} K \cap (u + H^\perp) \quad \text{for every } t \in [-1, 1].$$

Proof. Let $x \in P_H K$ and let $-\rho x \in \text{relbd}(P_H K)$, for some $\rho \geq 1$. Observe that
$$0 = \frac{\rho}{1 + \rho} x + \frac{1}{1 + \rho} (\rho x).$$
The convexity of $K$ implies that
$$\frac{\rho}{1 + \rho} K \cap (x + H^\perp) + \frac{1}{1 + \rho} K \cap (-\rho x + H^\perp) \subset K \cap H^\perp,$$ and Brunn-Minkowski inequality then implies that
$$|K \cap H^\perp| \geq \frac{\rho}{1 + \rho} |K \cap (x + H^\perp)|^{\frac{1}{n-i}} + \frac{1}{1 + \rho} |K \cap (-\rho x + H^\perp)|^{\frac{1}{n-i}}$$
$$\geq \frac{\rho}{1 + \rho} |K \cap (x + H^\perp)|^{\frac{1}{n-i}}$$
$$\geq \frac{1}{2} |K \cap (x + H^\perp)|^{\frac{1}{n-i}},$$
as desired.

If we have equality above, then we have equality in all inequalities. This means that there exists some $u \in \text{relbd}(P_H K)$ for which $|K \cap (u + H^\perp)| = \max |K \cap (x + H^\perp)|$, $2^{n-i}|K \cap H^\perp| = |K \cap (u + H^\perp)|$ and $|K \cap (-u + H^\perp)| = 0$. These three values together with Brunn-Minkowski inequality imply that $|K \cap (tu + H^\perp)|^{\frac{1}{n-i}}$ is an affine function on $t$, ranging from value 0 at $t = -1$ to the maximum value at $t = 1$, and thus
$$|K \cap (tu + H^\perp)|^{\frac{1}{n-i}} = \frac{(1 + t)}{2} |K \cap (u + H^\perp)|^{\frac{1}{n-i}}$$
for every $t \in [-1, 1]$. By the Brunn-Minkowski equality cases, we hence have that $K \cap (tu + H^\perp)$ are dilates for every $t \in [-1, 1]$, and thus there must exist $v \in H$ and another affine function $a + bt$, $a, b \in \mathbb{R}$, such that
$$K \cap (tu + H^\perp) = (a + bt)v + \frac{1 + t}{2} K \cap (u + H^\perp)$$
for every $t \in [-1, 1]$, as desired. \hfill \Box

Remark 4.2. We can construct very general examples of convex sets sharp in Theorem [4.1]. For instance, let $B \in \mathcal{K}_0^n$, $C \in \mathcal{K}^{n-i}$, and let $x_0 \in \partial B \times \{0\}^{n-1}$. Then the set
$$K = \text{conv} \left((B \times \{0\}^{n-i}) \cup (x_0 + (\{0\}^i \times C))\right)$$
attains equality in Theorem [4.1] for the subspace $H = \text{lin}(\{e_1, \ldots, e_i\})$. 
Remark 4.3. Using Theorem 4.1 we see that if $K \in \mathcal{K}^n$ is near the extreme cases (w.r.t. Hausdorff or Banach-Mazur distance),

$$\max |K \cap (x + H^\perp)| \approx 2^{n-i}|K \cap H^\perp|,$$

which applied in Theorem 1.1 gives us

$$\max |K \cap (x + H^\perp)| \gtrapprox (n - i + 1) \frac{|K|}{|P_H K|}.$$ 

If instead we consider (12) we have that

$$\max |K \cap (x + H^\perp)| = c |H \cap (x_K + H^\perp)|$$

for some $c \in [1, e]$, which applied in (2) gives

$$\max |K \cap (x + H^\perp)| \geq c \frac{|K|}{|P_H K|}.$$ 

Hence implying that Theorem 4.1 essentially improves the choice of (2) by the linear factor $(n - i + 1)/c$.

For the sake of completeness, we also show the general inequality in the regard of Theorem 4.1. In order to establish it, let us remember that Hammer \cite{Ha} proved that if $K \in \mathcal{K}^n$ has $x_K = 0$ and $u \in \partial K$ and $-\rho u \in \partial K$, then

\begin{equation}
\frac{1}{n} \leq \rho \leq n. \tag{13}
\end{equation}

**Theorem 4.4.** Let $K \in \mathcal{K}^n$ and let $H \in \mathcal{L}^n_i$. Then

$$\max_{x \in H} |K \cap (x + H^\perp)| \leq (i + 1)^n-i|K \cap (x_{P_H K} + H^\perp)|.$$ 

Moreover, equality holds if and only if after a suitable rigid motion, there exist $M \in \mathcal{K}^{i-1}$, $a, b \in \mathbb{R}$, $t_0 > 0$, $u \in \mathbb{R}^{i-1}$, and $v \in H^\perp$, such that $P_H K = \text{conv}((\{t_0\} \times M) \cup \{(-it_0, u)\})$ with $x_{P_H K} = 0$, and such that $\max_{x \in H} |K \cap (x + H^\perp)| = |K \cap ((-it_0, u) + H^\perp)|$ with

$$K \cap (te + H^\perp) = (a + bt)v + \frac{t_0 - t}{t_0(i + 1)} K \cap ((-it_0, u) + H^\perp)$$

for every $t \in t_0[-i, 1]$.

**Proof.** Let us suppose after a translation of $K$ that $x_{P_H K} = 0$. If $x \in P_H K$ and if $-\rho x \in \text{relbd}(P_H K)$, by (13) we have that $\rho \geq 1/i$.

Observe that $0 = \frac{\rho}{1+\rho} x + \frac{1}{1+\rho} (-\rho x)$. The convexity of $K$ implies that

$$\frac{\rho}{1+\rho} K \cap (x + H^\perp) + \frac{1}{1+\rho} K \cap (-\rho x + H^\perp) \subseteq K \cap H^\perp,$$
and Brunn-Minkowski inequality \(6\) then implies that
\[
\left| K \cap H^\perp \right|^{\frac{1}{n-1}} \geq \frac{\rho}{1+\rho} \left| K \cap (x + H^\perp) \right|^{\frac{1}{n-1}} + \frac{1}{1+\rho} \left| K \cap (-\rho x + H^\perp) \right|^{\frac{1}{n-1}}
\]
\[
\geq \frac{\rho}{1+\rho} \left| K \cap (x + H^\perp) \right|^{\frac{1}{n-1}}
\]
\[
\geq \frac{1}{1+\rho} \left| K \cap (x + H^\perp) \right|^{\frac{1}{n-1}},
\]
as desired.

The equality case follows proceeding as in the equality case of Theorem 4.1. \(\square\)

**Remark 4.5.** Using Theorem 4.4 for some \(H \in \mathcal{L}_{n-1}^n\) we see that if \(K \in \mathcal{K}_n\) is near the extreme cases (in Hausdorff or Banach-Mazur distance),
\[
\max |K \cap (x + H^\perp)| \approx n |K \cap H^\perp|,
\]
which applied in Theorem 3.2 gives us
\[
\max |K \cap (x + H^\perp)| \geq n \frac{|K|}{|P_H K|}.
\]
If instead we consider \(12\) we have that
\[
\max |K \cap (x + H^\perp)| = c |H \cap (x_K + H^\perp)|
\]
for some \(c \in [1,e]\), which applied in \(2\) gives
\[
\max |K \cap (x + H^\perp)| \geq c \frac{|K|}{|P_H K|}.
\]
Thus showing that Theorem 3.2 improves upon the choice of \(2\) by the linear factor \(n/c\).
