An integral formula for a pair of singular distributions

Paul Popescu* and Vladimir Rovenski†

Abstract

The paper is devoted to differential geometry of singular distributions (i.e., of varying dimension) on a Riemannian manifold. Such distributions are defined as images of the tangent bundle under smooth endomorphisms. We prove the novel divergence theorem with the divergence type operator and deduce the Codazzi type equation for a pair of singular distributions. Tracing our Codazzi type equation yields expression of the mixed scalar curvature through invariants of distributions, which provides some splitting results. Applying our divergence theorem, we get the integral formula, generalizing the known one, with the mixed scalar curvature of a pair of transverse singular distributions.

Keywords: Riemannian metric, singular distribution, second fundamental form, divergence, integral formula, mean curvature

Introduction

Distributions, being subbundles of the tangent bundle \( TM \) on a manifold \( M \), arise in such topics of differential geometry as vector fields, submersions, fiber bundles, Lie groups actions, \[3, 9, 14\], and in theoretical physics \[3, 10\]. Foliations, which are defined as partitions of a manifold \( M \) into collections of submanifolds-leaves (of the same dimension in regular case), correspond to integrable distributions. Riemannian foliations (that is having equidistant leaves) with singularities were defined by P. Molino \[11\], the orbit decomposition of an isometric actions of a Lie group gives an example, \[1\]. There is some interest of geometers and engineers to singular distributions, i.e., having varying dimension, e.g. \[7\]. We define such distributions as images of \( TM \) under smooth endomorphisms \( P \). The paper is devoted to differential geometry of singular distributions and foliations (i.e., the geometrical properties depending on structural tensors) and continues the study \[12, 13\]. In Section 1 we deduce the Codazzi equation for a pair of transverse singular distributions. In Section 2 we prove the new divergence theorem (and its modification for open Riemannian manifolds) with the divergence type operator, called the \( P \)-divergence. We give examples with Einstein tensors and with almost contact structure and \( f \)-structure. Tracing our Codazzi equation yields expression of the mixed scalar curvature \( S_{mix}^P \) (see \[3, 14\] for regular distributions) through invariants of distributions, which provides some splitting results. Integral formulas (mainly, based on the divergence theorem) provide obstructions to existence of foliations or compact...
leaves of them, see survey \[2\]. In Section \[3\] using our \(P\)-divergence theorem, we obtain the integral formula with \(S\) of a pair of transverse singular distributions, parameterized by self-adjoint endomorphisms; the formula generalizes the known one in \[16\], which has many applications.

## 1 Structural tensors of singular distributions

Let \(M\) be a smooth \(n\)-dimensional manifold, \(TM\) – the tangent bundle, \(\mathcal{X}_M\) – the Lie algebra of smooth vector fields on \(M\), and \(\text{End}(TM)\) – smooth endomorphisms of \(TM\), i.e., linear maps on the fibers of \(TM\). Let \(C^\infty(M)\) be the algebra of smooth functions on \(M\).

**Definition 1** An image \(\mathcal{D} = \Pi(TM)\) of an endomorphism \(\Pi \in \text{End}(TM)\) will be called a *generalized vector subbundle* of \(TM\) or a *singular distribution*. Let \(\Pi(\mathcal{X}_M)\) be an \(C^\infty(M)\)-submodule of \(\mathcal{X}_\mathcal{D}\) (smooth vector fields on \(\mathcal{D}\)), i.e., sections \(Y = \Pi(X) \in \mathcal{X}_\mathcal{D}\), where \(X \in \mathcal{X}_M\).

Let \(P_1, P_2\) be endomorphisms of \(TM\) such that the intersection of their images is trivial, hence \(\text{rank } P_1(x) + \text{rank } P_2(x) \leq n\) for any \(x \in M\). For example, \(P_i\) may be projectors from \(TM\) onto transverse distributions. Given distributions \(\mathcal{D}_1 = P_1(TM)\), put \(\mathcal{D} = P(TM)\) for \(P = P_1 + P_2 \in \text{End}(TM)\). Then \(P(TM) = \mathcal{D}_1 \oplus \mathcal{D}_2\) is the generalized vector subbundle of \(TM\), but not necessarily \(\mathcal{D}_1 \oplus \mathcal{D}_2 = TM\). A Riemannian metric \(g = \langle \cdot,\cdot \rangle\) on \(M\) is adapted if

\[
P_iP_j = P_i^*P_j = 0 \quad (i \neq j). \tag{1}
\]

In this case, \(\mathcal{D}_1 \perp_g \mathcal{D}_2\) and \(\mathcal{D}_1^* \perp_g \mathcal{D}_2^*\), where \(\mathcal{D}_i^* = P_i^*(TM)\) are generalized vector subbundles and \(P_i^*, P_2^*\) are adjoint endomorphisms of \(TM\), i.e., \(\langle P_i(X), Y \rangle = \langle X, P_i^*(Y) \rangle\). Similarly, we define endomorphism \(P^* = P_1^* + P_2^*\) and generalized vector subbundle \(\mathcal{D}^* = P^*(TM)\).

**Remark 1** By \[13\], given a Riemannian metric and a singular distribution \(\mathcal{D}_1\) on \(M\), there are self-adjoint endomorphisms \(P_1\) and \(P_2\) of \(TM\) such that \(P_1(TM) = \mathcal{D}_1\) and \(P_2(TM) = \mathcal{D}_2\) are smooth orthogonal distributions, the direct sum decomposition \(TM = P_1(TM) \oplus P_2(TM)\) is valid on a dense subset of \(M\). We use self-adjoint endomorphisms only in the last section.

Let \(\nabla : (\mathcal{X}_M)^2 \to \mathcal{X}_M\) be a linear connection, that is (for any \(X_1, Y \in \mathcal{X}_M\) and \(f \in C^\infty(M)\))

\[
\nabla_{fX_1 + X_2}Y = f\nabla_{X_1}Y + \nabla_{X_2}Y, \quad \nabla_Y(fX_1 + X_2) = f\nabla_YX_1 + Y(f) \cdot X_1 + \nabla_YX_2.
\]

The Levi-Civita connection of \(g\) is a metric and torsionless linear connection, that is

\[
Z\langle X, Y \rangle = \langle \nabla_Z X, Y \rangle + \langle X, \nabla_Z Y \rangle, \quad \nabla_X Y - \nabla_Y X - [X, Y] = 0.
\]

**Definition 2** Given \(P_1, P_2 \in \text{End}(TM)\), the *structural tensors* of singular distributions \(\mathcal{D}_i = P_i(TM)\) are bilinear maps \(B_i : (\mathcal{X}_M)^2 \to P_i(\mathcal{X}_M)\) \((i = 1, 2)\), given by

\[
B_1(Y, X) := P_1^*\nabla_{P_1X}P_2Y, \quad B_2(X, Y) := P_2^*\nabla_{P_2Y}P_1X. \tag{2a}
\]

Similarly, define *structural tensors* \(\hat{B}_i\) of dual distributions \(\mathcal{D}_i^*\) and auxiliary tensors \(\hat{B}_i\):

\[
\hat{B}_1(Y, X) := P_1\nabla_{P_1^*X}P_2^*Y, \quad \hat{B}_2(X, Y) := P_2\nabla_{P_2^*Y}P_1^*X, \tag{2b}
\]

\[
\hat{B}_1(Y, X) := P_1\nabla_{P_1^*X}P_2^*Y, \quad \hat{B}_2(X, Y) := P_2\nabla_{P_2^*Y}P_1^*X. \tag{2c}
\]
For self-adjoint endomorphisms $P_i$ ($i = 1, 2$), we have $B_i = \hat{B}_i = \check{B}_i$ and $D^*_i = D_i$. In particular, for orthoprojectors $P_i$ (thus, $P_i^2 = P_i$) from $TM$ onto complementary orthogonal regular distributions $D_i$ and the Levi-Civita connection, the structural tensors $B_i$ have been defined in [14, p. 31].

**Definition 3** A pair $(P_1, P_2)$ (or a tensor $P = P_1 + P_2$) is allowed for a connection $\nabla$ if

$$b^{(i)}_j = 0, \quad i, j \in \{1, 2\}.$$  

The bilinear forms $b^{(i)}_1 : (\mathcal{X}_M)^2 \to P_2(\mathcal{X}_M)$ and their dual $b^{(i)}_2 : (\mathcal{X}_M)^2 \to P_1(\mathcal{X}_M)$ are given by

$$b^{(1)}_1(X, Y) = P_1^* P_2 \nabla_{P_1 X} P_1^* Y - P_2^* \nabla_{P_1 X} P_1 P_2^* Y,$$

$$b^{(2)}_1(X, Y) = P_2^* P_2 \nabla_{P_1 X} P_1^* Y - P_2 \nabla_{P_1 X} P_1 P_2^* Y,$$

$$b^{(1)}_2(X, Y) = P_1^* P_1 \nabla_{P_2 X} P_2^* Y - P_1 \nabla_{P_2 X} P_2 P_2^* Y,$$

$$b^{(2)}_2(X, Y) = P_1^* P_1 \nabla_{P_2 X} P_2^* Y - P_1 \nabla_{P_2 X} P_2 P_2^* Y.$$  

**Example 1** A simple example of allowed endomorphism is $P = f \text{id}$, where $P = f P_1 + f P_2$, $P_i$ are orthoprojectors onto complementary orthogonal regular distributions, $\text{id}$ is the identity endomorphism of $TM$ and $f$ is a real function on $M$ such that its supporting set is dense in $M$. More examples of singular distributions of this type, even integrable, are given in [12].

**Lemma 1** If $(P_1, P_2)$ is allowed for a metric connection $\nabla$, then for all $X, Y \in \mathcal{X}_M$ we have

$$P_2 B_2(X, Y) = \hat{B}_2(X, P_2 Y) = \hat{B}_2(P_1 X, Y),$$

$$P_1 B_1(Y, X) = \hat{B}_1(Y, P_1 X) = \hat{B}_1(P_2 Y, X).$$

**Proof.** Using $b^{(2)}_2 = 0$ and (1), we obtain

$$0 = \langle P_1^* P_1 \nabla_{P_2 Y} P_2^* Z, X \rangle - \langle P_1 \nabla_{P_2 Y} P_2^* Z, P_1 X \rangle = \langle \nabla_{P_2 Y} P_2^* Z, P_1 X \rangle - \langle \nabla_{P_2 Y} P_2^* Z, P_1^* X \rangle = -\langle P_2^* Z, \nabla_{P_2 Y} P_1^* P_1 X \rangle + \langle P_2^* Z, \nabla_{P_2 Y} P_1^* P_1 X \rangle = \langle \hat{B}_2(X, P_2 Y) - \hat{B}_2(P_1 X, Y), Z \rangle.$$  

Similarly, using $b^{(1)}_2 = 0$, we obtain

$$0 = \langle P_1^* P_1 \nabla_{P_2 Y} P_2^* Z - P_1^* \nabla_{P_2 Y} P_2 P_2^* Z, X \rangle = \langle \hat{B}_2(P_1 X, Y) + P_2 B_2(X, Y), Z \rangle.$$  

Then (3), 1 follows. Note that (3), 2 is dual to (3), 1 and follows from $b^{(1)}_2 = b^{(2)}_2 = 0$.  

**Definition 4** Define maps $R^P, S_i, T_i : (\mathcal{X}_M)^4 \to C^\infty(M)$, $i \in \{1, 2\}$ by

$$T_1(Y, X_1, X_2, Z) = (P_2 \nabla_{P_1 X_1} B_2(X_2, Y) - \hat{B}_2(\nabla_{P_1 X_1} P_1 X_2, Y) - \check{B}_2(X_2, \nabla_{P_1 X_1} P_2 Y), Z),$$

$$T_2(Y, X_1, X_2, Z) = (P_1 \nabla_{P_2 Y} B_1(Z, X_1) - \hat{B}_1(\nabla_{P_2 Y} P_2 Z, X_1) - \check{B}_1(Z, \nabla_{P_2 Y} P_1 X_1), X_2),$$

$$S_1(Y, X_1, X_2, Z) = (\hat{B}_2(X_2, \nabla_{P_2 Y} P_1 X_1), Z),$$

$$S_2(Y, X_1, X_2, Z) = (\hat{B}_1(Z, \nabla_{P_1 X_1} P_2 Y), X_2),$$

$$R^P(Y, X_1, X_2, Z) = (P_1^* \nabla_{P_2 Y} P_2 \nabla_{P_1 X_1} P_1^* X_2 + P_2 \nabla_{P_2 Y} P_1^* \nabla_{P_1 X_1} P_1 X_2 - P_1^* \nabla_{P_1 X_1} P_1^* X_2 - P_2 \nabla_{P_1 X_1} P_1 P_2^* X_2 - P_2 \nabla_{P_1 X_1} P_1 P_2^* X_2, Z).$$
Proposition 1 If $P = P_1 + P_2$ is allowed for the Levi-Civita connection, then $S_1, T_i$ and $R^P$ are tensor fields and the following Codazzi type equation holds:

$$S_1 + T_1 + S_2 + T_2 + R^P = 0. \tag{4}$$

Proof. Let us show that all maps in Definition 4 are tensor fields. In general, we have

$$\mathcal{T}(Y, fX_1, X_2, Z) = \mathcal{T}(Y, X_1, X_2, fZ)$$

for any $f \in C^\infty(M)$, using (3) to cancel underlying terms; and similarly, for $\mathcal{T}_i$. From the above and (3) follows that $\mathcal{T}_i$ are tensors. Using (1,2)-tensor fields $\tilde{B}_i$,

$$\tilde{B}_1(Y, X) := P_1\nabla X P_2^* Y, \quad \tilde{B}_2(Y, X) := P_2\nabla Y P_1^* X,$$

we obtain

$$S_1(Y, X_1, X_2, Z) = \langle \tilde{B}_2(X_2, B_2(X_1, Y)), Z \rangle, \quad S_2(Y, X_1, X_2, Z) = \langle \tilde{B}_1(Z, B_1(Y, X_1)), X_2 \rangle.$$ 

Thus, $S_i : \mathcal{X}(M)^4 \to \mathcal{X}(M)$ are tensor fields. We have, using also that $\nabla$ is torsion-free,

$$(\mathcal{T}_1 + S_1)(Y, X_1, X_2, Z) = \langle P_2\nabla P_1 x_1 B_2(Y, X_1, X_2, Z) - P_2\nabla P_2 Y P_1^* \nabla P_1 x_1 P_1 X_2$$

and similarly, using (3) to cancel underlying terms on the last step,

$$(\mathcal{T}_2 + S_2)(Y, X_1, X_2, Z)$$

By the above and Definition 4 we obtain (4):

$$(\mathcal{T}_1 + S_1 + \mathcal{T}_2 + S_2)(Y, X_1, X_2, Z) = -R^P(Y, X_1, X_2, Z).$$

By the above, since $\mathcal{T}_i$ and $S_i$ are tensor fields, also $R^P$ is a tensor field. \hfill \square

Remark 2 If $P_1$ and $P_2$ are orthoprojectors from $TM$ onto complementary orthogonal distributions $\mathcal{D}_1$ and $\mathcal{D}_2$, respectively, then $P = \text{id}_{TM}$ and

$$\mathcal{T}_1(Y, X_1, X_2, Z) = \langle P_2(\nabla P_1 x_1 B_2)(X_2, Y), Z \rangle,$$

$$\mathcal{T}_2(Y, X_1, X_2, Z) = \langle P_1(\nabla P_2 Y B_1)(Z, X_1), X_2 \rangle,$$

$$S_1(Y, X_1, X_2, Z) = \langle B_2(X_2, B_2(X_1, Y)), Z \rangle,$$

$$S_2(Y, X_1, X_2, Z) = \langle B_1(Z, B_1(Y, X_1)), X_2 \rangle,$$

$$R^P(Y, X_1, X_2, Z) = R(P_2 Y, P_1 X_1, P_1 X_2, P_2 Z).$$
Thus, (4) yields the Codazzi equation, see [14, Lemma 2.25],
\[
R(P_2Y, P_1X_1, P_1X_2, P_2Z) + \langle (\nabla_X B_2)(X_2, Y), Z \rangle + \langle (\nabla_Y B_1)(Z, X_1), X_2 \rangle \\
+ \langle B_2(X_2, B_2(X_1, Y)), Z \rangle + \langle B_1(Z, B_1(Y, X_1)), X_2 \rangle = 0,
\]
where \(X_i \in \mathcal{D}_1, Y, Z \in \mathcal{D}_2\). For \(B_1 = 0, X_i = X\), (5) yields the Riccati equation
\[
(\nabla_X B_2)(X, Y) + B_2(X, B_2(X, Y)) + R(P_2Y, P_1X)P_1X = 0.
\]

**Example 2** We show the existence of allowed \(P = P_1 + P_2\) in some cases. We say that \(P_1, P_2 \in \text{End}(TM)\) give a local split of \(V = U \times \bar{U} \subset M\) if the following property holds:

- **S_1**: \(P_1(TV)\) is tangent to \(\mathcal{F}\) and \(P_2(TV)\) is tangent to \(\bar{\mathcal{F}}\), when restricted to \(V = U \times \bar{U}\), where \(\mathcal{F}\) and \(\bar{\mathcal{F}}\) are simple foliations with leaves \(U\) and \(\bar{U}\), respectively.

We say that \(P_1\) and \(P_2\) give a \(\nabla\)-local split of \(V = U \times \bar{U}\) as in \(S_1\), if in addition to \(S_1\), the following condition holds:

- **S_2**: The connection \(\nabla\) restricts to Levi-Civita connections along the leaves of \(\mathcal{F}\) and \(\bar{\mathcal{F}}\), that is \(\nabla_X Y\) belongs to \(T\mathcal{F}\) when \(X, Y \in T\mathcal{F}\), and \(\nabla_X Y\) belongs to \(T\bar{\mathcal{F}}\) when \(X, Y \in T\bar{\mathcal{F}}\).

We say that \(P_1\) and \(P_2\) give \(\nabla\)-split of \(P = P_1 + P_2\) if there is an open cover of domains \(V = U \times \bar{U}\), where \(P_1\) and \(P_2\) give a \(\nabla\)-local split of \(P\). We conclude with the claim: If \(P_1\) and \(P_2\) give a \(\nabla\)-split of \(V \subset M\), then \(P = P_1 + P_2\) is allowed for the Levi-Civita connection \(\nabla\).

## 2 The modified divergence

Here, we assume that \(P \in \text{End}(TM)\) is allowed for the Levi-Civita connection \(\nabla\) of metric \(g\), and (11) holds. We extend the divergence formula for vector and tensor fields. Recall that the divergence \(\text{div} X\) of a vector field \(X \in \mathcal{X}_M\) on a Riemannian manifold \((M, g)\) is given by

\[
d(\iota_X d\text{vol}) = (\text{div} X) d\text{vol},
\]
where \(d\text{vol}\) is the volume form of \(g\) and \(\iota_X\) is operator of contraction. The divergence of a \((1, k)\)-tensor \(S\) is a \((0, k)\)-tensor \(\text{div} S = \text{trace}(Y \mapsto \nabla_Y S)\), that is in coordinates,

\[
(\text{div} S)_{i_1, \ldots, i_k} = \nabla_j S^j_{i_1, \ldots, i_k}.
\]

**Remark 3** Using the equality
\[
\partial_i (\sqrt{\det g}) = \sqrt{\det g} \cdot g^{ij} \frac{\partial g_{jk}}{\partial x^i}
\]
and definition of Christoffel symbols, we obtain
\[
\text{div} X = X^i_{,i} + \frac{1}{2} g^{ij} g_{ij,k} X^k = X^i_{,i} + X^i \frac{\partial (\ln \sqrt{\det g})}{\partial x^i} = \frac{1}{\sqrt{\det g}} \frac{\partial (\sqrt{\det g} X^i)}{\partial x^i}.
\]

In coordinates, for a \((1,1)\)-tensor \(S\) we have \((\nabla_{\partial_i} S)(\partial_j) = (S^k_{j,i} + S^j_i \Gamma^k_{ij} - \Gamma^k_{ij} S^k_l) \partial_k\), where \(\partial_i = \frac{\partial}{\partial x^i}\). Then, using (11), we get
\[
(\text{div} S)_j = S^i_{j,i} + S^j_i \Gamma^k_{ij} - \Gamma^k_{ij} S^k_l = S^i_{j,i} - \frac{1}{2} S^{ik} \left( \frac{\partial g_{ik}}{\partial x^j} - g_{jk} g^{ql} \frac{\partial g_{ql}}{\partial x^i} \right) = \frac{1}{\sqrt{\det g}} \frac{\partial (\sqrt{\det g} S^i_j)}{\partial x^i} - \frac{1}{2} S^{ik} \frac{\partial g_{ik}}{\partial x^j}.
\]
**Definition 5** Given $P \in \text{End}(TM)$, the $P$-divergence of a $(1, k)$-tensor $S$ is a $(0, k)$-tensor
\[
\text{div}_P S = \text{trace}(Y \to P^* \nabla_{PY} S),
\]
e.g. for a vector field $X$ on $M$ we get a function $\text{div}_P X = \text{trace}(Y \to P^* \nabla_{PY} X)$ on $M$.

**Lemma 2** For $P \in \text{End}(TM)$ and any vector field $X$ on $M$, we have in coordinates
\[
\text{div}_P X = (PP^*)_j^i X^j_{,i} + \frac{1}{2} (PP^*)^i_{jk} g_{ij} X^k.
\]  \hfill (10)

**Proof.** Given $X \in \mathcal{X}_M$, the map $Y \to P^* \nabla_{PY} X$ has the local form
\[
\partial_i \to P^* \nabla_{P \partial_i} (X^k \partial_k) = P^i_j \left( X^k_{,i} + X^s \Gamma^k_{is} \right) \partial_j,
\]
where $\partial_i = \frac{\partial}{\partial x^i}$ and $(P^i_j)$ – the components of $P$. The trace of the above map is
\[
\text{div}_P X = P^i_j \left( X^k_{,i} + X^s \Gamma^k_{is} \right) (PP^*)_k^j = (PP^*)_k^l \left( X^l_{,i} + X^s \Gamma^l_{is} \right).
\]
By the above, using the symmetry of $PP^*$, i.e., $\langle PP^*(X), Y \rangle = \langle X, PP^*(Y) \rangle$, and definition of Christoffel symbols $\Gamma^i_{jk}$, we get $\text{(10)}$. \hfill \square

**Proposition 2** Given $P \in \text{End}(TM)$, condition
\[
\text{div}(PP^*) = 0
\]  \hfill (11)
is equivalent to the following:
\[
\text{div}_P X = \text{div}(PP^*(X)), \quad X \in \mathcal{X}_M,
\]  \hfill (12)
which means that $(\text{div}_P X) d\text{vol}$ is an exact form:
\[
(\text{div}_P X) d\text{vol} = d(\iota_{PP^*(X)} d\text{vol}).
\]  \hfill (13)
Moreover, we have
\[
\text{div}_P X = \langle PP^*, \nabla X \rangle, \quad X \in \mathcal{X}_M.
\]  \hfill (14)

**Proof.** From the definition of $\text{div}_P X$ and $\text{(8), (9)}$, we have for $S = PP^*$:
\[
\text{div}(S(X)) = 8 \frac{1}{\sqrt{\det g}} \left( \frac{\partial (\sqrt{\det g} S^i_j X^j)}{\partial x^i} \right) = S^i_j X^j_{,i} + \frac{1}{\sqrt{\det g}} \frac{\partial (\sqrt{\det g} S^i_j)}{\partial x^i} X^j
\]
\[
= S^i_j X^j_{,i} + \frac{1}{2} S^i_k \frac{\partial g_{ik}}{\partial x^j} X^j + (\text{div} S)_j X^j \text{\quad (19)} = \text{div}_P X + \text{div}(PP^*)(X),
\]
thus the first claim follows. By $\text{(6)}$ and $\text{(12)}$, we obtain $\text{(13)}$. From the above and identity
\[
\text{div}(PP^*(X)) = \langle PP^*, \nabla X \rangle + \langle X, \text{div}(PP^*) \rangle, \quad X \in \mathcal{X}_M,
\]
follows $\text{(14)}$. \hfill \square

**Remark 4** Similar to $\text{(12)}$ result can be obtained for a $(1, k)$-tensor $S$. Conditions $\text{(11)–(14)}$ are satisfied for $P = \text{id}_{TM}$.
Corollary 1 Let $\text{II}$ hold. Then the following (well-known for $P = \text{id}$) formula is valid:
\[
\text{div}_P(f \cdot X) = f \cdot \text{div}(PP^*(X)) + (PP^*(X))(f), \quad X \in \mathcal{X}_M, \ f \in C^\infty(M).
\]

From Proposition $\text{I}$ we obtain the following generalization of Stokes theorem, which for $P = \text{id}_{TM}$ reduces to the classical divergence theorem.

Theorem 1 If $\text{II}$ holds on a compact manifold $(M, g)$, then for any $X \in \mathcal{X}_M$,
\[
\int_M (\text{div}_P X) \, d\text{vol} = \int_{\partial M} \langle X, PP^*(\nu) \rangle \, d\omega.
\]

Next, we modify Stokes’ theorem on a complete open Riemannian manifold $(M, g)$.

Proposition 3 (see $\text{[6]}$ for regular case and $P = \text{id}_{TM}$) Let $(M, g)$ be a complete open Riemannian manifold endowed with a vector field $X$ such that $\text{div}_P X \geq 0$ (or $\text{div}_P X \leq 0$), where $P \in \text{End}(TM)$ such that $\text{II}$ and $\|PP^*(X)\|_g \in L^1(M, g)$ hold. Then $\text{div}_P X \equiv 0$.

Proof. Let $\omega$ be the $(n - 1)$-form in $M$ given by $\omega = \iota_{PP^*(X)} \, d\text{vol}_g$, i.e., the contraction of the volume form $d\text{vol}_g$ in the direction of a smooth vector field $PP^*(X)$ on $M$. If $\{e_1, \ldots, e_n\}$ is an orthonormal frame on an open set $U \subset M$, with coframe $\omega_1, \ldots, \omega_n$, then
\[
\iota_{PP^*(X)} \, d\text{vol}_g = \sum_{i=1}^n (-1)^{i-1} \langle PP^*(X), e_i \rangle \, \omega_1 \wedge \ldots \wedge \hat{\omega}_i \wedge \ldots \wedge \omega_n.
\]
Since the $(n - 1)$-forms $\omega_1 \wedge \ldots \wedge \hat{\omega}_i \wedge \ldots \wedge \omega_n$ compose an orthonormal frame in $\Omega^{n-1}(M)$, we get
\[
\|\omega\|_g^2 = \sum_{i=1}^n \langle PP^*(X), e_i \rangle^2 = \|PP^*(X)\|_g^2.
\]
By this and conditions, we get $\|\omega\|_g \in L^1(M, g)$ and $d\omega = d(\iota_{PP^*(X)} \, d\text{vol}_g) = (\text{div}_P X) \, d\text{vol}_g$, see $\text{[12]}$. According to $\text{[17]}$, there exists a sequence of domains $B_i$ on $M$ such that $M = \bigcup_{i \geq 1} B_i$, $B_i \subseteq B_{i+1}$ and $\lim_{i \to \infty} \int_{B_i} d\omega = 0$. Then we obtain
\[
\int_{B_i} (\text{div}_P X) \, d\text{vol}_g = \int_{B_i} d(\text{div}(PP^*(X)) \, d\text{vol}_g = \int_{B_i} d\omega \to 0.
\]

By conditions and Proposition $\text{II}$ we find that $\text{div}_P X = 0$ on $M$. $\square$

Example 3 Recall that Einstein tensor is divergence free, thus it can play a role of $PP^*$. Consider the product $M^5 = S^3 \times T^2$ and the coordinates $(x, y, z, u, v)$, where $(x, y, z) \in \mathbb{R}^3$ are stereographic projections from the north pole of $S^3$ and $(u, v) \in [0, 2\pi)^2$ are the angular coordinates on $T^2 = S^1 \times S^1$. Consider the following Einstein metric $g$ on $M^5$:
\[
ds^2 = \frac{4}{(x^2 + y^2 + z^2 + 1)^2} (dx^2 + dy^2 + dz^2) + (1 + \sin^2 u)(du^2 + dv^2).
\]
The Einstein tensor has diagonal form $E = \text{diag}(-E_1, -E_1, -E_1, -E_2, -E_2)$ with
\[
E_1 = -\frac{\sin^2 u(4 \cos^4 u - 5 \cos^2 u + 10)}{(1 + \sin^2 u)^3}, \quad E_2 = -3.
\]
Thus, $E$ is divergence free and there is a mixed $(1,1)$-tensor, $P = \sqrt{-E}$, i.e., $-E = PP^*$, which has diagonal form $P = \text{diag}(a_1, a_1, a_1, a_2, a_2)$ with
\[
a_1 = \frac{\sin u \sqrt{4 \cos^4 u - 5 \cos^2 u + 10}}{(1 + \sin^2 u)^{3/2}}, \quad a_2 = \sqrt{3}.
\]
The positive endomorphism $P$ is a sum $P = P_1 + P_2$, where $P_1$ and $P_2$ have diagonal forms

$$P_1 = \text{diag}(a_1, a_1, a_1, 0, 0), \quad P_2 = \text{diag}(0, 0, a_2, a_2).$$

We claim that $P$ is allowed for the Levi-Civita connection $\nabla$. Indeed, consider the Christoffel symbols $\Gamma^A_{BC}$, where $A, B, C \in \{1, \ldots, 6 \}$ and $(x^1, x^2, x^3, x^4, x^5, x^6) = (x, y, z, u, v)$. Then one can check that $\Gamma^A_{BC} = 0$, provided that $\{B, C\} \subset \{1, 2, 3\}$ and $A \in \{4, 5\}$, or $A \in \{1, 2, 3\}$ and $\{B, C\} \subset \{4, 5\}$. This implies the claim.

**Example 4** If $P$ is an almost complex structure, then $PP^* = \text{id}_{TM}$ and $\text{div}_P X = \text{div} X$. This simple observation can be developed as follows.

a) An almost contact manifold $(M, \phi, \xi, \eta)$ is an odd-dimensional manifold $M$, which carries a $(1, 1)$-tensor field $\phi$, a (Reeb) vector field $\xi$, and a 1-form $\eta$ satisfying, see [4],

$$\phi^2 = -\text{id}_{TM} + \eta \otimes \xi, \quad \eta(\xi) = 1.$$ 

One may show that $\phi \xi = 0$ and $\eta \circ \phi = 0$. We get an almost contact metric structure, if there is metric $g = \langle \cdot, \cdot \rangle$ such that

$$\langle \phi X, \phi Y \rangle = \langle X, Y \rangle - \eta(X)\eta(Y) \iff \phi^* \phi = \text{id}_{TM} - \eta \otimes \xi.$$ 

Thus, $\phi^* = -\phi$ restricted on $\ker \eta$, and $\phi^*(\xi) = \xi$. Setting $Y = \xi$ we get $\eta(X) = \langle X, \xi \rangle$. Hence $\langle \xi, \xi \rangle = 1$. We have, using $\nabla_{e_i}X = 0$,

$$\text{div}(\phi \phi^*)(X) = \sum_i \langle (\nabla_{e_i}(\phi \phi^*))(X), e_i \rangle$$

$$= -\sum_i \langle (\nabla_{e_i}(\eta \otimes \xi))(X), e_i \rangle = -\sum_i \langle (\nabla_{e_i}(\eta(\eta(\xi)))X), e_i \rangle$$

$$= -\sum_i [e_i(\eta(\xi))(\xi, e_i)] + (\text{div} \xi) \eta(X)] = -\xi(\xi, X) - (\text{div} \xi) \eta(X) = -(\nabla_{\xi} \xi - (\text{div} \xi) \xi, X).$$

Note that $\nabla_{\xi} \xi$ is orthogonal to $\xi$. Thus, the condition $\text{div}(\phi \phi^*) = 0$, see [11], holds if and only if $\xi$ is a geodesic vector field ($\nabla_{\xi} \xi = 0$) and the distribution $\ker \phi$ is harmonic ($\text{div} \xi = 0$).

b) An $f$-structure (due to Yano, 1961) on a manifold $M$ is a non null $(1, 1)$-tensor $f$ on $M$ of constant rank such that $f^3 + f = 0$, which generalizes the almost complex and the almost contact structures. It is known that $TM$ splits into two complementary subbundles $\mathcal{D} = f(TM)$ and $\mathcal{D} = \ker f$, and that the restriction of $f$ to $\mathcal{D}$ determines a complex structure on it. An interesting case of $f$-structure occurs when $\mathcal{D}$ is parallelizable for which there exist global vector fields $\xi_i$, $i \in \{1, \ldots, p \}$, with their dual 1-forms $\eta^i$, satisfying [8]

$$f^2 = -\text{id}_{TM} + \sum_i \eta^i \otimes \xi_i, \quad \eta^i(\xi_j) = \delta^i_j.$$ 

A Riemannian metric $g = \langle \cdot, \cdot \rangle$ is compatible, if

$$\langle f(X), f(Y) \rangle = \langle X, Y \rangle - \sum_i \eta^i(X) \eta^i(Y) \iff f^* f = \text{id}_{TM} - \sum_i \eta^i \otimes \xi_i.$$ 

Thus, $f^* = -f$ restricted on $\bigcap_i \ker \eta_i$, and $f^*(\xi_i) = \xi_i$. Setting $Y = \xi_j$ we get $\eta^j(X) = \langle X, \xi_j \rangle$. Hence $\langle \xi_i, \xi_j \rangle = \delta^i_j$. Similarly to point b), we obtain

$$(\text{div} f f^*)(X) = \sum_i \langle (\nabla_{e_i} f f^*)(X), e_i \rangle = -\sum_{i,j} \langle (\nabla_{e_i}(\eta^i \otimes \xi_j))(X), e_i \rangle$$

$$= -\sum_{i,j} e_i(\eta^j(X))(\xi_j, e_i) - \sum_j (\text{div} \xi_j) \eta^j(X) = -\sum_j \langle \nabla_{\xi_j} \xi_j + (\text{div} \xi_j) \xi_j, X \rangle.$$ 

Note that $\sum_j \nabla_{\xi_j} \xi_j$ (belongs to $f(TM)$) is the mean curvature vector of $\ker f$. From $\text{div} \xi_j = 0$ we get $\langle H, \xi_j \rangle = 0$, where $H$ is the mean curvature vector of $f(TM)$. Thus, the condition $\text{div}(ff^*) = 0$, see [11], holds if and only if both distributions, $f(TM)$ and $\ker f$, are harmonic.
3 The integral formula

In this section, we assume that $P_i$ $(i = 1, 2)$ are self-adjoint for adapted metric (with the Levi-Civita connection $\nabla$), see Remark 11 then (11) means the orthogonality of singular distributions $P_i(TM)$ and Definition 3 for $R^P$ reads as

$$R^P(Y, X_1, X_2, Z) = \langle P_2(\nabla P_1 P \nabla P_1 X_1 - \nabla P_1 X_1 P \nabla P_2 Y - \nabla P \nabla P_2 Y, P_1 X_2, Z) \rangle.$$

Let $\{e_i\}$ be a local orthonormal frame in $M$.

**Lemma 3** Given $P_1, P_2 \in \text{End}(TM)$, we have

$$\sum_{s,t} T_1(e_t, e_s, e_t, e_t) = \sum_{s,t} \left( (\nabla P_{1e_s} P_1 e_t, P_1 \nabla P_{2e_t} P_2 e_t) - P_1 e_s \langle P_1 \nabla P_{2e_t} P_2 e_t, P_1 e_s \rangle \right),$$

$$\sum_{s,t} T_2(e_t, e_s, e_t, e_t) = \sum_{s,t} \left( P_2 e_t (\nabla P_{1e_s} P_2 e_t, P_1 e_s) + \langle \nabla P_{2e_t} P_2 e_t, P_2 \nabla P_{1e_s} P_1 e_s \rangle \right),$$

$$\sum_{s,t} S_2(e_t, e_s, e_t, e_t) = \sum_{s,t} \left( P_2 \nabla P_{1e_s} P_1 e_t, \nabla P_{2e_t} P_1 e_s \right),$$

$$\sum_{s,t} S_1(e_t, e_s, e_t, e_t) = \sum_{s,t} \left( P_1 \nabla P_{2e_s} P_2 e_t, \nabla P_{2e_t} P_2 e_s \right).$$

**Proof.** First we will prove the equality

$$\sum_{s,t} \left( \langle P_1 \nabla P_{2e_s} P_2 e_t, \nabla P_{2e_t} P_2 e_s \rangle + \langle \nabla P_2 \nabla P_{2e_t} P_1 e_s, P_2 e_t, P_1 e_s \rangle \right) = 0. \quad (16)$$

Put $P_1 e_s = \Pi_s^u e_u$, $P_2 e_t = \tilde{\Pi}_t^u e_u$ and

$$\nabla P_{1e_s} P_2 e_t = \omega_s^u e_u,$$

$$\nabla P_{2e_t} P_1 e_s = \tilde{\omega}_t^u e_u,$$

$$\nabla P_{2e_t} P_2 e_s = \tilde{\omega}_t^u e_u.$$

Since $P_1$ and $P_2$ are self-adjoint and $P_1 P_2 = P_2 P_1 = 0$, we have $\Pi_s^u = \Pi_s^u$, $\tilde{\Pi}_t^u = \tilde{\Pi}_t^u$, $\Pi_s^u \Pi_t^u = 0$, $\tilde{\Pi}_s^u \tilde{\Pi}_t^u = 0$. We obtain for both two terms of (16),

$$A = \sum_{s,t} \langle P_1 \nabla P_{2e_s} P_2 e_t, \nabla P_{2e_t} P_2 e_s \rangle = \sum_{s,t,u,v} \langle P_1 (\tilde{\omega}_t^u e_u), \tilde{\omega}_t^u e_u \rangle = \sum_{s,t,u,v} \tilde{\omega}_t^u \tilde{\omega}_t^u \Pi_s^u,$$

$$B = \sum_{s,t} \langle \nabla P_2 \nabla P_{2e_t} P_1 e_s, P_2 e_t, P_1 e_s \rangle = \sum_{s,t,u,v} \langle \nabla P_2 (\Pi_s^u e_u) P_2 e_t, P_2 e_s \rangle$$

$$= \sum_{s,t,u,v} \Pi_s^u \tilde{\omega}_t^u \Pi_s^u = \sum_{s,t,u,v} \Pi_s^u \tilde{\omega}_t^u \Pi_s^u.$$

It follows that the left hand side of (16) vanishes:

$$A + B = \sum_{s,t,u,v} \tilde{\omega}_t^u \Pi_s^u (\tilde{\omega}_t^u + \Pi_s^u)$$

$$= \sum_{s,t,u,v} \left( \langle \nabla P_{2e_s} P_2 e_t, P_1 e_u \rangle \left( \langle \nabla P_{2e_t} P_2 e_s, e_u \rangle + \langle \nabla P_{2e_t} P_1 e_u, e_s \rangle \right) \right)$$

$$= \sum_{s,t,u,s_1,u_1} \langle \nabla e_{s_1} P_2 e_t, e_{u_1} \rangle \left( \langle \Pi_{s_1} \nabla P_{2e_t} P_2 e_s, P_1 e_{u_1} \rangle + \langle \Pi_{u_1} \nabla P_{2e_t} P_1 e_u, P_2 e_{s_1} \rangle \right)$$

$$= \sum_{s,t,u,s_1,u_1} \langle \nabla e_{s_1} P_2 e_t, e_{u_1} \rangle \left( \langle \nabla P_{2e_t} P_2 e_{s_1}, P_1 e_{u_1} \rangle + \langle \nabla P_{2e_t} P_1 e_{u_1}, P_2 e_{s_1} \rangle \right) = 0,$$
since the expression in the last large parenthesis vanishes for any $s, t$. For the fourth line in above calculation of $A + B$ we used orthogonality of the distributions, e.g. 

$$\langle \Pi_{s_1}^t, \nabla P_{s_2} e_s, P_1 e_{u_1} \rangle = \langle \Pi_{s_1}^t, \nabla P_{s_2} (\Pi_{s_2}^t e_{s_2}), P_1 e_{u_1} \rangle$$

$$= \langle \nabla P_{s_2} (\Pi_{s_1}^t \Pi_{s_2}^t e_{s_2}), P_1 e_{u_1} \rangle = \langle \nabla P_{s_2} (P_2^2 e_{s_1}), P_1 e_{u_1} \rangle$$

The underlined term of line 5 was obtained using equalities (3):

$$\langle \nabla P_{s_2} P_2^2 e_{u_1}, P_2 e_{s_1} \rangle = \langle P_2 \nabla P_{s_2} P_2^1 e_{u_1}, e_{s_1} \rangle = \langle P_2^2 \nabla P_{s_2} P_1 e_{u_1}, e_{s_1} \rangle = \langle \nabla P_{s_2} P_1 e_{u_1}, P_2^2 e_{s_1} \rangle.$$ 

By Definition 4 we have

$$T_1(Y, X_1, X_2, Z) = \langle \nabla P_{s_1} X_1 P_2 \nabla P_{s_2} Y P_1 X_2 - \nabla P_{s_2} Y P_1 \nabla P_{s_1} X_1 P_1 X_2 - \nabla P_{s_2} \nabla P_{s_1} X_1 P_2 Y P_1 X_2, P_2 Z \rangle,$$

where (using the metric property of $\nabla$)

$$\langle \nabla P_{s_1} X_1 P_2 \nabla P_{s_2} Y P_1 X_2, P_2 Z \rangle = \langle P_1 X_1 \rangle \langle P_2 \nabla P_{s_2} Y P_1 X_2, P_2 Z \rangle - \langle P_2 \nabla P_{s_2} Y P_1 X_2, \nabla P_{s_1} X_1 P_2 Z \rangle,$$

$$\langle \nabla P_{s_2} Y P_1 \nabla P_{s_1} X_1 P_1 X_2, P_2 Z \rangle = - \langle P_1 \nabla P_{s_1} X_1 P_1 X_2, \nabla P_{s_2} Y P_2 Z \rangle.$$

By the above and (16), we have (15a):

$$\sum_{s, t} T_1(e_t, e_s, e_s, e_t) = - \sum_{s, t} \langle P_1 e_s \rangle \langle P_1 \nabla P_{s_2} P_2^2 e_t, e_s \rangle - \sum_{s, t} \langle P_2 \nabla P_{s_2} P_1 e_s, \nabla P_{s_1} e_s, P_2 e_t \rangle$$

$$+ \sum_{s, t} \langle P_1 \nabla P_{s_1} e_s, P_1 e_s, \nabla P_{s_2} e_t, P_2 e_t \rangle - \sum_{s, t} \langle \nabla P_{s_2} \nabla P_{s_1} e_s, P_2 e_t \rangle$$

$$= \sum_{s, t} \langle P_1 \nabla P_{s_1} e_s, P_1 e_s, \nabla P_{s_2} e_t \rangle - \langle P_1 e_s \rangle \langle P_1 \nabla P_{s_2} P_2^2 e_t, e_s \rangle$$

$$= \sum_{s, t} \langle P_1 \nabla P_{s_1} e_s, P_1 e_s, \nabla P_{s_2} e_t \rangle - \langle P_1 e_s \rangle \langle P_1 \nabla P_{s_2} P_2 e_t, P_1 e_s \rangle.$$ 

The underlined term in above calculation was obtained using equality $b_2^{(1)}(e_t, e_t) = 0$. Similarly, using $\langle \nabla P_{s_1} e_s, P_2 e_t \rangle + \langle \nabla P_{s_1} e_s, P_2 e_t \rangle = 0$, we get (15b). By Definition 4 we have 

$$S_1(Y, X_1, X_2, Z) = \langle \nabla P_{s_1} X_1 P_2 \nabla P_{s_2} Y P_1 X_2, P_2 Z \rangle, \quad S_2(Y, X_1, X_2, Z) = \langle \nabla P_{s_1} X_1 P_2 Y P_2 Z, P_1 X_2 \rangle.$$

Then, using dual for (16), we get (15d):

$$\sum_{s, t} S_2(e_t, e_s, e_s, e_t) = - \sum_{s, t} \langle \nabla P_{s_1} \nabla P_{s_1} e_s, P_2 e_t \rangle = \sum_{s, t} \langle P_2 \nabla P_{s_1} e_s, P_1 e_t, \nabla P_{s_1} e_s \rangle.$$ 

By symmetry in indices, we get (15d).

**Definition 6** The second fundamental forms $h_i$, the integrability tensors $T_i$ and the mean curvature vectors $H_i = \text{Trace}_g h_i$ of of singular distributions are defined by

$$h_1(X, Y) = \frac{1}{2} P_2 (\nabla P_{s_1} X P_1 Y + \nabla P_{s_1} P_1 X), \quad h_2(X, Y) = \frac{1}{2} P_1 (\nabla P_{s_2} X P_2 Y + \nabla P_{s_2} P_2 X),$$

$$T_1(X, Y) = \frac{1}{2} P_2 (\nabla P_{s_1} X P_1 Y - \nabla P_{s_1} P_1 X), \quad T_2(X, Y) = \frac{1}{2} P_1 (\nabla P_{s_2} X P_2 Y - \nabla P_{s_2} P_2 X),$$

$$H_1 = \sum_{s} P_2 \nabla P_{s_1} P_1 e_s, \quad H_2 = \sum_{s} P_1 \nabla P_{s_2} P_2 e_s.$$

The definition of $H_i$ is correct because of orthogonality of distributions $P_i(TM)$. If the second fundamental form vanishes then certain distribution is called totally geodesic, if the integrability tensor vanishes then the distribution is integrable, and if the second fundamental form and integrability tensor vanish simultaneously then the distribution is called autoparallel (for regular case see [3]). If the mean curvature vector vanishes then certain distribution is called harmonic. A distribution $D_1$ is called totally umbilical if there is $\alpha: M \to \mathbb{N}$ such that 

$$P_2 \nabla P_{s_1} X P_1 Y = (1/\alpha) \langle P_1 X, P_1 Y \rangle H_1.$$
Totally umbilical regular distributions appear on twisted products of Riemannian manifolds. Observe that
\[ \langle H_1, X \rangle = -\text{Trace}(Y \to B_1(Y, X)), \quad \langle H_2, X \rangle = -\text{Trace}(Y \to B_2(X, Y)) . \]

**Definition 7** Define the square of the P-norm of a vector \( X \in P_1(TM) \cup P_2(TM) \) by
\[
\|X\|_P^2 = \begin{cases} 
\langle P_1(X') , X' \rangle & \text{if } X = P_1(X') \in P_1(TM), \\
\langle P_2(X'), X' \rangle & \text{if } X = P_2(X') \in P_2(TM). 
\end{cases}
\] (17)

**Remark 5** For a general endomorphism \( P = P_1 + P_2 \), the value of \( |X|_P^2 \) is not positive, but we will not use it without its square. We claim that definition (17) is correct. Indeed, if \( X = P_1(X') = P_1(X'') \), then \( \langle X, X' \rangle = \langle P_1X'', P_1X' \rangle = \langle X'', P_1X' \rangle = \langle X'', X \rangle = \langle X, X'' \rangle \).

In particular, by (17) we have,
\[
\|H_2\|_P^2 = \sum_{s,t} \langle P_1 \nabla_{P_2e_s} P_2e_t, \nabla_{P_2e_t} P_2e_t \rangle, \quad \|H_1\|_P^2 = \sum_{s,t} \langle P_2 \nabla_{P_1e_s} P_1e_t, \nabla_{P_1e_t} P_1e_t \rangle, 
\] (18)

which makes sense, since \( H_1 \in P_2(TM) \) and \( H_2 \in P_1(TM) \). Then we define similarly the “squares of the P-norms” of tensors,
\[
\|h_1\|_P^2 = \sum_{s,t} \|h_1(e_s, e_t)\|_P^2, \quad \|T_1\|_P^2 = \sum_{s,t} \|T_1(e_s, e_t)\|_P^2, \quad \text{and so on},
\]
which makes sense, since \( h_1 = P_2h'_1 \) and \( T_1 = P_2T'_1 \), etc.

**Lemma 4** We have
\[
\text{div}_P H_1 = \text{div}_P H_1 + \|H_1\|_P^2, \quad \text{div}_P H_2 = \text{div}_P H_2 + \|H_2\|_P^2.
\]

**Proof.** We use Definition 5
\[
\text{div}_P X = \sum_s \langle P \nabla_{P_2e_s} X, e_s \rangle, \quad \text{div}_P X = \sum_s \langle P_1 \nabla_{P_1e_s} X, e_s \rangle,
\]
and equality \( H_2 = P_1X_0 \), where \( X_0 = \sum_s \nabla_{P_2e_s} P_2e_s \). Thus
\[
\text{div}_P H_2 - \text{div}_P H_2 = - \sum_s \langle P_2 \nabla_{P_1e_s} P_1X_0 , e_s \rangle = \sum_s \langle P_1X_0 , \nabla_{P_2e_s} P_2e_s \rangle = \langle P_1X_0 , X_0 \rangle = \|H_2\|_P^2,
\]
since \( \sum_s \langle P_2 \nabla_{P_2e_s} P_1X_0 , e_s \rangle = \sum_s \langle \nabla_{P_1e_s} P_1X_0 , P_2e_s \rangle = 0 \). Indeed, if \( P_1e_s = \sum_u \Pi^u_s e_t = \Pi^u_s e_u \) and \( P_2e_s = \Pi^v_s e_v \), then \( \sum_s \Pi^u_s \Pi^v_s = 0 \) (1 \( \leq \) \( u, v \leq \) \( m \)), since \( \{e_i\}_{1 \leq i \leq m} \) is an orthonormal frame and \( P_i \) are self-adjoint. This completes the proof for \( H_2 \). The proof for \( H_1 \) is similar.\( \Box \)

The mixed scalar curvature, \( S_{\text{mix}} \), which is an averaged mixed sectional curvature (a plane, which intersects nontrivially both distributions, is called mixed), is the simplest curvature invariant of a Riemannian manifold endowed with two complementary orthogonal distributions, e.g. \[14\]. The **mixed scalar curvature of a pair** \( (P_1, P_2) \) is defined by
\[
S_{\text{mix}}^P = \sum_{s,t} R^P(e_t, e_s, e_s, e_t).
\]
and coincides with \( S_{\text{mix}} \) for the regular case of an almost product structure.

The above tensors are involved in the formula below, which for regular case belongs to \[16\].
Proposition 4  Given self-adjoint $P_1, P_2 \in \text{End}(TM)$, put $P = P_1 + P_2$. Then we have
\[ \text{div}_P(H_1 + H_2) = S_{\text{mix}}^P + \|h_1\|^2_P + \|h_2\|^2_P - \|T_1\|^2_P - \|T_2\|^2_P - H_1 H_2. \] (19)

Proof. We find
\[
\text{div}_P(H_1 + H_2) = \text{div}_P H_2 + \text{div}_P H_1 - \|H_2\|^2_P - \|H_1\|^2_P = \sum_{s,t} (P_1 e_t (P_1 \nabla_{P_{2s}} P_{2e_s}, P_1 e_t) - \langle P_1 \nabla_{P_{2s}} P_{2e_s} \nabla_{P_{1e_t}} P_1 e_t \rangle) \\
+ \sum_{s,t} (P_2 e_t (P_2 \nabla_{P_{1s}} P_{1e_s}, P_2 e_t) - \langle P_2 \nabla_{P_{1s}} P_{1e_s} \nabla_{P_{2e_t}} P_2 e_t \rangle) \\
- \sum_{s,t} (P_1 \nabla_{P_{2s}} P_{2e_s}, \nabla_{P_{2e_t}} P_2 e_t) - \sum_{s,t} (P_2 \nabla_{P_{1s}} P_{1e_s}, \nabla_{P_{1e_t}} P_1 e_t) \] (20)
and
\[
\|h_1\|^2_P + \|h_2\|^2_P - \|T_1\|^2_P - \|T_2\|^2_P = \sum_{s,t} (\langle P_2 \nabla_{P_{1s}} P_{1e_t}, \nabla_{P_{1e_t}} P_1 e_s \rangle + \langle P_1 \nabla_{P_{2s}} P_{2e_t}, \nabla_{P_{2e_t}} P_2 e_s \rangle). \] (21)

Summing (18), (20) and (21) and eliminating underlined terms, we have
\[
- \text{div}_P(H_1 + H_2) + \|h_1\|^2_P + \|h_2\|^2_P - \|T_1\|^2_P - \|T_2\|^2_P - H_1 H_2 = \sum_{s,t} (P_2 \nabla_{P_{1s}} P_{1e_t}, \nabla_{P_{1e_t}} P_1 e_s) + \sum_{s,t} (P_1 \nabla_{P_{2s}} P_{2e_t}, \nabla_{P_{2e_t}} P_2 e_s) \\
+ \sum_{s,t} (P_1 \nabla_{P_{1s}} P_{1e_s}, \nabla_{P_{1e_t}} P_1 e_t) + \sum_{s,t} (P_2 \nabla_{P_{2s}} P_{2e_s}, \nabla_{P_{2e_t}} P_2 e_t) \] (22)

Tracing Codazzi equation (4) and using (15a)–(15d), we obtain
\[
-S_{\text{mix}}^P = \sum_{s,t} (T_1 + T_2 + S_1 + S_2) (e_t, e_s, e_s, e_t) \\
= \sum_{s,t} (P_1 e_s (P_1 \nabla_{P_{2e_t}} P_{2e_t}, P_1 e_s) + \nabla_{P_{1e_s}} P_1 e_s, P_1 \nabla_{P_{2e_t}} P_{2e_t}) \\
- P_{2e_t} (P_2 \nabla_{P_{1s}} P_{1e_s}, P_{2e_t}) + \nabla_{P_{1e_s}} P_2 e_t, P_2 \nabla_{P_{1e_s}} P_{1e_s} \) \\
+ \langle P_1 \nabla_{P_{2e_t}} P_{2e_t}, \nabla_{P_{2e_t}} P_2 e_s \rangle + \langle P_2 \nabla_{P_{1s}} P_{1e_s}, \nabla_{P_{1e_s}} P_1 e_s \rangle), \] (23)

Comparing (22) and (23), completes the proof of (19). \qed

For general $P \in \text{End}(M)$, the integral of the $P$-divergence of a vector field over a closed manifold vanishes if we assume (14), see Theorem 1. Thus, under certain assumption for self-adjoint $P$, the integral over the right hand side of (19) vanishes.
Theorem 2 Given self-adjoint $P_i \in \text{End}(TM)$ ($i = 1, 2$) on a closed Riemannian manifold $(M, g)$, let
\[
\text{div}(P^2) = 0
\] for $P = P_1 + P_2$. Then the following integral formula holds:
\[
\int_M \left( S_{\text{mix}}^P + \|h_1\|^2_P + \|h_2\|^2_P - \|T_1\|^2_P - \|T_2\|^2_P - \|H_1\|^2_P - \|H_2\|^2_P \right) \text{d vol} = 0.
\]

Proof. This follows from Propositions 2 and 4.

Theorem 3 Let distributions $P_i(TM)$ be integrable with $H_i = 0$ on a complete open Riemannian manifold $(M, g)$, and the leaves $(M', g')$ of $P_i(TM)$ satisfy condition $\|H_2|_{M'}\|_{g'} \in L^1(M', g')$, e.g. $(M', g')$ are compact, and $\text{div}(P^2) = 0$. If $S_{\text{mix}}^P \geq 0$ then $S_{\text{mix}}^P \equiv 0$ and the distributions are autoparallel.

Proof. By conditions, we get
\[
\text{div}_P H_2 = S_{\text{mix}}^P + \|h_1\|^2_P + \|h_2\|^2_P.
\]
Using Proposition 3 for each leaf (a complete open manifold), and since $S_{\text{mix}}^P \geq 0$ (and $P_i$ are non-negative), we get $\text{div}_P H_2 = 0$. Thus, $h_i = 0$.

Theorem 4 Let distributions $P_i(TM)$ on a complete open Riemannian manifold $(M, g)$ satisfy $H_i = 0$ and $T_i = 0$. If $S_{\text{mix}}^P \geq 0$ then $S_{\text{mix}}^P \equiv 0$ and the distributions are autoparallel.

Proof. Under assumptions of our Theorem, we get $\text{div}_P(H_1 + H_2) = S_{\text{mix}}^P + \|h_1\|^2_P + \|h_2\|^2_P$. By Proposition 3 and since $S_{\text{mix}}^P \geq 0$ (and $P_i$ are non-negative), we get $\text{div}_P(H_1 + H_2) = 0$. Thus, $h_1 = h_2 = 0$.

The next result generalizes [15, Theorem 4].

Theorem 5 Let the sets, where the ranks of distributions $P_1$ and $P_2$ are at least 2, are dense in a complete open Riemannian manifold $(M, g)$, and $\|P^2(H_1 + H_2)\|_g \in L^1(M, g)$ for $P = P_1 + P_2$ and (24) hold. Suppose that there exist endomorphisms $Q_1$ and $Q_2$ such that
\[
Q_i^2 = P_i \quad (i = 1, 2),
\]
and the pairs of distributions $(P_1, Q_2)$ and $(Q_1, P_2)$ are totally umbilical. If $S_{\text{mix}}^P \leq 0$ then $S_{\text{mix}}^P \equiv 0$ and the distributions $P_i(TM)$ are autoparallel.

Proof. By conditions,
\[
Q_2 \nabla_{P_1 X} P_1 Y = (1/\alpha_1) \langle P_1 X, P_1 Y \rangle H_{1,Q_2}, \quad Q_1 \nabla_{P_2 X} P_2 Y = (1/\alpha_2) \langle P_2 X, P_2 Y \rangle H_{2,Q_1}.
\]
We have
\[
\|h_1\|^2_P - \|T_1\|^2_P = \sum_{s,t} \langle P_2 \nabla_{P_1 e_s} P_1 e_t, \nabla_{P_1 e_t} P_1 e_s \rangle = \sum_{s,t} \langle Q_2 \nabla_{P_1 e_s} P_1 e_t, Q_2 \nabla_{P_1 e_t} P_1 e_s \rangle = (\alpha_1)^{-2} \|H_{1,Q_2}\|^2 \sum_{s,t} \langle P_1 e_s, P_1 e_t \rangle^2.
\]
Similarly,
\[
\|H_1\|^2_P = (\alpha_1)^{-2} \|H_{1,Q_2}\|^2 \sum_{s,t} \langle P_1 e_s, P_1 e_t \rangle \langle P_1 e_t, P_1 e_t \rangle.
\]
By the Cauchy-Schwarz inequality (and since $P_i$ are non-negative), $\|h_1\|^2_P - \|T_1\|^2_P - \|H_1\|^2_P \leq 0$. By symmetry, $\|h_2\|^2_P - \|T_2\|^2_P - \|H_2\|^2_P \leq 0$. By conditions, from Proposition 4 we get $\text{div}_P(H_1 + H_2) - S_{\text{mix}}^P \leq 0$. By this, Proposition 3 and condition $S_{\text{mix}}^P \leq 0$, we get $\text{div}_P(H_1 + H_2) = 0$ and vanishing of $H_{1,Q_2}$ and $H_{2,Q_1}$. Then, using (25), the conclusion follows.
