Optimal Investment with Correlated Stochastic Volatility Factors

Maxim Bichuch * Jean-Pierre Fouque †

Thursday 22\textsuperscript{nd} August, 2019

Abstract

The problem of portfolio allocation in the context of stocks evolving in random environments, that is with volatility and returns depending on random factors, has attracted a lot of attention. The problem of maximizing a power utility at a terminal time with only one random factor can be linearized thanks to a classical distortion transformation. In the present paper, we address the problem with several factors using a perturbation technique around the case where these factors are perfectly correlated reducing the problem to the case with a single factor. We illustrate our result with a particular model for which we have explicit formulas. A rigorous accuracy result is also derived using sub- and super-solutions of the HJB equation involved. In order to keep the notations as explicit as possible, we treat the case with one stock and two factors and we describe an extension to the case with two stocks and two factors.

Keywords Optimal investment, asymptotic analysis, utility maximization, stochastic volatility.

1 Introduction

The portfolio optimization problem was first introduced and studied in the continuous-time framework in [15, 16], which provided explicit solutions on how to trade stocks and/or how to consume so as to maximize one’s utility, with risky assets following the Black-Scholes-Merton model (that is, geometric Brownian motions with constant returns and constant volatilities), and when the utility function is of specific types (for instance, Constant Relative Risk Aversion (CRRA)).

Stochastic volatility models have been widely studied over the last thirty years in the context of option pricing and the presence of several factors driving volatility has been well documented (see for instance [10], [8] and references therein). In general setting the models are intractable and often asymptotical solutions are sought, see e.g. [17], [11], [12], [5].

In a general setting [13] showed existence and uniqueness of an optimal strategy using the duality approach. As an alternative approach, in a Markovian setting, the portfolio optimization problem with factors driving returns and volatility can be solved directly by describing it as a solution to an HJB equation with terminal condition given by the utility function. Example of the latter approach in a portfolio optimization problem with multiscale factor models for risky assets include [7], where return and volatility are driven by fast and slow factors. Specifically, the authors heuristically derived the asymptotic approximation to the value function and the optimal strategy for general utility functions. This analysis is complemented in [6] and in [27] in a non-Markovian context. The multiscale feature is essential to be able to consider multiple factors, because each factor requires a unique time scale. The analysis simplifies considerably in the case of

a single factor and power utilities thanks to a distortion transformation which linearizes the problem (see [8], [9], [7]).

Our aim in this paper is to solve a problem with multiple factors of the same time scale. We do so by considering the case with multi factors and power utility as a perturbation problem around the case where the factors are perfectly correlated which in turns allows for an explicit solution given by a linear problem. Additionally, we find a ”nearly-optimal” strategy, among all admissible strategies, without limiting them to strategies that asymptotically a-priori converge to the zeroth order strategy. The ”nearly-optimal” strategy if followed has expected utility of the terminal wealth matching the value function at both zeroth and first order asymptotic expansion.

The main idea of this paper is to first calculate a heuristic asymptotic expansion in the correlation parameter. Then based on these expansion to construct a sub- and super solutions to the HJB equation, which in turn allow us to bound the value function from above and below similar to the method used e.g. in [2] and [3]. This procedure also produces a ”nearly-optimal” strategy, and shows that the expected utility of the terminal wealth associated with strategy is also within the same bounds as the value function.

The rest of the paper is structured in the following way. In Section 2, we study in details the case of investments in one stock and a risk-free account where the returns and volatility of the stock are driven by two factors. Our asymptotics around the case of perfect correlation between these two factors reveals a simple strategy that asymptotically a-priori converge to the zeroth order strategy. The “nearly-optimal” strategy additionally, we find a “nearly-optimal” strategy, among all admissible strategies, without limiting them to the factors are perfectly correlated which in turns allows for an explicit solution given by a linear problem.

2 Models with one Stock and two Factors

We consider a model with a stock price driven by two correlated stochastic volatility factors:

\[
\frac{dS_t}{S_t} = \mu(Z_1(t), Z_2(t)) dt + \sigma(Z_1(t), Z_2(t)) dW_t, \tag{1}
\]

\[
dZ_i(t) = \alpha_i(Z_i(t)) dt + \beta_i(Z_i(t)) dB_i(t) \quad i = 1, 2. \tag{2}
\]

The three Brownian motions \(B_1, B_2, \) and \(W\) are defined on a filtered probability space \((\Omega, \mathcal{F}, \mathcal{F}_{t \geq 0}, \mathbb{P})\). We assume that the two Brownian Motions \(B_1, B_2\) are correlated according to \(d\langle B_1, B_2 \rangle_t = \rho_{12} dt\), and that they are correlated to the Brownian Motion \(W\) according to \(d\langle W, B_i \rangle_t = \rho_i dt\), \(i = 1, 2\), with constant coefficients \(\rho_{12}, \rho_1, \rho_2\) such that \(|\rho_{12}| \leq 1, |\rho_1| < 1, |\rho_2| < 1\) and

\[
1 + 2\rho_1 \rho_2 \rho_{12} - \rho_1^2 - \rho_2^2 - \rho_{12}^2 \geq 0. \tag{3}
\]

Throughout the paper, we work under standing classical hypotheses on the coefficients of the system (1)-(2) ensuring existence and uniqueness of a strong solution.

We assume also that the market contains a bond, that carries zero interest rate for convenience. Let \(\pi_t\) be the number of shares of stock held at time \(t\). Thus, the evolution of the wealth \(X_t\) following the self-financing strategy \(\pi_t\) is given by:

\[
dX_t = \pi_t \frac{dS_t}{S_t} = \pi_t \mu(Z_1(t), Z_2(t)) dt + \pi_t \sigma(Z_1(t), Z_2(t)) dW_t,
\]

and the value function of the optimal investment problem with terminal time \(T\) and utility \(U\) is the following:

\[v(t, x, z_1, z_2) = \sup_{\pi} \mathbb{E}_{t, x, z_1, z_2}[U(X_T)],\]

where \(\mathbb{E}_{t, x, z_1, z_2}[\cdot]\) denotes the conditional expectation \(\mathbb{E}[\cdot|X_t = x, Z_1(t) = z_1, Z_2(t) = z_2]\), and the supremum is taken over all admissible Markovian strategies \(\pi_s = \pi(s, X_s, Z_1(s), Z_2(s))\) such that \(X_s\) stays nonnegative.
for all $t \leq s \leq T$ given $X_t = x, Z_1(t) = z_1, Z_2(t) = z_2$, and satisfy the integrability condition

$$\mathbb{E}\left\{ \int_0^T \pi_t^2 \sigma^2(Z_1(t), Z_2(t))dt \right\}.$$  

In this paper we consider the case with utility functions $U$ being of power type: $U(c) = \frac{c^p}{p}$, $p < 1, p \neq 0$.

Define the differential operators

$$L_{z_1, z_2}^{\rho_1, \rho_2} = \mu(z_1, z_2) \frac{\partial}{\partial x} + \frac{1}{2} \sigma^2(z_1, z_2) \sigma^2 \frac{\partial^2}{\partial x^2} + \sigma(z_1, z_2) \mu \sum_{i=1}^2 \rho_i \beta_i(z_i) \frac{\partial^2}{\partial x \partial z_i},$$

$$L_{z_1, z_2}^{\rho_1^2} = 2 \sum_{i=1}^2 \rho_i(z_i) \frac{\partial}{\partial z_i} + \frac{1}{2} \sum_{i=1}^2 \beta_i^2(z_i) \frac{\partial^2}{\partial z_i^2} + \rho_1^2 \beta_1(z_1) \beta_2(z_2) \frac{\partial^2}{\partial z_1 \partial z_2}.$$

In this case, the value function $v$ satisfies:

$$\partial_t v + L_{z_1, z_2}^{\rho_1^2} v + \sup_{\pi} L_{z_1, z_2}^{\rho_1, \rho_2} v = 0, \quad \text{for all } t \leq s \leq T,$$

$$v(T, x, z_1, z_2) = U(x).$$

Maximization over $\pi$ gives:

$$\pi^* = -\frac{\mu(z_1, z_2)}{\sigma^2(z_1, z_2)} \frac{v_x}{v_{xx}} - \frac{1}{\sigma(z_1, z_2)} \sum_{i=1}^2 \rho_i \beta_i(z_i) \frac{v_{xi}}{v_{xx}},$$

where $v_i$ denotes a derivative with respect to $z_i$, $i = 1, 2$. Substituting (5) into (4), it follows that

$$\partial_t v + L_{z_1, z_2}^{\rho_1^2} v - \left( \lambda(z_1, z_2) v_x + \sum_{i=1}^2 \rho_i \beta_i(z_i) v_i \right)^2 = 0,$$

where the Sharpe ratio $\lambda$ is defined by $\lambda(z_1, z_2) = \frac{\mu(z_1, z_2)}{\sigma(z_1, z_2)}$.

### 2.1 Fully Correlated Factors

Our goal is to find the value function $v$ and the optimal strategy to achieve the maximum expected utility from the terminal wealth. We start by recalling the result from [9] as applied to our case. More specifically in the case of fully correlated factors $Z_1, Z_2$ we are able to easily adapt the computations there as follows. Let us temporarily assume that $\rho_{12} = 1$, then condition (3) forces us to also assume that $\rho_1 = \rho_2 = \rho$, with $|\rho| < 1$. We consider the “distortion transformation” used in [18] and [9]:

$$v(t, x, z_1, z_2) = \frac{\rho^p}{p} \left( \Psi^{(0)}(t, z_1, z_2) \right)^q,$$

where the superscript $(0)$ indicates that this function will be the zeroth order in the asymptotics presented in the following section. Denoting $\Gamma = \frac{p-1}{p}$, the function $\Psi^{(0)}$ satisfies

$$\partial_t \Psi^{(0)} + L_{z_1, z_2}^{\rho_1^2} \Psi^{(0)} + \frac{\Gamma}{2q} \lambda^2(z_1, z_2) \Psi^{(0)} + \Gamma \rho \lambda(z_1, z_2) \sum_{i=1}^2 \beta_i(z_i) \Psi^{(0)}$$

$$+ \frac{1}{2} \left( (q-1) + q \rho^2 \Gamma \right) \left( \sum_{i=1}^2 \beta_i(z_i) \Psi^{(0)} \right)^2 = 0.$$

Choosing $q = \frac{1}{1+\rho^2}$ linearizes the equation to get:

$$\partial_t \Psi^{(0)} + \frac{\Gamma}{2q} \lambda^2(z_1, z_2) \Psi^{(0)} + L\Psi^{(0)} = 0,$$

$$\Psi^{(0)}(T, z_1, z_2) = 1,$$

where $L\Psi^{(0)}$ denotes a derivative with respect to $i$. 

3
where

$$\mathcal{L}\phi = \mathcal{L}^1_{z_1, z_2}\phi + \Gamma \rho \lambda (z_1, z_2) \sum_{i=1}^{2} \beta_i(z_i) \phi_i.$$  (8)

Noting that in this case ($\rho_{12} = 1$), we may assume that $B_1(t) = B_2(t) = B(t)$, and we get a Feynman–Kac type formula:

$$\Psi^{(0)}(t, z_1, z_2) = \mathcal{E}_{t, z_1, z_2} \left[ e^{\int_t^T \lambda^2 (Z_t(s), Z_2(s)) ds} \right],$$  (9)

where $\mathcal{E}$ is defined so that $\mathcal{E}_t$ is a standard Brownian Motion under it.

### 2.2 Asymptotics Around the Fully Correlated Case

We now go back to the general correlation structure. Our goal is to try and expand it around the fully correlated case that has been worked out now, the case when $\rho_{12} = 1$, and $\rho_1 = \rho_2$. Therefore, we now assume that $\rho_1, \rho_2, \rho_{12}$ have the following form:

$$\rho_i = \rho + \rho_i^{(1)} \varepsilon, \quad i = 1, 2 \quad \text{and} \quad \rho_{12} = 1 + \rho_{12}^{(1)} \varepsilon,$$  (10)

where $\rho_{12}^{(1)} < 0$ and $\varepsilon$ is a small parameter, $0 < \varepsilon \ll 1$, small enough to ensure a proper covariance structure. Consider the ansatz

$$v(t, x, z_1, z_2) = \frac{p}{p} \left( \Psi^{(0)}(t, z_1, z_2) + \varepsilon \Psi^{(1)}(t, z_1, z_2) \right)^q + O(\varepsilon^2),$$  (11)

where the exponent $q$, chosen as in the perfectly correlated case, is given by $q = \frac{1}{1 + \rho^2} = \frac{1-p}{1-p(1-\rho^2)}$. Plugging this ansatz in the HJB equation (6) and canceling terms of zero order in $\varepsilon$ gives that the function $\Psi^{(0)}$ satisfies (7) and is given by (9). Cancelling the terms of order one in $\varepsilon$, we deduce that the function $\Psi^{(1)}$ must solve:

$$2(1-p)^2p \left( \beta_1 \beta_2 \Psi^{(0)}_1 \Psi^{(0)}_2 (\rho_1^{(1)} - \rho \rho_{12}^{(1)} + \rho_2^{(1)}) + \sum_{i=1}^{2} \beta_i^2 \rho_i^{(1)} (\Psi^{(0)}_i)^2 \right)$$

$$+ (1-p(1-\rho^2)) \Psi^{(0)} \left( p \lambda^2 (1-p(1-\rho^2)) \Psi^{(1)} + 2(1-p) \left( p \lambda \sum_{i=1}^{2} \rho_i^{(1)} \beta_i \Psi^{(0)}_i + (1-p) \rho_{12}^{(1)} \beta_1 \beta_2 \Psi^{(0)}_{12} \right. \right.$$

$$\left. + \sum_{i=1}^{2} (\alpha_i(1-p) + \beta_i \lambda p) \Psi^{(1)}_i + \frac{1}{2} (1-p) \left( \beta_2^2 \Psi^{(1)}_{11} + 2 \beta_1 \beta_2 \Psi^{(1)}_{12} + \beta_2^2 \Psi^{(1)}_{22} \right) + (1-p) \partial_t \Psi^{(1)} \right) = 0,$$

$$\Psi^{(1)}(T, z_1, z_2) = 0,$$

where we have omitted the arguments of the functions $\beta_i$ and $\lambda$.

Dividing by $2(1-p(1-\rho^2))(1-p) \Psi^{(0)}$, and recalling that $q = \frac{1-p}{1-p(1-\rho^2)}$, this equation can be written:

$$\partial_t \Psi^{(1)} + \mathcal{L} \Psi^{(1)} + \frac{\Gamma}{2q} \lambda^2 \Psi^{(1)} = f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathcal{H}(\Psi^{(0)})),$$  (12)

$$\Psi^{(1)}(T, z_1, z_2) = 0,$$

where

$$f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathcal{H}(\Psi^{(0)})) = -q \rho \frac{\Psi^{(0)}}{\Psi^{(0)} + \Psi^{(1)}} \left( \beta_1 \beta_2 \Psi^{(0)}_1 \Psi^{(0)}_2 (\rho_1^{(1)} - \rho \rho_{12}^{(1)} + \rho_2^{(1)}) + \sum_{i=1}^{2} \beta_i^2 \rho_i^{(1)} (\Psi^{(0)}_i)^2 \right)$$

$$- \Gamma \sum_{i=1}^{2} \rho_i^{(1)} \beta_i \Psi^{(0)}_i - \rho_{12}^{(1)} \beta_1 \beta_2 \Psi^{(0)}_{12}.$$
We now consider a zeroth order approximation to \( \pi^* \) given in [5], by substituting the zeroth order approximation for \( v \) from (11), namely, \( v(t, x, z_1, z_2) \approx \frac{\epsilon}{p} (\Phi(0)(t, z_1, z_2))^q \) and by using \( \rho_{12} = 1, \rho_1 = \rho_2 = \rho \), the zeroth order approximation from [10]. We obtain

\[
\pi^{0,*} = -\frac{x}{(p-1)\sigma^2} \left( \mu (\Phi(0)) + \rho q \sigma \sum_{i=1}^2 \beta_i \Phi(0)^{(1)} \right).
\]  

(13)

We next use \( \pi = \pi^{0,*} \) in the supremum of (4) and evaluate the equation, and get:

\[
\begin{align*}
\frac{\partial_t v + \mathcal{L}_{z_1,z_2} v + \mathcal{L}^{0,*}_{z_1,z_2} v}{v} &= q \left( (\Phi(0) + \varepsilon \Phi^{(1)}) \left( \partial_t \Phi(0) + \frac{\Gamma}{2q} \lambda^2 \Phi(0) + \mathcal{L} \Phi(0) \right) \right) \\
&+ q \left( (\Phi(0) + \varepsilon \Phi^{(1)}) \left( \partial_t \Phi^{(1)} + \mathcal{L} \Phi^{(1)} + \frac{\Gamma}{2q} \lambda^2 \Phi^{(1)} - f_1(\Phi(0), \nabla \Phi^{(0)}, \mathcal{H}(\Phi(0))) \right) \right) + O(\varepsilon^2) \\
&= O(\varepsilon^2),
\end{align*}
\]

(14)

where the last equality is obtained by cancelling the first two terms using the equations (7) and (12) satisfied by \( \Phi(0) \) and \( \Phi^{(1)} \) respectively.

To summarize, this formal computation shows that the strategy \( \pi = \pi^{0,*} \) given by (13) generates the value \( v \) given by (4) up to order \( \varepsilon \).

3 An Example with Explicit Formula

We now consider a specific choice of a model [1]-[2], inspired by a model of Chacko and Viceira [4], given by:

\[
\mu(z_1, z_2) = \tilde{\mu}, \quad \sigma(z_1, z_2) = \frac{\sigma}{\sqrt{z_1 + z_2}}, \quad \text{and} \quad \alpha_i(z_i) = m_i - z_i, \quad i = 1, 2, \quad \text{and} \quad \beta_1(z_1, z_2) = \beta_2(z_1, z_2) = \sqrt{z_1 + z_2}.
\]

Note that, in this example, the coefficients \( \beta_i \) depend on both \( z_1 \) and \( z_2 \) which could have been included in [2] from the beginning without additional difficulties.

For convenience, also set \( \tilde{\lambda} = \tilde{\mu}/\tilde{\sigma} \). In this case, the solution to the zeroth order \( \Phi(0) \) is explicit. Noticing that at the zeroth order, there is a symmetry between \( z_1 \) and \( z_2 \), we assume the ansatz:

\[
\Phi(0)(t, z_1, z_2) = e^{A(t)(z_1+z_2)+B(t)}.
\]

Substituting this ansatz into (7) results in:

\[
\begin{align*}
A' &= -2 \left( A^2 + \left( \Gamma \tilde{\lambda} \rho - \frac{1}{2} \right) A + \frac{\Gamma}{4q} \lambda^2 \right), \quad A(T) = 0, \\
B' &= -(m_1 + m_2) A, \quad B(T) = 0.
\end{align*}
\]

(15)

Assuming the right hand side of (15) has two distinct solutions, \( a_{\pm} = \frac{1}{4} \left( 1 - 2\Gamma \tilde{\lambda} \rho \pm \sqrt{(1 - 2\Gamma \tilde{\lambda} \rho)^2 - 4\Gamma \lambda^2 q} \right) \), which is the case, when \( p < 1 \), we get that

\[
\begin{align*}
A(t) &= a_+ a_- \frac{1 - e^{2(T-t)(a_+-a_-)}}{a_- - a_+ e^{2(T-t)(a_+-a_-)}}, \\
B(t) &= -(m_1 + m_2) \left( \frac{1}{2} \log \left( \frac{a_- - a_+ e^{2(a_+-a_-)(T-t)}}{a_- - a_+} \right) - a_+(T-t) \right).
\end{align*}
\]

We conclude from (13) that

\[
\pi^{0,*} = -\frac{x}{(p-1)\sigma^2} \left( \mu + \rho q \sigma A(t) \sum_{i=1}^2 \beta_i \right) = \frac{x}{1-p} \left( \frac{\mu}{\sigma^2} + \frac{2\rho q A(t)}{\sigma} \right)(z_1 + z_2).
\]
Equation (12) for $\Psi^{(1)}$ becomes:

$$\partial_t \Psi^{(1)} + \mathcal{L} \Psi^{(1)} + \frac{1}{2q} \bar{\lambda}^2 \Psi^{(1)} = f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathbb{H}(\Psi^{(0)}))$$

$$= -qpp \rho \left( \beta_1 \beta_2 \Psi^{(0)}_1 \Psi^{(0)}_2 (\rho_1^{(1)} - \rho_{12}^{(1)} + \rho_2^{(1)}) + \sum_{i=1}^{2} \beta_i^2 \rho_i^{(1)} (\Psi^{(0)}_i)^2 \right) - \Gamma \sum_{i=1}^{2} \rho_i^{(1)} \beta_i \Psi^{(0)}_i - \rho_{12}^{(1)} \beta_1 \beta_2 \Psi^{(0)}_{12}$$

$$= -qpp \Psi^{(0)} A^2(t)(z_1 + z_2) \left( 2\rho_1^{(1)} - \left( \rho + \frac{1}{qpp} \right) \rho_{12}^{(1)} + 2\rho_2^{(1)} \right) - \Gamma \Psi^{(0)} A(t) \frac{\bar{\mu}}{\sigma} (\rho_1^{(1)} + \rho_2^{(1)})$$

$$\Psi^{(1)}(T, z_1, z_2) = 0.$$  

Using the fact that $\Psi^{(0)}$ satisfies (3), we look for a solution $\Psi^{(1)}$ in the form

$$\Psi^{(1)} = ((z_1 + z_2)A_1(t) + B_1(t)) \Psi^{(0)}.$$  

In this case, $A_1$ and $B_1$ satisfy:

$$A'_1(t) + (4A(t) - 1 + 2\Gamma \rho \bar{\lambda})A_1 + qpp A^2(t) \left( 2\rho_1^{(1)} - \left( \rho + \frac{1}{qpp} \right) \rho_{12}^{(1)} + 2\rho_2^{(1)} \right) = 0, \quad A_1(T) = 0,$$

$$B'_1(t) + (m_1 + m_2) A_1(t) + \Gamma A(t) \bar{\lambda} (\rho_1^{(1)} + \rho_2^{(1)}) = 0, \quad B_1(T) = 0.$$  

It then follows that

$$A_1(t) = -qpp \left( 2\rho_1^{(1)} - \left( \rho + \frac{1}{qpp} \right) \rho_{12}^{(1)} + 2\rho_2^{(1)} \right) \int_t^T A^2(s) e^{-\int_t^s f_1^{(1)} - 2\Gamma \rho \bar{\lambda} - 4A(u) du} ds,$$

$$B_1(t) = (m_1 + m_2) \int_t^T A_1(s) ds + \Gamma \bar{\lambda} (\rho_1^{(1)} + \rho_2^{(1)}) \int_t^T A(s) ds.$$  

### 3.1 Numerical Illustration

We illustrate our finding numerically, in the example of the extended Chacko and Viceira [4] model from Section 2. We use the parameters:

$$\bar{\mu} = 0.05, \quad m_1 = m_2 = 1, \quad \bar{\sigma} = 0.2, \quad \bar{\lambda} = \frac{\bar{\mu}}{\sigma} = 0.05, \quad \rho_{12} = 1 - \varepsilon, \quad \rho_1 = 0.5, \quad \rho_2 = 0.5 - \frac{\varepsilon}{2}, \quad p = -1, \quad T = 1. \quad (16)$$

The graphs are all drawn as surfaces of $(z_1, z_2)$ assuming $t = 0$. In this case it is easily seen that the Feller condition for the diffusion $(Z_1 + Z_2)$ is satisfied, which guarantees that $Z_1(t) + Z_2(t) > 0$. Figures 1 and Figures 3 illustrate the numerical solution of $\Psi$ with these parameters, and with $\varepsilon = 0.1$ and $\varepsilon = 0.05$ respectively. Both decline in both $z_1$ and $z_2$. The left graphs in Figures 2 and Figures 4 illustrate the error of the zeroth order approximation, i.e. $\Psi - \Psi^{(0)}$, whereas the right graphs in those figures illustrates the the error of the first order approximation, i.e. $\Psi - \Psi^{(0)} - \bar{\varepsilon} \Psi^{(1)}$. As expected, these errors are of order $O(\varepsilon)$ and $O(\varepsilon^2)$ respectively.
Figure 1: Graph of the numerical solution of $\Psi$ using $\varepsilon = 0.1$ together with the other parameters from [16].

Figure 2: Graphs of the errors in the approximation of $\Psi$ using $\varepsilon = 0.1$ together with the other parameters from [16]. Left: Error of approximation $\Psi - \Psi^{(0)}$. Right: Error of approximation $\Psi - \Psi^{(0)} - \varepsilon \Psi^{(1)}$.

Figure 3: Graph of the numerical solution of $\Psi$ using $\varepsilon = 0.05$ together with the other parameters from [16].
Proof of Accuracy

We now go back to the general case as in Section 2. The goal now is making the previous heuristic results rigorous. In other words, we prove the expansion in (11) is correct. Moreover, we want to show that the zeroth order strategy \( \pi_0^* \) from (13) indeed, achieves a good order approximation as claimed in (14).

We again consider the original HJB equation (4), and attempt the substitution

\[ v(t,x,z_1,z_2) = x^{p_0}(\Psi(t,z_1,z_2)) \]

Then \( \Psi \) satisfies:

\[ \partial_t \Psi + L_{z_1 z_2} \Psi + \Gamma(z_1,z_2) \sum_{i=1}^{2} \rho_i \beta_i(z_i) \Psi_i + \sum_{i=1}^{2} \left( (q-1) + q \rho_i^2 \Gamma \right) \beta_i^2 \Psi_i^2 + \beta_1 \beta_2 (\rho_1 (q-1) + q \rho_2 \Gamma) \Psi_2 = 0, \]

\[ \Psi(T,z_1,z_2) = 1, \]

4.1 Building Sub- and Super-Solutions

The goal is now to construct sub- and super-solution and to obtain bounds for the value function. Consider \( \Psi^{(0)} \) and \( \Psi^{(1)} \) given as a solutions to (7) and (12). Using those, define

\[ v^\pm(t,x,z_1,z_2) = x^{p_0} \left( \Psi^{(0)}(t,z_1,z_2) \pm \varepsilon \Psi^{(1)}(t,z_1,z_2) \right)^q \]

where \( M > 0 \) is a constant to be determined later. Since we want to use the fact that \( \Psi^{(i)}, i = 0,1 \) are solutions to (7) and (12), we first need to show that these exists and are unique. We will additionally show that they have smooth and bounded derivatives, as this will be useful in future calculations.

**Lemma 1.** Assume that \( \lambda, \alpha_i, \beta_i \) are bounded, twice differentiable with bounded derivatives, and that \( \beta_i \) are bounded away from zero. Then, \( \Psi^{(0)} \) and \( \Psi^{(1)} \), the solutions of (7) and (12) respectively, exist and they are unique and bounded. Moreover, their derivatives up to order two are bounded.

**Proof.** We show the proof for \( \Psi^{(0)} \), whereas the proof for \( \Psi^{(1)} \) is similar.

First, note that under our coefficient assumptions, the operator \( L \) appearing in (8) is uniformly elliptic. Then, existence and uniqueness of the classical solution \( \Psi^{(0)} \) of (7) follows from [13][Theorems 10,16]. By the Feynman–Kac formula [9], it follows that \( \Psi^{(0)} \) is bounded.
Since $\Psi^{(0)}$ is a classical solution to (7), it is differentiable, and we can consider $\Psi_i^{(0)}$, its derivative with respect to $z_i$, $i = 1, 2$. They satisfy the system of PDEs:

$$
\partial_t \Psi_i^{(0)} + \frac{\Gamma}{2q} \lambda^2(z_1, z_2) \Psi_i^{(0)} + \mathcal{L} \Psi_i^{(0)} + (\alpha_i'(z_i) + \beta_i(z_i) \beta_i'(z_i) \lambda_i(z_1, z_2) + \gamma_i(z_i) \beta_i(z_i) + \Gamma q \lambda_i(z_1, z_2) \beta_i(z_i) + \lambda(z_1, z_2) \beta_i'(z_i)) \Psi_i^{(0)}
= -\frac{\Gamma}{q} \lambda(z_1, z_2) \lambda_i(z_1, z_2) \Psi_i^{(0)} - \Gamma q \lambda(z_1, z_2) \beta_i(z_j) \Psi_j^{(0)},
$$

(18)

Note that $\lambda_i$ here as per our convention denotes the derivative of $\lambda$ with respect to $z_i$, $i = 1, 2$. Denoting by $D\Psi^{(0)}$ the vector $(\Psi_1^{(0)}, \Psi_2^{(0)})^T$ and by $D\lambda$ the vector $(\lambda_1, \lambda_2)^T$, the system of equations (18) can be rewritten:

$$
\partial_t D\Psi^{(0)} + LI_{2 \times 2} D\Psi^{(0)} + V(z_1, z_2) D\Psi^{(0)} + \Gamma q \lambda(z_1, z_2) \Psi^{(0)} D\lambda = 0, \quad D\Psi^{(0)}(T, z_1, z_2) = 0,
$$

where $I_{2 \times 2}$ is the $2 \times 2$ identity matrix, $V$ is a $2 \times 2$ potential matrix, and the last term being a source term.

Therefore, $D\Psi^{(0)}$ is given by the Feynman–Kac formula

$$
D\Psi^{(0)}(t, z_1, z_2) = \mathbb{E}_{t, z_1, z_2} \left[ \int_t^T e^{\int_u^T V(Z_1(u), Z_2(u)) du} \left[ \frac{\Gamma}{q} \lambda \Psi^{(0)} D\lambda \right](Z_1(s), Z_2(s)) ds \right].
$$

Under our coefficient assumptions, this shows that $\Psi_1^{(0)}$ and $\Psi_2^{(0)}$ are bounded. Differentiating the system (18) with respect to $z_i$, $i = 1, 2$, one obtains equations for the second order derivatives $\Psi_{11}^{(0)}, \Psi_{12}^{(0)}, \Psi_{22}^{(0)}$ and their boundedness is derived by using again a Feynman–Kac representation and our coefficient assumptions. Here, we omit these straightforward lengthy details as well as the calculation details for $\Psi^{(1)}$ given by (12) and its derivatives.

As a simple conclusion, assuming $\varepsilon > 0$ small enough, we also see that the sign of $v^\pm$ is the sign of $p$, as $\Psi^{(0)} > 0$, from its Feynman–Kac formula (9), and $\Psi^{(1)}$ is bounded.

We next utilize the boundedness of the derivatives of $\Psi^{(0)}$, $i = 0, 1$ to show that $v^\pm$ from (17) are indeed super- and sub-solutions. From the heuristic calculation we expect the error in the expansion (11) to be of $O(\varepsilon^2)$. The main idea of the proof is to show that the error can indeed be bounded by $M\varepsilon^2$, for $M > 0$ big enough. This together with boundedness of the derivatives, will allow us to conclude that $v^\pm$ are sub- and supermartingales and to conclude that they sandwich the value function $v$. More specifically, we will show that $v^+$ is a supermartingale along any admissible strategy $\pi$, whereas $v^-$ is a submartingale, along the strategy $\pi^{0,*}$. This will also allow us to conclude that the strategy $\pi^{0,*}$ is “nearly-optimal”, in the sense that the error when this strategy is employed is indeed of $O(\varepsilon^2)$ as heuristically calculated in (14).

**Theorem 2.** In addition to the coefficient assumptions in Lemma 4, we assume that $\lambda$ is bounded and bounded away from zero. Moreover, assume that $p < 0$. Then, for $M > 0$ large enough (independent of $\varepsilon$), the functions $v^\pm$ defined in (17) satisfy $v^- \leq v \leq v^+$. Moreover, the strategy $\pi^{0,*}$ given by (13), is “nearly-optimal”, in other words, if followed, then the expected utility of the terminal wealth will differ from the value function by $O(\varepsilon^2)$, i.e.

$$
v(t, x, z_1, z_2) - \mathbb{E}_t \left[ X_T^{\pi^{0,*}} \right] \leq 2 \left| \frac{p}{x} \right| M T \varepsilon^2.
$$

**Proof.** From the boundary conditions of $\Psi^{(0)}$ and $\Psi^{(1)}$, it is easily seen that

$$
v^\pm(T, x, z_1, z_2) = \mathcal{U}(x).
$$
Moreover, assuming that \( \rho_{12} = 1 + \rho_{12}^{(1)} \varepsilon \) and \( \rho_1 = \rho + \rho_{1}^{(1)} \varepsilon \), it follows that using \( \pi^{0,*} \) from (13)

\[
\begin{align*}
\frac{\partial_t v^- + \mathcal{L}_{\Psi_{1,z_2}}^+(t) v^- + \mathcal{L}_{\Psi_{1,z_2}}^+(t) v^-}{v^- (\Psi^{(0)}(t, z_1, z_2) + \varepsilon \Psi^{(1)}(t, z_1, z_2) - \varepsilon^2 M(T - t))}
&= q \left( \frac{\partial_t \Psi^{(0)}}{2q} + \frac{\Gamma}{2q} \lambda^2(z_1, z_2) \Psi^{(0)} + \mathcal{L} \Psi^{(0)} \right) \\
&+ q \left( \frac{\partial_t \Psi^{(1)}}{2q} + \frac{\Gamma}{2q} \lambda^2 \Psi^{(1)} - f_1(\Phi^{(0)}, \nabla \Phi^{(0)}, \mathbb{H}(\Phi^{(0)})) \right) \varepsilon \\
&+ \frac{M}{2} \left( \Gamma(t, z)(T - t) \lambda^2 - 2q + \frac{(1 - q)(1 - p) - q^2 p \rho^2}{1 - p} \left( \frac{\beta_1 \Psi_1^{(0)} + \beta_2 \Psi_2^{(0)}}{\Psi^{(0)}} \right)^2 \right) \varepsilon^2 \\
&+ \frac{2q}{2(1 - p) \sigma(\Psi^{(0)})^3} \left( \sigma(\Psi^{(0)})^2 \left( \beta_1^2 \left( \alpha p \rho_1^{(1)} \right)^2 (\Psi^{(0)})^2 + 4 \alpha p \rho_1^{(1)} \Psi_1^{(0)} \Psi_1^{(1)} - (\alpha - 1)(p - 1)(\Psi_1^{(1)})^2 \right) \\
&+ 2 \beta_1 \beta_2 (\Psi_2^{(1)})^2 (\Psi_1^{(0)} \left( \alpha p \rho_1^{(1)} + \rho_2^{(1)} \right) - (\alpha - 1)(p - 1) \rho_1^{(1)}) - (\alpha - 1)(p - 1) (\Psi_1^{(1)})^2 \right) \\
&+ 2 \beta_2 \Psi_2^{(1)} \left( \beta_1^2 \left( \alpha p \rho_1^{(1)} + \rho_2^{(1)} \right) + (\alpha - 1)(p - 1) \rho_1^{(1)} \right) + \alpha \beta_1^2 \rho_2 \rho_2^{(1)} \left( \beta_1 \Psi_1^{(0)} + \beta_2 \rho \Psi_2^{(1)} \right) \right) \right) \\
&+ \alpha \beta_1^2 \rho_2 \rho_2^{(1)} \left( \beta_1 \Psi_1^{(0)} + \beta_2 \rho \Psi_2^{(1)} \right) + \beta_2 \left( \beta_1 \Psi_1^{(0)} + \beta_2 \rho \Psi_2^{(1)} \right) \right) \\
&+ \beta_1 \Psi_1^{(0)} \left( - \alpha \beta_1 \rho_1^{(1)} \Psi_1^{(0)} + \alpha - 1 \beta_1 (p - 1) \Psi_1^{(1)} + (\alpha - 1) \beta_2 (p - 1) \Psi_2^{(1)} \right) \right) - \alpha \beta_2^2 \rho^2 \rho_2^{(1)} \left( \Psi_2^{(0)} \right)^2 \right) \\
&- 2 \Psi^{(0)}^2 \left( \beta_1 \beta_2 (p - 1) \rho_1^{(1)} \sigma \Psi_1^{(1)} - \mu \frac{\beta_1 \rho_1^{(1)} \Psi_1^{(1)} + \beta_2 \rho_1^{(1)} \Psi_2^{(1)}}{\Psi_1^{(0)}} \right) \right) \\
&+ (\alpha - 1)(1 - p) \sigma \Psi^{(1)}^2 \left( \beta_1 \Psi_1^{(0)} + \beta_2 \rho_2^{(0)} \right) \right) \right) \varepsilon^2 + O(\varepsilon^3). \quad (19)
\end{align*}
\]

Note that \( \Psi^{(0)} \) given out by (9), by our assumption is bounded, and bounded away from zero, and, by Lemma 3, the derivatives of \( \Psi^{(0)} \) and \( \Psi^{(1)} \) appearing in the expression above are bounded.

Looking at the factor of \( M \varepsilon^2 \), for \( p < 0 \), we have that \( \Gamma < 0 \), and thus \( q \geq \frac{1}{1 - p} = 1 - p \). Therefore, since

\[
\frac{\partial}{\partial \rho} \left( q(1 - q)(1 - p) - q^2 p \rho^2 \right) = -2q(1 - p) + (1 - p) - 2qp^2 \\
\leq -2q(1 - p) + (1 - p) - 2q = -2q + (1 - p) \leq 0,
\]

thus

\[
(q(1 - q)(1 - p) - q^2 p \rho^2) \leq (1 - p)^2 p - (1 - p)^2 p \rho^2 \leq (1 - p)^2 p(1 - \rho^2) \leq 0.
\]

We conclude that the \( (-M \varepsilon^2) \) term is positive, assuming \( \lambda \) is bounded away from zero. Thus, assuming \( M > 0 \) is large enough, the entire \( O(\varepsilon^3) \) term is negative. Recalling that \( v^- < 0 \), whereas for \( \varepsilon > 0 \) small enough, \( \Psi^{(0)} + \varepsilon \Psi^{(1)}(t, z_1, z_2) - \varepsilon^2 M(T - t) > 0 \), it then follows that \( v^- \) using the strategy \( \pi^{0,*} \) is a submartingale. Thus

\[
v^- (t, x, z_1, z_2) \leq \mathbb{E}_t \left[ v^+ \left( T, X^0_{T}, Z_1(T), Z_2(T) \right) \right] = \mathbb{E}_t \left[ \mathcal{U} \left( X^0_{T} \right) \right].
\]

Recall that \( v^+ < 0 \) whereas, whereas for \( \varepsilon > 0 \) small enough, \( \Psi^{(0)} + \varepsilon \Psi^{(1)}(t, z_1, z_2) + \varepsilon^2 M(T - t) > 0 \). Then, similar calculation with any admissible strategy \( \pi \) reveals
\[
\frac{\partial_t v^+ + \mathcal{L}_{x,z}^{\pi} v^+}{\partial_t v^+ + \mathcal{L}_{x,z}^{\pi} v^+ + \sup_{\pi} \mathcal{L}_{x,z}^{\pi} v^+} = \frac{\partial_t v^+ + \mathcal{L}_{x,z}^{\pi} v^+ + \varepsilon^2 M(T - t)}{\partial_t v^+ + \mathcal{L}_{x,z}^{\pi} v^+} + \varepsilon^2 M(T - t)
\]

where the difference between this expression and \([19]\) is only in the \(O(\varepsilon^2)\) term that does not depend on \(M\), and the sign of the \(\frac{\alpha}{2} \varepsilon^2\) term. Therefore, similarly we see that \(v^+\) is a supermartingale, for any admissible strategy \(\pi\), and we conclude that

\[
v^+(t, x, z_1, z_2) \geq E_t \left[ v^+(T, (X_T^x, Z_1(T), Z_2(T))) \right] = E_t \left[ \mathcal{U} \left( X_T^x \right) \right].
\]

Maximizing the right hand side over \(\pi\), and combining with \([19]\), we obtain

\[
v^-(t, x, z_1, z_2) \leq E_t \left[ \mathcal{U} \left( X_T^{\pi_{\Pi^*}} \right) \right] \leq v(t, x, z_1, z_2) \leq v^+(t, x, z_1, z_2).
\]

Moreover, the strategy \(\pi_{\Pi^*}\) is nearly optimal, that is the expectation of the utility of the terminal wealth using that strategy matches the \(O(\varepsilon)\) of the value function.
5 Extension to Models with Multi Assets

We now show how to extend our results to a model with multi-assets, and multi-factors. Consider now a model with multiple assets governed by

\[
\frac{dS_i(t)}{S_i(t)} = \mu_i(Z(t))dt + \sigma_i(Z(t))dW_i(t), \quad i = 1, 2, \ldots, n, \tag{20}
\]

\[
dZ_k(t) = \alpha_k(Z_k(t))dt + \beta_k(Z_k(t))dW_k(t) \quad k = 1, 2, \ldots, m, \tag{21}
\]

where we use the vector notation \( Z := [Z_1, \ldots, Z_m]^T \) and the correlation structure between the Brownian motions \((W_1, \ldots, W_n, B_1, \ldots, B_m)\) is given by:

\[
d\langle W_i, W_j \rangle_t = \rho_{ij}^WDt, \quad d\langle B_i, B_j \rangle_t = \rho_{ij}^BDt, \quad d\langle W_i, B_j \rangle_t = \rho_{ij}^Wdt, \quad 1 \leq i, j \leq n, 1 \leq k, l \leq m,
\]

with parameters \((\rho_{ij}^W, \rho_{kl}^B, \rho_{ik})\) ensuring a proper correlation structure (in particular \(\rho_{ii}^W = \rho_{kk}^B = 1\) and symmetries \(\rho_{ij}^W = \rho_{ji}^W, \rho_{kl}^B = \rho_{lk}^B\)).

Assuming that the wealth is fully invested in the \( n \) stocks in a self-financed way, and \( r = 0 \), then, the wealth process is given by:

\[
dX_t = \sum_{i=1}^n \pi_i(t) \frac{dS_i(t)}{S_i(t)} = \sum_{i=1}^n \pi_i(t) [\mu_i(Z(t))dt + \sigma_i(Z(t))dW_i(t)],
\]

where \( \pi_i(t) \) is the amount invested in asset \( i \) at time \( t \). The value function of the optimal investment problem with terminal time \( T \) and utility \( U \) is:

\[
v(t, x, z) = \sup_{\pi} \mathbb{E}_{t,x,z}[U(X_T)],
\]

where \( U(x) = \frac{x^p}{p}, \quad p < 1, p \neq 0. \)

We define the following operators:

\[
\mathcal{L}^{\rho^W, \rho^B}_{\pi, Z} = \sum_{i=1}^n \mu_i(z)\pi_i \frac{\partial}{\partial x} + \frac{1}{2} \left( \sum_{i,j=1}^n \rho_{ij}^W \pi_i \pi_j \sigma_i(z) \sigma_j(z) \right) \frac{\partial^2}{\partial x^2} + \sum_{i=1}^n \sum_{k=1}^m \rho_{ik} \pi_i(z) \beta_k(z) \frac{\partial^2}{\partial x \partial z_k},
\]

\[
\mathcal{L}^{\rho^B}_{\pi, Z} = \sum_{k=1}^m \alpha_k(z) \frac{\partial}{\partial z_k} + \frac{1}{2} \left( \sum_{k,l=1}^m \rho_{kl}^B \beta_k(z) \beta_l(z) \right) \frac{\partial^2}{\partial z_k \partial z_l}.
\]

The value function \( v \) then satisfies:

\[
\partial_t v + \mathcal{L}^{\rho^B}_{\pi, Z} v + \sup_{\pi} \mathcal{L}^{\rho^W, \rho^B}_{\pi, Z} v = 0, \tag{22}
\]

\[
v(T, x, z) = U(x).
\]

Our asymptotics will be around the case where the Brownian motions \( B_k \) are fully correlated. In order to model this regime, we define:

\[
\rho_{ik} = \rho_i + \rho_{ik}^{(1)} \varepsilon, \quad 1 \leq i \leq n, 1 \leq k \leq m, \quad \text{and} \quad \rho_{kl}^B = 1 + \rho_{kl}^{(1,B)} \varepsilon, \tag{23}
\]

with \( \rho_{kk}^B = 0 \) and \( \rho_{kl}^{(1,B)} < 0 \), and \( \varepsilon \) is a small parameter, \( 0 < \varepsilon \ll 1 \), small enough to ensure a proper covariance structure.

**Remark 1.** The model that we are perturbing corresponding to \( \varepsilon = 0 \) in (23), cannot be of eigenvalue equality (EVE) type as considered in [11], unless \( m = 1 \), that is models with a single factor. Indeed, the matrix \( \rho \rho^T \) with \( \rho_{ik} = \rho_i, \quad 1 \leq i \leq n, 1 \leq k \leq m \), admits zero as eigenvalue as soon as \( m \geq 2 \) and therefore, cannot satisfy the EVE condition \( \rho \rho^T = pI \) unless in the uncorrelated case \( \rho = 0 \).

In order to keep the formulas as explicit as possible, we present the case with two assets and two factors.
5.1 Model with Two Assets

We continue illustrate the calculation of the expansions in an example with two assets and two driving factors. Therefore the now model will be governed by (20)-(21) with \( n = m = 2 \). Maximization over \( \pi \) in (22) gives:

\[
\pi^*_i = \frac{\sigma_i \sum_{k=1}^2 \beta_k \rho_{ik} v_{xk} + \mu_i v_x - \rho_{12}^W \sigma_i \left( \sum_{j=1}^2 \beta_j \rho_{jk} v_{xk} + \mu_j v_x \right)}{\left( (\rho_{12}^W)^2 - 1 \right) \sigma_i^2 \sigma_j v_{xx}}, \quad i, j = 1, 2, \ i \neq j,
\]

(24)

where \( v_k \) denotes a derivative with respect to \( z_k, \ k = 1, 2 \).

Substituting (24) into (22), it follows that

\[
\partial_t v + L^P_x v
- \frac{\sum_{i=1}^2 \beta_i^2 \left( -2\rho_{2i} \rho_{12}^W + \rho_{i1}^2 + \rho_{i2}^2 \right) v_{x,i}^2 + 2\beta_1 \beta_2 \left( \rho_{21} \left( \rho_{22} - \rho_{12}^W \right) + \rho_{11} \left( \rho_{12} - \rho_{22}^W \right) \right) v_{x,1} v_{x,2}}{2(1 - (\rho_{12}^W)^2)v_{xx}}
- \left( \frac{2}{1} \right) \beta_i v_{x,i} \left( \rho_{1i}(\lambda_1 - \lambda_2^2 \rho_{12}^W) + \rho_{2i}(\lambda_2 - \lambda_1^2 \rho_{12}^W) \right) \left( \frac{v_x}{(1 - (\rho_{12}^W)^2)v_{xx}} \right) - \frac{(\lambda_1^2 - 2\lambda_1 \lambda_2 \rho_{12}^W + \lambda_2^2) v_x^2}{2(1 - (\rho_{12}^W)^2)v_{xx}} = 0,
\]

where \( \lambda_i(z_1, z_2) = \frac{\mu_i(z_1, z_2)}{\sigma_i(z_1, z_2)}, \ i = 1, 2 \).

5.1.1 Fully Correlated Case

Analogous to Section 2.2, we temporarily assume that the two stochastic volatility factors are fully correlated: \( \rho_{12}^B = 1 \), \( B_1(t) = B_2(t) = B(t) \), and \( d \langle W_i, B \rangle_t = \rho_i dt, \ i, j = 1, 2 \).

We consider the ansatz

\[
v(t, x, z_1, z_2) = \frac{x^p}{p} \left( \Psi^{(0)}(t, z_1, z_2) \right)^q.
\]

Let \( \Gamma = \frac{\rho_i}{1 - \rho_i^2} \). Then, it follows that \( \Psi^{(0)} \) satisfies

\[
\partial_t \Psi^{(0)} + \frac{1}{2} \left( \beta_1^2 \Psi^{(0)}_{11} + \beta_1 \beta_2 \Psi^{(0)}_{12} + \frac{1}{2} \beta_2^2 \Psi^{(0)}_{22} \right) + \left( \alpha_1 + \frac{\Gamma \beta_1}{1 - (\rho_{12}^W)^2} \left( \lambda_1 \left( \rho_1 - \rho_2 \rho_{12}^W \right) + \lambda_2 \left( \rho_2 - \rho_1 \rho_{12}^W \right) \right) \right) \Psi^{(0)}_1
+ \left( \alpha_2 + \frac{\Gamma \beta_2}{1 - (\rho_{12}^W)^2} \left( \lambda_1 \left( \rho_1 - \rho_2 \rho_{12}^W \right) + \lambda_2 \left( \rho_2 - \rho_1 \rho_{12}^W \right) \right) \right) \Psi^{(0)}_2
+ \left( \frac{(q - 1) + p (q (\rho_1^2 + \rho_2^2 - 1) + 1) - 2q \rho_1 \rho_2 (\rho_{12}^W) (1 - q)(1 - p)(\rho_{12}^W)^2 \left( \beta_1 \Psi^{(0)}_{11} + \beta_2 \Psi^{(0)}_{22} \right)}{2(1 - p)(1 - (\rho_{12}^W)^2)} \right)^2 = 0.
\]

Choosing \( q = \left( 1 + \Gamma \frac{\rho_1^2 + \rho_2^2 - 2 \rho_1 \rho_2 \rho_{12}^W}{1 - (\rho_{12}^W)^2} \right)^{-1} \) linearizes the equation to get:

\[
\partial_t \Psi^{(0)} + \frac{\Gamma}{2q(1 - (\rho_{12}^W)^2)} \left( \lambda_1^2 - 2\lambda_1 \lambda_2 (\rho_{12}^W) + \lambda_2^2 \right) \Psi^{(0)} + L \Psi^{(0)} = 0,
\]

(25)

\[
\Psi^{(0)}(T, z_1, z_2) = 1,
\]

where

\[
L \phi = L^P_x \phi + \frac{\Gamma}{1 - (\rho_{12}^W)^2} \left( \lambda_1 \left( \rho_1 - \rho_2 \rho_{12}^W \right) + \lambda_2 \left( \rho_2 - \rho_1 \rho_{12}^W \right) \right) \sum_{i=1}^2 \beta_i(z_i) \phi_i.
\]
We have the Feynman–Kac representation:

$$\Psi^{(0)}(t, z_1, z_2) = \mathbb{E}_{t, z_1, z_2} \left[ e^{\frac{B_t}{2}} f \int_0^T \lambda^2(Z_1(s), Z_2(s)) ds \right],$$

where $\tilde{\mathbb{P}}$ is defined so that

$$\tilde{B}_t = B_t - \frac{\Gamma}{1 - (\rho_{12}^W)^2} \int_0^t \left( \lambda_1(Z_1(s), Z_2(s)) (\rho_1 - \rho_2 \rho_{12}^W) + \lambda_2(Z_1(s), Z_2(s)) (\rho_2 - \rho_1 \rho_{12}^W) \right) ds$$

is standard Brownian Motion under it.

5.1.2 Asymptotics

In the general case, we will assume a correlation structure of the form (23):

$$\rho_k = \rho_k^{(1)} \varepsilon, \ i, k = 1, 2, \ \text{and} \ \rho_{12}^B = 1 + \rho_{12}^{(1, B)} \varepsilon,$$

with $\rho_{12}^{(1, B)} < 0$ and $\varepsilon$ is a small parameter, $0 < \varepsilon \ll 1$, small enough to ensure a proper covariance structure. As was done previously, we will now expand the general case, around the known case of $\varepsilon = 0$, and calculate the asymptotic expansion similar to (11).

$$v(t, x, z_1, z_2) = \frac{\varepsilon^p}{p} \left( \Psi^{(0)}(t, z_1, z_2) + \varepsilon \Psi^{(1)}(t, z_1, z_2) \right)^q + O(\varepsilon^2),$$

Note that the expansion has the same number of arguments as before, as there are still two factors, though the functions $\Psi^{(i)}, \ i = 0, 1, \ \text{will be different.}$

Expanding the correlation coefficients as in (26) and the value function as in (27), we see that $\Psi^{(1)}$ satisfies an equation similar to (12):

$$\partial_t \Psi^{(1)} + \mathcal{L} \Psi^{(1)} + \frac{\Gamma}{2q(1 - (\rho_{12}^W)^2)} \left( \lambda_1^2 - 2 \lambda_1 \lambda_2 (\rho_{12}^W + \lambda_2^2) \right) \Psi^{(1)} = f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathbb{H}(\Psi^{(0)})),$$

where

$$f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathbb{H}(\Psi^{(0)})) = -\frac{q \Gamma}{(1 - (\rho_{12}^W)^2) \Psi^{(0)}} \left( \sum_{i=1}^2 \beta_i^2 \left( (\rho_1 \rho_2 \rho_{12}^W)^{\rho_{i1}^{(1)}} + (\rho_2 \rho_1 \rho_{12}^W)^{\rho_{i2}^{(1)}} \right) \Psi^{(0)} \right)^2$$

$$+ \beta_1 \beta_2 \Psi^{\Psi^{(1)}(1)} \Psi^{(0)} \left( (\rho_1 - \rho_2 \rho_{12}^W)^{\rho_{11}^{(1)}} + (\rho_2 - \rho_1 \rho_{12}^W)^{\rho_{22}^{(1)}} \right) \Psi^{(0)}$$

$$- \frac{\Gamma}{1 - (\rho_{12}^W)^2} \sum_{i=1}^2 \left( \lambda_1 - \lambda_2 \rho_{12}^W \right) \beta_i \Psi^{(0)} - \rho_{12}^{(1, B)} \Psi^{(0)}.$$

We now consider a first order approximation to $\pi^*$ given in (24), by substituting the first order approximation for $v$ from (11), namely, $v(t, x, z_1, z_2) \approx \frac{\varepsilon^p}{p} \left( \Psi^{(0)}(t, z_1, z_2) \right)^q$. Therefore,

$$\pi_{i1}^{0,*} = \frac{q \left( \beta_1 (\rho_{11} - \rho_{12}^W) \Psi^{(1)} + \beta_2 (\rho_{22} - \rho_{21}^W) \Psi^{(1)} \right) + \Psi^{(0)} (\lambda_1 - \lambda_2 \rho_{12}^W)}{(1 - p) (1 - (\rho_{12}^W)^2) \sigma_i \Psi^{(0)}} i, j = 1, 2, i \neq j (29)$$

We next use $(\pi_1^{0,*}, \pi_2^{0,*})$ in the supremum of (22) together with the expansions (26), (27) and evaluate the equation, to get that:

$$\frac{\partial_v \Psi^{(0)} + \mathcal{L}^{\Psi^{(0)} \Psi^{(1)}} + \mathcal{L}^{\Psi^{(0)} \Psi^{(1)}} \rho_{12}^W \rho_{12}^W}{\Psi^{(0)}}$$

$$= q \left( \Psi^{(0)} + \varepsilon \Psi^{(1)} \right) \left[ \partial_t \Psi^{(1)} + \frac{\Gamma}{2q(1 - (\rho_{12}^W)^2)} \left( \lambda_1^2 - 2 \lambda_1 \lambda_2 \rho_{12}^W + \lambda_2^2 \right) \Psi^{(0)} + \mathcal{L} \Psi^{(0)} \right]$$

$$+ \left( \partial_t \Psi^{(1)} + \mathcal{L} \Psi^{(1)} + \frac{\Gamma}{2q(1 - (\rho_{12}^W)^2)} \left( \lambda_1^2 - 2 \lambda_1 \lambda_2 \rho_{12}^W + \lambda_2^2 \right) \Psi^{(1)} - f_1(\Psi^{(0)}, \nabla \Psi^{(0)}, \mathbb{H}(\Psi^{(0)})) \right) \varepsilon + O(\varepsilon^2) = O(\varepsilon^2).$$
where the last equality is obtained by cancelling the first two terms using the equations (25) and (28) satisfied by $\Psi(0)$ and $\Psi(1)$ respectively.

To summarize, this formal computation shows that the strategy $(\pi_1, \pi_2) = (\pi_1^{(0)}, \pi_2^{(0)})$ given by (29) generates the value $v$ given by (22) up to order $\varepsilon$.

5.1.3 Explicit Formulas

We again consider a specific choice of a model, inspired by a model of Chacko and Viceira [4], given by:

$\mu_i(z_1, z_2) = \bar{\mu}_i, \sigma_i(z_1, z_2) = \frac{\sigma_i}{\sqrt{z_1 + z_2}}, i = 1, 2,$ and $\alpha_i(z_i) = m_i - z_i, i = 1, 2,$ together with $\beta_i(z_1, z_2) = \beta(z_1, z_2) = \sqrt{z_1 + z_2}$, in (20) and (21). Also, set $\bar{\lambda}_i = \frac{\bar{\sigma}_i}{\sigma_i}, i = 1, 2$. In this case, the solution to the zeroth order $\Psi(0)$ is explicit. Noticing that at the zeroth order, there is a symmetry between $z_1$ and $z_2$, we assume the ansatz

$$\Psi(0)(t, z_1, z_2) = e^{A(t)(z_1 + z_2) + B(t)}.$$ Substituting this ansatz into (25) results in:

$$A' = -2A^2 - 2 \left( \frac{\Gamma}{1 - (\rho_{12}^W)^2} \left( \bar{\lambda}_1 (\rho_1 - \rho_2 \rho_{12}^W) + \bar{\lambda}_2 (\rho_2 - \rho_1 \rho_{12}^W) \right) - \frac{1}{2} \right) A$$

(30)

$$B' = -(m_1 + m_2)A, \quad B(T) = 0.$$

Assuming the right hand side of (30) has two distinct solutions which is the case when $p < 0$, they are

$$a_{\pm} = \frac{1}{4} \left( 1 - 2\left( \frac{\Gamma}{1 - (\rho_{12}^W)^2} \left( \bar{\lambda}_1 (\rho_1 - \rho_2 \rho_{12}^W) + \bar{\lambda}_2 (\rho_2 - \rho_1 \rho_{12}^W) \right) \right) \pm \sqrt{\left( 1 - 2\left( \frac{\Gamma}{1 - (\rho_{12}^W)^2} \left( \bar{\lambda}_1 (\rho_1 - \rho_2 \rho_{12}^W) + \bar{\lambda}_2 (\rho_2 - \rho_1 \rho_{12}^W) \right) \right) \right)^2 - \frac{\Gamma}{2q(1 - (\rho_{12}^W)^2) \left( \bar{\lambda}_1^2 - 2\bar{\lambda}_1 \bar{\lambda}_2 (\rho_{12}^W) + \bar{\lambda}_2^2 \right)}}.$$

Indeed, if $p < 0$, it follows that $-1 < \Gamma < 0$, and $q > 0$, as $1 - \rho_1^2 - \rho_2^2 + 2 \rho_1 \rho_2 \rho_{12}^W - (\rho_{12}^W)^2 > 0$ which in turn is the result of the positive definiteness of the correlation matrix.

We then get that

$$A(t) = a_{+} a_{-} \left( \frac{1}{a_{-} - a_{+}} e^{2(T-t)(a_{+} - a_{-})} \right)^t,$$

$$B(t) = -(m_1 + m_2) \left( \frac{1}{2} \log \left( \frac{a_{-} - a_{+}}{a_{-} + a_{+}} e^{2(a_{+} - a_{-})(T-t)} \right) - a_{+} (T - t) \right).$$

We conclude from (24) that

$$\pi_{i0} = \frac{(z_1 + z_2)x}{p - 1} \left( \frac{2\tilde{\sigma}_i A(t) \rho_i + \bar{\mu}_i}{(\rho_{12}^W)^2 - 1} \sigma_i^2 - \rho_{12}^W \frac{2\tilde{\sigma}_j A(t) \rho_j + \bar{\mu}_j}{(\rho_{12}^W)^2 - 1} \sigma_i \sigma_j \right), i, j = 1, 2, i \neq j.$$  

(31)
Equation (28) for $\Psi^{(1)}$ becomes:

$$\partial_t \Psi^{(1)} + \mathcal{L} \Psi^{(1)} + \frac{\Gamma}{2q} \lambda^2 \Psi^{(1)} = f_1(\Phi^{(0)}, \nabla \Psi^{(0)}, \mathbb{H}(\Psi^{(0)}))$$

$$= -\frac{q \Gamma}{(1 - (\rho_2^{(1)} W_{12})^2) \Psi^{(0)}} \left( \sum_{i=1}^{2} \beta_i \left( (\rho_1 - \rho_2 \rho_1^{W_{12}})^{(1)} + (\rho_2 - \rho_1 \rho_2^{W_{12}})^{(1)} \right) \right) (\Psi^{(0)})^2$$

$$+ \beta_1 \beta_2 \Psi^{(0)} \left( (\rho_1 - \rho_2 \rho_1^{W_{12}})^{(1)} + (\rho_2 - \rho_1 \rho_2^{W_{12}})^{(1)} \right)$$

$$= -\frac{\Gamma}{1 - (\rho_2^{(1)} W_{12})^2} \left( (\lambda_1 - \lambda_2 \rho_2^{W_{12}})^{(1)} + (\lambda_2 - \lambda_1 \rho_1^{W_{12}})^{(1)} \right) \beta_1 \beta_2 \Psi^{(0)}$$

Using the fact that $\Psi^{(0)}$ satisfies (25), we look for a solution in the form $\Psi^{(1)} = ( (z_1 + z_2) A_1(t) + B_1(t) ) \Psi^{(0)}$. In this case, $A_1$ and $B_1$ satisfy:

$$A_1'(t) + \left( 4A(t) - 1 + \frac{\Gamma}{1 - (\rho_2^{(1)} W_{12})^2} \left( \lambda_1 (\rho_1 - \rho_2 \rho_1^{W_{12}}) + \lambda_2 (\rho_2 - \rho_1 \rho_1^{W_{12}}) \right) \right) A_1(t) - \bar{A} A^2(t) = 0, \quad A_1(T) = 0,$n

$$B_1'(t) + (m_2 + m_1) A_1(t) - \bar{B} A(t) = 0, \quad B_1(T) = 0,$$

where

$$\bar{A} = -\rho_2^{(1) W_{12}} - \frac{q \Gamma}{(1 - (\rho_2^{(1)} W_{12})^2)} \left( \sum_{i=1}^{2} \left( (\rho_1 - \rho_2 \rho_1^{W_{12}})^{(1)} + (\rho_2 - \rho_1 \rho_2^{W_{12}})^{(1)} \right) \right)$$

$$+ \left( (\rho_1 - \rho_2 \rho_1^{W_{12}})^{(1)} + (\rho_2 - \rho_1 \rho_1^{W_{12}})^{(1)} \right) \beta_1 \beta_2$$

$$\bar{B} = -\frac{\Gamma}{1 - (\rho_2^{(1)} W_{12})^2} \left( (\lambda_1 - \lambda_2 \rho_2^{W_{12}})^{(1)} + (\lambda_2 - \lambda_1 \rho_1^{W_{12}})^{(1)} \right).$$

It then follows that

$$A_1(t) = \bar{A} \int_t^T A^2(s) e^{-\int_{t}^{s} \left( \lambda_1 (\rho_2 - \rho_2 \rho_1^{W_{12}}) + \lambda_2 (\rho_2 - \rho_1 \rho_2^{W_{12}}) \right) - 4A(u) du} ds,$n

$$B_1(t) = (m_1 + m_2) \int_t^T A(s) ds - \bar{B} \int_t^T A(s) ds.$$n

Finally, note that, as in the case of one stock, the strategy [31] generates the optimal value up to order $\varepsilon$.
