August 23, 2019

Abstract. We introduce and analyze a class of Galerkin–collocation discretization schemes in time for the wave equation. Its conceptual basis is the establishment of a direct connection between the Galerkin method for the time discretization and the classical collocation methods, with the perspective of achieving the accuracy of the former with reduced computational costs provided by the latter in terms of less complex linear algebraic systems. Continuously differentiable in time discrete solutions are obtained by the application of a special quadrature rule involving derivatives. Optimal order error estimates are proved for fully discrete approximations based on the Galerkin–collocation approach. Further, the concept of Galerkin–collocation approximation is extended to twice continuously differentiable in time discrete solutions. A direct connection between the two families by a computationally cheap post-processing is presented. The error estimates are illustrated by numerical experiments.

Keywords. Wave equation, variational time discretization, collocation methods, space-time finite element methods, error estimates, post-processing.

1 Introduction

In this work we introduce and analyze a Galerkin–collocation (cGP–C^k, k ∈ {1, 2}) approach in time combined with a continuous Galerkin (cG) finite element method in space to approximate the solution to the second order hyperbolic wave problem

\[
\begin{align*}
\partial_t^2 u - \Delta u &= f & \text{in } \Omega \times [0,T], \\
u &= 0 & \text{on } \partial \Omega \times [0,T], \\
u(\cdot,0) &= u_0, \quad \partial_t u(\cdot,0) &= u_1 & \text{in } \Omega,
\end{align*}
\]

(1.1)

with C^k regular functions in time. In (1.1), T > 0 denotes some final time and \( \Omega \) is a polygonal or polyhedral bounded domain in \( \mathbb{R}^d \), with \( d = 2 \) or \( d = 3 \). The function \( f : \Omega \times (0,T] \to \mathbb{R} \) and the

1 bause@hsu-hh.de (corresponding author)
initial values \( u_0, u_1 : \Omega \to \mathbb{R} \) are given data. The system (1.1) is studied as a prototype model for more sophisticated wave phenomena of practical interest like, for instance, elastic wave propagation governed by the Lamé–Navier equations, the Maxwell system, or wave equations in coupled systems such as fluid-structure interaction and fully dynamic poroelasticity [35].

Our modification of the standard continuous Galerkin–Petrov method (cGP) for time discretization (cf., e.g., [7,8,12,30]) and the innovation of this work comes through imposing collocation conditions involving the discrete solution’s derivatives at the discrete time nodes while on the other hand downsizing the test space of the discrete variational problem compared with the standard cGP approach. This idea was recently introduced in [17] by two of the authors of this work for first-order systems of ordinary differential equations. We refer to our schemes as Galerkin–collocation methods. The collocation equations at the discrete time nodes then enable us to ensure regularity of higher order in time of the discrete solutions. A further key ingredient in the construction of the Galerkin–collocation approach comes through the application of a special quadrature formula, investigated in [28], and the definition of a related interpolation operator for the right-hand side term of the variational equation. Both of them use derivatives of the given function. The Galerkin–collocation schemes rely in an essential way on the perfectly matching set of polynomial spaces (trial and test space), quadrature formula, and interpolation operator. For the discretization of the spatial variables a continuous finite element approach is used here. This is done for the sake of brevity. Usually, discontinuous Galerkin methods are preferred; cf. [6,11,31]. Beyond the higher order regularity in the time, the Galerkin–collocation schemes offer appreciable advantages for the solution of the arising linear systems by a favorable impact on the matrix block structure; cf. [6] for details.

For the subclass of discrete solutions being once continuously differentiable in time an error analysis with optimal order error estimates in time and space and in various norms is given. We will stress the key ideas of our error analysis and present a fundamental concept for analyzing generalized Galerkin approximations to wave problems. One key point of our convergence proof for second-order hyperbolic problems is the weak stability result of Lemma 5.9. Compared with usual stability results for parabolic problems or for first-order hyperbolic problems (cf., e.g., [21] Lemma 4.2) a stability is obtained such that in the resulting error analysis some contributions can no longer be absorbed by terms on the left-hand side of the error inequality like it is typically done. Therefore, to prove error estimates of optimal order, the error in the time derivatives \( \partial_t u^0_{\tau,h}, \partial_t u^1_{\tau,h} \) for the discrete approximation pair \((u_{\tau,h}, \partial_t u_{\tau,h})\) of \((u, \partial_t u)\) is bounded firstly. For this, a variational problem that is satisfied by \((u_{\tau,h}, \partial_t u_{\tau,h})\) is identified. Then, a minor extension of a result of [30] becomes applicable to the thus obtained problem. This yields an estimate for \( \partial_t u - \partial_t u^0_{\tau,h} \) and \( \partial^2_t u - \partial_t u^1_{\tau,h} \). These auxiliary results then enable us to prove the desired optimal-order error estimates for \( u - u^0_{\tau,h} \) and \( \partial_t u - u^1_{\tau,h} \).

Space-time finite element methods with continuous and discontinuous discretizations of the time and space variables for parabolic and hyperbolic problems are well-known and have been studied carefully in the literature; cf., e.g., [1,2,7,8,10,12,14,15,18,20,23,27,29,31,33,40,42] and the references therein. The space-time approaches of these works differ by the choices of the trial and, in particular, of the test spaces. Depending on the construction of the test basis functions, either time-marching schemes defined by local problems on the respective subintervals \([t_{n-1}, t_n]\) of \([0, T]\) (cf., e.g., [1,2,12,20,26,27]) or schemes where all time steps are solved simultaneously (cf., e.g., [20,25,41]) are obtained. Here, by choosing basis test functions supported on a single subinterval \([t_{n-1}, t_n]\), we end up with a time-marching approach. Further, strong relations between cGP schemes, collocation, and Runge–Kutta methods have been observed. In [4,5] they are studied thoroughly. Moreover, nodal superconvergence properties of the cGP method are known; cf. [5, Eq. (2.2)]. In a recent work [12], co-authored by one author of this work, a recursive post-processing of the original continuous in time cGP solution is presented and analyzed. The post-processed approximation is built on each time interval upon the Gauss–Lobatto quadrature points of the actual time interval, at which the classical cGP solution is superconvergent with one extra order of accuracy. On the one hand, the post-processing lifts the superconvergence of the original cGP solution at the Gauss–Lobatto quadrature points to all points of the time interval by adding a higher order correction term which vanishes at the Gauss–Lobatto quadrature points.
On the other hand, the post-processing, which is done sequentially on the advancing time intervals and is of low computational costs, yields a numerical approximation that is globally $C^1$-regular in time. In [21, Subsec. 3.2] and [36, p. 494], similar post-processing techniques and lifting operators were studied for discontinuous Galerkin approximations in time. The post-processing can nicely be exploited, for instance, for an a-posteriori error control in time and an adaptive choice of the time mesh. We explicitly note that in contrast to [12], where the continuous differentiability is obtained by a post-processing of the continuous Galerkin–Petrov approximation, the higher order regularity in time that is built in this work is an inherent part of the construction of the discrete solution itself. This demands a different quadrature formula and interpolation operator for the right-hand side function.

This work is organized as follows. In Sec. 2 we introduce our notation and summarize preliminaries. In particular, quadrature formulas and related interpolation operators are introduced. In Sec. 3 our class of Galerkin–collocation schemes is presented. In Sec. 4 some auxiliary results for our error analysis are provided. Sec. 5 contains our error analysis for our family of once continuously differentiable in time Galerkin–collocation methods. In Sec. 6 the conservation of energy by the numerical schemes is studied. In Sec. 7 our construction principle is extended to define a class of twice continuously differentiable in time Galerkin-collocation approximation schemes for the wave equation. A link to the first class of schemes by a post-processing procedure is presented. Finally, in Sec. 8 our error estimates are illustrated and confirmed by numerical experiments.

2 Notation and preliminaries

2.1 Function spaces and evolution form of continuous problem

We use standard notation. $H^m(\Omega)$ is the Sobolev space of $L^2(\Omega)$ functions with derivatives up to order $m$ in $L^2(\Omega)$ and $\langle \cdot, \cdot \rangle$ denotes the inner product in $L^2(\Omega)$. Further, $\langle \cdot, \cdot \rangle$ defines the $L^2$ inner product on the product space $L^2(\Omega) \times L^2(\Omega)$. We let $H^1_0(\Omega) := \{ u \in H^1(\Omega) : u = 0 \text{ on } \partial \Omega \}$. For short, we put $H := L^2(\Omega)$ and $V := H^1_0(\Omega)$.

We denote by $V'$ the dual space of $V$ and use the notation

$$\| \cdot \| := \| \cdot \|_{L^2(\Omega)}, \quad \| \cdot \|_m := \| \cdot \|_{H^m(\Omega)}, \quad m \in \mathbb{N},$$

for the norms of the Sobolev spaces where we do not differ between the scalar- and vector-valued cases. Throughout, the meaning will be obvious from the context. For a Banach space $B$, we let $L^2(0, T; B)$, $C([0, T]; B)$, and $C^m([0, T]; B)$, $m \in \mathbb{N}$, be the Bochner spaces of $B$-valued functions, equipped with their natural norms. For a subinterval $J \subseteq [0, T]$, we use the notations $L^2(J; B)$, $C^m(J; B)$, and $C^0(J; B) := C(J; B)$.

In what follows, for non-negative numbers $a$ and $b$, the expression $a \lesssim b$ stands for the inequality $a \leq C b$ with a generic constant $C$ that is independent of the sizes of the spatial and temporal meshes. The value of $C$ can depend on the regularity of the space mesh, the polynomial degrees used for the space-time discretization, and the data (including $\Omega$).

For any given $u \in V$, let the operator $A : V \to V'$ be uniquely defined by

$$\langle Au, v \rangle := \langle \nabla u, \nabla v \rangle \quad \forall v \in V,$$

where $\langle \cdot, \cdot \rangle$ on the left-hand side is understood as duality pairing between $V'$ and $V$. Further, we denote by $A : V \times H \to H \times V'$ the operator

$$A = \begin{pmatrix} 0 & -I \\ A & 0 \end{pmatrix}$$

with the identity mapping $I : H \to H$. We let

$$X := L^2(0, T; V) \times L^2(0, T; H).$$
Introducing the unknowns \( u^0 = u \) and \( u^1 = \partial_t u \), problem (1.1) can be recovered in evolution form.

**Problem 2.1.**

Let \( f \in L^2(0, T; H) \) and \((u_0, u_1) \in V \times H\) be given and \( F = (0, f) \). Find \( U = (u^0, u^1) \in X \) such that

\[
\partial_t U + AU = F \quad \text{in} \quad (0, T), \quad U(0) = U_0 = (u_0, u_1).
\] (2.1)

Problem (2.1) admits a unique solution \( U \in X \) and the mapping \((f, u_0, u_1) \mapsto (u^0, u^1)\) is a linear continuous map from \( L^2(0, T; H) \times V \times H \) to \( X \); cf. [24], p. 273, Thm. 1.1]. Further, \( u^0 \in C([0, T]; V) \) and \( u^1 \in C((0, T]); H) \) are satisfied; cf. [35], p. 275, Thm. 8.2]. It follows from (2.1) that \( \partial_t u^1 \in L^2(0, T; V') \).

**Assumption 2.2.**

Throughout, we tacitly assume that the solution \( u \) of (1.1) satisfies all the additional regularity conditions that are required in our analysis. In addition, let \( f \in C^s([0, T]; H) \) for some sufficiently large parameter \( s \in \mathbb{N} \) be satisfied.

The first of the conditions in Assumption 2.2 implies further assumptions on the data \( f, u_0, u_1 \) and the boundary \( \partial \Omega \) of \( \Omega \). Improved regularity results for solutions to the wave problem (1.1) can be found, e.g., [22, Sec. 7.2]. The second condition in Assumption 2.2 will allow us to apply an interpolation in time that is based on derivatives of the right-hand side function \( f \).

### 2.2 Time and space discretization

For the time discretization, we decompose the time interval \( I = [0, T] \) into \( N \) subintervals \( I_n = (t_{n-1}, t_n] \), \( n = 1, \ldots, N \), where \( 0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T \) such that \( I = \bigcup_{n=1}^{N} I_n \). We put \( \tau = \max_{n=1,\ldots,N} t_n \) with \( t_n = t_n - t_{n-1} \). Further, the set \( \mathcal{M}_\tau := \{ I_1, \ldots, I_N \} \) of time intervals is called the time mesh. For a Banach space \( B \) and any \( k \in \mathbb{N}_0 \), we let

\[
\mathbb{P}_k(I_n; B) := \left\{ w_\tau : I_n \to B : w_\tau(t) = \sum_{j=0}^{k} W^j t^j \forall t \in I_n, \ W^j \in B \forall j \right\}.
\] (2.2)

For an integer \( k \in \mathbb{N} \), we introduce the space

\[
X^k \infty_B := \left\{ w_\tau \in C(\overline{I}; B) : w_\tau|_{I_n} \in \mathbb{P}_k(I_n; B) \forall I_n \in \mathcal{M}_\tau \right\}
\] (2.3)

of globally continuous functions in time and for an integer \( l \in \mathbb{N}_0 \) the space

\[
Y^l_B := \{ w_\tau \in L^2(I; B) : w_\tau|_{I_n} \in \mathbb{P}_l(I_n; B) \forall I_n \in \mathcal{M}_\tau \}
\]

of global \( L^2 \)-functions in time.

For any non-negative integer \( s \) and a function \( w : I \to B \) that is piecewise sufficiently smooth with respect to the time mesh \( \mathcal{M}_\tau \), we define by

\[
\partial_s w(t_n^+) := \lim_{t \to t_n^+} \partial_s w(t) \quad \text{and} \quad \partial_s w(t_n^-) := \lim_{t \to t_n^-} \partial_s w(t)
\] (2.4)

the one-sided limits of the \( s \)th derivative of \( w \).

For the space discretization, let \( T_h \) be a shape-regular mesh of \( \Omega \) consisting of quadrilateral or hexahedral elements with mesh size \( h > 0 \). For some integer \( r \in \mathbb{N} \), let \( V_h = V_h^r \) be the scalar finite element space given by

\[
V_h = V_h^r = \{ v_h : v_h|_{T} \in Q_r(K) \forall K \in T_h \} \cap H^1_0(\Omega)
\] (2.5)

where \( Q_r(K) \) is the space defined by the multilinear reference mapping of polynomials on the reference element with maximum degree \( r \) in each variable. Our restriction in this work to continuous finite
Throughout this work, the polynomial degree 2.3 Quadrature formulas and interpolation operators 
PWe denote by continuous ones for the discretization of wave equations; cf., e.g., [3,11,31,32] and the references therein.

We denote by discontinuous finite element methods in space of offer appreciable advantages over elements in space is only done for simplicity and in order to reduce the technical methodology of analyzing our Galerkin–collocation discretization scheme to its key points. In the literature it has been mentioned that discontinuous finite element methods in space offer appreciable advantages over continuous ones for the discretization of wave equations; cf., e.g., [3,11,31,32] and the references therein.

We denote by $P_h : H \to V_h$ the $L^2$-orthogonal projection onto $V_h$ such that for $w \in H$,

$$\langle P_h w, v_h \rangle = \langle w, v_h \rangle$$

for all $v_h \in V_h$. The operator $R_h : V \to V_h$ defines the elliptic projection onto $V_h$ such that for $w \in V$,

$$\langle \nabla R_h w, \nabla v_h \rangle = \langle \nabla w, \nabla v_h \rangle$$

(2.6)

for all $v_h \in V_h$. Finally, by $P_{h,0} : H \times H \to V_h \times V_h$ we denote the $L^2$-projection onto the product space $V_h \times V_h$ and by $R_h : V \times V \to V_h \times V_h$ the elliptic projection onto the product space $V_h \times V_h$. Let $A_h : H^1_0(\Omega) \to V_h$ be the operator that is defined by

$$\langle A_h w, v_h \rangle = \langle \nabla w, \nabla v_h \rangle$$

(2.7)

for all $v_h \in V_h$. Then, for $w \in V \cap H^2(\Omega)$ it holds that

$$\langle A_h w, v_h \rangle = \langle \nabla w, \nabla v_h \rangle = \langle Aw, v_h \rangle$$

for all $v_h \in V_h$. Hence, we have $A_h w = P_{h,0} Aw$ for $w \in V \cap H^2(\Omega)$. Let $A_h : V \times H \to V_h \times V_h$ be defined by

$$A_h = \begin{pmatrix} 0 & -P_{h,0} \\ A_{h,0} & 0 \end{pmatrix}.$$

Hence, we have for $W = (w^0, w^1) \in (V \cap H^2(\Omega)) \times H$

$$\langle A_h W, \Phi_h \rangle = \langle -w^1, \phi^0_h \rangle + \langle \nabla w^0, \nabla \phi^1_h \rangle = \langle -w^1, \phi^0_h \rangle + \langle Aw^0, \phi^1_h \rangle = \langle AW, \Phi_h \rangle$$

for all $\Phi_h = (\phi^0_h, \phi^1_h) \in V_h \times V_h$. This provides the consistency

$$A_h W = P_{h,0} AW$$

(2.8)

of $A_h$ on $(V \cap H^2(\Omega)) \times H$.

Finally, let $U_{0,h} \in V_h^2$ denote a suitable approximation of the initial value $U_0 \in V \times H$ in (2.1) that will we used as the initial value $U_{\tau,h}(0)$ of the discrete solution. Further restrictions will be made below.

2.3 Quadrature formulas and interpolation operators

Throughout this work, the polynomial degree $k \geq 3$ is assumed to be fixed. Let $\hat{t}_1^H = -1, \hat{t}_b^H = 1$, and $\hat{t}_s^H, s = 2, \ldots, k-2$, be the roots of the Jacobi polynomial on $\bar{I} := [-1, 1]$ with degree $k-3$ associated to the weighting function $(1 - \hat{t})^2(1 + \hat{t})^2$. Let $\tilde{I}^H : C^1(\bar{I}; B) \to P_k(\bar{I}; B)$ denote the Hermite interpolation operator with respect to point value and first derivative at both $-1$ and $1$ as well as the point values at $\hat{t}_s^H, s = 2, \ldots, k-2$. By

$$\hat{Q}^H(\hat{g}) := \int_{-1}^1 \tilde{I}^H(\hat{g})(\hat{t}) d\hat{t}$$

(2.9)

we define an Hermite-type quadrature on $[-1, 1]$ which can be written as

$$\hat{Q}^H(\hat{g}) = \hat{Q}_L \hat{g}'(-1) + \sum_{s=1}^{k-1} \hat{Q}_s \hat{g}(\hat{t}_s^H) + \hat{Q}_R \hat{g}'(1),$$

(2.10)
where all weights are non-zero. Using the affine mapping \( T_n : \hat{T} \to T_n \) with \( T_n(-1) = t_{n-1} \) and \( T_n(1) = t_n \), we obtain

\[
Q^H_n(g) = \left( \frac{\tau_n}{2} \right)^2 \hat{\omega}_L \partial_t g(t_{n+1}^-) + \frac{\tau_n}{2} \sum_{s=1}^{k-1} \hat{\omega}_s g(t_{n,s}^H) + \left( \frac{\tau_n}{2} \right)^2 \hat{\omega}_R \partial_t g(t_n^-)
\]  

(2.11)

as Hermite-type quadrature formula on \( I_n \), where \( t_{n,s}^H := T_n(\hat{t}_s^H) \), \( s = 1, \ldots, k - 1 \). We note that \( Q^H_n \) given in (2.11) integrates all polynomials up to degree \( 2k - 3 \) exactly, cf. [28]. Using \( \hat{T}^H \) and \( T_n \), the local Hermite interpolation on \( I_n \) is given by

\[
I^H_n : C^1(\hat{T}; B) \to \mathbb{P}_k(T_n; B), \quad v \mapsto (\hat{T}^H(v \circ T_n)) \circ T_n^{-1}.
\]

Moreover, we define the global Hermite interpolation \( I^H_n : C^1(\hat{T}; B) \to X^k(B) \) by means of

\[
I^H_n(w)|_{I_n} := I^H_n(w|_{I_n})
\]

(2.12)

for all \( n = 1, \ldots, N \).

In addition to Hermite-type interpolation and quadrature formula, Gauss and Gauss-Lobatto quadrature formulas will be used. To this end, we denote by \( \hat{t}_s^G \), \( s = 1, \ldots, k - 1 \), the roots of the Legendre polynomial with degree \( k - 1 \) and by \( \hat{t}_s^{GL} \), \( s = 2, \ldots, k - 1 \), the roots of the Jacobi polynomial on \( \hat{T} \) with degree \( k - 2 \) associated to the weighting function \((1 - \hat{t})(1 + \hat{t})\). Furthermore, we set \( \hat{t}_1^{GL} = -1 \) and \( \hat{t}_k^{GL} = 1 \). The operators \( \hat{T}^G : C(\hat{T}; B) \to \mathbb{P}_{k-2}(\hat{T}; B) \) and \( \hat{T}^{GL} : C(\hat{T}; B) \to \mathbb{P}_{k-1}(\hat{T}; B) \) are the Lagrange interpolation using the Gauss points \( \hat{t}_s^G \), \( s = 1, \ldots, k - 1 \), and the Gauss-Lobatto points \( \hat{t}_s^{GL} \), \( s = 1, \ldots, k \), respectively. We define by

\[
\hat{Q}^G(\hat{g}) := \int_{-1}^1 \hat{T}^G(\hat{g})(\hat{t}) \, d\hat{t} \quad \text{ and } \quad \hat{Q}^{GL}(\hat{g}) := \int_{-1}^1 \hat{T}^{GL}(\hat{g})(\hat{t}) \, d\hat{t}
\]

(2.13)

Gauss and Gauss-Lobatto quadrature formulas on \([-1,1]\) which are transformed to

\[
Q^G_n(g) = \frac{\tau_n}{2} \sum_{s=1}^{k-1} \hat{\omega}_s^G g(t_{n,s}^G) \quad \text{ and } \quad Q^{GL}_n(g) = \frac{\tau_n}{2} \sum_{s=1}^k \hat{\omega}_s^{GL} g(t_{n,s}^{GL})
\]

(2.14)

on \( I_n \) by using the affine mapping \( T_n \). The Gauss and Gauss-Lobatto formulas also integrate polynomials up to degree \( 2k - 3 \) exactly. Local Lagrange-type interpolation operators on \( I_n \) are given by

\[
I^G_n : C(\hat{T}; B) \to \mathbb{P}_{k-2}(\hat{T}; B), \quad v \mapsto (\hat{T}^G(v \circ T_n)) \circ T_n^{-1},
\]

\[
I^{GL}_n : C(\hat{T}; B) \to \mathbb{P}_{k-1}(\hat{T}; B), \quad v \mapsto (\hat{T}^{GL}(v \circ T_n)) \circ T_n^{-1}.
\]

Furthermore, we define the global Lagrange interpolation operators \( I^G_r : C(\hat{T}; B) \to Y^{k-2}(B) \) and \( I^{GL}_r : C(\hat{T}; B) \to X^{k-1}(B) \) by

\[
I^G_r(w)|_{I_n} := I^G_r(w|_{I_n}) \quad \text{ and } \quad I^{GL}_r(w)|_{I_n} := I^{GL}_r(w|_{I_n})
\]

for all \( n = 1, \ldots, N \).

### 3 Galerkin–collocation discretization and auxiliaries

In this section we introduce the approximation of the wave problem (2.1) by our Galerkin–collocation approach that combines collocation conditions at the endpoints \( t_{n-1} \) and \( t_n \) of the subintervals \( I_n \), with variational equations for reduced test spaces compared with the standard continuous finite element approximation of the wave equation (cf. [12, 24, 30]). A family of discrete solutions that are once continuously differentiable in time is obtained. For this family an optimal order error analysis is then developed in Sec. [5]. For the sake of completeness and in order to show the impact of the collocation conditions, the standard continuous Galerkin approximation (cf. [24, 30]) of the wave problem (2.1) is briefly recalled in Subsec. [5.1].
3.1 Space-time discretization with continuous Galerkin–Petrov method \( cGP(k) \)

For completeness and comparison, we briefly present the standard continuous Galerkin–Petrov method of order \( k \geq 1 \) (in short, \( cGP(k) \)) as time discretization applied to the evolution problem \( (2.1) \). For the space discretization, the continuous Galerkin approach \( cG(r) \) in \( V_h \), defined in \( (2.5) \), is used for the sake of simplicity. This yields the following fully discrete problem; cf., e.g., [12, 30] for details.

**Problem 3.1** (Global, fully discrete problem of \( cGP(k)–cG(r) \)).
Find \( U_{\tau,h} \in (X^k_T(V_h))^2 \) such that \( U_{\tau,h}(0) = U_{0,h} \) and

\[
\int_0^T \left( \left\langle \partial_t U_{\tau,h}, V_{\tau,h} \right\rangle + \left\langle A_h U_{\tau,h}, V_{\tau,h} \right\rangle \right) dt = \int_0^T \left\langle F, V_{\tau,h} \right\rangle dt
\]

for all \( V_{\tau,h} \in (Y^{k-1}_T(V_h))^2 \).

Both components of \( U_{\tau,h} = (u^0_{\tau,h}, u^1_{\tau,h}) \) are computed in the same discrete space \( X^k_T(V_h) \). By choosing test functions supported on a single subinterval \( I_n \) and using the \((k+1)\)-point Gauss–Lobatto quadrature formula, we recast Problem 3.1 as a sequence of local problems on \( I_n \).

**Problem 3.2** (Local, numerically integrated, fully discrete problem of \( cGP(k)–cG(r) \) on \( I_n \)).
Find \( U_{\tau,h}|_{I_n} \in \left( (\mathbb{P}_k(I_n; V_h))^2 \right) \) with \( U_{\tau,h}(t_{n-1}^+) = U_{\tau,h}(t_{n-1}^-) \) for \( n > 1 \) and \( U_{\tau,h}(t_0^+) = U_{0,h} \) such that

\[
Q_{n,k+1}^{GL} \left( \left\langle \partial_t U_{\tau,h}, V_{\tau,h} \right\rangle + \left\langle A_h U_{\tau,h}, V_{\tau,h} \right\rangle \right) = Q_{n,k+1}^{GL} \left( \left\langle F, V_{\tau,h} \right\rangle \right)
\]

for all \( V_{\tau,h} \in (\mathbb{P}_{k-1}(I_n; V_h))^2 \).

In Problem 3.2 we use a Gauss–Lobatto quadrature formula with \( k + 1 \) points, which is in contrast to \( Q_n^{GL} \) in \( (2.14) \) that uses \( k \) points. Furthermore, the quadrature formula on the left-hand side can be replaced by exact integration or by any quadrature formula which is exact for polynomials of degree up to order \( 2k - 1 \).

3.2 Space-time discretization with Galerkin–collocation method \( cGP-C^1(k) \)

From now on we suppose that \( k \geq 3 \) is a fixed integer without always mentioning this explicitly.

**Problem 3.3** (Local, numerically integrated, fully discrete problem of \( cGP-C^1(k)–cG(r) \) on \( I_n \)).
Given \( U_{\tau,h}(t_{n-1}^-) \) for \( n > 1 \) and \( U_{\tau,h}(t_0^-) = U_{0,h} \) for \( n = 1 \), find \( U_{\tau,h}|_{I_n} \in \left( (\mathbb{P}_k(I_n; V_h))^2 \right) \) such that

\[
U_{\tau,h}(t_{n-1}^+) = U_{\tau,h}(t_{n-1}^-), \quad (3.1a)
\]

\[
\partial_t U_{\tau,h}(t_{n-1}^+) = -A_h U_{\tau,h}(t_{n-1}^-) + \mathcal{P}_h F(t_{n-1}^-), \quad (3.1b)
\]

\[
\partial_t U_{\tau,h}(t_0^-) = -A_h U_{\tau,h}(t_0^-) + \mathcal{P}_h F(t_0^-), \quad (3.1c)
\]

and

\[
Q_n^{H} \left( \left\langle \partial_t U_{\tau,h}, V_{\tau,h} \right\rangle + \left\langle A_h U_{\tau,h}, V_{\tau,h} \right\rangle \right) = Q_n^{H} \left( \left\langle F, V_{\tau,h} \right\rangle \right) \quad (3.1d)
\]

for all \( V_{\tau,h} \in (\mathbb{P}_{k-3}(I_n; V_h))^2 \).

For this scheme we make the following observations.
Remark 3.4. It directly follows from the definition of the scheme that \( U_{\tau,h} \in (C^1(\mathcal{T}; V_h))^2 \) is satisfied. Instead of the condition (3.1b) at \( t^+_n \), we could also demand that

\[
\partial_t U_{\tau,h}(t^+_n) = \partial_t U_{\tau,h}(t^-_n),
\]

where we set \( \partial_t U_{\tau,h}(t^+_n) = -A_h U_{0,h} + \mathcal{P}_h F(0) \).

Since the time discretization is of Galerkin–Petrov type, we refer to it as a continuously differentiable Galerkin–Petrov approximation, for short cGP-C1(k).

Compared to Problem 5.3, the test space of the variational constraint (3.1d) reduces from \( (\mathbb{P}_{k-1}(I_n; V_h))^2 \) to \( (\mathbb{P}_{k-3}(I_n; V_h))^2 \). For \( k = 3 \) the test space just becomes the set \( (\mathbb{P}_0(I_n; V_h))^2 \) of piecewise constant functions in time. Introducing the collocation conditions (3.1b) and (3.1c) along with downsizing the test space of the variational condition impacts the block structure of the resulting linear algebraic system.

Proof. For arbitrarily chosen \( V_{\tau,h} \in (\mathbb{P}_{k-2}(I_n; V_h))^2 \), there exists some \( d_n = d_n(V_{\tau,h}) \in V_h^2 \) such that \( V_{\tau,h} \) admits the representation

\[ V_{\tau,h} = \tilde{V}_{\tau,h} + d_n(V_{\tau,h}) \psi_n \]

with

\[ \tilde{V}_{\tau,h} \in (\mathbb{P}_{k-3}(I_n; V_h))^2 \quad \text{and} \quad \psi_n(t) = \prod_{\mu=2}^{k-1} (t - t_{n,\mu}^{GL}) \in \mathbb{P}_{k-2}(I_n) \]

where \( t_{n,\mu}^{GL}, \mu = 2, \ldots, k-1 \), denote the inner Gauss–Lobatto quadrature points on \( \mathcal{T}_n \). From (3.1d) along with the exactness of the Hermite-type quadrature formula (2.11) for all polynomials in \( \mathbb{P}_{2k-3}(I_n) \) and of the Gauss–Lobatto quadrature formula (2.11) for all polynomials in \( \mathbb{P}_{2k-3}(I_n) \), it follows that

\[
Q_n^{GL}(\langle \partial_t U_{\tau,h}, \tilde{V}_{\tau,h} \rangle + \langle A_h U_{\tau,h}, \tilde{V}_{\tau,h} \rangle) = Q_n^{H}(\langle \partial_t U_{\tau,h}, \tilde{V}_{\tau,h} \rangle + \langle A_h U_{\tau,h}, \tilde{V}_{\tau,h} \rangle) = Q_n^{GL}(\langle F, \tilde{V}_{\tau,h} \rangle) = Q_n^{GL}(\langle I^H F, \tilde{V}_{\tau,h} \rangle)
\]

Therefore, it remains to prove that

\[
Q_n^{GL}(\langle \partial_t U_{\tau,h}, d_n \psi_n \rangle + \langle A_h U_{\tau,h}, d_n \psi_n \rangle) = Q_n^{GL}(\langle I^H F, d_n \psi_n \rangle)
\]

is satisfied. Since \( \psi_n \) vanishes in the interior Gauss–Lobatto quadrature nodes \( t_{n,\mu}^{GL}, \mu = 2, \ldots, k-1 \), and the quantities \( \langle \partial_t U_{\tau,h}, d_n \psi_n \rangle + \langle A_h U_{\tau,h}, d_n \psi_n \rangle \) and \( \langle I^H F, d_n \psi_n \rangle \) coincide in the endpoints \( t_{n-1}^+ \) and \( t_{n-1}^- \) by means of the conditions (3.1b) and (3.1c), the variational problem (3.3) is satisfied. Along with (3.4), this proves the assertion (3.3).
Furthermore, the solution of Problem 3.3 fulfills an evolution problem on \( I \).

**Lemma 3.6.** The solution \( U_{\tau,h} \) of Problem 3.3 satisfies

\[
\partial_t U_{\tau,h} + I^G_{\tau} A_h U_{\tau,h} = P_h I^GL_{\tau} I^H_{\tau} F
\]

on the whole time interval \( \bar{T} \).

**Proof.** Since all quantities in (3.3) are continuous on \( \bar{T} \), it suffices to prove the relation locally on each \( I_n \). To this end, let \( n \in \{1, \ldots, N\} \) be fixed.

From 3.10 along with \( I^G_{n,k} = t_n \) and the interpolation properties of \( I^G_{\tau} \) and \( I^H_{\tau} \), we get that

\[
\partial_t U_{\tau,h}(I^G_{n,k}) + I^G_{\tau} A_h U_{\tau,h}(I^G_{n,k}) - P_h I^GL_{\tau} I^H_{\tau} F(I^G_{n,k}) = 0.
\]

Using (3.3), it follows that

\[
Q_n^G(\langle \partial_t U_{\tau,h} + I^G_{\tau} A_h U_{\tau,h} - P_h I^GL_{\tau} I^H_{\tau} F, V_{\tau,h} \rangle) = Q_n^G(\langle \partial_t U_{\tau,h} + A_h U_{\tau,h} - I^H_{\tau} F, V_{\tau,h} \rangle) = 0
\]

for all \( V_{\tau,h} \in (P_{k-2}(I_n; V_h))^2 \). Choosing now test functions \( V_{\tau,h}^i \in (P_{k-2}(I_n; V_h))^2 \), \( i = 1, \ldots, k-1 \), such that \( V_{\tau,h}^i(I^G_{n,i}) = \delta_{i,j} \Phi_h, \mu = 1, \ldots, k-1 \), and \( \Phi_h \in V_h \times V_h \), the properties (3.8) and (3.7) result in

\[
\partial_t U_{\tau,h}(I^G_{n,i}) + I^G_{\tau} A_h U_{\tau,h}(I^G_{n,i}) - P_h I^GL_{\tau} I^H_{\tau} F(I^G_{n,i}) = 0, \quad \text{for } i = 1, \ldots, k-1.
\]

Thus, by means of (3.3) and (3.7), the polynomial \( \partial_t U_{\tau,h} + I^G_{\tau} A_h U_{\tau,h} - P_h I^GL_{\tau} I^H_{\tau} F \in (P_{k-1}(I_n; V_h))^2 \) vanishes in the \( k \) different nodes \( I^G_{n,i}, i = 1, \ldots, k \). Therefore, it vanishes for all \( t \in I_n \), which proves the local version of (3.3). The statement of this lemma follows from the global continuity.

**Remark 3.7.** The statements of Lemma 3.3 and Lemma 3.6 are quite similar to the statements of Lemma 4.4 and Lemma 3.11 given in [12], respectively. However, in contrast to the analysis of [12], the pointwise identity (3.6) is not needed for the proof of (3.3) since the collocation conditions 3.10 and 3.11 already provide the needed additional information.

### 4 Preparation for the error analysis

We will use in our error analysis some interpolants in time introduced in [12,21]. To keep this work self-contained, their definition and some auxiliaries are briefly summarized here. Remember that \( k \geq 3 \).

In the following, let \( B \) be a Banach space satisfying \( B \subset H \) and \( \ell \in \mathbb{N} \). We define for \( n = 1, \ldots, N \) the local \( L^2 \)-projections \( \Pi^G_n : L^2(I_n; B) \to P_{\ell}(I_n; B) \) by

\[
\int_{I_n} (\Pi^G_n w, q) \, dt = \int_{I_n} (w, q) \, dt \quad \forall q \in P_{\ell}(I_n; B).
\]

Next, a special interpolant in time is constructed. To this end, we define the Hermite interpolation operator \( I^{k+1}_{\tau} : C^1(\bar{T}; B) \to C^1(\bar{T}; B) \cap X^{k+1}_\tau(B) \) by

\[
I^{k+1}_{\tau} u(t_n) = u(t_n), \quad \partial_t I^{k+1}_{\tau} u(t_n) = \partial_t u(t_n), \quad n = 0, \ldots, N,
\]

and

\[
I^{k+1}_{\tau} u(I^G_{n,\mu}) = u(I^G_{n,\mu}), \quad n = 1, \ldots, N, \quad \mu = 2, \ldots, k-1.
\]

If \( u \) is smooth enough, then the standard Hermite interpolant \( I^{k+1}_{\tau} u \) provides the error estimates

\[
\| \partial_t u - \partial_t I^{k+1}_{\tau} u \|_{C^0(\bar{T}; B)} \lesssim \tau_{k+1} u \|_{C^{k+2}(\bar{T}; B)},
\]

\[
\| \partial^2_t u - \partial^2_t I^{k+1}_{\tau} u \|_{C^0(\bar{T}; B)} \lesssim \tau_{k} u \|_{C^{k+2}(\bar{T}; B)}.
\]
on each interval \( I_n \). For a function \( u \in C^1(\bar{T}; B) \), we construct a local interpolant \( R^k_n u \in \mathbb{P}_k(I_n; B) \) by

\[
R^k_n u(t^+_n) = I^k_{t_n} u(t^+_n) \tag{4.3}
\]

and

\[
\partial_t R^k_n u(t^+_{n,\mu}) = \partial_t I^k_{t_n} u(t^+_{n,\mu}), \quad \mu = 1, \ldots, k, \tag{4.4}
\]
on each time subinterval \( I_n \) and a global interpolant \( R^k u \in Y^k(B) \) by

\[
(R^k u)|_{I_n} := R^k_n(u|_{I_n}), \quad n = 1, \ldots, N.
\]

Finally, we put \( R^k u(0) := u(0) \).

In the following we summarize some basic properties of the operator \( R^k_n \); cf. [12, 21] for their proofs.

**Lemma 4.1.** Let \( u \in C^1(\bar{T}; B) \) where \( B \subset H \). Then, the function \( R^k_n u \) is continuously differentiable in time on \( \bar{T} \) with \( R^k_n u(t_n) = u(t_n) \) and \( \partial_t R^k_n u(t_n) = \partial_t u(t_n) \) for all \( n = 0, \ldots, N \).

**Lemma 4.2.** For all \( n = 1, \ldots, N \) and all \( u \in C^{k+1}(\bar{T}_n; B) \), there holds that

\[
\|u - R^k_n u\|_{C^0(\bar{T}_n; B)} \lesssim \tau_n^{k+1}\|u\|_{C^{k+1}(\bar{T}_n; B)}. \tag{4.5}
\]

Moreover, the estimate \( \|R^k_n u\|_{C^0(\bar{T}_n; B)} \lesssim \|u\|_{C^0(\bar{T}_n; B)} + \tau_n\|u\|_{C^1(\bar{T}_n; B)} \) is satisfied for all \( u \in C^1(\bar{T}_n; B) \).

**Lemma 4.2** implies the following result.

**Corollary 4.3.** For all \( n = 1, \ldots, N \) and all \( u \in C^{k+1}(\bar{T}_n; B) \), there holds that

\[
\|\partial_t u - \partial_t R^k_n u\|_{C^0(\bar{T}_n; B)} \lesssim \tau_n^k\|u\|_{C^{k+1}(\bar{T}_n; B)}. \tag{4.6}
\]

Moreover, the estimate \( \|\partial_t R^k_n u\|_{C^0(\bar{T}_n; B)} \lesssim \|u\|_{C^1(\bar{T}_n; B)} \) is satisfied for all \( u \in C^1(\bar{T}_n; B) \).

For the operator \( \Pi_T^H \) defined in (4.12) we recall the following approximation properties. They directly follow from the standard error estimates for Hermite interpolation.

**Lemma 4.4.** The operator \( \Pi_T^H : C^1(\bar{T}; H) \to X_B^k(H) \) provides

\[
\|u - \Pi_T^H u\|_{C^0(\bar{T}_n; B)} \lesssim \tau_n^{k+1}\|u\|_{C^{k+1}(\bar{T}_n; B)},
\]

\[
\|\partial_t u - \partial_t \Pi_T^H u\|_{C^0(\bar{T}_n; B)} \lesssim \tau_n^k\|u\|_{C^{k+1}(\bar{T}_n; B)},
\]

for all \( n = 1, \ldots, N \) and all \( u \in C^{k+1}(\bar{T}_n; B) \).

Finally, we present a norm bound that will be used later in our analysis.

**Lemma 4.5.** For any \( u \in \mathbb{P}_k(I_n; H) \) the norm inequality

\[
\int_{I_n} \|u\|^2 \, dt \lesssim \tau_n\|u(t_n-1)\|^2 + \tau_n^2 \int_{I_n} \|\partial_t u\|^2 \, dt
\]

holds.
5 Error estimates

The overall goal of this work is to prove error estimates for the error
\[ E(t) := U(t) - U_{\tau,h}(t), \tag{5.1} \]
where the Galerkin–collocation approximation \( U_{\tau,h} \) is the solution of Problem \( \text{SL} \). We will use in the sequel the componentwise representation \( E(t) = (e^0(t), e^1(t)) \). We observe that \( E \) is continuously differentiable in time on \( \mathcal{T} \) if we assume for our analysis that for the exact solution \( U = (u^0, u^1) \in (C^1(\mathcal{T}; V))^2 \) is satisfied.

For each time interval \( I_n, n = 1, \ldots, N \), we define the bilinear form
\[ B_n^{\text{GL}}(W, V) := Q_n^{\text{GL}}(\langle \partial_t W, V \rangle) + Q_n^{\text{GL}}(\langle A_h W, V \rangle) \]
where \( W \) and \( V \) have to satisfy some smoothness conditions to ensure that \( B_n^{\text{GL}} \) is well-defined.

Our analysis will follow the main lines given in [12] since the solution \( U_{\tau,h} \) in this paper is related to \( L_r U_{\tau,h} \) there with the difference that our polynomial order \( k \) is related to \( k + 1 \) in [12]. This relation is motivated by the fact that the solution of the numerically integrated cGP-C\(^1\)-cG(r), given in Problem 3.3 could also be interpreted as the post-processed solution of a numerically integrated cGP(k-1)-cG(r) scheme, given in Problem 5.2 with a modified right-hand side in that \( F \) is replaced by \( I_\tau^h F \). In order to keep this work self-contained, we will cite the results used from [12] and will focus on the new aspects in the error analysis.

5.1 Error estimates for \( \partial_t U_{\tau,h} \)

We start with proving an \( L^\infty(L^2) \)-norm estimate for the time derivative \( \partial_t E(t) \) of the error as an auxiliary result. This represents an essential argument in our proof and is specific to the hyperbolic character of (2.1). Based on the \( L^\infty(L^2) \)-bound for \( \partial_t E(t) \) an estimate for \( E(t) \) will be proved in Subsec. 5.2.

In order to bound \( \partial_t E(t) \), we derive a variational problem that is satisfied by \( \partial_t U_{\tau,h} \).

**Theorem 5.1.** Let \( U_{\tau,h} \in (X_{\tau,h}^k(V_h))^2 \) be the solution of Problem 3.3. Then, its time derivative \( \partial_t U_{\tau,h} \in (X_{\tau,h}^{k-1}(V_h))^2 \) satisfies for all \( n = 1, \ldots, N \) the equation
\[ B_n^{\text{GL}}(\partial_t U_{\tau,h}, V_{\tau,h}) = Q_n^{\text{GL}}(\langle \partial_t I_\tau^h F, V_{\tau,h} \rangle) = \int_{I_n} \langle \partial_t I_\tau^h F, V_{\tau,h} \rangle \, dt \tag{5.2} \]
for all \( V_{\tau,h} \in (P_{k-2}(I_n; V_h))^2 \).

**Proof.** Recalling that \( \partial_t U_{\tau,h} \in (P_{k-1}(I_n; V_h))^2 \), we get by the exactness of the Gauss–Lobatto formula (2.14) for all polynomials in \( P_{2k-3}(I_n; \mathbb{R}) \) along with integration by parts that
\[ B_n^{\text{GL}}(\partial_t U_{\tau,h}, V_{\tau,h}) = Q_n^{\text{GL}}(\langle \partial_t^2 U_{\tau,h} + A_h \partial_t U_{\tau,h}, V_{\tau,h} \rangle) = \int_{I_n} \langle \partial_t \partial_t U_{\tau,h} + A_h \partial_t U_{\tau,h}, V_{\tau,h} \rangle \, dt \tag{5.3} \]
\[ = - \int_{I_n} \langle \partial_t U_{\tau,h} + A_h U_{\tau,h}, \partial_t V_{\tau,h} \rangle \, dt + \int_{I_n} \langle \partial_t U_{\tau,h} + A_h U_{\tau,h}, V_{\tau,h} \rangle \, dt \bigg|_{t_n}^{t_{n-1}} \]
for \( V_{\tau,h} \in (P_{k-2}(I_n, V_h))^2 \). Using the exactness of the Hermite quadrature formula \( Q_n^{\text{H}} \) for polynomials
in $\mathbb{P}_{2k-3}(I_n; \mathbb{R})$ and (3.1c), we conclude from (5.3) that
\[ B_n^{GL}(\partial_t U_{\tau,h}, V_{\tau,h}) = -Q_n^H(\langle F, \partial_t V_{\tau,h} \rangle) + \langle \partial_t U_{\tau,h} + A_h U_{\tau,h}, V_{\tau,h} \rangle \bigg|_{t_n^{-}}^{t_n^{+}} \]
\[ = - \int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F, \partial V_{\tau,h} \rangle \, dt + \langle \partial_t U_{\tau,h} + A_h U_{\tau,h}, V_{\tau,h} \rangle \bigg|_{t_n^{-}}^{t_n^{+}} \]
\[ = \int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F, V_{\tau,h} \rangle \, dt - \langle \partial_t I_{\tau}^H F, V_{\tau,h} \rangle \bigg|_{t_n^{-}}^{t_n^{+}} + \langle \partial_t U_{\tau,h} + A_h U_{\tau,h}, V_{\tau,h} \rangle \bigg|_{t_n^{-}}^{t_n^{+}}. \] (5.4)

From (3.1b) and (3.1c) along with the interpolation properties of $I_{\tau}^H$, it follows that
\[ \partial_t U_{\tau,h}(t_*) + A_h U_{\tau,h}(t_*) = P_h I_{\tau}^H F(t_*) \] (5.5)
for $t_* \in \{ t_{n^{-}}, t_{n^{+}} \}$. Combining (5.4) with (5.5) shows that
\[ B_n^{GL}(\partial_t U_{\tau,h}, V_{\tau,h}) = \int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F, V_{\tau,h} \rangle \, dt \]
for all $V_{\tau,h} \in (P_{k-2}(I_n; V_h))^2$. Recalling that $\partial_t I_{\tau}^H F|_{t_n} \in (P_{k-1}(I_n; V_h))^2$ and the exactness of the Gauss–Lobatto quadrature for functions of $\mathbb{P}_{2k-3}(I_n; \mathbb{R})$, this proves the assertion of the theorem. 

**Remark 5.2.** If the solution $u$ of (1.1) is sufficiently regular, the time derivative $\partial_t U = (\partial_t u, \partial^2_t u)$ solves the evolution problem
\[ \partial_t (\partial_t U) + A(\partial_t U) = \partial_t F \text{ in } (0, T), \quad \partial_t U(0) = -A U(0) + F(0). \] (5.6)
Assumptions on the data such that (5.6) is satisfied can be found in, e.g., [22, p. 410, Thm. 5].

Rewriting (5.2) as
\[ B_n^{GL}(\partial_t U_{\tau,h}, V_{\tau,h}) = \int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F, V_{\tau,h} \rangle \, dt + \int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F - \partial_t F, V_{\tau,h} \rangle \, dt, \] (5.7)
its discrete solution can now be regarded as the cGP($k - 1$)–cG($r$) approximation of the evolution problem (5.6) up to the perturbation term $\int_{t_n^{-}}^{t_n^{+}} \langle \partial_t I_{\tau}^H F - \partial_t F, V_{\tau,h} \rangle \, dt$ on the right-hand side. Further, the collocation condition (3.1b) for $n = 1$ along with the initial condition that $U_{\tau,h}(0) = U_{0,h}$ shows that $\partial_t U_{\tau,h}(0) = -A_h U_{0,h} + P_h F(0)$ is satisfied.

We point out that there is a strong analogy between Remark 5.2 and [12, Remark 5.3]. The main difference of the two statements comes through the different perturbation terms. However, having in mind the relation of the polynomial orders, both perturbation terms are of the same approximation order. Hence, we can directly follow the further arguments used in [12]. Especially, some assumptions about the discrete initial value $\partial_t U_{\tau,h}(0)$ with respect to the continuous initial value $\partial_t U(0)$ have to be fulfilled.

**Lemma 5.3.** Let $U_{0,h} := (R_h u_0, R_h u_1)$. Then there holds that
\[ \partial_t U_{\tau,h}(0) = \begin{pmatrix} R_h & 0 \\ 0 & P_h \end{pmatrix} \partial_t U(0). \]

We refer to [12, Lemma 5.4] for the proof of Lemma 5.3 taking into consideration that $U_{\tau,h}$ here is associated to $L_{\tau} U_{\tau,h}$ in [12]. Also note that the analog of [12, Assumption 3.6] is obviously satisfied by $U_{\tau,h}$ due to (3.1a) and (3.1b) for $n = 1$.

Finally, before proving the error estimate for $\partial_t U_{\tau,h}$, we want to cite Theorem 5.5 of [12] that is a slightly generalized result of the analysis in [30] for the cGP($k$)–cG($r$) approximation of the wave equation.
Theorem 5.4. Let \( \hat{u} \) denote the solution of \( \left(1.1\right) \) with data \( \hat{f}, \hat{u}_0, \hat{u}_1 \) instead of \( f, u_0, u_1 \). Suppose \( \ell \in \mathbb{N} \) and let \( \hat{f}_\tau \) be an approximation of \( \hat{f} \) such that
\[
\| \hat{f} - \hat{f}_\tau \|_{C(T, H^1)} \leq C_f \tau_n^{\ell+1}, \quad n = 1, \ldots, N,
\] (5.8)
where the constant \( C_f \) depends on \( \hat{f} \) but is independent of \( n, N \), and \( \tau_n \). Furthermore, let \( \tilde{U}_{\tau,h} = (\hat{u}_{\tau,h}^0, \hat{u}_{\tau,h}^1) \in (X_{\ell}^1(V_h))^2 \) be the solution of the local (on \( I_n \)) perturbed cGP(\( \ell \))-cG(\( r \)) problem
\[
\int_{I_n} \left( \langle \partial_t \hat{U}_{\tau,h}, V_{\tau,h} \rangle + \langle A_h \hat{U}_{\tau,h}, V_{\tau,h} \rangle \right) dt = \int_{I_n} \langle \tilde{F}_\tau, V_{\tau,h} \rangle dt
\] (5.9)
for all test functions \( V_{\tau,h} = (v_{\tau,h}^0, v_{\tau,h}^1) \in (\mathbb{P}_{\ell-1}(I_n; V_h))^2 \) with \( \tilde{F}_\tau := (0, f_\tau) \) and the initial value \( \hat{U}_{\tau,h}(t_{n-1}^1) = \tilde{U}_{\tau,h}(t_{n-1}^1) \) for \( n > 1 \) and \( \hat{U}_{\tau,h}(t_0) = \tilde{U}_{\tau,h}(t_0) := (R_{\hat{h}} \hat{u}_0, P_{\hat{h}} \hat{u}_1) \). For a sufficiently smooth exact solution \( \hat{u} \), the estimates
\[
\| \hat{u}(t) - \hat{u}_{\tau,h}(t) \| + \| \partial_t \hat{u}(t) - \partial_t \hat{u}_{\tau,h}(t) \| \lesssim \tau_n^{\ell+1} C_I(\hat{u}) + h^{\ell+1} C_x(\hat{u}),
\]
(5.10)
\[
\| \nabla (\hat{u}(t) - \hat{u}_{\tau,h}(t)) \| \lesssim \tau_n^{\ell+1} C_I(\hat{u}) + h^{\ell} C_x(\hat{u}),
\]
(5.11)
hold for all \( t \in \bar{T} \) where \( C_I(\hat{u}) \) and \( C_x(\hat{u}) \) are quantities depending on various temporal and spatial derivatives of \( \hat{u} \).

We conclude from Theorem 5.4 the following error estimates.

Theorem 5.5. Let \( U_{0,h} := (R_{\hat{h}} u_0, R_{\hat{h}} u_1) \) and assume that the exact solution \( U = (u^0, u^1) := (u, \partial_t u) \) is sufficiently smooth. Then the error estimates
\[
\| \partial_t U(t) - \partial_t U_{\tau,h}(t) \| \lesssim \tau_k C_I(\partial_t u) + h^{\ell+1} C_x(\partial_t u) \lesssim \tau_k + h^{\ell+1},
\]
(5.12)
\[
\| \nabla (\partial_t u^0(t) - \partial_t u_{\tau,h}^0(t)) \| \lesssim \tau_k C_I(\partial_t u) + h^{\ell} C_x(\partial_t u) \lesssim \tau_k + h^{\ell},
\]
(5.13)
hold for all \( t \in \bar{T} \) where \( C_I(\partial_t u) \) and \( C_x(\partial_t u) \) are quantities depending on various temporal and spatial derivatives of \( \partial_t u \).

Proof. To prove (5.12) and (5.13), we apply Theorem 5.4. Since the solution \( u \) is sufficiently smooth, the function \( \hat{u} := \partial_t u \) is the solution of the wave equation \( \left(1.1\right) \) with the right-hand side \( f := \partial_t f \) and the initial conditions \( \hat{u}(0) = \hat{u}_0 := u_1 \) and \( \partial_t \hat{u}(0) = \hat{u}_1 := f(0) - A u_0 \). Let us define the modified right-hand side \( f_\tau := \partial_t \hat{f} \) and \( \tilde{F}_\tau := (0, f_\tau) \). Then, the discrete function \( \tilde{U}_{\tau,h} := \partial_t U_{\tau,h} \in (X_{\ell}^1(V_h))^2 \) satisfies all the conditions required for the discrete solution \( \tilde{U}_{\tau,h} \) in Theorem 5.4 with \( \ell = k - 1 \). In fact, by the construction of the discrete solution \( U_{\tau,h} \) in Problem 5.3, the continuity of \( \partial_t U_{\tau,h} \) in the discrete points \( t_n, n = 0, \ldots, N \), is ensured by the conditions (5.1.10) (5.1.13). Therefore, it holds that \( \tilde{U}_{\tau,h} \in (\mathbb{P}_{k-1}(I_n; V_h))^2 \) and \( \tilde{U}_{\tau,h}(t_{n-1}^1) = \tilde{U}_{\tau,h}(t_{n-1}^1) \). Moreover, from \( U_{0,h} := (R_{\hat{h}} u_0, R_{\hat{h}} u_1) \) and Lemma 5.3 we get that \( \tilde{U}_{0,h} = \tilde{U}_{\tau,h}(0) = \partial_t U_{\tau,h}(0) = (R_{\hat{h}} \hat{u}_0, P_{\hat{h}} \hat{u}_1) \). Theorem 5.4 implies for all \( n = 1, \ldots, N \) and all \( V_{\tau,h} \in (\mathbb{P}_{k-2}(I_n; V_h))^2 \) that
\[
B_n^{GL}(\tilde{U}_{\tau,h}, V_{\tau,h}) = Q_n^{GL}(\langle \partial_t \tilde{U}_{\tau,h}, V_{\tau,h} \rangle + \langle A_h \tilde{U}_{\tau,h}, V_{\tau,h} \rangle) = Q_n^{GL}(\langle \tilde{F}_\tau, V_{\tau,h} \rangle).
\]
Each quadrature formula in the previous equation is exact since all integrands are polynomials in \( t \) with degree not greater than \( 2k-3 \) such that the variational equation (5.9) of Theorem 5.4 is satisfied. Thus, we have shown that \( \tilde{U}_{\tau,h} \) is the discrete solution of Theorem 5.4 for the above defined data. To verify the approximation property for \( \tilde{F}_\tau \), we use the definition of \( \tilde{f} \) and \( \tilde{f}_\tau \), apply the estimate (4.16), and obtain (5.8) with a constant \( C_f = C \| \tilde{f}_\tau \|_{C(T, H)} \). Then, we use Theorem 5.4 with \( \ell = k - 1 \). Recalling the representation by components, \( \partial_t U = (\partial_t u^0, \partial_t u^1) = (\hat{u}, \partial_t \hat{u}) \) and \( \hat{U}_{\tau,h} = (\hat{u}_{\tau,h}^0, \hat{u}_{\tau,h}^1) = (\partial_t u_{\tau,h}^0, \partial_t u_{\tau,h}^1) \), we directly get assertion (5.12) from (5.10) and assertion (5.13) from (5.11). \( \square \)
5.2 Error estimates for $U_{\tau,h}$

This section is devoted to the desired norm estimates for the error $E(t) := U(t) - U_{\tau,h}(t)$ where $U_{\tau,h}$ is the solution of Problem 3.3. For our error analysis we consider the decomposition

$$E(t) = \Theta(t) + E_{\tau,h}(t) \quad \text{with} \quad \Theta(t) := U(t) - \mathcal{R}_h R^I U(t) \quad \text{and} \quad E_{\tau,h} := \mathcal{R}_h R^I U(t) - U_{\tau,h} \quad (5.14)$$

for all $t \in \mathcal{T}$ and define the components $E_{\tau,h}(t) = (e_{\tau,h}^r(t), e_{\tau,h}^k(t))$. We observe that both $\Theta$ and $E_{\tau,h}$ are continuously differentiable in time on $\mathcal{T}$ if the exact solution $U$ is sufficiently smooth. We refer to $\Theta$ as interpolation error. We note that both $\Theta$ and $E_{\tau,h}$ are smooth enough to be used as arguments in the bilinear form $B^\text{GL}_n$.

The following estimates of $\Theta$ in (5.14) can be found in [12, Lemma 5.7]. They rely on the properties of $\mathcal{R}_h$ and $R^I_M$.

**Lemma 5.6** (Estimation of the interpolation error). Let $m \in \{0, 1\}$. Then, the error estimates

$$\|\Theta(t)\|_m \lesssim h^{r+1-m} + \tau_n^{k+1}, \quad t \in \mathcal{T}_n, \quad (5.15)$$

$$\|\partial_t \Theta(t)\|_m \lesssim h^{r+1-m} + \tau_n^k, \quad t \in \mathcal{T}_n, \quad (5.16)$$

hold for all $n = 1, \ldots, N$ where $\| \cdot \|_0 := \| \cdot \|$.

Next, we address the discrete error $E_{\tau,h}$ of the decomposition (5.14) between the interpolation $\mathcal{R}_h R^I U$ and the fully discrete solution $U_{\tau,h}$. We start with some auxiliary results.

**Lemma 5.7** (Consistency error). Assume that $U \in C^1(\mathcal{T}; V) \times C^1(\mathcal{T}; H)$. Then, for all $n = 1, \ldots, N$ the identity

$$B_n^{\text{GL}}(E, V_{\tau,h}) = Q_n^{\text{GL}}(\langle I^F_{\tau} F - I^H_{\tau} F, V_{\tau,h} \rangle) = Q_n^{\text{GL}}(\langle F - I^H_{\tau} F, V_{\tau,h} \rangle)$$

is satisfied for all $V_{\tau,h} \in (Y_{\tau,h}^{k-2}(V_h))^2$.

**Proof.** We recall from Lemma 5.5 that for all $n = 1, \ldots, N$ the identity

$$B_n^{\text{GL}}(U_{\tau,h}, V_{\tau,h}) = Q_n^{\text{GL}}(\langle I^H_{\tau} F, V_{\tau,h} \rangle) \quad (5.17)$$

holds for all $V_{\tau,h} \in (P_{k-2}(I_n; V_h))^2$. We have under sufficient smoothness assumptions on the exact solution that

$$\partial_t U(t_{n,\mu}^\text{GL}) + A U(t_{n,\mu}^\text{GL}) = F(t_{n,\mu}^\text{GL}), \quad \mu = 1, \ldots, k. \quad (5.18)$$

By the consistency (2.8) of $A_h$, the identity (5.18) implies

$$B_n^{\text{GL}}(U, V_{\tau,h}) = Q_n^{\text{GL}}(\langle \partial_t U + A_h U, V_{\tau,h} \rangle) = Q_n^{\text{GL}}(\langle I^H_{\tau} F, V_{\tau,h} \rangle) \quad (5.19)$$

Combining (5.17) with (5.19) and recalling that $E = U - U_{\tau,h}$ prove the assertion. \qed

The following lemma is slightly more general than [12, Lem. 5.9] where the proof can be found.

**Lemma 5.8.** Let $p \in P_h(I_n)$ be an arbitrary polynomial of degree less than or equal to $k$. Then, the relation

$$\partial_t p(t_{n,\mu}^\text{GL}) = \partial_t I^\text{GL}_{\tau} p(t_{n,\mu}^\text{GL})$$

holds for all Gauss points $t_{n,\mu}^\text{GL} \in I_n, \mu = 1, \ldots, k-1$.

Exploiting the correspondence of $U_{\tau,h}$ in this paper to $L_u U_{\tau,h}$ in [12] and keeping in mind that $k$ here is related to $k+1$ there, we can recall from [12] the results of stability (cf. [12, Lemma 5.10]) and boundedness (cf. [12, Lemma 5.11]).

14
Lemma 5.9 (Stability). We have
\[
B_n^{GL} ((e_{\tau,h}^0, e_{\tau,h}^1), (\Pi_n^{k-2} A_h I_{\tau}^{GL} e_{\tau,h}^0, \Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1)) = \frac{1}{2} \left( \|\nabla e_{\tau,h}^0(t_n)\|^2 - \|\nabla e_{\tau,h}^0(t_{n-1})\|^2 + \|e_{\tau,h}^1(t_n)\|^2 - \|e_{\tau,h}^1(t_{n-1})\|^2 \right) \tag{5.20}
\]
for all \( n = 1, \ldots, N \).

Lemma 5.10 (Boundedness). Let \( V_{\tau,h} = (\Pi_n^{k-2} A_h I_{\tau}^{GL} e_{\tau,h}^0, \Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1) \). Then, the bound
\[
|B_n^{GL} (\Theta, V_{\tau,h})| \lesssim \tau_n^{1/2} (\tau^{k+1} + h^{r+1}) \left\{ \tau_n \|E_{\tau,h}(t_{n-1})\|^2 + \tau_n^2 Q_n^G (\|\partial_t E_{\tau,h}\|^2) \right\}^{1/2}
\]
holds for all \( n = 1, \ldots, N \).

We proceed with estimating the consistency error given in Lemma 5.7.

Lemma 5.11 (Estimates on right-hand side term). Let \( V_{\tau,h} = (v_{\tau,h}^0, v_{\tau,h}^1) = (\Pi_n^{k-2} A_h I_{\tau}^{GL} e_{\tau,h}^0, \Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1) \). Then, the estimate
\[
Q_n^{GL} (\langle (0, f - I_{\tau}^H f), (v_{\tau,h}^0, v_{\tau,h}^1) \rangle) \lesssim \tau_n^{1/2} \tau_n^{k+1} \left\{ \tau_n \|E_{\tau,h}(t_{n-1})\|^2 + \tau_n^2 Q_n^G (\|\partial_t E_{\tau,h}\|^2) \right\}^{1/2}
\]
holds for all \( n = 1, \ldots, N \).

Proof. Using the Cauchy–Schwarz inequality along with Lemma 5.10, we get that
\[
Q_n^{GL} (\langle (0, f - I_{\tau}^H f), (v_{\tau,h}^0, v_{\tau,h}^1) \rangle) = Q_n^{GL} (\langle f - I_{\tau}^H f, \Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1 \rangle)
\leq (Q_n^{GL} (\|f - I_{\tau}^H f\|^2))^{1/2} (Q_n^{GL} (\|\Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1\|^2))^{1/2}
\lesssim \tau_n^{1/2} \tau_n^{k+1} (Q_n^{GL} (\|\Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1\|^2))^{1/2}.
\]
Using the exactness of \( Q_n^{GL} \) for polynomials up to degree \( 2k-3 \), the stability of the \( L^2 \)-projection \( \Pi_n^{k-2} \), the norm bound from Lemma 5.7 and Lemma 5.8 we finally conclude that
\[
Q_n^{GL} (\|\Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1\|^2) = \int_{I_n} \|\Pi_n^{k-2} I_{\tau}^{GL} e_{\tau,h}^1\|^2 \, dt \leq \int_{I_n} \|I_{\tau}^{GL} e_{\tau,h}^1\|^2 \, dt
\lesssim \tau_n \|I_{\tau}^{GL} e_{\tau,h}(t_{n-1})\|^2 + \tau_n^2 \int_{I_n} \|\partial_t I_{\tau}^{GL} e_{\tau,h}\|^2 \, dt
= \tau_n \|e_{\tau,h}(t_{n-1})\|^2 + \tau_n^2 Q_n^G (\|\partial_t I_{\tau}^{GL} e_{\tau,h}\|^2)
= \tau_n \|e_{\tau,h}(t_{n-1})\|^2 + \tau_n^2 Q_n^G (\|\partial_t e_{\tau,h}\|^2).
\]
Combining both estimates, the assertion of the lemma follows directly.

Lemma 5.12 (Estimates on \( E_{\tau,h} \)). Let \( U_{0,h} := (R_h u_0, R_h u_1) \). Then, the estimate
\[
\|e_{\tau,h}^0(t_n)\|^2 + \|e_{\tau,h}^1(t_n)\|^2 \lesssim (\tau^{k+1} + h^{r+1})^2 \tag{5.21}
\]
is satisfied for all \( n = 1, \ldots, N \). Moreover, we have that
\[
\|\nabla e_{\tau,h}^0(t)\| \lesssim \tau^{k+1} + h^{r}, \tag{5.22}
\|e_{\tau,h}^0(t)\| + \|e_{\tau,h}^1(t)\| \lesssim \tau^{k+1} + h^{r+1} \tag{5.23}
\]
for all \( t \in \overline{T} \).
Proof. We conclude from Lemma [5.7] that
\[
B_n^{GL}(E_{\tau,h}, V_{\tau,h}) = -B_n^{GL}(\Theta, V_{\tau,h}) + Q_n^{GL}(\langle F - I^H F, V_{\tau,h} \rangle)
\]
is satisfied for all \(V_{\tau,h} \in \mathbb{V}_{\tau,h}^{k-2}(V_h)\). Choosing here \(V_{\tau,h} = (\Pi_n^{k-2} A_h I^GL e_{\tau,h}^0, \Pi_n^{k-2} I^GL e_{\tau,h}^1)\) and using Lemma [5.10] and Lemma [5.11] yield that
\[
B_n^{GL}\left((e_{\tau,h}^0, e_{\tau,h}^1), (\Pi_n^{k-2} A_h I^GL e_{\tau,h}^0, \Pi_n^{k-2} I^GL e_{\tau,h}^1)\right)
= -B_n^{GL}\left((\Theta^0, \Theta^1), (\Pi_n^{k-2} A_h I^GL e_{\tau,h}^0, \Pi_n^{k-2} I^GL e_{\tau,h}^1)\right)
+ Q_n^{GL}\left((0, f - I^H f), (\Pi_n^{k-2} A_h I^GL e_{\tau,h}^0, \Pi_n^{k-2} I^GL e_{\tau,h}^1)\right)
\leq \tau_n^{1/2}(\tau_n^{k+1} + h^{r+1}) \left\{ \tau_n \|E_{\tau,h}(t_n-1)\|^2 + \tau_n^2 Q_n^G(\|\partial_t E_{\tau,h}\|)^2 \right\}^{1/2}.
\] (5.24)

Since the upper bound in (5.24) coincides with that in Eq. (5.46) of [12] and our \(E_{\tau,h}\) can be identified with \(\tilde{E}_{\tau,h}\) of [12], we present here just a short summary of the proof of Lemma 5.12 in [12].

Combining the stability property (5.20) of \(B_n^{GL}\) with (5.24), applying the Cauchy–Schwarz inequality, and telescoping summing lead to
\[
\|\nabla e_{\tau,h}^1(t_n)\|^2 + \|e_{\tau,h}^1(t_n)\|^2 \lesssim \|\nabla e_{\tau,h}^1(t_0)\|^2 + \|e_{\tau,h}^1(t_0)\|^2 + \sum_{s=1}^n \tau_s (\tau_s^{k+1} + h^{r+1})^2
+ \sum_{s=1}^n \tau_s^2 Q_s^G(\|\partial_t E_{\tau,h}\|)^2 + \sum_{s=1}^n \tau_s \|E_{\tau,h}(t_{s-1})\|^2.
\] (5.25)

Using
\[
\|\partial_t E_{\tau,h}(t)\| \leq \|\partial_t U(t) - \partial_t U_{\tau,h}(t)\| + \| - \partial_t \Theta(t)\| \lesssim \tau^k + h^{r+1}, \quad t \in \mathcal{T},
\] (5.26)

together with the estimates (5.12) and (5.16), we obtain that
\[
\|\nabla e_{\tau,h}^1(t_n)\|^2 + \|e_{\tau,h}^1(t_n)\|^2 \lesssim \|\nabla e_{\tau,h}^1(t_0)\|^2 + \|e_{\tau,h}^1(t_0)\|^2 + \left(\tau^{k+1} + h^{r+1}\right)^2
+ \sum_{s=0}^{n-1} \tau_s (\|\nabla e_{\tau,h}^1(t_s)\|^2 + \|e_{\tau,h}^1(t_s)\|^2),
\] (5.27)

where we also used the definition of the Gauss quadrature and the Poincaré inequality. Applying the discrete Gronwall lemma (cf. [39, p. 14]) results in
\[
\|\nabla e_{\tau,h}^1(t_n)\|^2 + \|e_{\tau,h}^1(t_n)\|^2 \lesssim \|\nabla e_{\tau,h}^1(t_0)\|^2 + \|e_{\tau,h}^1(t_0)\|^2 + \left(\tau^{k+1} + h^{r+1}\right)^2
\]

Exploiting \(e_{\tau,h}^1(t_0) = 0, i \in \{0, 1\}\), which holds due to the choice \(U_{\tau,h} = (R b_0, u_{\tau,h})\) of the discrete initial value, this estimate along with the Poincaré inequality proves the assertion (5.21).

To show (5.22) and (5.23), we start for the error component \(e_{\tau,h}^i \in \mathbb{P}_h(I_n, V_h), i \in \{0, 1\}\), with
\[
\|e_{\tau,h}^i(t)\| \leq \|e_{\tau,h}^i(t_n)\| + \tau_n \max_{s \in T_n} \|\partial_t e_{\tau,h}^i(s)\|, \quad t \in I_n,
\] (5.28)

that is deduced from the fundamental theorem of calculus. Applying (5.21) and (5.26), we get from (5.28) with \(m = 0\) that
\[
\|e_{\tau,h}^i(t)\| \lesssim (\tau^{k+1} + h^{r+1}) + \tau_n (\tau^k + h^{r+1}) \lesssim \tau^{k+1} + h^{r+1}, \quad t \in \mathcal{T}, i \in \{0, 1\},
\] which proves (5.23).

Similarly to (5.26), we get for the \(H^1\)-norm that
\[
\|\partial_t e_{\tau,h}^0(t)\| \leq \|\partial_t u_0(t) - \partial_t u_{\tau,h}^0(t)\|_1 + \| - \partial_t \theta^0(t)\|_1 \lesssim \tau^k + h^r, \quad t \in \mathcal{T},
\] (5.29)
where we used (5.13) along with the Poincaré inequality and (5.16). Applying (5.21) and (5.29), we get from (5.28) with \( m = 1 \) that
\[
\| e_\tau,h(t) \|_1 \lesssim (r^{k+1} + h^{r+1}) + \tau_n(r^{k+1} + h^r) \lesssim \tau^{k+1} + h^r, \quad t \in T,
\]
which proves (5.22).

We are now able to derive our final error estimates for the proposed Galerkin–collocation approximation of the solution to (1.1).

**Theorem 5.13** (Error estimate for \( U_{\tau,h} \)). Let \( U = (u, \partial_t u) \) be the solution of the problem (1.1) and \( U_{\tau,h} \) be the fully discrete solution of Problem 3.3 with initial value \( U_{0,h} = (R_h u_0, R_h u_1) \). Then, the error \( E(t) = (e^0(t), e^1(t)) = U(t) - U_{\tau,h}(t) \) can be bounded for all \( t \in T \) by
\[
\| e^0(t) \| + \| e^1(t) \| \lesssim \tau^{k+1} + h^{r+1}, \quad (5.30)
\]
\[
\| \nabla e^0(t) \| \lesssim \tau^{k+1} + h^r. \quad (5.31)
\]
Moreover, the estimates
\[
\| e^0 \|_{L^2(I;H)} + \| e^1 \|_{L^2(I;H)} \lesssim \tau^{k+1} + h^{r+1}, \quad (5.32)
\]
\[
\| \nabla e^0 \|_{L^2(I;H)} \lesssim \tau^{k+1} + h^r \quad (5.33)
\]
hold true.

**Proof.** Recalling the error decomposition
\[
E(t) = U(t) - U_{\tau,h}(t) = \Theta(t) + E_{\tau,h}(t), \quad (5.34)
\]
we conclude assertion (5.30) by applying the triangle inequality along with estimate (5.15) with \( m = 0 \) and (5.22) to the terms on the right-hand-side of (5.34). Similarly we conclude (5.31) using the estimate (5.15) with \( m = 1 \) and (5.22). The assertions (5.32) and (5.33) follow from the definition of the \( L^2(I;H) \)-norm together with the estimates (5.30) and (5.31).

**Remark 5.14.** We note that the estimates (5.30) to (5.33) are of optimal order in space and time.

Similarly to the estimate of \( \partial_t E_{\tau,h} \) in Subsec. 5.1, the estimation of \( E_{\tau,h} \) in Lemma 5.12 follows the analysis of [12]. The main difference comes through the consistency error of Lemma 5.7. However, this does not cause any difficulties since the consistency error is of the same order as the further terms that get involved in the error analysis through Lemma 5.10 of boundedness.

## 6 Energy conservation principle for \( f \equiv 0 \)

In this section we address the issue of energy conservation for the considered space-time finite element scheme. For vanishing right-hand side term \( f \equiv 0 \) it is well-known that the solution \( u \) of the initial-boundary value problem (1.1) satisfies the energy conservation
\[
\| u^1(t) \|^2 + \| \nabla u^0(t) \|^2 = \| u_1 \|^2 + \| \nabla u_0 \|^2, \quad t \in I.
\]

We will prove that the space-time finite element discretization \( U_{\tau,h} \) of Problem 5.3 also satisfies the energy conservation principle at the discrete time nodes \( t_n \). Preserving this fundamental property of the solution of (1.1) is an important quality criterion for discretization schemes of (1.1).
Recalling (2.7), it follows for \( n \) maximum degree 2 we conclude for \( g \) gives now the exactness of the discretization schemes with twice continuously differentiable in time discrete solutions, that are referred.

In this section, let \( k \) be satisfied. Firstly, we propose a family of Galerkin–collocation time discretization schemes with twice continuously differentiable in time discrete solutions, that are referred.
to as cGP-C$^2(k)$–cG(r) schemes. Similarly to the cGP-C$^1(k)$–cG(r) approach of Problem 3.3, the higher order regularity in time is ensured by collocation conditions that are imposed in the endpoints $t_{n-1}$ and $t_n$ of the subinterval $I_n$. This construction principle can be generalized to discrete solutions of even higher order regularity in time. For this generalization we also refer to [16,17] where the Galerkin–collocation approximation of first-order ordinary differential equations systems is studied in detail. Secondly, we show how the cGP-C$^2(k+1)$–cG(r) approximation can be computed efficiently in a simple and computationally cheap post-processing step from the cGP-C$^1(k)$–cG(r) approach. The post-processing introduced in [37] and generalized in [16] was recently applied in [12] to the cGP(k)–cG(r) family of schemes given in Problem 3.1. There the post-processing is used to lift continuous in time discrete solutions to continuously differentiable ones. Moreover, an optimal order error analysis is provided for the post-processed solution.

**Problem 7.1** (Local, numerically integrated, fully discrete problem of cGP-C$^2(k)$–cG(r) on $I_n$). Given $U_{\tau,h}(t_{n-1})$ for $n > 1$ and $U_{\tau,h}(t_0) = U_{0,h}$ for $n = 1$, find $U_{\tau,h}|_{I_n} \in (\mathbb{P}_k(I_n;V))^2$ such that

$$
U_{\tau,h}(t_{n-1}^+) = U_{\tau,h}(t_{n-1}^-), 
$$

(7.1a)

$$
\partial_t U_{\tau,h}(t_{n-1}^+) = -A_h U_{\tau,h}(t_{n-1}^-) + \mathcal{P}_h F(t_{n-1}^-),
$$

(7.1b)

$$
\partial_t^2 U_{\tau,h}(t_{n-1}^+) = -A_h \partial_t U_{\tau,h}(t_{n-1}^-) + \mathcal{P}_h \partial_t F(t_{n-1}^-),
$$

(7.1c)

$$
\partial_t U_{\tau,h}(t_n^-) = -A_h U_{\tau,h}(t_n^-) + \mathcal{P}_h F(t_n^-),
$$

(7.1d)

$$
\partial_t^2 U_{\tau,h}(t_n^-) = -A_h \partial_t U_{\tau,h}(t_n^-) + \mathcal{P}_h \partial_t F(t_n^-),
$$

(7.1e)

and

$$
Q^H_{n,h}(\langle \partial_t U_{\tau,h}, V_{\tau,h} \rangle + \langle A_h U_{\tau,h}, V_{\tau,h} \rangle) = Q^H_{n,h}(\langle F, V_{\tau,h} \rangle)
$$

(7.1f)

for all $V_{\tau,h} \in (\mathbb{P}_{k-5}(I_n;V))^2$.

We note that a Hermite-type quadrature formula with $k$ evaluations of function values is used in (7.1f). This differs from $Q^R_n$ in (2.11) that is used in the cGP-C$^1(k)$–cG(r) family of schemes of Problem 3.3 and is based on $k - 1$ evaluations of function values only. In both cases the derivatives of the integrand are evaluated additionally in the endpoints of the subinterval $I_n$. Further, the cGP-C$^2(k)$ approach presented here differs from that in [17] by the applied quadrature formula.

**Remark 7.2.** A careful inspection of the conditions on $U_{\tau,h}$ shows that

$$
\partial_t U_{\tau,h}(t_{n-1}^+) = \partial_t U_{\tau,h}(t_{n-1}^-) \quad \text{and} \quad \partial_t^2 U_{\tau,h}(t_{n-1}^+) = \partial_t^2 U_{\tau,h}(t_{n-1}^-),
$$

where the discrete initial conditions are determined using

$$
\partial_t U_{\tau,h}(0) = -A_h U_{\tau,h}(0) + \mathcal{P}_h F(0), \quad \partial_t^2 U_{\tau,h}(0) = -A_h \partial_t U_{\tau,h}(0) + \mathcal{P}_h \partial_t F(0).
$$

Hence, the obtained trajectory in time is twice continuously differentiable on $\overline{T}$.

Compared to Problem 3.3, the test space of the condition (7.1f) is decreased from $(\mathbb{P}_{k-3}(I_n;V))^2$ to $(\mathbb{P}_{k-5}(I_n;V))^2$ while the number of collocation conditions is increased from two to four. For $k = 5$ this results in a test space which consists of piecewise constant functions only and to two additional collocation conditions in both endpoints of the time subinterval $I_n$.

Finally we address the connection between the cGP-C$^1$ and cGP-C$^2$ families of Galerkin–collocation schemes.
Theorem 7.3. Let $U_{\tau,h}$ denote the solution of the cGP-C^{1}(k)-cG(r) method given in Problem 3.3. For $n=1,\ldots,N$ we put

$$\tilde{U}_{\tau,h}|_{n} := U_{\tau,h}|_{n} - K_{n}\vartheta_{n},$$

where $\vartheta_{n} \in P_{k+1}(I_{n};\mathbb{R})$ is uniquely determined by

$$I_{n}^{H}\vartheta_{n} = 0 \quad \text{and} \quad \partial_{t}^{2}\vartheta_{n}(t_{n-1}^{+}) = 1.$$ 

If the correction coefficient $K_{n}$ is chosen as

$$K_{n} := \begin{cases} \partial_{t}^{2}U(t_{0}^{+}) - \partial_{t}^{2}u(t_{0}), & n = 1, \\ \partial_{t}^{2}U(t_{n-1}^{+}) - \partial_{t}^{2}\tilde{U}(t_{n-1}^{+}), & n > 1, \end{cases}$$

then $\tilde{U}_{\tau,h} \in (X^{k+1}_{\tau}(V_{h}))^{2}$ is the solution of the cGP-C^{2}(k + 1)-cG(r) method given in Problem 7.1.

The post-processing or lifting operator that is introduced in Theorem 7.3 is similar to the lifting operator of [12] that is studied there in the context of the cGP(k)-cG(r) approach of Problem 5.2. Both post-processing procedures provide the correction as a product of a scalar polynomial $\vartheta_{n}$ and a coefficient $K_{n} \in V_{h}^{2}$ that are, however, different for the two procedures. In particular, the lifting in [12] is based on the difference of first derivatives while our post-processing uses the difference of second order derivatives. We refer to [10] for details on post-processing techniques for general nonlinear systems of ordinary differential equations and the proof of the analogue to Theorem 7.3.

8 Numerical studies

In this section we present the results of two numerical experiments for the Galerkin–collocation approximation schemes introduced in Problem 3.3 and Problem 7.1 respectively. In particular, we aim to illustrate the error estimates given in Theorem 5.13 for the cGP-C^{1}(k)-cG(r) Galerkin–collocation approximation of Problem 3.3. The implementation of the numerical schemes was done in the high-performance DTM++/awave frontend solver (cf. [32]) for the deal.11 library [9]. For further details including a presentation of the applied algebraic solver and preconditioner we refer to [6, 32].

EOC | 4.00 | 4.00 | 3.00 | 4.00 | 4.00 | 3.00

In our first we study the convergence behavior of the Galerkin–collocation approximation $U_{\tau,h} \in (X^{3}(V_{h}^{3}(3)) \cap C^{1}(I; V_{h}^{3}(3)))^{2}$ of Problem 3.3 for the prescribed solution

$$u(x,t) := \sin(4\pi t) \cdot \sin(2\pi x_{1}) \cdot \sin(2\pi x_{2}) \quad (8.1)$$

20
of the wave problem on the space-time domain $\Omega \times I = (0,1)^2 \times (0,1)$. For the piecewise polynomial order in space and time the finite element approach the choice $k = 3$ and $r = 3$ is thus made; cf. (2.3) and (2.4). Beyond the norms of $L^\infty(I; L^2(\Omega))$ and $L^2(I; L^2(\Omega))$ the convergence behavior is studied further with respect to the energy quantities

$$\|E\|_{L^\infty} = \max_{t \in I} (\|\nabla e^0(t)\|^2 + \|e^1(t)\|^2)^{1/2} \quad \text{and} \quad \|E\|_{L^2} = \left( \int_I (\|\nabla e^0(t)\|^2 + \|e^1(t)\|^2) dt \right)^{1/2} (8.2)$$

with $E(t) = U(t) - U_{r,h}(t)$. Throughout, the $L^\infty$-norms in time are computed on the discrete time grid

$$I = \{t_n^0 : t_n^0 = t_{n-1} + j \cdot \kappa_n \cdot \tau_n, \kappa_n = 0.001, j = 0, \ldots, 999, n = 1, \ldots, N \} \cup \{t_N \}.$$  

In the numerical experiments the domain $\Omega$ is decomposed into a sequence of successively refined meshes $\Omega_h$, with $l = 0, \ldots, 4$, of quadrilateral finite elements. On the coarsest level, we use a uniform decomposition of $\Omega$ into 4 cells, corresponding to the mesh size $h_0 = 1/\sqrt{2}$, and of the time interval $I$ into $N = 10$ subintervals which amounts to the time step size $\tau_0 = 0.1$. In the experiments the temporal and spatial mesh sizes are successively refined by a factor of two in each refinement step.

In Table 8.1 we summarize the calculated results for this experiment. The experimental order of convergence (EOC) was calculated using the results from the two finest meshes. The numerical results of Table 8.1 nicely confirm our error estimates (5.30) and (5.32) by depicting the expected optimal fourth order rate of convergence in space and time. The third order convergence of the energy errors (8.2) is in agreement with the error estimates (5.31) and (5.33). Increasing the piecewise polynomial order in space to $r = 4$ and thus considering an approximation $\tilde{U}_{r,h} \in \left( X^4_r(V_h^{(4)}) \cap C^1(I; V_h^{(4)}) \right)^2$ in Problem 8.3 leads a fourth order convergence behavior in space and time which is not shown here for the sake of limited space.

### 8.2 Convergence test for cGP-C$^1$(4)–cG(5) and post-processing

Table 8.2: Error $E = (\varepsilon^0, \varepsilon^1) = U - U_{r,h}$ and error $\tilde{E} = (\tilde{\varepsilon}^0, \tilde{\varepsilon}^1) = U - \tilde{U}_{r,h}$ of the post-processed solution $\tilde{U}_{r,h}$ of Thm. 8.3 both with the corresponding experimental orders of convergence (EOC), for the solution $U = (u, \partial_t u)$ of 8.3 and the Galerkin–collocation approximation $U_{r,h} \in \left( X^2_r(V_h^{(3)}) \cap C^1(I; V_h^{(3)}) \right)^2$ of Problem 8.3

In the second numerical experiment we study the Galerkin–collocation scheme of Problem 3.3 for $k = 4$ to obtain a fully discrete solution $U_{\tau,h} \in \left( X^4_h(V_h^{(5)}) \cap C^1(I;V_h^{(5)}) \right)^2$. In addition, we will apply the post-processing considered in Sect. 7 and obtain a solution $\tilde{U}_{\tau,h}$ belonging to $\left( X^5_h(V_h^{(5)}) \cap C^2(I;V_h^{(5)}) \right)^2$. The numerical study is done for the prescribed solution

$$u(x,t) := \sin(4\pi t) x_1(1 - x_1)x_2(1 - x_2)$$

(8.3)

described on the space-time domain $\Omega \times I = (0,1)^2 \times (0,1)$. For the piecewise polynomial order in space and time of the finite element approach the choice $k = 4$ and $r = 5$ is made. Since this work focuses on the temporal discretization, the polynomial degree $r$ in space is chosen such that the spatial approximation becomes exact. Hence, the convergence behavior in time can be illustrated on a fixed spatial grid that consists of $4 \times 4$ congruent squares leading to $h_0 = 0.25\sqrt{2}$. The largest time length is $\tau_0 = 0.1$.

In Table 8.2 we summarize the calculated results for this experiment. The experimental order of convergence (EOC) was determined from the results on the two finest meshes. The numerical results of Table 8.2 nicely confirm the fifth order rate of convergence of the cGP-C$^1(4)$ time discretization. The application of the post-processing presented in Theorem 7.3 increased all convergence rates from 5 to 6. This order can at most be expected for a polynomial approximation in time with piecewise polynomials of fifth order. By means of Theorem 7.3 Table 8.2 thus underlines the optimal order approximation properties of the cGP-C$^2(5)$ member of the family of Galerkin–collocation schemes of Problem 7.1.

If the cGP-C$^2(5)$–cG(5) method of Problem 7.1 is directly applied for the computation, instead of using the post-processing of Thm. 7.3 then exactly the same errors as shown in Table 8.2 for $\tilde{E}$ are obtained. However, using the post-processing has certain computational advantages. Since the cGP-C$^1(k)$ approach leads to system matrices of simpler block structure compared to the cGP-C$^2(k+1)$ method, the construction of efficient preconditioners simplifies; cf. [6] for details.

9 Summary

In this work we presented a family of space-time finite element methods for wave problems. The schemes combine the concepts of collocation methods and Galerkin approximation. Continuously differentiable in time fully discrete solutions were obtained. An optimal order error analysis was provided for this class of methods. By a direct extension of the construction principle a further class of schemes with twice continuously differentiable in time discrete solutions was presented. A theorem regarding the connection of the two classes of schemes to each other by means of a post-processing was given. The proven error estimates and the expected convergence rates for the second class of schemes were illustrated by numerical experiments. The construction of the methods can be transferred to further classes of non-stationary partial differential equations. The approach offers large potential for the approximation of multi-physics problems in that the coefficient functions of the subproblems are given by the solutions and their time derivatives of coupled further subproblems. In addition, the presented post-processing can nicely be exploited for a posteriori error control and adaptive refinement of the temporal mesh.
