THERMODYNAMIC FORMALISM FOR COARSE EXPANDING DYNAMICAL SYSTEMS

TUSHAR DAS, FELIKS PRZYTYCKI, GIULIO TIOZZO, MARIUSZ URBAŃSKI, AND ANNA ZDUNIK

ABSTRACT. We consider a class of dynamical systems which we call weakly coarse expanding, which generalize to the postcritically infinite case expanding Thurston maps as discussed by Bonk–Meyer and are closely related to coarse expanding conformal systems as defined by Haïssinsky–Pilgrim. We prove existence and uniqueness of equilibrium states for a wide class of potentials, as well as statistical laws such as a central limit theorem, law of iterated logarithm, exponential decay of correlations and a large deviation principle. Further, if the system is defined on the 2-sphere, we prove all such results even in presence of periodic (repelling) branch points.

1. INTRODUCTION

The study of dynamical systems through thermodynamic formalism goes back to Sinai [20], Bowen [4], and Ruelle [18]. The paradigmatic example in this theory is the one-sided shift map on the space of sequences on a finite alphabet. This space is endowed with a natural metric under which the shift is uniformly expanding. This feature is essential in most applications: indeed, various systems which possess a certain degree of expansion can be encoded by a shift of finite type (see [16]), and this technique has allowed to establish statistical laws for a large class of dynamical systems.

For instance, in the case of rational maps, i.e. holomorphic endomorphisms of the 2-sphere, statistical laws are obtained in [17].

A related class of examples of topological maps of the 2-sphere is represented by expanding Thurston maps. Such maps are postcritically finite, and can be described by a finite set of “cut and fold” rules [5]; note that they need not be realized by holomorphic maps. These maps are discussed by Bonk–Meyer [3], who among other things construct the measure of maximal entropy. In a series of papers ([9], [10], [11], [12]), Li works out the thermodynamic formalism for expanding Thurston maps, with respect to the visual metric.

In a similar vein, Haïssinsky–Pilgrim [13] define more generally the concept of coarse expanding conformal (cxc) system, developing in an axiomatic way the notion of expansion for maps of general metric spaces. In particular, they prove for cxc systems existence and uniqueness of the measure of maximal entropy.

The goal of this paper is to develop the thermodynamic formalism (in particular, prove existence and uniqueness of equilibrium states and statistical laws) for a more general class of dynamical systems, which we call weakly coarse expanding. These systems are finite branched coverings of locally connected topological spaces which
are expanding in a weak metric sense, and generalize most cases discussed by [3] and [13]. In particular, they need not be postcritically finite, and the metric we consider need not be the visual metric, but it could be more generally an exponentially contracting metric (see Section 2 for the definitions). Our main results are contained in the following two theorems.

**Theorem 1.1.** Let \( f : W_1 \to W_0 \) be a weakly coarse expanding dynamical system without periodic critical points, let \( X \) be its repellor, \( \rho \) an exponentially contracting metric on \( X \) compatible with the topology, and let \( \varphi : (X, \rho) \to \mathbb{R} \) be a Hölder continuous function. Then:

1. there exists a unique equilibrium state \( \mu_\varphi \) for \( \varphi \) on \( X \).

Let \( \psi : (X, \rho) \to \mathbb{R} \) be a Hölder continuous observable, and denote

\[
S_n \psi(x) := \sum_{k=0}^{n-1} \psi(f^k(x)).
\]

Then there exists a constant

\[
\sigma := \lim_{n \to \infty} \frac{1}{n} \int_X \left( S_n \psi(x) - n \int \psi \, d\mu_\varphi \right)^2 \, d\mu_\varphi \geq 0
\]

such that the following statistical laws hold:

2. (Central Limit Theorem, CLT) If \( \sigma > 0 \), we have for any \( a < b \)

\[
\mu_\varphi \left( \left\{ x \in X : \frac{S_n \psi(x) - n \int \psi \, d\mu_\varphi}{\sqrt{n}} \in [a, b] \right\} \right) \to \frac{1}{\sqrt{2\pi \sigma^2}} \int_a^b e^{-t^2/2\sigma^2} \, dt
\]

as \( n \to \infty \). If \( \sigma = 0 \), one has convergence in probability to the Dirac \( \delta \)-mass at 0.

3. (Law of Iterated Logarithm, LIL) For \( \mu_\varphi \)-a.e. \( x \in X \),

\[
\limsup_{n \to \infty} \frac{S_n \psi(x) - n \int \psi \, d\mu_\varphi}{\sqrt{n \log \log n}} = 2\sigma.
\]

4. (Exponential Decay of Correlations, EDC) For any \( \mu_\varphi \)-integrable function \( \chi : X \to \mathbb{R} \) there exist constants \( a > 0 \) and \( C \geq 0 \) such that for any \( n \geq 0 \),

\[
\left| \int_X \psi \cdot (\chi \circ f^n) \, d\mu_\varphi - \int_X \psi \, d\mu_\varphi \cdot \int_X \chi \, d\mu_\varphi \right| \leq Ce^{-na}.
\]

5. (Large Deviations, LD) For every \( t \in \mathbb{R} \), we have that

\[
\lim_{n \to \infty} \frac{1}{n} \log \mu_\varphi \left( \left\{ x \in X : \text{sgn}(t) S_n \psi(x) \geq \text{sgn}(t) n \int \psi \, d\mu_\varphi + t \psi \right\} \right) = -t \int_X \psi \, d\mu_\varphi + P_{\text{top}}(\varphi + t \psi) - P_{\text{top}}(\varphi).
\]

6. Moreover, \( \sigma = 0 \) if and only if there exists a continuous \( u : X \to \mathbb{R} \) such that

\[
\psi - \int_X \psi \, d\mu_\varphi = u \circ f - u.
\]

7. Finally, \( \mu_{\varphi_1} = \mu_{\varphi_2} \) if and only if there exists \( K \in \mathbb{R} \) and a continuous \( u : X \to \mathbb{R} \) such that

\[
\varphi_1 - \varphi_2 = u \circ f - u + K.
\]
In (6) and (7), the function $u$ is Hölder continuous with respect to the visual metric.

Just as in classical holomorphic dynamics, a special role is played by critical points, i.e. points where the map is not locally injective, also called branch points. A major source of difficulty in the study of expanding systems is the presence of periodic critical points in the repellor (indeed, those systems do not satisfy the [Degree] condition, hence they are not coarse expanding in the sense of [13]).

Our second result addresses this issue in case the underlying space is an open subset of the 2-sphere (which is the case considered by [3] and [12]): there, our results also hold in the presence of periodic critical points as follows.

**Theorem 1.2.** If $f : W_1 \to W_0$ is a weakly coarse expanding system and $W_0 \subseteq S^2$ is an open subset of the 2-sphere, then all claims (1)-(2)-(3)-(4)-(5)-(6)-(7) of Theorem 1.1 hold even if there are periodic critical points.

Examples of weakly coarse expanding systems are given, other than in [3] and [13], in [14]; in particular, iterated function systems [7], skew products, maps on Sierpiński carpets and gaskets, as well as expanding polynomials ([11], [2]).

Note that all results in Theorems 1.1 and 1.2 work for $\varphi$ and $\psi$ lying in the slightly more general class of topologically Hölder functions, as defined in Section 5.1.

Let us also remark that our proofs follow a different, and in a way simpler, route than [12]: indeed, there the author directly applies the analytic methods of [16] on the metric space $X$. In the present paper, on the other hand, we first encode the dynamics of the system by a geometric coding tree, in the footsteps of [15], obtaining a measurable isomorphism with the shift space; then, our statistical laws follow easily from the corresponding ones for the shift space.

As for the second part (proof of Theorem 1.2), our technique consists in blowing up periodic critical points (and their grand orbit) to circles. The new space obtained is a Sierpiński carpet, and the dynamics becomes truly coarse expanding (without periodic critical points) on it, hence we can apply the same techniques of Theorem 1.1 to this new space, obtaining the desired results.

We have been informed by Peter Haïssinsky that he independently obtained a statement similar to Theorem 1.1.

The paper is organized as follows. The first part deals with the case without periodic critical points. In Section 2, we introduce the definition of weakly coarse expanding systems and construct the geometric coding trees. In Section 3, we prove that entropy does not drop under the projection from the symbolic space and in Section 4 we prove existence and uniqueness of equilibrium states as well as the statistical laws, proving Theorem 1.1 (1)-(5).

In the second part we deal with periodic critical points; in particular, in Section 5 we define a new space by blowing up the sphere along the critical orbits and produce, using Frink’s lemma, an exponentially contracting metric, which we use to prove Theorem 1.2 (1)-(5). In Section 6 we deal with the cohomological equation, proving (6) and (7) of Theorem 1.1 and 1.2.

Finally, in Appendix A we provide an alternative proof by constructing explicitly an exponentially contracting metric on the blown up space, and in Appendix B we prove that the blown up space embeds into the sphere.
Acknowledgements. We thank P. Haïssinsky, Z. Li, and K. Pilgrim for useful conversations.

2. Definitions

Let us start by introducing the fundamental definitions of the objects we are dealing with. We follow [13] in several places, though with some notable changes.

2.1. Finite branched coverings. Let $f : Y \to Z$ be a continuous map between locally compact Hausdorff topological spaces. The degree of $f$ is defined as

$$\deg(f) := \sup \{ #f^{-1}(z) : z \in Z \}.$$ 

Given a point $y \in Y$, the local degree of $f$ at $y$ is

$$\deg(f; y) := \inf \sup \# \{ f^{-1}(z) \cap U : z \in f(U) \}$$

where $U$ ranges over all open neighborhoods of $y$. A point $y$ is critical if $\deg(f; y) > 1$.

Definition 2.1. The map $f : Y \to Z$ is a finite branched cover of degree $d$ if $\deg(f) = d < \infty$ and the two following conditions hold:

1. For any $z \in Z$,

$$\sum_{y \in f^{-1}(z)} \deg(f; y) = \deg(f)$$

2. For any $y_0 \in Y$ there are compact neighborhoods $U, V$ of $y_0$ and $f(y_0)$ such that

$$\sum_{y \in U, f(y) = z} \deg(f; y) = \deg(f; y_0)$$

for all $z \in V$.

We define the branch set as $B_f := \{ y \in Y : \deg(f; y) > 1 \}$, and the set of branch values as $V_f = f(B_f)$. Note that $Z \setminus V_f$ is the set of principal values, i.e. the values $z \in Z$ so that $#f^{-1}(z) = d$.

Lemma 2.2 ([13], Lemma 2.1.2). A finite branched cover is open, closed, onto and proper. Furthermore, $B_f$ and $V_f$ are closed and nowhere dense.

A simple corollary of the lemma is that $f$ is a local homeomorphism away from critical points; i.e., for any $y \notin B_f$ there exists an open set $U$ which contains $y$ and such that $f : U \to f(U)$ is a homeomorphism.

Definition 2.3. A topological space $\mathcal{X}$ is strongly path connected if for any countable subset $S \subset \mathcal{X}$, the space $\mathcal{X} \setminus S$ is path connected.

Note that we need such an assumption: for instance, a tree is path connected but it becomes disconnected if you remove any point.
2.2. Coarse expanding dynamical systems. Let $W_1, W_0$ be two locally compact, locally connected, Hausdorff topological spaces, each with finitely many connected components, and suppose that $W_1$ is an open subset of $W_0$ and the closure of $W_1$ is compact.

We define a system as a triple $(f, W_0, W_1)$, where $W_0, W_1$ satisfy the hypotheses above, and $f : W_1 \to W_0$ is a finite branched cover.

**Definition 2.4.** We define the repellor $X$ of the system $(f, W_0, W_1)$ as

$$X := \bigcap_{n=0}^{\infty} f^{-n}(W_1).$$

By definition, $f(X) \subseteq X$ and $X = f^{-1}(X) \cap W_1$. Moreover, we define the post-branch set as

$$P_f := X \cap \bigcup_{n>0} V_{f^n}.$$

Note that we do not take the closure of the post-branch set (differently from [13]).

Haissinsky and Pilgrim [13, Section 2.2] give the following topological definition of expansion. Let $U_0$ be a finite cover of $X$ by connected, open subsets of $W_1$ whose intersection with $X$ is not empty. For each $n$, we define $U_n$ as the open cover whose elements are the connected components of $f^{-n}(U)$ where $U$ belongs to $U_0$.

**Definition 2.5.** A system $(f, W_0, W_1)$ satisfies the [Expansion] axiom if there exists a finite cover $U_0$ of $X$ such that the following holds: for any open cover $Y$ of $X$ by open subsets of $W_0$, there exists $N$ such that for all $n \geq N$ each element of $U_n$ is contained in some element of $Y$.

If $W_0$ is equipped with a metric, this axiom implies that the diameter of the cover $U_n$ tends uniformly to zero as $n \to \infty$.

**Definition 2.6.** A system $(f, W_0, W_1)$ is locally eventually onto if for any $x \in X$ and any neighborhood $W$ of $x$ in $X$ there is some $n$ with $f^n(W) = X$.

In the language of [13], this property is called the [Irreducibility] axiom.

2.3. Weakly coarse expanding systems. Let us now give a definition of weakly coarse expanding system.

**Definition 2.7.** A system $(f, W_0, W_1)$ is weakly coarse expanding if:

1. it satisfies the [Expansion] axiom;
2. it is locally eventually onto;
3. the branch set $B_f$ is finite.

Note that if $W_0 \subseteq S^2$ is an open subset of the 2-sphere, then the set $B_f$ is always finite (see [22]).

2.4. Visual metrics. A very important property of coarse expanding systems is that we can find a metric so that preimages shrink exponentially fast.

**Theorem 2.8.** Suppose $f : W_1 \to W_0$ is a finite branched cover and axiom [Expansion] holds. Then there exists a metric $\rho$ on $X$ and constants $C > 0$, $\theta < 1$ such that for all $n \geq 0$

$$\sup_{U \in U_n} \text{diam}_\rho(U) \leq C \theta^n.$$
We call a metric $\rho$ which satisfies the above property an exponentially contracting metric. An important example (with additional properties) is the visual metric constructed in [13, Chapter 3].

Note that since the closure of $W_1$ is compact, then also $X$, which is closed in $W_1$, is compact. Hence any metric $\rho$ on $X$ which induces this topology is complete.

The above theorem is essentially [13, Theorem 3.2.5]. We will, however, give a complete proof below, using a different method. We use Frink’s metrization lemma [8], in the following form.

**Lemma 2.9** (Frink’s metrization lemma, [16], Lemma 4.6.2). Let $X$ be a topological space, and let $(\Omega_n)_{n \geq 0}$ be a sequence of open neighborhoods of the diagonal $\Delta \subseteq X \times X$, such that

1. $\Omega_0 = X \times X$
2. $\bigcap_{n=0}^{\infty} \Omega_n = \Delta$
3. For any $n \geq 1$, $\Omega_n \circ \Omega_n \circ \Omega_n \subseteq \Omega_{n-1}$

where $\circ$ is the composition in the sense of relations: i.e., $R \circ S = \{(x, y) \in X \times X : \exists z \in X \text{ s.t. } (x, z) \in R \text{ and } (z, y) \in S\}$.

Then there exists a metric $\rho$ on $X$, compatible with the topology, such that

$\Omega_n \subseteq \{(x, y) \in X \times X : \rho(x, y) < 2^{-n}\} \subseteq \Omega_{n-1}$

for any $n \geq 1$.

Theorem 2.8 is an immediate consequence of the following Proposition.

**Proposition 2.10.** Let $f : W_1 \to W_0$ be a finite branched cover with repellor $X$, let $\mathcal{U}$ be a finite cover of $X$ by open subsets of $W_1$ and let $\rho$ be a metric on $X$ such that

$$\lim_{n \to \infty} \sup_{U \in \mathcal{U}_n} \{\text{diam}_\rho(U) : U \in \mathcal{U}_n\} = 0$$

as $n \to \infty$. Then there exist a metric $\rho'$ on $X$, which induces the same topology as $\rho$, and constants $C, \beta > 0$ such that

$$\text{diam}_{\rho'}(U) \leq Ce^{-\beta n}$$

for any $n \geq 0$ and any $U \in \mathcal{U}_n$.

**Proof.** The proof follows from Lemma 2.9. Let us define $V_n$ as the set of pairs $(x, y) \in X \times X$ such that there exists an element $U$ of $\mathcal{U}_n$ which contains both $x$ and $y$. Let $\eta > 0$ be the Lebesgue number of $\mathcal{U}_0$ with respect to $\rho$. By hypothesis there exists an integer $M \geq 1$ such that

$$\sup_{U \in \mathcal{U}_l} \{\text{diam}_\rho(U) : U \in \mathcal{U}_l\} < \eta/3$$

for any $l \geq M$. Now, let us define $\Omega_0 := X \times X$ and $\Omega_n := \bigcup_{k=0}^{M-1} V_{Mn+k}$. We need to check the hypotheses of Lemma 2.9. Equation (a) is trivially true, as is the inclusion $\Delta \subseteq \bigcap_{n=0}^{\infty} \Omega_n$ in (b). To prove the other inclusion, suppose that
(x, y) ∈ Ω_n for any n ≥ 0. Then for any n there exists a connected set Γ_n ∈ U_{Mn+k}
which contains x, y. Hence
\[ ρ(x, y) ≤ \sup\{\text{diam}_\mu(U) : U ∈ U_l, l ≥ Mn\} → 0 \]
as n → ∞. Thus x = y, as claimed.

To prove (c), suppose to have sets Γ_i ∈ U_{M+k_i} for i = 1, 2, with 0 ≤ k_i < M
and Γ_i ∩ Γ_{i+1} = ∅ for i = 1, 2. Then diam_ρ(Γ_1 ∪ Γ_2 ∪ Γ_3) < η, hence by definition
of Lebesgue number there exists Γ ∈ U_0 such that Γ_1 ∪ Γ_2 ∪ Γ_3 ⊆ Γ. Hence
\[ Ω_1 ∩ Ω_1 ∩ Ω_1 ⊆ Ω_0 \]
and by taking f^{M(n-1)}-preimages,
\[ Ω_n ∩ Ω_n ∩ Ω_n ⊆ Ω_{n-1} \]
for any n ≥ 1, proving (c).

Thus, we can apply Lemma 2.9, obtaining that there exists a metric ρ’ on X,
which induces the same topology as ρ, such that
\[ Ω_n ⊆ \{(x, y) ∈ X × X : ρ'(x, y) < 2^{-n}\} ⊆ Ω_{n-1} \]
for any n ≥ 1. Thus for any U ∈ U_n we have
\[ \text{diam}_ρ U < 2^{-\left\lfloor \frac{M}{2} \right\rfloor} \]
as claimed.

2.5. Equilibrium states. Let us now recall some basic notions from ergodic theory. For more details, see e.g. [16].

Let f : X → X be a continuous map of a compact metric space. A probability
measure µ on X is f-invariant if f_µ = µ, and we let M(f) be the set of f-invariant
probability measures on X. We denote as h_µ(f) the metric entropy of f with respect
to µ.

Now, consider a continuous function ϕ : X → ℝ, which we call a potential. The
topological pressure of f with potential ϕ is defined as
\[ P_{\text{top}}(f) = \sup_{\mu ∈ M(f)} \left\{ h_\mu(f) + \int_X f \, d\mu \right\}. \]
Note that P_{\text{top}}(f) may also be defined topologically ([16], Section 3.2). An f-
invariant probability measure µ on X is an equilibrium state for ϕ if it realizes the
supremum, namely if
\[ P_{\text{top}}(f) = h_\mu(f) + \int_X f \, d\mu. \]

In the following, we will consider a weakly expanding system f : W_1 → W_0, and
study the equilibrium states on its repellor X.

2.6. The geometric coding tree. Let us now construct a symbolic coding for a
coarse expanding dynamical system. We start by proving the path lifting property.

Lemma 2.11. Let f : Y → Z be a finite branched covering, and let γ be a con-
tinuous arc in Z which is disjoint from the set of branch values V_f. Let x = γ(0),
and ˘x such that f(˘x) = x. Then there exists a continuous arc ˘γ in Y such that
f(˘γ) = γ and ˘γ(0) = ˘x.
Proof. Let \( p \in \gamma \), and \( \tilde{p} \) a preimage of \( p \). Then since \( \gamma \) is disjoint from \( V_f \), the local degree of \( f \) at \( \tilde{p} \) is 1. Hence, there exists a neighbourhood \( U \) of \( \tilde{p} \) such that \( f : U \to f(U) \) is injective, open, and closed, hence a homeomorphism; moreover, \( f(U) \) is open. Hence, one can lift \( \gamma \cap f(U) \) to an arc \( f^{-1}(\gamma) \cap U \) which contains \( \tilde{p} \). Thus, any point \( p \) in \( \gamma \) has a neighborhood \( U_p \) over which \( \gamma \) can be lifted, and moreover such that \( f^{-1}(U_p) \) is the union of \( d \) disjoint open sets which are homeomorphic to \( U_p \); since \( \gamma \) is compact, this implies that the entire \( \gamma \) can be lifted.

The key point in our approach is that one constructs a semiconjugacy of a weakly coarse expanding system of degree \( d \) to the shift map on \( d \) symbols.

Let \( \Sigma := \{1, \ldots, d\}^\mathbb{N} \) be the space of infinite sequences of \( d \) symbols, and \( \sigma : \Sigma \to \Sigma \) the left shift. If \( \eta := (\eta_1, \ldots, \eta_n) \in \{1, \ldots, d\}^n \) is a finite sequence, the cylinder associated to \( \eta \) is the set \( C(\eta) := \{(\epsilon_i) \in \Sigma : \epsilon_i = \eta_i \text{ for all } 1 \leq i \leq n\} \). The integer \( n \) is called the depth of the cylinder \( C(\eta) \). Note that for any \( n \geq 1 \), the set \( \Sigma \) is the disjoint union of \( d^n \) cylinders of depth \( n \), and all cylinders are both open and closed.

**Proposition 2.12.** Let \( f : W_1 \to W_0 \) be a weakly coarse expanding system of degree \( d \) and assume \( W_0 \) is strongly path connected. Then there exists a H"older continuous semiconjugacy \( \pi : \Sigma \to X \) such that \( \pi \circ \sigma = f \circ \pi \). Moreover, if \( f \) is locally eventually onto, then \( \pi \) is surjective.

**Proof.** The construction is based on the idea of “geometric coding tree” as in [15]. Namely, pick \( w \in X \setminus P_f \), and let \( w_1, \ldots, w_d \) be its preimages. For each \( i = 1, \ldots, d \), choose a continuous path \( \gamma_i \) in \( W_0 \) connecting \( w \) and \( w_i \) and avoiding \( P_f \). This exists since the space is strongly path connected and the set \( P_f \) is countable. For each sequence \( \alpha = (i_1, i_2, \ldots) \in \Sigma \), define \( z_n(\alpha) \) by letting \( z_0(\alpha) = w_i \) and \( z_n(\alpha) \) for \( n \geq 1 \) inductively as follows. Let \( \gamma(z_n) \) be a curve which is the branch of \( f^{-n}(\gamma_{i_n}) \) such that one of its ends is \( z_{n-1}(\alpha) \). Such lifts exist by Lemma 2.11 since we chose the curves \( \gamma_i \) to be disjoint from \( P_f \). Then define \( z_n(\alpha) \) as the other end of \( \gamma(z_n) \).

Now, there exists \( k \) such that each path \( \gamma_i \) for \( i = 1, \ldots, d \) is contained in the union of at most \( k \) open sets of \( \mathcal{U}_0 \). Then, any lift of \( \gamma_i \) by \( f^n \) is also contained in the union of at most \( k \) sets of \( \mathcal{U}_n \). Thus, by the exponential contraction property of Theorem 2.8 we have \( \rho(z_n(\alpha), z_{n-1}(\alpha)) \leq Ck\theta^n \), hence

\[
\lim_{n \to \infty} z_n(\alpha)
\]

exists, and we define \( \pi(\alpha) \) as the limit. By construction the map \( \pi \) satisfies \( f \circ \pi = \pi \circ \sigma \). To prove the H"older continuity, let \( \alpha = (i_1, i_2, \ldots) \) and \( \beta = (j_1, j_2, \ldots) \) be two sequences, and let \( r := \min\{s : i_s \neq j_s\} \), so that \( z_{r-1}(\alpha) = z_{r-1}(\beta) \) if \( r > 1 \). Hence

\[
\rho(\pi(\alpha), \pi(\beta)) \leq \rho(\pi(\alpha), z_{r-1}(\alpha)) + \rho(z_{r-1}(\beta), \pi(\beta)) \leq 2kC\theta^r
\]

which is what we need, as the distance between \( \alpha \) and \( \beta \) in the symbolic space is \( 2^{-r} \).

To prove the coding map \( \pi \) is surjective, let \( x \in X \). Since \( f \) is locally eventually onto, for each \( k > 0 \) there exists \( n_k \) such that \( f^{n_k}(B(x, \frac{1}{k})) \supset X \). In particular, there exists \( w_k \in X \) with \( d(x, w_k) < \frac{1}{k} \) and such that \( f^{n_k}(w_k) = w \). This means, there exists a finite sequence \( \alpha_k = (i_1^{(k)}, \ldots, i_{n_k}^{(k)}) \) such that \( w_k = z_{n_k}(\alpha_k) \) and
lim_{k \to \infty} w_k = x. By compactness of the shift space, up to passing to a subsequence there exists an infinite sequence \( \alpha = (i_1, \ldots, i_n, \ldots) \) such that \( \alpha_k \to \alpha \). That is, for each \( N \) there exists \( k \) such that \( \alpha \) and \( \alpha_k \) coincide for the first \( N \) symbols, hence by the exponential contraction property

\[
\rho(z_N(\alpha), z_{n_k}(\alpha_k)) \leq C\theta^N
\]

for some \( \theta < 1 \). Then

\[
\lim_N z_N(\alpha) = \lim_k z_{n_k}(\alpha_k) = x
\]

thus \( \pi(\alpha) = x \), as claimed. \( \square \)

3. No entropy drop

Let \( f : W_1 \to W_0 \) be a finite branched cover with repellor \( X \), let \( \rho \) be a metric on \( X \), and let \( \varphi : (X, \rho) \to \mathbb{R} \) be a Hölder continuous potential. We now show that if there are no periodic critical points, then the entropy of any equilibrium state on \( \Sigma \) is the same as the entropy of its pushforward on \( X \).

Inspired by [15, Lemma 4], we give the following definition. We say \( x \) is an \( \epsilon \)-singular point if there exists \( y \neq x \) such that \( \rho(x, y) < \epsilon \) and \( f(x) = f(y) \) (note this is slightly different from the definition of singular value in [15]). Let \( (x_i)_{0 \leq i \leq n} \) be a finite orbit segment, i.e., a sequence of points such that \( f(x_i) = x_{i+1} \). Then we say \( i \) is an \( \epsilon \)-singular time if \( x_i \) is an \( \epsilon \)-singular point.

**Lemma 3.1.** Suppose that no critical point is periodic. Then for any \( 0 < \zeta < 1 \), there exists \( \epsilon > 0 \) such that for any \( x \in X \) and any finite orbit segment \( (x_i)_{0 \leq i \leq n} \) with \( x_n = x \) we have

\[
\#\{0 \leq i \leq n : i \text{ is } \epsilon \text{-singular time}\} \leq \zeta n
\]

**Proof.** Let \( p \) be the number of critical points. Given \( \zeta < 1 \), let us choose \( k \) such that \( \frac{\zeta}{k} < \zeta \). Fix a critical point \( c \), and let \( \beta := \rho(c, \{f^n(c)\}_{1 \leq n \leq k}) > 0 \).

We readily see that there exists \( \eta > 0 \) such that if \( y \in B(c, \eta) \), then \( f^l(y) \notin B(c, \eta) \) for any \( l \leq k \). Indeed, by continuity of \( f \), there exists \( 0 < \eta < \beta/2 \) such that \( f^l(B(c, \eta)) \subseteq B(f^l(c), \beta/2) \) for any \( l \leq k \). Then if \( y \in B(c, \eta) \) then \( f^l(y) \notin B(f^l(c), \beta/2) \), which is disjoint from \( B(c, \eta) \) since \( \eta < \beta/2 \).

We then claim that for every \( \eta \) there exists \( \epsilon \) such that if \( x \) is \( \epsilon \)-singular, then \( B(x, \eta) \) contains at least a critical point.

Indeed, there exists \( \gamma > 0 \) such that if \( x \notin B(\text{Crit} f, \eta) \), then the restriction of \( f \) to \( B(x, \gamma) \) is 1-1. Then if we let \( \epsilon = \frac{\gamma}{2} \) and \( x \) is \( \epsilon \)-singular, then the restriction of \( f \) to \( B(x, 2\epsilon) \) is not injective, hence \( x \) lies within distance \( \eta \) of a critical point.

Now suppose \( (x_i) \) is an orbit segment, and \( i < j \) are two singular times such that \( x_i \) and \( x_j \) lie within distance \( \eta \) of the same critical point \( c \). Then by the argument above \( j - i \geq k \).

Thus, the number of singular times is at most \( \frac{\rho}{\epsilon} < \zeta n \), as desired. \( \square \)

Let us denote as \( \sigma : \Sigma \to \Sigma \) the shift map on the symbolic space and \( f : W_1 \to W_0 \) the topological branched cover, with repellor \( X \). Moreover, let \( \pi : \Sigma \to X \) be the semiconjugacy.

**Lemma 3.2.** For any \( x \in X \), denote as \( S_{n,x} \) the number of cylinders of depth \( n \) which intersect \( \pi^{-1}(x) \). Then

\[
\limsup_{n \to \infty} \frac{1}{n} \log \sup_{x \in X} S_{n,x} = 0.
\]
Proof. First, by exponential convergence of backward orbits, there exists $C > 0$, $\lambda < 1$ such that
\[
\rho(z_n(\alpha), \pi(\alpha)) \leq C\lambda^n
\]
for any $\alpha \in \Sigma$ and any $n \geq 0$.

Now note that, if $\pi(\alpha) = \pi(\beta)$, then
\[
\rho(f^m(z_n(\alpha)), f^m(z_n(\beta))) \leq 2C\lambda^n
\]
for any $n, m \geq 0$. Indeed,
\[
\rho(f^m(z_n(\sigma^m\alpha)), f^m(z_n(\sigma^m\beta))) \leq \rho(z_n(\sigma^m\alpha), \pi(\sigma^m\alpha)) + \rho(\pi(\sigma^m\alpha), \pi(\sigma^m\beta)) + \rho(\pi(\sigma^m\beta), z_n(\sigma^m\beta)) \leq C\lambda^n + 0 + C\lambda^n.
\]

Fix $\zeta$ with $0 < \zeta < 1$, and let $\epsilon > 0$ such that Lemma 3.1 is satisfied for $\zeta$. Then there exists $N_1$ such that $2C\lambda^n \leq \epsilon$ for any $n \geq N_1$.

Let $G := \{z_n(\beta) : \beta \in S_{n,x}\}$. For each point $w$ in $G$, by Lemma 3.1, the number of $\epsilon$-singular times in its forward orbit $(w, f(w), \ldots, f^n(w))$ is at most $\zeta n$. Thus, there are at most $n^n$ choices for the set of singular times, and there are at most $d^n$ paths in the tree which have a given set of singular times. Furthermore, there are at most $d^{N_1}$ possible elements in $S_{N_1,x}$, hence
\[
S_{n,x} = \#G \leq d^{N_1} \binom{n}{\zeta n} d^n
\]
thus, using Stirling’s formula,
\[
\lim_{n \to \infty} \frac{1}{n} \log \sup_{x \in X} S_{n,x} \leq \log \left( \frac{\zeta}{\zeta - \zeta(1 - \zeta)^{\zeta - 1}} \right) + \zeta \log d.
\]
The claim follows taking $\zeta \to 0$. \hfill \Box

**Lemma 3.3.** Let $\mu$ be a $\sigma$-invariant measure on the symbolic space $\Sigma$, and let $\nu = \pi_* \mu$ be the pushforward measure on $X$. Then
\[
h_\mu(\sigma) = h_\nu(f).
\]

Proof. Let $A^n$ denote the partition of $\Sigma$ into cylinders of depth $n$, let $\theta$ be the partition in preimages of points under $\pi$, and for $\nu$-a.e. $x \in X$ let $\mu_x$ be the conditional measure on the fiber over $x$. By definition of relative entropy (see e.g. [21]),
\[
h_\mu(\sigma|f) = \lim_{n \to \infty} \frac{1}{n} H_\mu(A^n|\theta)
\]
\[
= \lim_{n \to \infty} \frac{1}{n} \int_X d\nu(x) \sum_{a \in A^n} -\mu_x(a) \log \mu_x(a)
\]
and, by the comparison between measure-theoretic and conditional entropy,
\[
\leq \limsup_{n \to \infty} \frac{1}{n} \int_X \log S_{n,x} d\nu(x)
\]
hence the claim follows from Lemma 3.2. \hfill \Box
4. Existence and uniqueness of equilibrium states

We start by showing that the pushforward of an equilibrium state on $\Sigma$ is an equilibrium state on $X$.

**Lemma 4.1.** Let $\varphi : (X, \rho) \to \mathbb{R}$ be a Hölder continuous potential, and let $\tilde{\mu}$ be an equilibrium state for $\tilde{\varphi} = \varphi \circ \pi$. Then $\mu := \pi_*\tilde{\mu}$ is an equilibrium state for $\varphi$.

**Proof.** Since $\pi$ is a semiconjugacy,
$$P_{\text{top}}(\varphi) \leq P_{\text{top}}(\varphi \circ \pi) =$$
and since $\tilde{\mu}$ is an equilibrium state
$$= h_{\tilde{\mu}}(\sigma) + \int \tilde{\varphi} \, d\tilde{\mu} =$$
and using Lemma 3.3 (no entropy drop)
$$= h_{\mu}(f) + \int \varphi \, d\mu \leq P_{\text{top}}(\varphi)$$
where in the last step we used the variational principle. Hence
$$P_{\text{top}}(\varphi) = P_{\text{top}}(\varphi \circ \pi)$$
and $\mu$ is an equilibrium state for $\varphi$. \qed

Then we prove that the equilibrium state on $X$ is unique.

**Lemma 4.2.** Let $\mu$ be an equilibrium state for $\varphi$. Then there exists a probability measure $\nu$ on $\Sigma$ which is $\sigma$-invariant and such that $\pi_*\nu = \mu$.

**Proof.** We will use Riesz’ extension theorem. Namely, the measure $\mu$ defines a positive functional on $C_0(\Sigma) := \{ f \in C(\Sigma) : \exists g \in C(X) \text{ with } f = g \circ \pi \}$ by setting
$$\mu(g \circ \pi) := \int g \, d\mu.$$  
The functional is well-defined since $\pi$ is surjective. Now, we need to check that
$$C(\Sigma) = C_0(\Sigma) + P$$
where $P$ is the convex cone of non-negative functions. This is obvious since given $f \in C(\Sigma)$ we have
$$f = \inf f + (f - \inf f)$$
where $\inf f$ is constant, hence belongs to $C_0(\Sigma)$, and $f - \inf f \geq 0$. Then by the Riesz’ extension theorem ([19] Theorem 5.5.8) there exists a positive functional on $C(\Sigma)$ which extends $\mu$. By Riesz’ representation theorem, this functional is represented by a measure $\nu$ on $\sigma$ which has the property that
$$\int f \circ \pi \, d\nu = \int f \, d\mu$$
for any $f \in C(X)$. Now, by taking a limit point of the sequence
$$\mu_n := \frac{1}{n} \sum_{j=0}^{n-1} \sigma^j \nu$$
we obtain a measure $\tilde{\mu}$ on $\Sigma$ which is $\sigma$-invariant and satisfies $\pi_*\tilde{\mu} = \mu$. \qed
Lemma 4.3. Let $\mu$ be an equilibrium state for $\varphi$. Then there exists a measure $\bar{\mu}$ which is an equilibrium state for $\bar{\varphi}$ and $\pi_*\bar{\mu} = \mu$.

Proof. By the previous lemma,
$$P_{\text{top}}(\varphi \circ \pi) = P_{\text{top}}(\varphi) =$$
and, since $\mu$ is an equilibrium state,
$$= h_\mu(f) + \int \varphi \, d\mu \leq$$
and, using that entropy increases by taking an extension and that $\pi_*\bar{\mu} = \mu$,
$$\leq h_\nu(\sigma) + \int \bar{\varphi} \, d\bar{\mu}$$

hence by the variational principle $\bar{\mu}$ is an equilibrium state. □

Lemma 4.4. For any Hölder continuous potential $\varphi : X \to \mathbb{R}$ there is a unique equilibrium state.

Proof. Let $\mu_1, \mu_2$ be two equilibrium states for $\varphi$ on $X$. Then the measures $\bar{\mu}_i$ for $i = 1, 2$ produced in the previous Lemma are equilibrium states for $\varphi \circ \pi$ on $\Sigma$, and we know that this is unique. Hence $\mu_1 = \pi_*\bar{\mu}_1 = \pi_*\bar{\mu}_2 = \mu_2$. □

Proof of Theorem 1.1 (1)-(5). Consider a Hölder continuous potential $\varphi : X \to \mathbb{R}$ and a Hölder continuous observable $\psi : X \to \mathbb{R}$, and let $\pi : \Sigma \to X$ be the semiconjugacy of Proposition 2.12. Then $\varphi \circ \pi$ and $\psi \circ \pi$ are Hölder continuous with respect to the metric on $\Sigma$. Now, by the previous discussion there is a unique equilibrium state $\mu_{\varphi}$ on $X$ for the potential $\varphi$ and a unique equilibrium state $\nu_{\varphi \circ \pi}$ for the potential $\varphi \circ \pi$. Moreover, it is well-known that equilibrium states for Hölder potentials on the full shift space on $d$ symbols satisfy the statistical laws (CLT, LIL, EDC, LD); for CLT, LIL, EDC see [19], for LD see for example [8] and references therein. Hence the sequence $\left(\psi \circ \pi \circ \sigma^n\right)_{n \in \mathbb{N}}$ satisfies the statistical laws with respect to $\nu_{\varphi \circ \pi}$. Since $\psi \circ \pi \circ \sigma^n = \psi \circ f^n \circ \pi$ and $\nu_{\varphi \circ \pi}$ pushes forward to $\mu_{\varphi}$, the sequence $\left(\psi \circ f^n\right)_{n \in \mathbb{N}}$ also satisfies CLT, LIL, EDC and LD with respect to $\mu_{\varphi}$. □

5. Periodic critical points

Let us now focus on the case where $f : W_1 \to W_0 \subseteq S^2$ is defined on an open subset of the 2-sphere, but periodic critical points are allowed. In this case, we can blow up the sphere along the preimages of the critical orbits and obtain a coarse expanding map of a Sierpiński carpet (or a subset thereof) without periodic critical points.

The main result of this section is the following proposition, whose proof we will give in several steps.

Proposition 5.1. Let $f : W_1 \to W_0 \subseteq S^2$ be a weakly coarse expanding map on an open subset of the 2-sphere, and let $\rho$ be an exponentially contracting metric on $X$. Then there exists a strongly path connected space $\tilde{W}_0$ and a weakly coarse expanding system $g : \tilde{W}_1 \to \tilde{W}_0$ without periodic critical points with repellor $Y$ and a metric $\rho'$ on $Y$ which is exponentially contracting with respect to $g$, and there is a continuous map $\pi : \tilde{W}_0 \to W_0$ such that $\pi \circ g = f \circ \pi$.

Let us start the proof of Proposition 5.1 by obtaining a local model in a neighborhood of a fixed critical point.
Lemma 5.2. Let $f : W_1 \rightarrow W_0 \subseteq S^2$ be a weakly coarse expanding map, and let $z \in X$ be a fixed critical point. Then for any $\lambda > 1$ there exists $d \in \mathbb{Z} \setminus \{0\}$, a neighborhood $U$ of $z$ and a homeomorphism $h : \overline{D} \rightarrow \overline{U}$ such that $f \circ h = h \circ g$ where $g : \overline{D}_\lambda \rightarrow \overline{D}$ is defined as

$$g(re^{i\theta}) = \lambda re^{i\theta}$$

for any $r \leq 1$, $\theta \in \mathbb{R}$.

Remark. Note that $d$ may be negative if $f$ is orientation reversing in a neighborhood of $p$. The absolute value $|d|$ is the local degree of $f$ at $p$.

Proof. Let $U$ be small a closed topological disc in $S^2$ containing the branched $f$-fixed point $p$ in its interior.

Claim. There exists a Jordan curve $\gamma$ in $U \setminus \{p\}$ such that a component of $f^{-1}(\gamma)$ is a Jordan curve disjoint from $\gamma$ and separates $\gamma$ from $p$.

Proof of the Claim. Let $U$ be small a closed topological disc in $S^2$ containing the branched $f$-fixed point $p$ in its interior. For any $k$, let $U_k$ be the pullback of $U$ by $f^k$ which contains $p$. By [Expansion], there exists $N > 0$ such that $U_N$ is contained in the interior of $U$. Let $V := \bigcup_{n=0}^{N-1} U_n$. Then $V_1 := \text{Comp}_p f^{-1}(V) = \bigcup_{n=0}^{N-1} U_{n+1} \subseteq V$, where $\text{Comp}_p$ means the component containing $p$.

Now, add to $V$ and $V_1$ all the holes to make them simply connected. Since $f$ is open, we still have $f(V_1) \subseteq V$, and the claim is satisfied if the boundaries of $V$ and $V_1$ are disjoint.

Otherwise, let $\gamma := \partial V$ and $\gamma_1 := \partial V_1$. We shall correct $V$ so that its pullback $V_1$ is contained in the interior of $V$. To this end, denote $a := \gamma \cap \gamma_1$. If $f(a) \subset a$ then $a$ is non-escaping, contradicting the [Expansion] axiom.

Otherwise we modify in $\gamma \setminus a$ a neighborhood of $f(a) \setminus a$, by pushing it slightly into $V$, to obtain a new arc $\gamma_1$ which satisfies $\gamma_1 \cap f^{-1}(\gamma_1) = a \cap f^{-1}(a)$.

If the latter intersection is not empty, we repeat this process by considering for any $n$ the set

$$a_n := \{x \in a : f^k(x) \in a \text{ for all } k = 1, \ldots, n\},$$

and we modify in $\gamma^{n-1} \setminus a_{n-1}$ a neighborhood of $f(a_{n-1}) \setminus a_{n-1}$ to obtain a new curve $\gamma_n$ so that $\gamma_n \cap f^{-1}(\gamma_n) = a_n$.

Now, we claim there exists $N$ such that $a_N = \emptyset$. Indeed, otherwise the set $a_\infty = \{x \in \gamma : f^n(x) \in a \forall n \geq 1\}$ would be non-empty with $f(a_\infty) \subset a_\infty$, contradicting the [Expansion] axiom.

Thus, the inductive procedure stops after $N$ steps, and $\gamma^N$ is disjoint from the preimage $f^{-1}(\gamma^N)$, completing the proof of the claim.

Let us now complete the proof of the lemma. By induction, let us define as $\gamma_0$ the curve $\gamma$ given by the previous claim, and as $\gamma_{n+1} := f^{-1}(\gamma_n) \cap U$, obtaining a sequence of disjoint, nested simple closed curves which contain $z$ in their interior. By the expansion property, the diameter of $\gamma_n$ converges to 0 exponentially fast. For each $n$, let us define as $R_n$ the annulus bounded by $\gamma_n$ and $\gamma_{n+1}$. Let us pick a point $p_0$ on $\gamma_0$, and let us choose as $p_1 \in \gamma_1$ as one of the $d$ preimages of $p_0$. Let us pick a continuous arc $\alpha = \alpha_0$ which joins $p_0$ and $p_1$ and is contained in $R_0$. Then for each $n \geq 1$ let us define as $\alpha_{n+1}$ the component of $f^{-1}(\alpha_n)$ which starts at $p_n$, and let $p_{n+1}$ be other end of $\alpha_{n+1}$. Let $\beta := \bigcup_{n=0}^{\infty} \alpha_n$, which is a continuous (open)
arc joining $p_0$ to $z$. Note that by construction, $f(\beta) \cap U \subseteq \beta$. Now, for each $n$ denote as $\beta_n,j$ for $0 \leq j \leq d^n - 1$ the connected components of $f^{-n}(\beta) \cap U$.

Let us now fix $\lambda > 1$, and consider the map $g : \mathbb{D} \to \mathbb{D}$ defined as $g(re^{i\theta}) = \lambda r e^{i\theta}$. Let $\gamma'_0 = \partial \mathbb{D}$ and for each $n$ denote as $\gamma'_n := g^{-n}(\gamma'_0)$. Moreover, let $\beta' := (0, 1] \subseteq \mathbb{D}$, and for each $n$ let $\beta_{n,j}$ for $0 \leq j \leq d^n - 1$ denote the components of $g^{-n}(\beta')$. Finally, let us define the annuli $R'_n \subseteq \mathbb{D}$ bounded by the curves $\gamma'_n$.

Now, let us construct $h$ by first defining $h : R'_0 \to R_0$ a homeomorphism such that $h \circ g = f \circ h$ on $\gamma'_1$. By successive pullbacks we now extend the map to each $R'_n$ and finally we define $h(0) = z$.

**Proof of Proposition 5.1.** By Lemma 5.2 we can topologically conjugate the map $f$ on a neighborhood of each periodic critical point to a map which linearly expands radial distances. Then using the linear model we can blow up each point in the periodic critical orbit to a circle, and define the map on each circle as multiplication by the local degree. Moreover, we also need to blow up points in the backward orbit of the critical point and then we obtain a map $g : \overset{\sim}{W}_1 \to \overset{\sim}{W}_0 \subseteq \overset{\sim}{S}$, where $\overset{\sim}{S}$ is the Sierpiński carpet obtained by replacing any point in the backward orbit of a critical point by a circle. This space is still strongly path connected, so we can apply the techniques of the previous section.

**Construction of the blowup.** In order to discuss the details of this construction, let $\mathcal{C}$ denote the (finite) set of periodic critical points which lie in $X$, and let $\mathcal{E} = \bigcup_{n \geq 0} f^{-n}(\mathcal{C})$. We can define a space $\overset{\sim}{S}$ which is given by blowing up every point of $\mathcal{E}$ to a circle. Namely, for each $q \in \mathcal{E}$ let $S_q$ be a copy of $S^1$. The space $\overset{\sim}{S}$ is defined as a set as

$$\overset{\sim}{S} = (S^2 \setminus \mathcal{E}) \cup \bigcup_{q \in \mathcal{E}} S_q.$$ 

The topology on $\overset{\sim}{S}$ will be defined shortly. Note there is a natural projection map $\pi : \overset{\sim}{S} \to S^2$ which sends each $S_q$ to $q$. Let $\overset{\sim}{W}_0 := \pi^{-1}(W_0)$, $\overset{\sim}{W}_1 := \pi^{-1}(W_1)$.

**Definition of $g$.** Let us now extend $f$ to a map $g : \overset{\sim}{W}_1 \to \overset{\sim}{W}_0$. Let $p$ be a periodic critical point of period $k$. Then by Lemma 5.2 there exists a neighborhood $U_p$ of $p$ such that the map $f^k : U_p \to f^k(U_p)$ is topologically conjugate to $(r, \theta) \mapsto (\lambda r, d\theta \mod 1)$ for some $\lambda > 1$ and $|d| = \deg(f^k; p)$ is the local degree of $f^k$ at $p$. In order to define $g : \overset{\sim}{W}_1 \to \overset{\sim}{W}_0$, let us identify all $S_q$ for $q \in \mathcal{E}$ with $\mathbb{R}/\mathbb{Z}$, and define $g : S_q \to S_{f(q)}$ as $g(\theta) := d\theta \mod 1$, where $d$ is the local (signed) degree of $f$ at $q$. Finally, let us define $g := f$ on $\overset{\sim}{W}_1 \setminus \bigcup_{q \in \mathcal{E}} S_q$.

**Definition of the topology.** Now, let us define a topology on $\overset{\sim}{W}_0$ as follows. For simplicity, let us start by assuming that no non-periodic critical point maps to a periodic critical point under forward iteration. First, consider all sets $\pi^{-1}(U)$, where $U$ is open in $W_0$. Moreover, for any periodic critical point $p$, consider the homeomorphism $h : \overset{\sim}{U} \to \overset{\sim}{U} \subseteq S^2$ given by Lemma 5.2 and let $(r, \theta)$ be the polar coordinates in $\overset{\sim}{U}$. Further, let us denote as $\theta$ the angular coordinate on $S_p$. We now fix some small values $r_0, \epsilon > 0$ and define for any $\theta_0 \in [0, 2\pi)$ the set

$$V_{p, \theta_0} = \pi^{-1}(h(\{0 < r < r_0, \theta_0 - \epsilon < \theta < \theta_0 + \epsilon\})) \cup \{\theta \in S_p : \theta_0 - \epsilon < \theta < \theta_0 + \epsilon\}.$$
We now define the topology on $\tilde{W}_0$ to be the topology generated by 
$$\{\pi^{-1}(U) : U \text{ open in } W_0\} \cup \{g^{-n}(V_{p,\theta_0}) : n \geq 0, p \in C, \theta_0 \in [0, 2\pi)\}.$$  

Note that by the above construction is immediate that the projection $\pi : \tilde{W}_0 \to W_0$ is continuous. Moreover, let us check that $g$ is also continuous with respect to this topology. First, if $U = \pi^{-1}(U)$ with $U$ open in $W_0$, then $g^{-1}(U) = \pi^{-1}(f^{-1}(U))$ is open in $W_0$ since $f$ and $\pi$ are continuous. If, on the other hand, $\tilde{U} = g^{-n}(V_{p,\theta_0})$ for some $n, p, \theta_0$, then $g^{-1}(U) = g^{-n-1}(V_{p,\theta_0})$ is also open by construction, hence $g$ is continuous.

If there are non-periodic critical points $p$ which map under forward iteration to periodic critical points, then in order to make it Hausdorff we also need to add to our topology sets analogous to $V_{p,\theta_0}$ for any such point.

**Compactness.** We now show that the closure of $\tilde{W}_1$ is compact.

Given a family $W$ of open sets covering $\tilde{S}^2$, we can assume they belong to a basis of the topology. Those of the form $\pi^{-1}(U)$ for $U \in \mathcal{U}$, the family of all open sets in $S^2$, will be called of type I, those intersecting $S_q$ of type II.

Given $q \in \mathcal{E}$, by the compactness of $S_q$ we can choose a finite family $\mathcal{W}_q$ of sets of the cover of type II which cover $S_q$. Their union contains an open neighbourhood $V_q$ of $S_q$, of type I (since $\mathcal{U}$ separates points). Pick an open set $V_q'$ of type I so that $V_q \cup V_q' = \tilde{S}^2$, and replace the cover $W$ by a finer one, by intersecting all its elements with $V_q$ and $V_q'$.

Do it for all $q \in \mathcal{E}$ getting a resulting cover $\mathcal{W}'$. Consider the cover consisting of all the sets of type I in $W$ and of the sets arising by replacing each finite family $\mathcal{W}_q$ by one set $V_q'$: this is a cover of $\tilde{S}^2$ by sets of type I, so we can find a finite subcover due to the compactness of $S^2$.

Replace back all $V_q$ in this finite cover by the finite family $\mathcal{W}_q$. This gives a finite cover of $\tilde{S}^2$ refining the original cover $W$. Compactness is proved.

**Local connectivity.** To show local connectivity of $\tilde{W}_0$, we show that every point $x \in \tilde{W}_0$ has a basis of path connected neighborhoods. As usual, there are two cases.

**Case 1.** Suppose $x \notin \pi^{-1}(\mathcal{E})$. Consider an open connected set $U \subseteq W_0 \subseteq S^2$ which contains $\pi(x)$, with the euclidean topology. Then, since $\mathcal{E}$ is countable and $U$ is a connected subset of the sphere, the set $U \setminus \mathcal{E}$ is path connected.

Now, by construction the projection map $\pi$ is a homeomorphism between the set $\pi^{-1}(U) \setminus \bigcup_{q \in \mathcal{E}} S_q$ and $U \setminus \mathcal{E}$. Thus, every point of $\tilde{W}_0$ which is not in $\pi^{-1}(\mathcal{E})$ has a neighborhood basis which is path connected.

**Case 2.** If $x$ belongs to some $S_p$ for some periodic critical point $p$, then consider for any $r_0 > 0, \epsilon > 0, \theta_0 \in [0, 2\pi)$ the set 
$$\mathcal{V} := \pi^{-1}(h(\{(0 < r < r_0, |\theta - \theta_0| < \epsilon)\}) \cup \{\theta \in S_p : |\theta - \theta_0| < \epsilon\}.$$  

Then, the set $\mathcal{V} \setminus \bigcup_{q \in \mathcal{E} \setminus \{p\}} S_q$ is homeomorphic to 
$$\{(r, \theta) \in \mathbb{R}^2 : 0 \leq r < r_0, \theta_0 - \epsilon < \theta < \theta_0 + \epsilon\} \setminus E$$  

where $E$ is a countable set, hence it is also path connected.

Finally, if $x \in S_q$ for some $q \in f^{-n}(\mathcal{C})$, then one repeats the previous argument considering the connected components $\mathcal{V}'$ of $g^{-n}(\mathcal{V})$, where $\mathcal{V}$ is defined as above.

**The repellor $Y$.** Now, we denote as $Y$ the repellor for $g : \tilde{W}_1 \to \tilde{W}_0$. 

Note that by construction \( Y = \pi^{-1}(X) \), so it contains \( S_p \). Moreover, \( S_p \) is contained in the closure of the lift of \( X \setminus \{ p \} \) (if this were not the case, the map \( g \) would not be topologically exact). To prove this, note that \( X \) is an uncountable perfect set, so there is \( x \in X \setminus O(p) \) (grand orbit of \( p \)) arbitrarily close to \( p \), and consider the set of all its \( f^n \)-preimages in \( U_0(p) \). Since the repellor \( X \) is backward invariant, these preimages belong to \( X \), hence their lifts belong to \( Y \) since \( Y = \pi^{-1}(X) \). But due to degree of \( f \) at \( p \) being \( d \geq 2 \), they have arguments in the coordinates \( h \) (see Lemma 5.2) being all numbers of the form \((\theta_n + 2\pi j)/d^n\) for a constant \( 0 \leq \theta_n < 2\pi \) and integers \( j \geq 0 \) accumulating on the whole \( S_p \) as \( n \to \infty \).

**A contracting metric.** We claim that \((g, \tilde{W}_0, \tilde{W}_1)\) with an appropriate metric is a weakly coarse expanding system without periodic critical points.

Let us assume for simplicity that there is only one periodic critical point \( p \) in \( X \), that \( f(p) = p \), \( f \) is orientation preserving near \( p \), and there is no other critical point in the grand orbit of \( p \). Let \( d \) be the local degree of \( f \) at \( p \), which we assume to be positive for simplicity.

Let \( X \subset W_1 \) denote our \( f \)-invariant compact repellor. Let \( \rho_1 \) be a metric on \( X \) compatible with the spherical topology given by the metric \( \rho_e^X \) defined as the restriction to \( X \) of the spherical metric \( \rho_e \) on \( S^2 \). Due to compactness both metrics are equivalent, that is for every \( \epsilon > 0 \) there exists \( \delta \) such that \( \rho_1(x, y) < \delta \) implies \( \rho_e^X(x, y) < \epsilon \), and vice versa.

Let \( U_0 \) be our cover of a neighbourhood of \( X \) and \( U_n \) the pullback covers of a neighbourhood of \( X \) for \( f^{-n} \). By [Expansion] we have

\[
\text{mesh}_{\rho_1}(U_n \cap X) \to 0
\]

as \( n \to \infty \), hence the same holds for \( \rho_e^X \). We measure here the elements of \( U_n \) intersected with \( X \). Moreover, as \( n \to \infty \) \( \text{mesh}_{\rho_e}(U_n) \to 0 \) in the spherical metric \( \rho_e \) in \( S^2 \) without intersecting with \( X \), by Definition 2.5.

The euclidean distance in \( \overline{D} \) being the domain of the chart \( h \) in Lemma 5.2 will be denoted by \( \rho_e \). The same symbol will be used for the image of the metric on the range set \( U \). The metrics \( \rho_e^X \) and \( \rho_e \) are equivalent on \( U_0(p) \) by compactness.

By replacing \( U_0 \) with some \( U_n \) (to be our new \( U_0 \)), assume

\[
(2) \quad \text{diam}_{\rho_e}(U_n \cap h(D)) \leq \frac{1}{3}(1 - \lambda^{-2})
\]

for any \( n \geq 0 \) and any \( U_n \in U_n \), where \( \lambda > 1 \) is given by Lemma 5.2.

We can assume that \( U_0(p) = h(B(0, \lambda^{-N_0})) \) for an arbitrary \( N_0 \), be the set in \( U_0 \) covering our branching fixed point \( p \). This may be realized by first replacing \( U_0 \) by \( U_n \) for an appropriate \( n \) so that \( U_n \in U_n \), which covers \( p \), is small enough; and next, replacing that \( U_n \) by its superset \( h(B(0, \lambda^{-N_0})) \).

For any connected \( Z \subset h(D \setminus \{0\}) \) denote by \( \Delta(Z) \) the oscillation of the angle \( \theta \) on \( Z \). Choose \( \hat{\tau} > 0 \) such that if \( A \subseteq h(D) \) is a connected set with \( A \not\subseteq U_0(p) \) and \( \text{diam}_{\rho_e}A < \hat{\tau} \), then \( \Delta(A) < \pi \).

Now, by further replacing \( U_0 \) with \( U_n \) (while keeping \( U_0(p) \) as part of the cover), we can also assume

\[
(3) \quad \text{diam}_{\rho_e}(U_n) < \hat{\tau}
\]

for any \( n \geq 0 \) and any \( U_n \in U_n \) which is not a pullback of \( U_0(p) \).
The cover and Frink’s lemma. Denote $\lambda^{-N_0}$ by $r_0$. Let $\tilde{U}_0$ be the lift of $U_0$ to a neighbourhood of $Y$ after blowing up a branching fixed point $p$ for $f$ and its grand orbit, to circles. We add to $\tilde{U}_0$ two neighbourhoods of arcs in the circle $S_p = \mathbb{R}/2\pi\mathbb{Z}$, $V_0$ and $V_1$ with $0 \leq r < r_0$ and $-\pi/4 < \theta < \pi + \pi/4$ and $\pi - \pi/4 < \theta < 2\pi + \pi/4$ respectively, in the polar coordinates of Lemma 5.2. We replace by them the lift of the set $U_0(p) \subset U_0$. Denote this cover by $\tilde{W}_0$, and for each $n$ by $\tilde{W}_n$ the cover given by connected components of the sets $g^{-n}(U)$ for any $U \subset \tilde{W}_0$.

Given a set $A \subset \tilde{W}_0$, let us denote $A^{(2)} := (A \cap Y) \times (A \cap Y)$. Moreover, if $A, B \subset \tilde{W}_0$, let us denote their “composition” as

$$A^{(2)} \circ B^{(2)} := \{(x, y) \in Y \times Y : \exists z \in Y \text{ s.t. } (x, z) \in A^{(2)}, (z, y) \in B^{(2)}\}.$$

**Lemma 5.3.** The cover $\tilde{W}_0$ satisfies the hypotheses of Frink’s metrization lemma, namely:

(a) There exists $N$ such that for any $n \geq 0$

$$\tilde{W}_n^{(2)} \circ \tilde{W}_n^{(2)} \circ \tilde{W}_n^{(2)} \subset \tilde{W}_n^{(2)}.$$  

(b) If $\Delta = \{(x, x) \in Y \times Y\}$ is the diagonal, then we have the intersection

$$\bigcap_{n=0}^{\infty} \tilde{W}_n^{(2)} = \Delta.$$

**Proof.** (a) We start by proving the claim for $n = 0$; the general case will follow by taking preimages. Consider $W(i) \in \tilde{W}_N$, $i = 1, 2, 3$ such that $W(i)$ intersects $W(i + 1)$ in $Y$, for $i = 1, 2$. We prove that if $N$ is large enough then there is $W_0 \subset \tilde{W}_0$ containing all three $W(i)$.

Let $\kappa_e$ be Lebesgue number for $U_0 \cap X$ and the metric $\rho^X_e$. Choose $N$ so that $\text{diam}_e \pi(W(i)) \leq \frac{1}{4}\kappa_e$ for $i = 1, 2, 3$. Additionally we assume that $N$ is so large that $\text{diam}_e \pi(W(i)) < r'$ and $\text{diam}_e \pi(W(i) \cap U_0(p)) < r'$ for a constant $r' << r_0$.

Consider $W := \bigcup_{i=1,2,3} \pi(W(i))$. By definition of $\kappa_e$, the set $\pi(W) \cap X$ is contained in some element of $U_0$.

If $W$ lies in one $U_0 \in U_0$ different from $U_0(p)$, then we are done when we lift these objects to a neighbourhood of $Y$.

So suppose $W$ lies in $U_0(p)$. Fix $r' << r_1 << r_0$. We consider two cases.

1. $W \cap X$ is not contained in $h(B(0, r_1))$. Then since its diameter in $\rho_e$ is at most $r'$, all $W(i)$ are contained either in $V_0$ or in $V_1$.

2. $W \cap X \subset h(B(0, r_1))$. Let $k > 0$ be the largest integer such that $f^j(W) \subset U_0(p)$ for all $j = 0, \ldots, k$. By $r_1 << r_0$ the number $k$ is large (note that we do not intersect here $W$ with $X$). There are two sub-cases.

2A. If $W(i)$ is a pullback of some $U$ in $U_0 \setminus \{U_0(p)\}$, then $k < N$. Then, since $f^{k+1}(\pi(W(i)))$ belongs to $U_{N-k-1}$ and by (3), we have

$$\Delta(f^{k+1}(\pi(W(i)))) < \pi.$$  

In the case $g^k(W(i)) = V_0$ or $V_1$, we obviously also have $\Delta(g^k(W(i))) < \pi$.

2B. Otherwise, $W(i)$ is a pullback of either $V_0$ or $V_1$ for $g^{-\ell}$ with $\ell > 0$. Then $\ell > N_0$ and by (2) the set $f^{k+N_0}(W)$ lies in the annulus

$$h(\{\lambda^{-2} \leq r \leq 1\})$$
hence by (2) we obtain $\Delta f^{k_N}(W) < \pi$.

Our $k$ is large, so $\Delta(\pi(W)) \leq \pi d^{-k}$, smaller than $\pi/2$. In 2B, we have used the fact that each $\pi(W(i))$ is a pullback of $f^{k_N}(W(i)) \subset h(\mathbb{R})$ for $f^{-k_N}$.

(We would have troubles if we intersected with $X$ without invoking full pullbacks.) Hence all three $W(i) \cap X$ are entirely in $V_0$ or in $V_1$. This ends the proof of the claim for the case $n = 0$.

Finally, by taking preimages $\tilde{W}_{n+1} = g^{-n}(\tilde{W}_n)$ in $\tilde{W}_n$ we obtain Frink's assumption for all $n \geq 0$.

(b) If $x, y \in Y$ are both in $W_n \in \tilde{W}_n$ for all $n$, then their $\pi$ projections to $S^1$ are in $U_n \in \mathcal{U}_n$ for all $n$, hence $\pi(x) = \pi(y)$ by Definition 2.5.

If $x$ or $y$ do not belong to $S_q, q \in O(p)$, then $x = y$ and we are done.

Suppose $x, y \in S_p$. Then for each $n$ there is a component of $f^{-n}(V_i), i = 0$ or 1 containing both $x$ and $y$ (since we assumed that no element of the cover $\mathcal{U}_0$ other than $V_0, V_1$ contains $p$). As the length of these components in the circle shrinks to 0, this implies $x = y$.

If $x, y \in S_q$, we consider $f^n(x)$ and $f^n(y)$ for the smallest integer $n \geq 0$ such that $f^n(p) = q$. By the previous argument, $f^n(x) = f^n(y)$, so $x = y$ since we assumed there are no branching points in $O(p) \setminus \{p\}$.

Now, we can apply Frink’s lemma (Lemma 2.9) to the sets $\Omega_0 = Y \times Y$ and $\Omega_n := \tilde{W}^{(2)}_{nN}$, for $n \geq 1$, obtaining a metric $\rho'$ on $Y$, which is compatible with the topology introduced above, such that

$$\text{diam}_{\rho'}(\tilde{W}_{nN}) \leq 2^{-n}$$

for any $n \geq 0$. This shows that the metric $\rho'$ is exponentially contracting with respect to the partition $\tilde{W}_M$. This completes the proof of Proposition 5.1.

5.1. **Topologically Hölder functions.** Given a cover $\mathcal{V}$ of a topological space $X$ and a function $f : X \to \mathbb{R}$, we define the total variation of $f$ with respect to $\mathcal{V}$ as

$$\text{var}_{\mathcal{V}} f = \sup_{V \in \mathcal{V}} \sup_{x,y \in V} |f(x) - f(y)|.$$ 

Moreover, given a sequence $(\mathcal{V}_n)_{n \geq 0}$ of covers of a topological space $X$, a function $f : X \to \mathbb{R}$ is topologically Hölder with respect to $(\mathcal{V}_n)$ if there exist constants $C, \alpha > 0$ such that

$$\text{var}_{\mathcal{V}_n} f \leq C e^{-\alpha n}$$

for any $n \geq 0$.

The definition is inspired by Bowen’s definition of Hölder continuous potentials for the shift map (see [4] Theorem 1.2). Let us collect a few fundamental properties about these functions, whose proofs are straightforward.

**Lemma 5.4.** Topologically Hölder functions satisfy the following properties.

1. Let $(X, \rho)$ be a metric space with $\rho$ exponentially contracting with respect to the partition $\mathcal{U}$. Then a function $\varphi : X \to \mathbb{R}$ which is Hölder continuous with respect to $\rho$ is topologically Hölder.
(2) If \( \varphi : X \rightarrow \mathbb{R} \) is topologically Hölder with respect to \((\mathcal{U}_n)\) and \( \pi : Y \rightarrow X \) is continuous, then \( \varphi \circ \pi \) is topologically Hölder with respect to \((\mathcal{V}_n) := (\pi^{-1}(\mathcal{U}_n))\).

(3) If \( X = \Sigma \) is the full shift space and \((\mathcal{U}_n)\) are the partitions in cylinders of rank \( n \), then \( \varphi : X \rightarrow \mathbb{R} \) is topologically Hölder with respect to \((\mathcal{U}_n)\) if and only if it is Hölder continuous with the respect to the standard metric on \( \Sigma \).

**Proposition 5.5.** Let \( f : W_1 \rightarrow W_0 \) be a weakly coarse expanding system, with \( W_0 \subseteq S^2 \), and let \((X, \rho)\) be its repellor, with \( \rho \) an exponentially contracting metric. Then for any Hölder continuous potential \( \varphi : (X, \rho) \rightarrow \mathbb{R} \) there exists a unique equilibrium state \( \mu_X \) on \( X \).

**Proof.** Let \( \varphi : X \rightarrow \mathbb{R} \) be a Hölder continuous potential with respect to an exponentially contracting metric \( \rho \). By Proposition 5.1 there is a metric space \((Y, \rho')\) with a continuous map \( g : Y \rightarrow Y \) such that \( \rho' \) is exponentially contracting, and a continuous projection \( \pi : Y \rightarrow X \) such that \( \pi \circ g = f \circ \pi \). Moreover, by Proposition 2.12 there exists a coding map \( \Pi : \Sigma \rightarrow Y \) with \( \Pi \circ \sigma = g \circ \Pi \).

By Lemma 5.4(1), the map \( \varphi : X \rightarrow \mathbb{R} \) is topologically Hölder. Then, by Lemma 5.4(2), the map \( \varphi \circ \pi \circ \Pi \) is also topologically Hölder, hence by Lemma 5.4(3) the map \( \varphi \circ \pi \circ \Pi \) is also Hölder continuous with respect to the standard metric on the shift space \( \Sigma \).

Thus, by Bowen [4, Theorem 1.22], there is a unique equilibrium state \( \mu \) on \( \Sigma \) for the potential \( \varphi \circ \pi \circ \Pi \). This measure is ergodic with respect to the shift map, and positive on non-empty open sets (as a consequence of the Gibbs property [4, Theorem 1.2]).

Notice that \( \Pi_\ast(\mu) \) is 0 on \( S_p \) and its \( g^n \)-pre-images. Otherwise, by ergodicity it would be supported on \( S_p \) (if it charged other preimages of \( S_p \) it would charge preimages under ite- rates, therefore being infinite). So \( \mu \) would be 0 on the open nonempty set \( \Sigma \setminus \Pi^{-1}(S_p) \), a contradiction.

So \( \pi \circ \Pi \) preserves the entropy of \( \mu \) since \( \Pi \) does (Lemma 5.3) and \( \pi \) does as it is a measurable isomorphism \( \pi : Y \setminus \bigcup_{p \in \mathcal{E}} S_p \rightarrow X \setminus \mathcal{E} \). Moreover, if we set \( \mu_X := (\pi \circ \Pi)_\ast(\mu) \), then \( \int_X \varphi \circ \pi \circ \Pi \, d\mu = \int_X \varphi \, d\mu_X \) by definition.

Hence the projection preserves pressure; namely, by the variational principle

\[
P_{\text{top}}(f, \varphi) \geq h_{\mu_X}(f) + \int_X \varphi \, d\mu_X = h_{\mu}(\sigma) + \int_{\Sigma} \varphi \circ \pi \circ \Pi \, d\mu = P_{\text{top}}(\sigma, \varphi \circ \pi \circ \Pi).
\]

Since the opposite inequality is true in general, following from definitions, this yields the equality \( P_{\text{top}}(f, \varphi) = P_{\text{top}}(\sigma, \varphi \circ \pi \circ \Pi) \). In particular, we have proved that \( \mu_X \) is an equilibrium state.

This equilibrium state is unique, since any other equilibrium state would have a lift to \( \Sigma \) also being an equilibrium state, as the lift cannot decrease either the entropy nor the integral, and this contradicts the uniqueness on \( \Sigma \). \( \square \)

**Proof of Theorem 1.2 (1)-(5).** By Proposition 5.5 for any Hölder continuous potential \( \varphi : X \rightarrow \mathbb{R} \) there is a unique equilibrium state \( \mu_X \) on \( X \), and this equilibrium state is obtained as the pushforward of the unique equilibrium state \( \nu \) for the potential \( \varphi \circ \pi \circ \Pi \), where \( \pi : Y \rightarrow X \) is the blowdown map and \( \Pi : \Sigma \rightarrow Y \) is the coding map. Then, as in the case without periodic critical points, for any Hölder continuous observable \( \psi \) statistical laws for the sequence \((\psi \circ f^n)_{n \in \mathbb{N}} \) follow
from the well-known statistical laws for the shift map with respect to the sequence $(ψ ◦ π ◦ Π ◦ σ^n)_{n ∈ N}$.

6. The cohomological equation

Let us now see the proof of (6) and (7) in Theorems 1.1 and 1.2.

Proposition 6.1. Let ρ be the visual metric on X. If the measures µϕ, µψ coincide then there exist a Hölder continuous function $u : X → R$ and a constant $K ∈ R$ such that

$$(4) \quad ϕ − ψ = u ◦ f − u + K.$$ 

Assume that $µϕ = µψ$. We know that $µϕ = π∗ νϕ ◦ π$ and $µψ = π∗ νψ ◦ π$ where $νϕ ◦ π$, $νψ ◦ π$ are, respectively, the equilibrium states for $ϕ ◦ π$ and $ψ ◦ π$. Put $η = ϕ − ψ$. Adding constants to $ϕ, ψ$, we may assume that $∫ ϕ dµ = 0$ and $∫ ψ dµ = 0$, so that $∫ η dµ = 0$. Denote by $S_k η(x)$ the sum

$S_k η(x) = η(x) + \cdots + η(f^{k−1}(x)).$ 

We can detect equality between invariant measures by looking at periodic points:

Proposition 6.2. If for Hölder continuous $ϕ, ψ : X → R$ the equilibrium states satisfy $µϕ = µψ$ (denote them by $µ$) and if $∫ η dµ = 0$ for $η = ψ − ϕ$, then there exists $C > 0$ such that

$$(5) \quad |S_n η(x)| < C$$ 

for all $x ∈ X$ and $n ∈ N$.

Proof of Proposition 6.2. If $µϕ$ and $µψ$ coincide, then also $νϕ ◦ π$ and $νψ ◦ π$ coincide. Indeed, the proof of Lemma 4.3 shows that any lift of $µϕ$ is an equilibrium state for $ϕ ◦ π$. Hence, $νϕ ◦ π$ is an equilibrium state for $ϕ ◦ π$, but equilibrium states are unique on the shift space, hence $νψ ◦ π = νϕ ◦ π$. But then (see, e.g., [4], Theorem 1.28) there exists a constant $C$ such that for every $ω ∈ Σ$ and every $n$,

$|S_n(η ◦ π)(ω)| ≤ C.$ 

Since the coding π is onto, this also implies (5). 

Note that $π^{−1}(p)$ is not necessarily finite, so it may not be a periodic orbit of $σ$. So, we conclude the following:

Corollary 6.3. If $µϕ$, $µψ$ coincide and the integral $∫ η dµ = ∫ (ϕ − ψ) dµ = 0$ then for every periodic point $p$ with $f^k(p) = p$ we have that

$$(6) \quad S_k η(p) = 0.$$ 

Proof. Suppose $S_k η(p) ≠ 0$. Then for any $n$

$S_{nk} η(p) = n \cdot S_k η(p),$ 

so that the sequence $(S_{nk} η)_{n ≥ 0}$ is not bounded, a contradiction. 

Using the above characterization, we can solve the cohomological equation (4).
Proof of Proposition 6.1. We can assume that the integral of \( \eta = \varphi - \psi \) is equal to zero. As in the classical proof (see [4], proof of Theorem 1.28), begin with choosing a point \( x \in X \) with dense trajectory, and define the function \( u \) on the set

\[ S := \{f^n(x)\}_{n \geq 0} \]

by putting

\[ u(x) = 0, \quad u(f^n(x)) = \eta(x) + \cdots + \eta(f^{n-1}(x)) \quad \text{for} \quad n > 0. \]

Then, clearly, for every \( z \in S, z = f^n(x) \) the equation

\[ u(f(z)) - u(z) = \eta(z) = \varphi(z) - \psi(z) \]

holds.

Now, it is enough to prove that the function \( u : S \to \mathbb{R} \) is Hölder continuous, i.e., that there exist \( C > 0, \alpha > 0 \) such that

\[ |u(f^k(x)) - u(f^m(x))| < C \rho(f^m(x), f^k(x))^\alpha. \]

Then \( u \) extends to a Hölder continuous function on \( X \) and the equation (7) extends to \( X \).

To prove that \( u \) is Hölder continuous, consider two points \( z = f^k(x), y = f^m(x) \), \( k < m \). Let \( n \) be the largest integer such that \( y, z \) are in the same component of \( U_n \). Denote this component by \( U_{n} \).

Let \( l := m - k \) so \( y = f^l(z) \), and for \( r = 1, \ldots, l \) denote, by induction by \( U_{r+n} \) the connected component of \( f^{-1}(U_{r-1+n}) \) containing the point \( f^{m-r}(x) \). To conclude the proof, we need the following

Lemma 6.4. There exists a periodic point \( p \) in \( U_{l+n} \), of period \( l \), such that \( f^{l-r}(p) \in U_{r+n}, r = 0, 1, \ldots, l, \) and

\[ |S_l\eta(p) - S_l\eta(z)| < C \rho(z, f^l(z))^\alpha. \]

From Lemma 6.4 the estimate (8) follows easily. We have:

\[ u(f^m(x)) - u(f^k(x)) = \eta(f^k(x)) + \cdots + \eta(f^{m-1}(x)) = S_l\eta(z) - S_l\eta(p) \]

since \( S_l\eta(p) = 0 \) by Corollary 6.3. By Lemma 6.4

\[ |S_l\eta(p) - S_l\eta(z)| < C \rho(z, f^l(z))^\alpha, \]

so finally

\[ |u(f^m(x)) - u(f^k(x))| < C \rho(f^k(x), f^m(x))^\alpha \]

and (8) holds, completing the proof of Proposition 6.1. \( \square \)

Proof of Lemma 6.4. We use the fact that the map \( f \) uniformly expands balls with respect to the visual metric. Indeed, let us fix \( \varepsilon > 0 \), and let \( \rho \) be its corresponding visual metric. Then, by [13, Theorem 3.2.1] and [13, Proposition 3.2.2], there exists \( r_0 > 0 \) such that for any \( r < r_0 \) and for any \( \xi \in X \) one has \( f(B(\xi, re^{-r})) = B(f(\xi), r) \) (in the language of [13], \( r_0 = |F(\xi)|_s \), and that is constant for any \( \xi \in \partial_s \Gamma \), which is our repellor \( X \).

Denote \( y = f^l(z) \) and assume \( \rho(y, z) < r \) sufficiently small so that we can apply [13, Proposition 3.2.2]. Denote \( y_s = f^{m-s}(x) \). Choose consecutive preimages \( z_s \) of \( z \) such that \( \rho(y_s, z_s) \leq e^{-r} \rho(y_{s-1}, z_{s-1}) \), for \( s = 0, 1, \ldots, l = m - k \). Thus, \( \rho(z, z_l) \leq e^{-lt} \rho(y, z) \).
for any the visual metric, which means it is continuous with respect to the original metric of $\nu$. We choose $z_s \in B_s$.

Now, continue choosing preimages $(z_s)$ for $s \geq l$ close to the previously chosen $z_s$. This way, we obtain $p(z_s, z_{s+l}) \leq e^{-\epsilon \rho(z, z_l)}$ for any $s \geq 0$, hence $p := \lim_{n \to \infty} z_{nl}$ is the required periodic point.

Indeed we have, for any $h$ with $0 \leq h < l$,
\[
\rho(f^h(p), f^h(z)) = \lim_{n \to \infty} \rho(z_{nl-h}, y_{l-h}) \leq \rho(z_{l-h}, y_{l-h}) + \sum_{n=1}^{\infty} \rho(z_{nl-h}, z_{(n+1)l-h}) \leq e^{-\epsilon(l-h)} \rho(y, z) + \sum_{n=1}^{\infty} e^{-(nl-h)\epsilon} e^{-l\epsilon} \rho(y, z) = e^{-\epsilon(l-h)} \frac{1}{1 - e^{-\epsilon}} \rho(y, z)
\]

hence, using the Hölder continuity of $\eta$, there exist $K, \beta > 0$ such that
\[
|S_l(p) - S_l(z)| \leq \sum_{h=0}^{l-1} K \rho(f^h(p), f^h(z)) \leq K \sum_{h=0}^{l-1} \left( e^{-\epsilon(l-h)} \frac{1}{1 - e^{-\epsilon}} \rho(y, z) \right)^\beta \leq C \rho(y, z) \beta
\]

with $C := K(1 - e^{-\epsilon})^{-\beta}(1 - e^{-\beta\epsilon})^{-1}$. This completes the proof.

Proposition 6.1 concludes the proof of Theorem 1.1 (7) in the introduction. Indeed, given any exponentially contracting metric $\rho$ on $X$ there exists a visual metric $\rho'$ which induces the same topology, and, by [13, proof of Theorem 3.2.1, page 58], such that the identity map $(X, \rho') \to (X, \rho)$ is Lipschitz.

Then, $\varphi$ and $\psi$ are also Hölder continuous with respect to $\rho'$, and we can apply Proposition 6.1 to $\rho'$. Thus, we obtain $u$ which is Hölder continuous with respect to the visual metric, which means it is continuous with respect to the original metric $\rho$. Note, however, that we do not know anything about the modulus of continuity of $u$.

A similar argument also yields the proof of Theorem 1.1 (6). If $\sigma = 0$ and we normalize $\varphi$ so that $\int \varphi \ d\mu = 0$, then by [17, Lemma 1] we have
\[
|S_n(\varphi \circ \pi)(\omega)| < C
\]
for any $\omega \in \Sigma$ and any $n \geq 0$, hence by surjectivity also
\[
|S_n \varphi(x)| < C
\]
for any $x \in X$ and any $n \geq 0$. Now, as in the proof of Proposition 6.1 (with $\psi = 0$) there exists $u : X \to \mathbb{R}$ which is Hölder continuous with respect to the visual metric on $X$ such that
\[
\varphi = u \circ f - u.
\]

Thus, $u$ is continuous with respect to the original metric, completing the proof.

Finally, the proofs of Theorem 1.2 (6) and (7) proceed exactly in the same way, by considering a visual metric on $X$ and running the same argument as in the proof of Proposition 6.2 and Proposition 6.1 just replacing $\pi$ with $\pi \circ \Pi$ where $\Pi : \Sigma \to Y$ is the coding map, $Y$ is the repellor for the blown up space as in Section 5 and $\pi : Y \to X$ is as constructed in Proposition 5.1.
7. Appendix A. Exponential contraction

Let us now present an alternative, direct construction of an exponentially contracting metric on the blown-up repellor $Y$.

Let $(X, \rho)$ be the repellor with a metric $\rho$ which is exponentially contracting with respect to a cover $\mathcal{U}$, let $Y$ be the repellor in the blown up space, let $\pi : Y \to X$ the blowdown map and let $g : Y \to Y$ the dynamics on $Y$, so that $\pi \circ g = f \circ \pi$.

Let us assume for simplicity that there is only one periodic critical point $p$ in $X$, that $f(p) = p$, and there is no other critical point in the grand orbit of $p$. Let $d$ be the local degree of $f$ at $p$.

According to Lemma 5.2, let $U$ be a neighborhood of $p$ in $X$ which is homeomorphic to the unit disk and such that $f : U \cap f^{-1}(U) \to U$ is topologically conjugate to $h(re^{i\theta}) = \lambda re^{i\theta}$ on $U$ for some $\lambda > 1$.

In the blown up space $Y$, the disk $U$ is replaced by an annulus $A$ which is homeomorphic to $[0,1) \times \mathbb{R}/\mathbb{Z}$, and the map $g$ is topologically conjugate to $(r, \theta) \mapsto (\lambda r, d\theta)$. Let $p : A \to \mathbb{R}/\mathbb{Z}$ be the projection to the angular coordinate.

Since we know a local model for $g$ on $A$, we can define in polar coordinates for each $n \geq 0$ the annulus $A_n := \{(r, \theta) \in A : \lambda^{-n-2} < r < \lambda^{-n}\}$. Then we know that $g(A_{n+1}) = A_n$. Moreover, let $B_n := \{(r, \theta) \in A : r < \lambda^{-n}\}$.

(Note that all our metrics are only defined on $X$. When we write $\text{diam}_p(A)$, we mean $\text{diam}_p(A \cap X)$.)

By replacing $f$ with a power, we can assume that

\begin{equation}
\text{diam}_p(A_1) < \rho(\partial A_1, Y \setminus A).
\end{equation}

Now, let us define for $0 \leq j \leq d^{n+1} - 1$ the open sets

$$A_{n,j} := \{(r, \theta) \in A : \lambda^{-n-2} < r < \lambda^{-n} \text{ and } j/d^{n+1} + \theta/2\pi \in (j + 2)/d^{n+1}\}.$$

Note that for any $n > 0$ and any $j$ the map $g^n$ is a homeomorphism from $A_{n,j}$ to some $A_{n,r}$ for $0 \leq r \leq d - 1$. Moreover, let $A^* := Y \setminus B_1$, which is an open neighborhood of the complement of $A$ in $Y$.

Let $\rho$ be an exponentially contracting metric on $X$, with respect to an open cover $\mathcal{U}$. Consider the projection map $\pi : Y \to X$, and let $\rho_1(x, y) := \rho(\pi(x), \pi(y))$ the pullback of the metric $\rho$ on $Y$.

On each open set $A_{n,j}$ let us define the pseudo-metric (for $x, y \in Y$)

$$\rho_{A_{n,j}}(x, y) := \lambda^{-n} \rho_1(g^n x, g^n y)$$

with $\lambda = d$. Moreover, on $A^*$ define $\rho_{A^*}(x, y) = 0$. Let $\mathcal{A}$ be the cover which is the union of the $A_{n,j}$ and $A^*$. Now, given $x, y$, we say an admissible chain $\gamma$ between $x$ and $y$ is a sequence $(x_i)_{i=0}^k$ of points such that $x = x_0$, $y = x_k$ and for any $0 \leq i \leq k - 1$ both points $x_i$ and $x_{i+1}$ lie in the same element $A_i$ of $\mathcal{A}$. We define the length of such an admissible chain as

$$L(\gamma) := \sum_{i=0}^{k-1} \rho_{A_i}(x_i, x_{i+1}).$$

Finally, we define the pseudo-metric $\rho_{\mathcal{A}}$ on $Y \setminus S_p$ as

$$\rho_{\mathcal{A}}(x, y) := \inf_{\gamma \in \Gamma_{x,y}} L(\gamma)$$

where $\Gamma_{x,y}$ is the set of all admissible chains between $x$ and $y$. Finally, extend $\rho_{\mathcal{A}}$ to $S_p$ by taking its completion.
Properties of $\rho_A$. Since every concatenation of admissible chains is admissible, $\rho_A$ satisfies the triangle inequality.

Moreover, if $x, y \in A_{n,j}$, then by definition
\begin{equation}
\rho_A(x, y) \leq \rho_{A_{n,j}}(x, y).
\end{equation}

Finally, if $V_1 \subseteq B_2$ is connected and $V_0 = g(V_1) \subseteq B_1$, then
\begin{equation}
\text{diam}_{\rho_A}(V_1) \leq \lambda^{-1}\text{diam}_{\rho_A}(V_0).
\end{equation}

Proof. Let $x, y \in V_0$ and $x', y' \in V_1$ with $g(x') = x, g(y') = y$. Now, fix $\epsilon > 0$ and consider an admissible chain $\gamma$ given by $x = x_0, \ldots, x_k = y$ between $x$ and $y$, such that
\begin{equation}
L(\gamma) \leq \rho_A(x, y) + \epsilon.
\end{equation}

By (10), for $\epsilon$ small such a chain lies entirely in $A$. Hence, by lifting $x_i$ we find a chain $(y_i)_{i=0}^k$ with $g(y_i) = x_i$. Then each pair $y_i, y_{i+1}$ lies in a set $A_{n,j_i}$ with $g(A_{n+1,j_i}) = A_{n,j_i}$, and by definition
\begin{equation}
\rho_{n+1,j_i}(z, w) = \lambda^{-1}\rho_{n,j_i}(g(z), g(w)) \quad \forall z, w \in A_{n,j_i}
\end{equation}

\begin{equation}
\rho_A(x', y') \leq \sum_{i=0}^{k-1} \rho_{n+1,j_i}(y_i, y_{i+1}) = \lambda^{-1} \sum_{i=0}^{k-1} \rho_{n,j_i}(x_i, x_{i+1}) \leq \lambda^{-1} \rho_A(x, y) + \epsilon
\end{equation}

and the claim follows as $\epsilon \to 0$. \hfill \Box

(Note that (10) is necessary since the shortest admissible chain between $x$ and $y$ might not lie entirely in $A$, using a “shortcut” through the complement of $A$, where $\rho_A$ is zero).

Now, for any $q$ in the grand orbit of $p$, let $k$ be the smallest integer such that $f^k(q) = p$. Let $A(q)$ be the pullback of $A$ by $g^k$. Define for each $k$ the set $E_k := f^{-k}(p) \setminus f^{-k+1}(p)$, and let $q \in E_k$. If $g^k : A(q) \to A$ is injective, we define the pseudo-metric
\begin{equation}
\rho_{A(q)}(x, y) := \rho_A(g^k x, g^k y)
\end{equation}

which is supported on $A(q)$, and given by pulling back the metric $\rho_A$ on $A = A(p)$. If $g^k : A(q) \to A$ is not injective, we define
\begin{equation}
\rho_{A(q)}(x, y) := \inf \left( \sum_{i=1}^{r} \rho_A(g^k x_i, g^k x_{i+1}) \right)
\end{equation}

where the infimum is taken over all finite sets $x = x_0, x_1, \ldots, x_r = y$ of points such that $x_i$ and $x_{i+1}$ are both contained in a connected, open set over which $g^k$ is injective.

Definition of the metric $\bar{\rho}$. We finally define the metric on $Y$ to be
\begin{equation}
\bar{\rho}(x, y) := \rho_1(\pi(x), \pi(y)) + \sum_{n \geq 0 \ q \in E_n} c^n \rho_{A(q)}(x, y)
\end{equation}

where $c < 1$ is a constant which will be determined later.

Let $U_n$ be the collection of all connected components of preimages $f^{-n}(U)$ for $U \in \mathcal{U}$. Since $\rho$ is exponentially contracting, then there exist $C_1, \alpha_1 > 0$ such that
\begin{equation}
\sup_{U \in \mathcal{U}_n} \text{diam}_\rho(U) \leq C_1 e^{-\alpha_1}.
\end{equation}
By substituting $\mathcal{U}$ with $\mathcal{U}_{n_0}$ for some $n_0$, we can assume $\text{diam}_p(U) < r$ for any $U \in \mathcal{U}_n$ and any $n$.

Choose $k > 0$ such that $\text{diam}_p A_k < r$. Moreover, denote $W_p^{(1)} := N_\epsilon((r, \theta) \in A : 0 \leq r \leq \lambda^{-k}, 0 \leq \theta \leq 1/2)$ and $W_p^{(2)} := N_\epsilon((r, \theta) \in A : 0 \leq r \leq \lambda^{-k}, 1/2 \leq \theta \leq 1)$ where $N_\epsilon$ denotes the $\epsilon$-neighborhood in the metric $\rho$ and $\epsilon > 0$ is small.

Let us consider the open cover $\mathcal{V} := \{ \pi^{-1}(U) : U \in \mathcal{U} \} \cup W_p^{(1)} \cup W_p^{(2)}$. We want to prove that $\tilde{p}$ is exponentially contracting with respect to the cover $\mathcal{V}$. Let $\mathcal{V}_n$ denote the set of connected components of the preimages $g^{-n}(V)$ of elements of $\mathcal{V}$.

**Proposition 7.1.** There exist constants $C, \alpha > 0$ such that for any $V \in \mathcal{V}_n$ we have

$$\text{diam}_p(V) \leq Ce^{-n\alpha}.$$

**Proof.** The proof is given in several steps.

**Step 1.** First of all, since $\rho$ is exponentially contracting and $\mathcal{V}$ is a refinement of $\pi^{-1}(\mathcal{U})$, we obtain

$$\sup_{V \in \mathcal{V}_n} \text{diam}_p(V) \leq C_1 e^{-n\alpha_1}.$$

**Step 2.** Now, we prove by induction that there exist $C_2, \alpha_2 > 0$ such that for each $V \in \mathcal{V}_n$,

$$\text{diam}_{p_\alpha}(V) \leq C_2 e^{-n\alpha_2}$$

and $p(V \cap A_0) \neq \mathbb{R}/\mathbb{Z}$. The case $n = 0$ is trivial, as one can just choose the appropriate $C_2$ since the cover $\mathcal{V}$ is finite.

Now, let $V \in \mathcal{V}_n$ and $V' = g(V) \in \mathcal{V}_{n-1}$. There are two cases.

1. Let us suppose that $V \subseteq B_2$, so that $V' \subseteq B_1$. If $V$ satisfies equation (10), then by (12)

$$\text{diam}_{p_\alpha}(V) \leq \lambda^{-1} \text{diam}_{p_\alpha}(V') \leq \lambda^{-1} C_2 e^{-(n-1)\alpha_2} \leq C_2 e^{-n\alpha_2}$$

by taking $\alpha_2 < \log \lambda$.

2. In the other case, $V$ must be disjoint from $B_{k_0}$ with $k_0 = 3$, hence by (11) and (15), for any $k \leq k_0$ we have

$$\text{diam}_{p_\alpha}(V \cap A_{k,j}) \leq \text{diam}_{p_{\alpha,k,j}}(V \cap A_{k,j}) = \lambda^{-k} \text{diam}_{p_1} (g^k(V) \cap A_0) \leq \lambda^{-k} \text{diam}_{p_1} (g^k(V)) \leq \lambda^{-k} C_1 e^{-(n-k)\alpha_1}$$

hence, by considering all $A_{k,j}$ for $k \leq k_0$,

$$\text{diam}_{p_\alpha}(V) \leq d^{k_0} \lambda^{-k} C_1 e^{-(n-k)\alpha_1}$$

which is less than $C_2 e^{-n\alpha_2}$ if one takes $\alpha_2 < \alpha_1$.

**Step 3.** Now, let us consider all other contributions to the sum in (13), i.e. the terms relative to $p_{\alpha,q}$ for $q \neq p$. Consider $V \in \mathcal{V}_n$, and let $V_0, V_1, \ldots, V_{n-1}, V_n = V$ be a chain of open sets with $V_k \in \mathcal{V}_k$ and $V_k$ the connected component of $g^{-1}(V_{k-1})$.

Consider $q \in E_k$. Then, since the degree of $g^k$ is at most $d^k$, where $d$ is the global degree of $f$, by definition of $p_{\alpha,q}$ we have

$$\text{diam}_{p_{\alpha,q}}(V) \leq d^k \text{diam}_{p_\alpha}(V_{n-k}) \leq C_2 d^k e^{-(n-k)\alpha_2}$$
Note moreover that the set \( f^{-k}(p) \) contains at most \( d^k \) elements. Thus, we have for \( k \leq n \),

\[
\sum_{k=0}^{n} \sum_{q \in E_n} c^k \text{diam}_{\mu_A(q)}(V) \leq \sum_{k=0}^{n} c^k d^{2k} C_2 e^{-(n-k)\alpha_2} \leq C_2 e^{-n\alpha_2} \sum_{k=0}^{n} (cd^2 e^{\alpha_2})^k
\]

which is exponentially bounded if \( cd^2 e^{\alpha_2} < 1 \).

Finally, let \( M := \text{diam}_{\mu_A}(Y) \). Then

\[
\sum_{k>n} \sum_{q \in E_n} c^k \text{diam}_{\mu_A(q)}(V) \leq \sum_{k>n} c^k d^{2k} M \leq C_4 (cd^2)^n
\]

which is also exponentially bounded if \( cd^2 < 1 \).

The claim now follows by combining (15), (17) and (18), by choosing an appropriate value of \( c < 1 \). \( \square \)

8. Appendix B. Embedding into the sphere

**Proposition 8.1.** The expanding system \( g : \hat{W}_1 \to \hat{W}_0 \) in the assertion of Proposition 5.2 can be continuously embedded into the sphere \( S^2 \), where \( Y \) becomes a repellor for the extended system.

More precisely, there exists a continuous embedding \( \iota : \hat{W}_0 \to S^2 \), a continuous map \( g' : S^2 \to S^2 \) with \( g' \circ \iota = \iota \circ g \) and an open set \( W'_0 \) which contains \( \iota(\hat{W}_0) \) so that \( \iota(Y) = \{ z \in D : |z| > 1/2 \} \) onto \( U \setminus \{p\} \).

Proof. Again for simplicity, let us assume that there is only one periodic critical point, and that it is actually fixed. Let \( p \) be the fixed point for \( f \), and note that \( D(p) := S^2 \setminus \{p\} \) is homeomorphic to the unit disc \( \mathbb{D} \), and, if \( U \) is the domain of the chart constructed in Lemma 5.2, then \( U \setminus \{p\} \) is homeomorphic to an annulus. Thus, let us define a homeomorphism \( h : \mathbb{D} \to D(p) \), which we can choose so that it maps the annulus \( \{ z \in \mathbb{D} : |z| > 1/2 \} \) onto \( U \setminus \{p\} \).

Now, we replace \( p \) by a circle \( S_p \) and add an open disc \( D'(p) \), which we parameterize by \( h' : \hat{S} \setminus S_p \to D'(p) \) and we identify to \( D(p) \) by some homeomorphism \( \phi : D(p) \to D'(p) \) so that \( \phi \circ h(z) = h'(1/z) \) for any \( z \in \mathbb{D} \).

Then, we construct the space

\[
\hat{S}_p := D(p) \cup S_p \cup D'(p)
\]

and define a topology on it by the standard neighbourhoods of points in \( D(p) \) and \( D'(p) \) and by

\[
V_{r,\alpha,\beta} := \{ (r, \theta) : 1 - \epsilon < r < 1 + \epsilon, \alpha < \theta < \beta \}
\]

for any point \( (1, \theta) \in S_p \) (note that here \( S_p \) is characterized by \( r = 1 \), differently from Lemma 5.2). Then the polar coordinates from \( h, h' \) glue along \( |z| = 1 \) to yield a homeomorphism \( S^2 \to \hat{S}_p \).

We conclude that \( D(p) \cup S_p \) with the topology defined in Section 5 embeds into \( S^2 \) with an open hole (open disc) removed.

Similarly we consecutively blow up the points \( q \) in the grand orbit \( O(p) \) to open discs, each time embedding the result in \( S^2 \). We use the charts \( f^{-k} \circ h \) for \( k = k(q) \) the least integer such that \( f^k(q) = p \) and \( f^{-k} \) is an adequate branch, extended symmetrically to \( D'(q) \) in case \( f^k \) has local degree 1 at \( q \) or applying adequate roots.
Consider $S^2 \setminus O(p)$, where $O(p)$ is the grand orbit of $p$. We arrange all $q \in O(p)$ different from $p$ into a sequence $(q_j)$ and perform a sequence of embeddings into $S^2$, blowing up $q_i$’s as above (the order need not be compatible with $k(q)$; we may forget about the dynamics).

We care that the complementary $D'(q_j)$ have diameters in the spherical metric in $S^2$ quickly shrinking to 0 and that consecutive embeddings on $D(q)$ differ from the preceding ones on sets of diameters also quickly shrinking to 0, so that they form a Cauchy sequence. So the limit embedding exists and extends to the closure $S^2 \setminus \bigcup_{q \in O(p)} D'(q)$, which is a Sierpiński carpet.

Crucially, it is possible to perform consecutive perturbations of the embedding not changing the embedding close to the previous $q_i$’s, i.e. not moving already constructed $D'(q)$’s.

Notice finally that we can extend $g$ to a neighbourhood of $Y$ embedded above in $S^2$ by the formula in $D'(p)$ symmetric to the one in Lemma 5.2. We proceed similarly at $q \in f^{-k}(p)$ using the charts $f^{-k} \circ h$. So $Y$ becomes a repeller in $S^2$.

In fact the extension can be easily defined on all the $D'(q)$’s, so that $D'(p)$ is the basin of immediate attraction to an attracting fixed point and $\bigcup_{q \in O(p)} D'(q)$ the full basin of attraction.
