COMPLETIONS OF SIMPLY $sm$-FACTORIZABLE (PARA)TOPOLOGICAL GROUPS

LI-HONG XIE*

Abstract. In this paper, firstly, we give some characterizations of simply $sm$-factorizable (para)topological groups by continuous real-valued functions. It mainly shows that $G$ is a simply $sm$-factorizable (para)topological group if and only if, for each continuous function $f : G \to \mathbb{R}$, there are a sub-$sm$-(para)topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \to \mathbb{R}$ such that $f = g \circ h$. Secondly, applying those results we study the completions of simply $sm$-factorizable topological groups. We prove that the equalities $\mu G = \varpi(G) = \upsilon G$ hold for each Hausdorff simply $sm$-factorizable topological group $G$. This result gives a positive answer to a question posed by Arhangel’shiǐ and Tkachenko [2, Problem 7.6]. Finally, we discuss the realcompactification of simply $sm$-factorizable paratopological groups. We mainly, among other results, the realcompactification $\upsilon G$ of a regular simply $sm$-factorizable paratopological group admits a natural structure of paratopological group containing $G$ as a dense subgroup and $\upsilon G$ is also simply $sm$-factorizable. Some results in [12] are improved.

1. Introduction

A paratopological group $G$ is a group $G$ with a topology such that the product mapping of $G \times G$ onto $G$ associating $xy$ with arbitrary $x, y \in G$ is jointly continuous. A paratopological group $G$ is called a topological group if the inverse mapping of $G$ onto itself associating $x^{-1}$ with arbitrary $x \in G$ is continuous.

Slightly reformulating the celebrated theorem of Comfort and Ross [4, Theorem 1.2], we can say that the pseudocompact topological groups are exactly the dense $C$-embedded subgroups of compact topological groups. In particular, the Stone-Čech compactification, $\beta G$, the Hewitt-Nachbin completion, $\upsilon G$, and the Räikov completion, $\varrho G$, of a pseudocompact topological group $G$ coincide. Hence the Hewitt-Nachbin completion of the group $G$ is again a topological group containing $G$ as a dense $C$-embedded subgroup. Recently, to study connections between properties of $X$ and its dense $C$-embedded subspace $Y$ when $Y$ is homeomorphic to a topological group, Arhangel’shiǐ and Tkachenko introduced some new notions of $sm$-factorizable, densely $sm$-factorizable and simply $sm$-factorizable (para)topological groups as following:

Definition 1.1. [2, Definition 5.11] A (para)topological group $G$ will be called $sm$-factorizable if for each co-zero subset $U$ of $G$ there exists a continuous homomorphism $h$ of $G$ onto a separable metrizable (para)topological group $H$ such that the set $h(U)$ is open in $H$ and $h^{-1}(h(U)) = U$. Replacing the assumption that $h(U)$ is open by that $h(U)$ is dense in some open subset of $H$, we obtain the definition of a densely

1A set $U$ in a space $X$ is called a co-zero set if there is a continuous real-valued function $f$ on $X$ such that $U = f^{-1}(\mathbb{R} \setminus \{0\})$. 

1
sm-factorizable (para)topological group. Removing the assumption that $h(U)$ is open, we obtain the definition of a simply sm-factorizable (para)topological group.

In [2], they showed the following implications and none of these implications can be inverted (see [2, Example 5.12, Proposition 5.13]):

\[
\text{sm-factorizable} \Rightarrow \text{densely sm-factorizable} \Rightarrow \text{simply sm-factorizable}.
\]

Recall that a (para)topological group $G$ is called $R$-factorizable if for every continuous real-valued function on $G$ can be factorized through a continuous homomorphism onto a separable metrizable (para)topological group. Arhangel’shiǐ and Tkachenko obtained that a (para)topological group $G$ is $R$-factorizable if and only if $G$ is $sm$-factorizable [2, Theorem 5.9]. In view of the proof of [2, Theorem 5.9], it is worth noting that it need not any separation axiom on $G$). However, there is a Hausdorff $\omega$-narrow and simply $sm$-factorizable Abelian topological group is not $R$-factorizable [2, Corollary 5.20]. In [2, Corollary 5.24] it shows that subgroups of Lindelöf topological groups need not be simply $sm$-factorizable. Since subgroups of Lindelöf topological groups are $\omega$-narrow, $\omega$-narrow topological groups can fail to be simply $sm$-factorizable. Also, there exists a densely $sm$-factorizable topological Abelian group $G$ such that $ib(G) = 2^\omega$ [2, Example 5.12], so densely $sm$-factorizable topological groups can fail to be $\omega$-narrow. Now we summarize the relations between $R$-factorizable, $sm$-factorizable, densely $sm$-factorizable, simply $sm$-factorizable and $\omega$-narrow (para)topological groups as following:

1. $R$-factorizable $\iff$ sm-factorizable;
2. $sm$-factorizable $\Rightarrow$ densely $sm$-factorizable $\Rightarrow$ simply $sm$-factorizable;
3. regular $sm$-factorizable (para)topological groups $\Rightarrow$ (totally) $\omega$-narrow (para)topological groups;
4. regular $\omega$-narrow topological groups $\Rightarrow$ simply $sm$-factorizable topological groups;
5. regular densely $sm$-factorizable topological groups $\Rightarrow$ $\omega$-narrow topological groups.

We denote the Dieudonné completion and Hewitt-Nachbin realcompactification of a completely regular space $X$ by $\mu X$ and $\nu X$, respectively. Recall that a topological group $G$ is called a $PT$-group if the group operations in $G$ can be continuously extended to Dieudonné completion $\mu G$. Since every $R$-factorizable topological group is a $PT$-group [1, Corollary 8.3.7], Arhangel’shiǐ and Tkachenko posed the following question:

**Question 1.2.** [2, Problem 7.6] Is every simply $sm$-factorizable topological group a $PT$-group? What about densely $sm$-factorizable topological groups?

It is well known that continuous open homomorphic images of $R$-factorizable topological groups are $R$-factorizable, but unknown whether continuous homomorphic images of $R$-factorizable topological groups are $R$-factorizable [1, Open Problem 8.4.1]. A weaker version of this problem is given below:

**Question 1.3.** [2, Problem 7.8] Is every continuous homomorphic image of an $R$-factorizable topological group $G$ simply $sm$-factorizable?

It is known that continuous homomorphic images of simply $sm$-factorizable topological groups need not be simply $sm$-factorizable [2]. Thus, Arhangel’shiǐ and Tkachenko posed the following question:

**Question 1.4.** [2, Problem 7.9] Is every quotient group of a simply $sm$-factorizable topological group $G$ simply $sm$-factorizable? What if $G$ is also $\omega$-narrow?

In this paper, we give some characterizations of simply $sm$-factorizable (para)topological groups. Applying those results, we give a positive answer to Question [1,2] and partially
answer Questions 1.3 and 1.4. The paper is organized as follows. In Section 2, by continuous real-valued functions we give some characterizations of simply $sm$-factorizable (para)topological groups. We mainly establish that: (1) $G$ is a simply $sm$-factorizable (para)topological group if and only if, for each continuous function $f : G \to \mathbb{R}$, there are a sub-$sm$-(para)topological group $H$, a continuous homomorphism $h : G \to H$ and a continuous function $g : H \to \mathbb{R}$ such that $f = g \circ h$ (see Theorem 2.3); (2) an $\omega$-narrow topological group $G$ is simply $sm$-factorizable if and only if for any continuous function $f : G \to \mathbb{R}$, there is an invariant admissible subgroup $N_f$ of $G$ such that $f$ is constant on $gN_f$ for each $g \in G$ (see Theorem 2.14). Section 3 gives a positive answer to a question posed by Arhangel’shiǐ and Tkachenko [2, Problem 7.8]. It mainly shows that the equalities $\mu G = \omega(G) = G$ hold for every Hausdorff simply $sm$-factorizable topological group $G$ and, therefore, $G$ is completion friendly (see Theorem 3.2). In the last section, we mainly study the completions of simply $sm$-factorizable paratopological groups. We establish that: (1) Let $G$ be a regular simply $sm$-factorizable paratopological group; then the realcompactification $vG$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and $vG$ is also a simply $sm$-factorizable paratopological group(see Theorem 4.3); (2) let $G$ be a regular paratopological group such that the topological group $G^*$ associated to $G$ is $\omega$-narrow and simply factorizable; then the realcompactification $vG$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and the equality $vG = \mu G$ holds(see Theorem 4.2).

All spaces are not assumed to satisfy any separation axiom unless otherwise stated. A space $X$ satisfies $T_3$-separation axiom if for any point $x \in X$ and a neighborhood $O_x \subseteq X$ of $x$, there is a neighborhood $U_x \subseteq X$ of $x$ such that $\overline{U}_x \subseteq O_x$. A space $X$ is regular if $X$ is a $T_3$-space with $T_1$-separation axiom.

Let $X$ be a space with topology $\tau$. Then the family $\{\text{Int } U : U \in \tau\}$ constitutes a base for a coarser topology $\sigma$ on $X$. The space $X_{sr} = (X, \sigma)$ is called the semiregularization of $X$. One of the main results regarding the semiregularization of paratopological groups is the following theorem proved by Ravsky in [9]:

**Theorem 1.5.** Let $G$ be an arbitrary paratopological group. Then the space $G_{sr}$ carrying the same group structure is a $T_3$ paratopological group. If $G$ is Hausdorff, then $G_{sr}$ is a regular paratopological group.

2. Characterizations of simply $sm$-factorizable (para)topological groups

In this section, we shall give some characterizations of simply $sm$-factorizable (para)topological groups by continuous real-valued functions. The following concept plays an important role.

A (para)topological group $G$ is sub-$sm$-(para)topological group if $G$ has a coarser separable metrizable (para)topological group topology.

The following Proposition 2.1 is obvious

**Proposition 2.1.** Every sub-$sm$-(para)topological group is simply $sm$-factorizable.

Recall that an cardinal function is the index of narrowness of a paratopological group $G$ denoted by $ib(G)$. By definition, $ib(G)$ is the minimal cardinal $\tau \geq \omega$ such that for each open neighbourhoof $U$ of the identity in $G$ there is a set $A$ of $G$ such that $AU = UA = G$ and $|A| \leq \tau$. If $ib(G) = \omega$ for a paratopological group, then $G$ is called $\omega$-narrow. For a paratopological group $G$ with a topology $\tau$, one defines the conjugate topology $\tau^{-1}$ on $G$ by $\tau^{-1} = \{U^{-1} : U \in \tau\}$. Then $G^\prime = (G, \tau^{-1})$ is also a paratopological group, and the inversion $x \to x^{-1}$ is a homeomorphism of $G$ onto
The upper bound $\tau^* = \tau \lor \tau^{-1}$ is a topological group topology on $G$, and we call $G^* = (G, \tau^*)$ the topological group associated to $G$. A paratopological group $G$ is totally $\omega$-narrow if the topological group $G^*$ associated to $G$ is $\omega$-narrow.

Since every $\omega$-narrow topological group with $T_0$-separation (totally $\omega$-narrow regular paratopological group) of countable pseudocharacter admits a continuous one-to-one homomorphism onto a separable metrizable (para)topological group (see [1 Corollary 3.4.25 ] and [8 Lemma 1.6]). Thus we have:

**Lemma 2.2.** Every $\omega$-narrow topological group with $T_0$-separation (totally $\omega$-narrow regular paratopological group) $G$ with countable pseudocharacter is a sub-sm-(para)topological group.

Now we give a characterization of simply $sm$-factorizable (para)topological groups by continuous real-valued functions as following:

**Theorem 2.3.** Let $G$ be a (para)topological group. Then the following statements are equivalent:

1. $G$ is simply $sm$-factorizable;
2. for each continuous function $f : G \to \mathbb{R}$, there are a sub-$sm$-(para)topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \to \mathbb{R}$ such that $f = g \circ h$.
3. for each continuous function $f : G \to \mathbb{R}$, there are a regular sub-$sm$-(para)topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \to \mathbb{R}$ such that $f = g \circ h$.

**Proof.** (1) $\Rightarrow$ (2). Let $V$ be a countable base of $\mathbb{R}$ consisting co-zero sets. Then each element of the family $U = \{ U_V = f^{-1}(V) : V \in V \}$ is a co-zero set in $G$. Since $G$ is simply $sm$-factorizable, for each $U_V \in U$ there is a separable metrizable (para)topological group $H_{U_V}$ and a continuous homomorphism $h_{U_V}$ of $G$ onto $H_{U_V}$ such that $V = h_{U_V}^{-1}(h_{U_V}(U_V))$. Let $h = \Delta_{U_V \in U} h_{U_V}$ be the diagonal mapping of the family $\{ h_{U_V} : U_V \in U \}$ and $\prod_{U_V \in U} H_{U_V}$ is the topological product of the family $\{ H_{U_V} : U_V \in U \}$. Clearly, $h : G \to h(G) \subseteq \prod_{U_V \in U} H_{U_V}$ is a continuous homomorphism and $H' = h(G)$ is a separable metrizable (para)topological group. Now let $H$ have a group structure as same as $H'$ and endow $H$ with the quotient topology of the mapping $h$. Then clearly $H$ is a sub-sm-(para)topological group and $h : G \to H$ is open. Thus it is enough to show that there is a mapping $g : H \to \mathbb{R}$ such that $f = g \circ h$. This is equivalent to show that for each $g_1, g_2 \in G$, if $h(g_1) = h(g_2)$ then $f(g_1) = f(g_2)$. In fact, if $f(g_1) \neq f(g_2)$, then there is a $V \in V$ such that $f(g_2) \in V$ and $f(g_1) \notin V$. Thus $g_2 \in U_V$ and $g_1 \notin U_V$. Since $U_V = h_{U_V}^{-1}(h_{U_V}(U_V))$, we have $h^{-1}(h(g_2)) = \bigcap_{W \in V} h_{U_W}^{-1}(h_{U_W}(g_2)) \subseteq h_{U_V}^{-1}(h_{U_V}(U_V)) = U_V$. This implies $h(g_1) \neq h(g_2)$. The proof is completes.

(2) $\Rightarrow$ (1). Let $U$ be a co-zero set in $G$. Then there is a continuous function $f : G \to \mathbb{R}$ such that $U = f^{-1}(\mathbb{R} \setminus \{ 0 \})$. Thus there are a sub-$sm$-(para)topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \to \mathbb{R}$ such that $f = g \circ h$. Let $i : H \to H'$ be the identity mapping and $H'$ is a separable metrizable (para)topological group. Then one can easily show that $U = (i \circ h)^{-1}(i(h(U)))$ and $i \circ h$ is a continuous homomorphism. This shows that $G$ is simply $sm$-factorizable.

Now we shall show that (2) $\Leftrightarrow$ (3). Since every $T_0$-topological group is regular, the implications (2) $\Leftrightarrow$ (3) for topological groups are obvious.

For paratopological groups, it is enough to show that (2) $\Rightarrow$ (3). Let $G$ be a paratopological group and satisfies (2). Then $H$ is a Hausdorff paratopological group. Let $H_{sr}$ be the semiregularization of $H$. Then $H_{sr}$ is a regular paratopological group by Theorem
From the fact that let \( f : X \to Y \) be a continuous mapping of \( X \) to a regular space \( Y \); then \( f \) remains continuous as a mapping of the semiregularization \( X_{sr} \) of \( X \) to \( Y \) \[1,5\], one can easily show that \( H_{sr} \) is a sub-sm-paratopological group and \( g : H_{sr} \to \mathbb{R} \) is continuous. Clearly, \( f = g \circ (i \circ h) \), where \( i : H \to H_{sr} \) is the identity mapping. The proof is finished. \( \square \)

A space \( X \) is called weakly Lindelöf if for each open cover \( V \) of \( X \) there is a countable subfamily \( U \) of \( V \) such that \( \bigcup U \) is dense in \( X \).

**Corollary 2.4.** \[2\] Proposition 5.18] Every weakly Lindelöf topological group \( G \) is simply sm-factorizable

**Proof.** Take any continuous function \( f : G \to \mathbb{R} \). According to \[1\] Theorem 8.1.18,\( X \) can find a continuous homomorphism \( \pi : G \to H \) onto a topological group \( H \) such that the pseudocharacter of \( H \) is countable and a continuous real-valued function \( h \) on \( H \) such that \( f = h \circ \pi \). Every weakly Lindelöf topological group is \( \omega \)-narrow \[1\] Proposition 5.2.8. Hence the group \( G \) and its continuous homomorphic image \( H \) are \( \omega \)-narrow as well. According to Lemma 2.2 \( H \) is a sub-sm-topological group and therefore, \( G \) is simply sm-factorizable by Theorem 2.3. \( \square \)

Let \( \varphi_{G,2} : G \to H \) be a continuous surjective homomorphism of semitopological groups. The pair \( (H, \varphi_{G,2}) \) is called a \( T_2 \)-reflection of \( G \) if \( H \) is a Hausdorff semitopological group and for every continuous mapping \( f : G \to X \) of \( G \) to a Hausdorff space \( X \), there exists a continuous mapping \( h : H \to X \) such that \( f = h \circ \varphi_{G,2} \). We denote by \( T_2(G) \) the \( T_2 \)-reflection of \( G \), thus omitting the corresponding homomorphism \( \varphi_{G,2} \). The mapping \( \varphi_{G,2} \) is called the canonical homomorphism of \( G \) onto \( T_2(G) \).

**Proposition 2.5.** A paratopological group \( G \) is simply sm-factorizable if and only if so is the \( T_2 \)-reflection \( T_2(G) \) of \( G \).

**Proof.** Let \( G \) be simply sm-factorizable. Take any continuous function \( f : T_2(G) \to \mathbb{R} \). Then \( f \circ \varphi_{G,2} \) is continuous real-valued function on \( G \), and therefore, there are a sub-sm-paratopological group \( H \), a continuous homomorphism \( h \) of \( G \) onto \( H \) and a continuous function \( g : H \to \mathbb{R} \) such that \( f \circ \varphi_{G,2} = g \circ h \) by Theorem 2.3. Since \( H \) is a Hausdorff paratopological group, there is continuous function \( k : T_2(G) \to H \) such that \( k \circ \varphi_{G,2} = h \). Observing that \( \varphi_{G,2} \) and \( h \) are homomorphisms, so one can easily show that \( k \) is also a homomorphism. Clearly, \( k(T_2(G)) \) as a subgroup of \( H \) is a sub-sm-paratopological group and \( f = g \circ k \), so \( T_2(G) \) is simply sm-factorizable by Theorem 2.3.

Let \( T_2(G) \) be simply sm-factorizable. Take any continuous function \( f : G \to \mathbb{R} \). Since \( \mathbb{R} \) is a Hausdorff space, there is continuous function \( k : T_2(G) \to \mathbb{R} \) such that \( k \circ \varphi_{G,2} = f \). Further, by Theorem 2.3 from the fact that \( T_2(G) \) is simply sm-factorizable it follows that there are a sub-sm-paratopological group \( H \), a continuous homomorphism \( h \) of \( T_2(G) \) onto \( H \) and a continuous function \( g : H \to \mathbb{R} \) such that \( k = g \circ h \). Thus we have that

\[
    f = k \circ \varphi_{G,2} = g \circ (h \circ \varphi_{G,2}).
\]

This implies that \( G \) is simply sm-factorizable by Theorem 2.3. \( \square \)

**Proposition 2.6.** A paratopological group \( G \) is simply sm-factorizable if and only if so is the semiregularization \( G_{sr} \) of \( G \).

**Proof.** Let \( G \) be simply sm-factorizable. Take any continuous function \( f : G_{sr} \to \mathbb{R} \). Clearly, \( f \) is continuous on \( G \), and therefore, there are a regular sub-sm-paratopological
group \(H\), a continuous homomorphism \(h\) of \(G\) onto \(H\) and a continuous function \(g : H \to \mathbb{R}\) such that \(f \circ \varphi_{G,2} = g \circ h\) by Theorem 2.3. Since \(H\) is regular, by [17, Lemma 3.5] \(h\) is also continuous on \(G_{sr}\). Therefore, \(G_{sr}\) is simply sm-factorizable by Theorem 2.3.

Let \(G_{sr}\) be simply sm-factorizable. Take any continuous function \(f : G \to \mathbb{R}\). Then by [17, Lemma 3.5] \(f\) is also continuous on \(G_{sr}\), and therefore, there is a sub-sm-paratopological group \(H\), a continuous homomorphism \(h\) of \(G_{sr}\) onto \(H\) and a continuous function \(g : H \to \mathbb{R}\) such that \(f \circ \varphi_{G,2} = g \circ h\) by Theorem 2.3. Thus we have that \(f = g \circ (h \circ i)\), where \(i : G \to G_{sr}\) is the identity mapping. This implies that \(G\) is simply sm-factorizable by Theorem 2.3.

Let \(f : X \to Y\) be a continuous mapping. Then \(f\) is said to be \(d\)-open if for each open set \(O\) of \(X\) there exists an open set \(V\) of \(f(X)\) such that \(f(O)\) is a dense subset of \(V\).

Recall that a Hausdorff paratopological group \(G\) has countable Hausdorff number, i.e. \(Hs(G) \leq \omega\), if for each open neighbourhood \(U\) of the identity \(e\) in \(G\) there is a countable family \(\{U_n : n \in \omega\}\) of open neighbourhoods of \(e\) such that \(\bigcap_{n \in \omega} U_n U_n^{-1} \subseteq U\). A paratopological group \(G\) is called \(\omega\)-balanced if for each open neighbourhood \(U\) of the identity \(e\) in \(G\) there is a countable family \(\{U_n : n \in \omega\}\) of open neighbourhoods of \(e\) such that for each \(g \in G\) there is \(U_n\) satisfying \(g U_n \subseteq U g\). It is well known that every (totally) \(\omega\)-narrow (para)topological group is \(\omega\)-balanced.

**Lemma 2.7.** Let \(G\) be a Hausdorff weakly Lindelöf paratopological group with \(Hs(G) \leq \omega\). If \(G\) is \(\omega\)-balanced, then for any continuous real-valued function \(f\) on \(G\) one can find a \(d\)-open continuous homomorphism \(\pi : G \to K\) of \(G\) onto a regular paratopological group \(K\) with countable pseudocharacter and a continuous function \(h : K \to \mathbb{R}\) such that \(f = h \circ \pi\).

**Proof.** By [8, Theorem 2.4], there is an open continuous homomorphism \(\pi : G \to K\) of \(G\) onto a Hausdorff paratopological group \(K\) and a sequence \(\{V_n : n \in \omega\}\) of open neighborhoods of the identity \(e_K\) in \(K\) such that \(\{e_K\} = \bigcap_{n \in \omega} \overline{V_n}\). Let \(K_{sr}\) be the semiregularization of \(K\). Since \(K\) is a Hausdorff paratopological group, \(K_{sr}\) is a regular paratopological group by Theorem 1.5. Clearly, the sequence \(\{\overline{V_n} : n \in \omega\}\) of open neighborhoods in \(K_{sr}\) containing the identity \(e_K\) and \(\{e_K\} = \bigcap_{n \in \omega} \overline{V_n}\). This implies that \(K_{sr}\) has countable pseudocharacter. By [17, Lemma 3.5], \(h\) remains continuous on \(K_{sr}\). Since the identity mapping \(i : X \to X_{sr}\) is \(d\)-open continuous for any space \(X\) [18, Lemma 3.2], one can easily check that \(i \circ \pi : G \to K_{sr}\) is \(d\)-open continuous homomorphism. Clearly, \(f = h \circ (i \circ \pi)\). The proof is finished.

**Corollary 2.8.** [8, Theorem 2.9] Every totally \(\omega\)-narrow weakly Lindelöf paratopological group \(G\) is simply sm-factorizable.

**Proof.** Since the properties weakly Lindelöf and totally \(\omega\)-narrowness are preserved by continuous functions and continuous homomorphisms, respectively, according to Propositions 2.5 and 2.6 we can assume that \(G\) is regular. In fact, by Theorem 1.5 \((T_2(G))_{sr}\) is a regular weakly Lindelöf and totally \(\omega\)-narrow paratopological group.

Take any continuous function \(f : G \to \mathbb{R}\). Since every regular totally \(\omega\)-narrow paratopological group \(H\) is \(\omega\)-balanced [10, Proposition 3.8] and satisfies that \(Hs(H) \leq \omega\) [13, Theorem 2], by Lemma 2.7 one can find a \(d\)-open continuous homomorphism \(\pi : G \to K\) of \(G\) onto a regular paratopological group \(K\) with countable pseudocharacter.
and a continuous function $h : K \to \mathbb{R}$ such that $f = h \circ \pi$. Clearly, $K$ is totally $\omega$-narrow, so by Lemma 2.2 $K$ is a sub-sm-paratopological group and therefore $G$ is simply sm-factorizable by Theorem 2.3. \hfill $\square$

It is well known that a subgroup $H$ of an $\mathbb{R}$-factorizable topological group $G$ is $z$-embedded in $G$ if and only if $H$ is $\mathbb{R}$-factorizable. Now we shall consider the $z$-embedded subgroups of simply sm-factorizable (para)topological groups.

**Proposition 2.9.** A (para)topological group $G$ is simply $sm$-factorizable if and only if for each continuous function $f : G \to \mathbb{R}^\omega$, there are a sub-sm-(para)topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \to \mathbb{R}^\omega$ such that $f = g \circ h$.

**Proof.** According to Theorem 2.3 it is enough to prove the necessity. Take any continuous function $f : G \to \mathbb{R}^\omega$. For each $i < \omega$, denote by $p_i$ the projection of $\mathbb{R}^\omega$ to the $i$th factor. Then $p_i \circ f : G \to \mathbb{R}$ is a continuous real-valued function. Since $G$ is simply sm-factorizable, there are a sub-sm-(para)topological group $H_i$, a continuous homomorphism $h_i$ of $G$ onto $H_i$ and a continuous function $g_i : H_i \to \mathbb{R}$ such that $p_i \circ f = g_i \circ h_i$, for each $i < \omega$. Denote by $h$ the diagonal product of the homomorphisms $\{h_i : i < \omega\}$. Then $h : G \to \prod_{i<\omega} H_i$ is a continuous homomorphism and the image $K = h(G)$ is sub-sm-(para)topological group. For each $i < \omega$, let $q_i : \prod_{j<\omega} H_j \to H_i$ be the projection. Then $h_i = q_i \circ h$. Finally, denote by $g'$ the Cartesian product of the family $\{g_i : i < \omega\}$. Then $g' : \prod_{i<\omega} H_i \to \mathbb{R}^\omega$ is continuous. Now we shall prove that $f = g' \circ h$. In fact, for each $i < \omega$ and each $x \in G$,

$$p_i \circ f(x) = g_i \circ h_i(x) = g_i \circ q_i \circ h(x) = p_i \circ g' \circ h(x).$$

Hence, put $g = g'|_K$, then $f = g \circ h$. \hfill $\square$

**Theorem 2.10.** Let $G$ be a simply sm-factorizable (para)topological group. If the subgroup $H$ is $z$-embedded in $G$, then $H$ is simply sm-factorizable.

**Proof.** Take any continuous function $f : H \to \mathbb{R}$. Let $\mathcal{V}$ be a countable base of $\mathbb{R}$ consisting co-zero sets. Then each element of the family $\mathcal{U} = \{U_V = f^{-1}(V) : V \in \mathcal{V}\}$ is co-zero set in $H$. Since $H$ is $z$-embedded in $G$, for each $U \in \mathcal{U}$ there is a continuous function $g_{U_V} : G \to \mathbb{R}$ such that $g_{U_V}^{-1}(\mathbb{R} \setminus \{0\}) \cap H = U_V$. Denote by $g$ the diagonal product of the family $\{g_{U_V} : U_V \in \mathcal{U}\}$. Then $g : G \to \mathbb{R}^\mathcal{U}$ is continuous. Since $\mathcal{U}$ is countable and $G$ is simply sm-factorizable, according to Proposition 2.9 there are a sub-sm-(para)topological group $K$, a continuous homomorphism $h$ of $G$ onto $K$ and a continuous function $k : K \to \mathbb{R}^\mathcal{U}$ such that $g = k \circ h$. Now we have the following Claim.

**Claim.** $f(x_1) = f(x_2)$ whenever $h(x_1) = h(x_2)$ for each $x_1, x_2 \in H$.

If $f(x_1) \neq f(x_2)$, then there is $V \in \mathcal{V}$ such that $f(x_1) \in V$ but $f(x_2) \notin V$. Thus $x_1 \in g_{U_V}^{-1}(\mathbb{R} \setminus \{0\})$ but $x_2 \notin g_{U_V}^{-1}(\mathbb{R} \setminus \{0\})$. This implies that

$$g^{-1}(g(x_1)) = \bigcap_{W \in \mathcal{V}} g_{U_W}^{-1}(g_{U_W}(x_1)) \subseteq g_{U_V}^{-1}(g_{U_V}(x_1)) \subseteq g_{U_V}^{-1}(\mathbb{R} \setminus \{0\}).$$

Since $x_2 \notin g_{U_V}^{-1}(\mathbb{R} \setminus \{0\})$, we have that $x_2 \notin g^{-1}(g(x_1))$. This implies that $g(x_1) \neq g(x_2)$. Thus, $h(x_1) \neq h(x_2)$ by $g = k \circ h$. This is a contradiction.

According to the above Claim, there is a function $j : h(H) \to \mathbb{R}$ such that $f = j \circ h|_H$ (j need not continuous when $h(H)$ is endowed with the subspace topology of the space $K$). Now denote by $h(H)^*$ with the quotient topology on $h(H)$. Then $h|_H : H \to h(H)^*$ is open, so the function $j : h(H)^* \to \mathbb{R}$ is continuous. Clearly, $h(H)^*$ is a sub-sm-(para)topological group. This finishes the proof. \hfill $\square$
Question 2.11. Let $H$ be a subgroup of a topological group $G$. Is $H$ $z$-embedded in $G$ when $H$ and $G$ are simply sm-factorizable?

Next, we shall give a characterization of simply sm-factorizable topological group in $\omega$-narrow topological groups.

Definition 2.12. Let $G$ be a topological group and $\{U_n : n \in \omega\}$ a sequence of open symmetric neighborhoods of the identity $e$ in $G$ such that $U_{n+1}^2 \subseteq U_n$, for each $n \in \omega$. Then $N = \bigcap_{n \in \omega} U_n$ is a subgroup of $G$ which is called admissible.

Lemma 2.13. Let $f : G \rightarrow H$ be a continuous function on topological group $G$ and $H$. If $H$ has countable pseudocharacter, then $f^{-1}(e)$ is an invariant admissible subgroup of $G$, where $e$ is the identity of $H$.

Proof. Clearly, $f^{-1}(e)$ is an invariant subgroup, so it is enough to show that $f^{-1}(e)$ is admissible. Since $H$ is a topological group with countable pseudocharacter, one can easily find $\{U_n : n \in \omega\}$ a sequence of open symmetric neighborhoods of the identity $e$ in $H$ such that $U_{n+1}^2 \subseteq U_n$, for each $n \in \omega$ and $\{e\} = \bigcap_{n \in \omega} U_n$. Then $\{f^{-1}(U_n) : n \in \omega\}$ a sequence of open symmetric neighborhoods of the identity $e'$ in $G$ such that $(f^{-1}(U_{n+1}))^2 \subseteq f^{-1}(U_n)$, for each $n \in \omega$ and $f^{-1}(e) = \bigcap_{n \in \omega} f^{-1}(U_n)$. This implies that $f^{-1}(e)$ is admissible. □

Theorem 2.14. An $\omega$-narrow topological group $G$ is simply sm-factorizable if and only if for any continuous function $f : G \rightarrow \mathbb{R}$, there is an invariant admissible subgroup $N_f$ of $G$ such that $f$ is constant on $gN_f$ for each $g \in G$.

Proof. Let $G$ be a simply sm-factorizable topological group. Then, according to Theorem 2.3 there are a sub-sm-topological group $H$, a continuous homomorphism $h$ of $G$ onto $H$ and a continuous function $g : H \rightarrow \mathbb{R}$ such that $f = g \circ h$. Clearly, $H$ has countable pseudocharacter, so by Lemma 2.13 the homomorphism kernel $N_f = h^{-1}(e)$ of $h$ is an invariant admissible subgroup. Since $f = g \circ h$, one can easily show that $f$ is constant on $gN_f$ for each $g \in G$.

Let $f : G \rightarrow \mathbb{R}$ be any continuous function. Then there is an invariant admissible subgroup $N_f$ of $G$ such that $f$ is constant on $gN_f$ for each $g \in G$. Let $G/N_f$ be the quotient topological group of $G$ and $\pi : G \rightarrow G/N_f$ is the quotient homomorphism. Since $G$ is $\omega$-narrow and every continuous homomorphism image of an $\omega$-narrow topological group is $\omega$-narrow, $G/N_f$ is an $\omega$-narrow topological group with countable pseudocharacter by [16] Lemma 2.3.6. Hence, by Lemma 2.2 $G/N_f$ is a sub-sm-topological group. Observing that $f$ is constant on $gN_f$ for each $g \in G$ and $\pi : G \rightarrow G/N_f$ is open, so one can find a continuous function $k : G/N_f \rightarrow \mathbb{R}$ such that $f = k \circ \pi$. From Theorem 2.3 it follows that $G$ is simply sm-factorizable. □

Remark 2.15. In view of the proof of Theorem 2.14 we obtain that: let $f : G \rightarrow \mathbb{R}$ be a continuous function on topological group $G$; Then if $G$ is simply sm-factorizable, then there is an invariant admissible subgroup $N_f$ of $G$ such that for each $g \in G$, $f$ is constant on $gN_f$.

The following result partially answers Question 1.3.

Corollary 2.16. Let $h : G \rightarrow H$ be a continuous homomorphism of topological groups $G$ and $H$ such that for each invariant admissible subgroup $K \subseteq G$, $h(K)$ contains an invariant admissible subgroup of $H$. If $G$ is simply sm-factorizable and $H$ is $\omega$-narrow, then $H$ is simply sm-factorizable.
Proof. Let \( f : H \to \mathbb{R} \) be any continuous function. Since \( G \) is simply \( sm \)-factorizable, according to Remark 2.15 there is an invariant admissible subgroup \( N_{f_{oh}} \) of \( G \) such that for each \( g \in G \) \( f \circ h \) is constant on \( gN_{f_{oh}} \). According to assumption \( h(N_{f_{oh}}) \) contains an invariant admissible subgroup \( N_f \) of \( H \). Since \( h \) is homomorphism and for each \( g \in G \) \( f \circ h \) is constant on \( gN_{f_{oh}} \), one can easily show that for each \( k \in H \), \( f \) is constant on \( kN_f \). Observing that \( H \) is \( \omega \)-narrow, from Theorem 2.14 it follows that \( H \) is simply \( sm \)-factorizable. \( \square \)

Every neighbourhood of the identity \( e \) in a topological group contains an admissible subgroup [1, Lemma 5.5.2]. If the topological group is \( \omega \)-balance, then we have that:

**Lemma 2.17.** Every neighbourhood of the identity \( e \) in an \( \omega \)-balanced topological group \( G \) contains an invariant admissible subgroup

Proof. Since every \( \omega \)-balance topological group is a subgroup of topological product of first countable topological groups [1, Theorem 5.1.9], one can easily show that for each open neighbourhood \( U \) of \( e \) there is a continuous homomorphism \( h \) on \( G \) onto a first countable topological group \( H \) such that there is an open neighbourhood \( V \) of the identity \( e_H \) in \( H \) satisfying \( h^{-1}(e_H) \subseteq h^{-1}(V) \subseteq U \). It is obvious that \( e_H \) is an invariant admissible subgroup in \( H \), so one can easily check that \( h^{-1}(e_H) \) is an invariant admissible subgroup in \( G \) and is contained in \( U \). \( \square \)

Recall that a space \( X \) is a \( P \)-space if every \( G_{\delta} \)-set in \( X \) is open. A \( P \)-group means that a (para)topological group \( G \) is a \( P \)-space when \( G \) as a space. The following result partially answers Question 1.14.

**Corollary 2.18.** Every \( \omega \)-narrow topological group \( H \) as a quotient group of simply \( sm \)-factorizable \( P \)-group is \( \mathbb{R} \)-factorizable.

Proof. Let \( h : G \to H \) be a quotient homomorphism and \( G \) is a simply \( sm \)-factorizable \( P \)-group. Since every \( \omega \)-narrow simply \( sm \)-factorizable \( P \)-group is \( \mathbb{R} \)-factorizable [2, Proposition 5.23], it is enough to show that \( H \) is simply \( sm \)-factorizable. Since \( G \) is simply \( sm \)-factorizable, according to Remark 2.15 there is an invariant admissible subgroup \( N_{f_{oh}} \) of \( G \) such that for each \( g \in G \), \( f \circ h \) is constant on \( gN_{f_{oh}} \). Therefore, \( f \) is constant on \( xh((N_{f_{oh}})) \) for each \( x \in H \). Observing that \( G \) is a \( P \)-space and \( h \) is open (every quotient homomorphism is open), so \( h((N_{f_{oh}})) \) is an open neighbourhood of the identity in \( H \). Since \( H \) is \( \omega \)-narrow, \( H \) is \( \omega \)-balanced, and furthermore, \( h((N_{f_{oh}})) \) contains an invariant admissible subgroup \( N_f \). It is obvious that \( f \circ h \) is constant on \( xN_f \) for each \( x \in H \), so \( H \) is simply \( sm \)-factorizable by Theorem 2.14, because of the \( \omega \)-narrowness of \( H \). \( \square \)

**Question 2.19.** Let \( h : G \to H \) be a quotient homomorphism of topological groups \( G \) and \( H \). Does \( h(N) \) contain an invariant admissible subgroup of \( H \) for each invariant admissible subgroup \( N \) of \( G \)?

3. Completions of simply \( sm \)-factorizable topological groups

In this section we shall study the completions of simply \( sm \)-factorizable topological groups. We shall answer Question 1.2 positively. A is \( G_{\delta} \)-dense in a space \( X \) if every \( G_{\delta} \)-set in \( X \) intersections with \( A \). A space \( X \) is called Moscow if for each open set \( U \) of \( X \) the closure \( \overline{U} \) of \( U \) is a union of some \( G_{\delta} \)-sets in \( X \).
Proposition 3.1. Let \( H \) be a \( G_\delta \)-dense simply \( sm \)-factorizable subgroup of a topological group \( G \). Then \( H \) is \( C \)-embedded\(^2\) in \( G \).

Proof. Take any continuous function \( f : H \to \mathbb{R} \). Then according to Theorem 2.3, there are a sub-\( sm \)-topological group \( F \), a continuous homomorphism \( h : H \to F \) and a continuous function \( g : F \to \mathbb{R} \) such that \( f = g \circ h \). Let \( g_G \) and \( g_F \) be Raikov completions of topological groups \( G \) and \( F \), respectively. Since \( H \) is dense in \( g_G \), one can extend \( h \) to a continuous homomorphism \( \tilde{h} : g_G \to g_F \). Denote by \( g_\omega G \) and \( g_\omega F \) the \( G_\delta \) closures of \( G \) and \( F \) in \( g_G \) and \( g_F \), respectively. Since \( F \) is a sub-\( sm \)-topological group, \( F \) has countable pseudocharacter and hence \( F \) is a Moscow space [1, Corollary 6.4.11 (1)]. It is well known that if a Moscow space \( Y \) is \( G_\delta \)-dense subspace of a homogeneous space \( X \), then \( X \) is also a Moscow space and \( Y \) is \( C \)-embedded in \( X \) [1, Theorem 6.18]. Since \( g_\omega F \) is a topological group and \( F \) is a Moscow space, \( F \) is \( C \)-embedded in \( g_\omega F \). Hence one can extend \( g \) to a continuous function \( \tilde{g} : g_\omega F \to \mathbb{R} \). Since \( H \) is \( G_\delta \) dense in \( G \), \( \tilde{h}(G) \subseteq g_\omega F \). Thus \( \tilde{g} \circ \tilde{h} |_G \) is a continuous extension of \( f \). It proves that \( H \) is \( C \)-embedded in \( G \). \( \square \)

Below \( c(X) \) denote the cellularity of a space \( X \). Let \( g_G \) be the Raikov completion of topological groups \( G \) and denote the \( G_\delta \)-closure of \( G \) in \( g_G \) by \( g_\omega G \). A topological group is called completion friendly if \( G \) is \( C \)-embedded in \( g_\omega G \). The following result gives a positive answer to Question 1.3.

Theorem 3.2. Let \( G \) be a Hausdorff simply \( sm \)-factorizable topological group. Then the equalities \( \mu G = g_\omega G = vG \) hold and therefore, \( G \) is completion friendly.

Proof. Since \( ib(H) \leq 2^{\omega} \) holds for every simply \( sm \)-factorizable topological group \( H \) [2, Proposition 5.14], we have that \( ib(G) \leq 2^{\omega} \). From the fact that \( c(H) \leq 2^{ib(H)} \) holds for every topological group \( H \) [1, Theorem 5.4.10] it follows that \( c(G) \leq 2^{2^{\omega}} \). From [1, Theorem 6.2.2] it follows that the cardinal number \( 2^{2^{\omega}} \) is Ulam non-measurable, so the cardinality of every discrete family of open sets in \( G \) is Ulam non-measurable and hence the equality \( \mu G = vG \) holds by [1, Lemma 8.3.1].

Since \( \mu G = vG \) and \( G \) is \( C \)-embedded in the Dieudonné complete group \( g_\omega(G) \) by Proposition 3.1, we conclude that \( \mu G = g_\omega(G) = vG \). \( \square \)

Corollary 3.3. Every Hausdorff simply \( sm \)-factorizable topological group \( G \) is PT-group, i.e., the Dieudonné completion \( \mu G \) of the space \( G \) admits a natural structure of topological group containing \( G \) as a dense subgroup.

By Corollary 2.4 and Theorem 3.2 one can obtain the following result:

Corollary 3.4. [11, Proposition 2.4] Every Hausdorff weakly Lindelöf topological group satisfies the equalities \( \mu G = g_\omega(G) = vG \) and, therefore, is completion friendly.

Corollary 3.5. [2, Theorem 5.21] Let \( G \) be a simply \( sm \)-factorizable topological group, which is \( C \)-embedded in a regular Lindelöf space. Then the group \( G \) is \( \mathbb{R} \)-factorizable.

Proof. Let \( G \) be \( C \)-embedded in a regular Lindelöf space \( X \). Without loss of generality, we can assume that \( G \) is dense in \( X \). Thus, \( vG = X \). Since every \( C \)-embedded subspace of a regular Lindelöf is pseudo-\( \omega_1 \)-compact [2, Corollary 3.3], the space \( G \) is pseudo-\( \omega_1 \)-compact. It now follows from [1, Corollary 8.3.3] that \( X = vG = \mu G \), i.e. the Hewitt-Nachbin and Dieudonné completions of \( G \) coincide. By Corollary 3.3, \( X \) is a

\(^2\)A subset \( A \) in a space \( X \) is called \( C \)-embedded if for each continuous real-valued function \( f \) on \( A \) there is a extension \( F \) of \( f \) on \( X \).
homeomorphic to a Lindelöf topological group and further more, is $\mathbb{R}$-factorizable, so $G$ as a $C$-embedded subgroup of the $\mathbb{R}$-factorizable topological group $X$ is $\mathbb{R}$-factorizable [7, Theorem 3.2].

4. Completions of simply $sm$-factorizable paratopological groups

From [12] Lemmas 3 and 4 it follows the following result:

**Lemma 4.1.** Let $G$ be a paratopological group satisfying $Hs(G) \leq \omega$. Then the $G_\delta$-closure of arbitrary subgroup $H$ of $G$ is again a subgroup of $G$.

**Lemma 4.2.** The topological product $G = \prod_{\alpha \in \Lambda} H_\alpha$ of any family sub-$sm$-paratopological groups satisfies $Hs(G) \leq \omega$.

**Proof.** According to [14] Proposition 2.3 it is enough to show that any sub-$sm$-paratopological group $H$ satisfies $Hs(H) \leq \omega$. Since $H$ is a sub-$sm$-paratopological group, the identity mapping $i : H \to H'$ is continuous, where $H'$ has a group structure as same as $H$ and $H'$ is a separable metrizable paratopological group.

Let $\{U_n : n \in \omega\}$ be a local base of the identity $e$ in $H'$. Since $H'$ is metrizable, one can easily show that $\{e\} = \bigcap_{n \in \omega} U_n U_n^{-1}$. Hence, for each open neighbourhood $V$ of $e$ in $H$, we have that $\{e\} = \bigcap_{n \in \omega} U_n U_n^{-1} \subseteq V$. This implies $Hs(H) \leq \omega$. $\square$

**Theorem 4.3.** Let $G$ be a regular simply $sm$-factorizable paratopological group. Then the realcompactification $vG$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and $vG$ is also a simply $sm$-factorizable paratopological group.

**Proof.** Since every regular paratopological group is a Tychonoff space [3, Corollary 5], so is $G$. Let $\{f_\alpha : \alpha \in \Lambda\}$ be all continuous functions on $G$. Since $G$ is simply $sm$-factorizable, from Theorem 2.3 it follows that for each $\alpha \in \Lambda$ there are a regular sub-$sm$-paratopological group $H_\alpha$, a continuous homomorphism $h_\alpha$ of $G$ onto $H_\alpha$ and a continuous function $g_\alpha : H_\alpha \to \mathbb{R}$ such that $f_\alpha = g_\alpha \circ h_\alpha$. Since the family $\{f_\alpha : \alpha \in \Lambda\}$ separates point and closed in $G$, so does $\{h_\alpha : \alpha \in \Lambda\}$. Therefore, the diagonal product $h$ of the family $\{h_\alpha : \alpha \in \Lambda\}$ is a topological isomorphism of $G$ onto the subgroup $h(G) \subseteq \Pi = \prod_{\alpha \in \Lambda} H_\alpha$. Now we assume that $G$ as a subspace of $\Pi$.

By Lemma 4.2 we have that $Hs(\Pi) \leq \omega$. Therefore, the $G_\delta$-closure $H$ of $G$ in $\Pi$ is a subgroup by Lemma 4.1. We claim that the subspace $H$ of $\Pi$ is realcompact. Since for each $\alpha \in \Lambda$, $H_\alpha$ is a sub-$sm$-paratopological group, i.e., $H_\alpha$ has a coarser separable metrizable paratopological group topology, $H_\alpha$ is Dieudonné complete [1, Proposition 6.10.8] and the cardinality $|H_\alpha|$ of $H_\alpha$ satisfying $|H_\alpha| \leq 2^{2^\omega}$. Hence, the cellularity of the space $H_\alpha$ is less than $2^{2^\omega}$, which is Ulam non-measurable by [1, Theorem 6.2.2] and therefore, the space $H_\alpha$ is realcompact by [1, Proposition 6.5.18]. Therefore, the space $\Pi = \prod_{\alpha \in \Lambda} H_\alpha$ is realcompact as a product of the realcompact $H_\alpha$. It also follows from the definition of $H$ that the complement $\Pi \setminus H$ is the union of family of $G_\delta$-sets in $\Pi$. Further, every $G_\delta$-set in $\Pi$ is the union of a family of zero-sets in $\Pi$, and the complement $\Pi \setminus Z$ is realcompact, for each zero-set $Z$ in $\Pi$ (see [3, Corollary 3.11.8]). By [3, Corollary 3.11.7], the intersection of a family of realcompact subspaces of a space is realcompact. Therefore, $H$ is realcompact as the intersection of a family of cozero-sets in $\Pi$. Now we shall show that $G$ is $C$-embedded in $H$, which implies that $vG = H$ [6, Theorem 8.6].

In fact, for each continuous real-valued function $f$ on $G$, without loss of generality, we assume that $f = f_\alpha$ for some $\alpha \in \Lambda$. Then $g_\alpha \circ \pi_\alpha|_H : H \to \mathbb{R}$ is the extension of $f_\alpha$, where $\pi_\alpha|_H$ is the restriction on $H$ of the $\alpha$th projection $\pi_\alpha : \Pi = \prod_{\alpha \in \Lambda} H_\alpha \to H_\alpha$. In
Corollary 4.4. Let $G$ be a regular simply $sm$-factorizable paratopological group with the cellularity $G$ is Ulam non-measurable. Then the equality $\mu G = vG$ holds. Furthermore, the Dieudonné completion $\mu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and $\mu G$ is also a simply $sm$-factorizable.

Proof. Since the cardinality of every discrete family of open sets in $G$ is Ulam non-measurable and hence the equality $\mu G = vG$ holds by [11 Lemma 8.3.1]. Therefore, the statement directly follows from Theorem 4.3.

Corollary 4.5. Let $G$ be a regular totally $\omega$-narrow and weakly Lindelöf paratopological group. Then the equality $\mu G = vG$ holds. Furthermore, the Dieudonné completion $\mu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and $\mu G$ is also a simply $sm$-factorizable.

Proof. According to Corollary 4.4 it is enough to show that $G$ is a simply $sm$-factorizable paratopological group with the cellularity of $G$ is Ulam non-measurable. Since $G$ is totally $\omega$-narrow and weakly Lindelöf, from Corollary 2.8 it follows that $G$ is simply $sm$-factorizable. Since, by [11 Theorem 5.4.10], the $c(H) \leq 2^\omega$ holds for every $\omega$-narrow topological group $H$ and $G^*$ associated to $G$ is $\omega$-narrow, $G$ as a continuous homomorphism image of $G^*$ satisfies that the cellularity of $G$ is less or equal $2^\omega$, which is Ulam non-measurable. The proof is finished.

Corollary 4.6. Let $G$ be a simply $sm$-factorizable paratopological group, which is $C$-embedded in a regular Lindelöf-$\Sigma$ space. Then the group $G$ is $\mathbb{R}$-factorizable.

Proof. Let $G$ be $C$-embedded in a regular Lindelöf-$\Sigma$ space $X$. Without loss of generality, we can assume that $G$ is dense in $X$. Thus, $vG = X$. Since every $C$-embedded subspace of a regular Lindelöf is pseudo-$\omega_1$-compact [2, Corollary 3.3], the space $G$ is pseudo-$\omega_1$-compact, i.e., the cellularity $G$ is Ulam non-measurable. It now follows from [1, Corollary 8.3.3] that $X = vG = \mu G$, i.e., the Hewitt-Nachbin and Dieudonné completions of $G$ coincide. By Corollary 4.4 $X$ is homeomorphic to a paratopological group containing $G$ as a dense paratopological subgroup and furthermore, is $\mathbb{R}$-factorizable [17 Corollary 4.14], so $G$ as a $C$-embedded subgroup of the $\mathbb{R}$-factorizable paratopological group $X$ is $\mathbb{R}$-factorizable [19 Theorem 3.2].

Remark 4.7. In Corollary 4.6 the condition ‘Lindelöf-$\Sigma$’ cannot be weakened to Lindelöf. In fact one can easily obtain that the Sorgenfrey line $\mathbb{S}$ is a simply $sm$-factorizable paratopological group by Theorem 2.3 but not $\mathbb{R}$-factorizable [17 Remark 3.22].

Corollary 4.8. [12, Theorem 1] Let $G$ be an $\mathbb{R}$-factorizable regular paratopological group. Then the Dieudonné completion $\mu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup.
Proof. Since every regular paratopological group is a Tychonoff space [3, Corollary 5], and every Tychonoff \( \mathbb{R} \)-factorizable paratopological group is totally \( \omega \)-narrow, i.e. the topological group \( G^* \) associated to \( G \) is \( \omega \)-narrow, the \( c(G^*) \leq 2\omega \) [1, Theorem 5.4.10] and furthermore, \( G \) as a continuous image of satisfies that \( c(G) \leq c(G^*) \leq 2\omega \). Therefore, the statement directly follows from Corollary [4.4] since \( G \) is \( \mathbb{R} \)-factorizable and furthermore, \( G \) is simply \( sm \)-factorizable.

Proposition 4.9. Let \( G \) be a regular paratopological group. If the topological group \( G^* \) associated to \( G \) is simply factorizable and \( \omega \)-narrow, then so is \( G \).

Proof. Let \( \mathcal{N} = \{ N_i : i \in I \} \) be all invariant subgroup \( N \) of \( G \) such that the quotient group \( G/N \) is a sub-sm-paratopological group.

Claim 1. The family \( \mathcal{N} \) is closed under countable intersections.

Take any countable subfamily \( \mathcal{N} = \{ N_i_k : i_k \in I, k \in \omega \} \subseteq \mathcal{N} \). Let \( \varphi_{N_i_k} : G \to G/N_i_k \) be the natural quotient homomorphism. Then the diagonal product \( \psi : G \to \prod_{N_i_k \in \mathcal{N}} G/N_i_k \) of the quotient homomorphisms \( \{ \varphi_{N_i_k} : i_k \in I, k \in \omega \} \) is a continuous homomorphism. Since every \( G/N_i_k \) is a sub-sm-paratopological group, so is the countable product \( \prod_{N_i_k \in \mathcal{N}} G/N_i_k \). Further, \( \psi(G) \) as a subgroup of \( \prod_{N_i_k \in \mathcal{N}} G/N_i_k \) is also a sub-sm-paratopological group. Clearly, the homomorphism kernel \( \ker \psi \) of \( \psi \) satisfying \( \ker \psi = \bigcap \mathcal{N} \). Then one can easily show that the quotient group \( G/ \ker \psi \) is a sub-sm-paratopological group and this implies that \( \bigcap \mathcal{N} = \ker \psi \in \mathcal{N} \). The proof of Claim 1 is finished.

Claim 2. The diagonal product \( \varphi : G \to \varphi(G) \subseteq \Pi = \prod_{N_i \in \mathcal{N}} G/N_i \) of the family \( \{ \varphi_{N_i} : N_i \in \mathcal{N} \} \) is a topological isomorphism, where each \( \varphi_{N_i} : G \to G/N_i \) be the natural quotient homomorphism.

Since \( G \) is regular totally \( \omega \)-narrow, \( G \) is \( \omega \)-balance [10, Proposition 3.8] and satisfies that \( \text{Irr}(G) \leq \omega \) [13, Theorem 2]. Then from [14, Theorem 3.6, Lemma 3.7], it follows that: for each open neighbourhood \( U \) of the identity \( e \) in \( G \), there is a continuous homomorphism \( h : G \to H \) onto a separable metrizable paratopological group \( H \) and an open neighbourhood \( V \) of the identity in \( H \) such that \( h^{-1}(V) \subseteq U \). Hence, one can easily show that the homomorphism kernel \( \ker h \) of \( h \) belongs to \( \mathcal{N} \). This implies that the family mapping \( \{ \varphi_{N_i} : N_i \in \mathcal{N} \} \) can separate the point and closed set in \( G \), and therefore, the diagonal product \( \varphi \) is a topological isomorphism. The proof of Claim 2 is completes.

Claim 3. Every \( G^\delta \)-set \( P \) in \( G^* \) with \( e \in P \) contains \( N_i \) for some \( i \in I \).

According to Claim 2, we can identify \( G \) with the subgroup \( \varphi(G) \) of \( \Pi \). Then item (a) of [12, Lemma 4] implies that \( G^* \) is a subgroup of topological group \( \Pi^* \) associated to \( \Pi \). Notice that \( \Pi^* \cong \prod_{N_i \in \mathcal{N}} (G/N_i)^* \) by item (c) of [12, Lemma 4], where \( (G/N_i)^* \) is the topological group associated to \( G/N_i \) for each \( i \in I \). Since \( P \) is a \( G^\delta \)-set in \( G^* \) with \( e \in P \), one can find a countable set \( J \) of \( I \) such that \( \bigcap_{j \in J} \pi_j(V_j) \cap G^* \subseteq P \), where \( \pi_j \) is the projection of the \( j \)th factor of \( \Pi^* \) and \( V_j \) is an open neighbourhood of the identity \( e_j \) of \( (G/N_j)^* \) for each \( j \in J \). This implies that \( \bigcap_{j \in J} \pi_j(e_j) \cap G^* \subseteq P \). Notice that the group structure of \( G \) is as same as \( G^* \), so we have that \( \bigcap_{j \in J} \pi_j(e_j) \cap G \subseteq P \). Put \( N = \bigcap_{j \in J} N_j \). Since \( J \) is countable, it follows from Claim 1 that \( N = N_i \) for some \( i \in I \). It also clear that \( N = \bigcap_{j \in J} \pi_j(e_j) \cap G \subseteq P \), whence Claim 3 follows.

Take any continuous function \( f : G \to \mathbb{R} \). Then \( f \) remains continuous on \( G^* \). Since \( G^* \) is simply \( sm \)-factorizable, there are a sub-sm-paratopological group \( H \), a continuous homomorphism \( h \) of \( G^* \) onto \( H \) and a continuous function \( g : H \to \mathbb{R} \) such that \( f = g \circ h \) by item (2) of Theorem 2.3. Since \( H \) is a sub-sm-paratopological group, the identity \( e_H \) of \( H \) is a \( G^\delta \)-set in \( H \). Therefore, the homomorphism kernel \( h^{-1}(e_H) \) is \( G^\delta \)-set in \( G^* \).
Then from Claim 3 it follows that there is an $N_i \in \mathcal{N}$ such that $N_i \subseteq h^{-1}(e_H)$. Since $f$ is constant on $gh^{-1}(e_H)$ for each $g \in G^*$ and the group structure of $G$ is as same as $G^*$, $f$ is constant on $gN_i$ for each $g \in G$. Therefore, there is a mapping $l : G/N_i \to \mathbb{R}$ such that $f = l \circ \varphi_{N_i}$, where $G/N_i$ is endowed with the quotient topology and $\varphi_{N_i}$ is the natural quotient homomorphism form $G$ onto $G/N_i$. Since $\varphi_{N_i}$ is continuous and open, $l$ is continuous. Clearly, $G/N_i$ is a sub-sm-paratopological group, $G$ is simply factorizable by Theorem 2.3.

\[\square\]

Question 4.10. Can the condition ‘$\omega$-narrow’ be dropped in Proposition 4.9?

Since every Hausdorff $\mathbb{R}$-factorizable topological group is $\omega$-narrow and simply $sm$-factorizable, from Proposition 4.9 it follows that:

Corollary 4.11. If the topological group $G^*$ associated to a regular paratopological group $G$ is $\mathbb{R}$-factorizable, then $G$ is simply $sm$-factorizable.

Theorem 4.12. Let $G$ be a regular paratopological group such that the topological group $G^*$ associated to $G$ is $\omega$-narrow and simply factorizable. Then the realcompactification $\nu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and the equality $\nu G = \mu G$ holds.

Proof. According to Proposition 4.9 $G$ is a regular simply $sm$-factorizable paratopological group. From the fact that $c(H) \leq 2^{\omega(H)}$ holds for every topological group $H$ [2, Theorem 5.4.10] it follows that $c(G) \leq 2^{\omega}$. From [11 Theorem 6.2.2] it follows that the cardinal number $2^{\omega}$ is Ulam non-measurable. Therefore, from Corollary 4.1 it follows that the realcompactification $\nu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and the equality $\nu G = \mu G$ holds. \[\square\]

It is well known that every Hausdorff $\mathbb{R}$-factorizable topological group is $\omega$-narrow and simply $sm$-factorizable [see [11 Proposition 8.1.3] and [2, Theorem 5.9]). Thus Corollary 4.13 follows from Theorem 4.12.

Corollary 4.13. [12 Theorem 2] Let $G$ be a regular paratopological group such that the topological group $G^*$ associated to $G$ is $\mathbb{R}$-factorizable. Then the realcompactification $\nu G$ of the space $G$ admits a natural structure of paratopological group containing $G$ as a dense subgroup and the equality $\nu G = \mu G$ holds.

Acknowledgement: This paper is dedicated to my Ph.D. adviser Professor Lin Shou’s 60-th birthday. He is a distinguished teacher and is one of the founders of the Chinese school of Generalized Metric Spaces Theory. His deep mathematical insight and his warm and sincere personality greatly influenced us. Also, we wish to thank Professor Mikhail Tkachenko, who leads us to study $\mathbb{R}$-factorizable (para)topological groups.
