FLATS, SPIKES AND CREVICES: THE EVOLVING SHAPE OF THE INHOMOGENEOUS CORNER GROWTH MODEL

ELNUR EMRAH, CHRISTOPHER JANJIGIAN, AND TIMO SEPPÄLÄINEN

Abstract. We study the macroscopic evolution of the growing cluster in the exactly solvable corner growth model with independent exponentially distributed waiting times. The rates of the exponentials are given by an additively separable function of the site coordinates. When computing the growth process (last-passage times) at each site, the horizontal and vertical additive components of the rates are allowed to also vary respectively with the column and row number of that site. This setting includes several models of interest from the literature as special cases. Our main result provides simple explicit variational formulas for the a.s. first-order asymptotics of the growth process under a decay condition on the rates. Formulas of similar flavor were conjectured in [51], which we also establish. Subject to further mild conditions, we prove the existence of the limit shape and describe it explicitly. We observe that the boundary of the limit shape can develop flat segments adjacent to the axes and spikes along the axes. Furthermore, we record the formation of persistent macroscopic spikes and crevices in the cluster that are nonetheless not visible in the limit shape. As an application of the results for the growth process, we compute the flux function and limiting particle profile for the TASEP with the step initial condition and disorder in the jump rates of particles and holes. Our methodology is based on concentration bounds and estimating the boundary exit probabilities of the geodesics in the increment-stationary version of the model, with the only input from integrable probability being the distributional invariance of the last-passage times under permutations of columns and rows.

1. Introduction

1.1. Some background and the contribution of the present work. Stochastic growth far from equilibrium arises in models of diverse phenomena such as propagation of burning fronts, spread of infections, colonial growth of bacteria, liquid penetration into porous media and vehicular traffic flow [34, 45]. In these models, a growth process describes the time-evolution of a randomly growing cluster that represents, for example, a tissue of infected cells. Mathematical study of growth processes dates at least back to Eden's model [23]. A fundamental type of result in this subject is that the cluster associated with a given growth process acquires a deterministic limit shape in a suitable scaling limit, analogously to the classical law of large numbers. Understanding the geometric properties of limit shapes has been one of the main research themes, for example, in percolation theory since at least the seminal work of D. Richardson [52]. See this brief introduction [19] and survey articles [3, 18, 48].

Of particular interest is to determine whether and in what manner local inhomogeneities in a growth model are manifested in the limit shape. This line of inquiry was pursued in
both mathematics and physics literature with some early work in the 1990s, particularly on disordered exclusion and related growth processes \[11, 35, 36, 41, 44, 56, 60, 63, 64\]. It has now been rigorously observed in various settings that suitably introduced inhomogeneity into the parameters of a growth model can create new geometric features in the limit shape including flat segments \[4, 7, 25, 29, 32, 33, 43, 60, 61\], spikes \[9\], corners \[29\] and pyramids \[1\]. Such features are often an indication of a phase transition at the level of fluctuations of the growth process as observed, for example, in \[5, 7, 10, 32, 33, 43\].

Significant research has been devoted particularly to the corner growth model (CGM), which enjoys rich connections to a variety of other models including last-passage percolation (LPP), random polymers, queueing systems, interacting particle systems, Young tableaux and determinantal point processes. The intense activity surrounding this model in the past three decades has been driven in part by rigorous results in connection with the Kardar-Parisi-Zhang universality \[42\]. Reviews of the CGM from many perspectives are available, for example, in \[12, 16, 40, 58\]. Subsection 1.2 will briefly recall the model and the notion of limit shape therein.

The present paper revisits the exactly solvable, inhomogeneous CGM from \[13, 39\] that has independent and exponentially distributed waiting times with possibly distinct rates given by an additively separable function of the site coordinates. Hence, the inhomogeneity can be represented in terms of real parameters (namely the additive components of the rates) attached to the columns and rows. The model arises naturally in several contexts, including from the totally asymmetric simple exclusion process (TASEP) with the step initial condition and particlewise and holewise disorder. As elaborated on in Subsection 1.4, we generalize the model slightly by computing the growth process at each site from a distinct collection of waiting times. With this enhancement, the model in particular unifies the following somewhat disparate settings from the literature.

(i) Random rates from some work in the 1990s on TASEP with the step initial condition and particlewise disorder \[11, 44, 60\] and more recently in \[25, 26\].

(ii) Macroscopically inhomogeneous rates as in \[14, 29\] in the special case that the speed function is additively separable. A discrete version of such a model (with geometrically distributed waiting times) appeared recently in \[33\].

(iii) Fixed defective rates on the south or west boundaries as in \[6\], on a thickened west boundary (a few columns) as in \[5\] and, more generally, on thickened south and west boundaries (a few columns and rows) as in \[10\].

(iv) Suitably rescaled defective rates in a few columns and rows considered in \[10, 13\]. The discrete version of the model in \[10\] appeared later in \[17\].

(v) Defective rates near north or east boundaries used in \[59\].

(vi) Growing rates as in \[39\].

Precise connections to the above models are made in Subsection 3.9.

When the rates are identical, a well-known result of H. Rost \[54\] identifies the limit shape as a certain explicit parabolic region (recalled in \[1.6\]). In this homogeneous case, the limit shape completely governs the growth of the cluster to the leading order in time. The purpose of this work is to study the macroscopic evolution of the cluster in presence of inhomogeneity.

We find that the inhomogeneity can influence the cluster qualitatively in two aspects, and the limit shape can fail to capture the full picture of growth at the macroscopic scale. We focus on the columns in the following discussion as analogous remarks hold also for the rows. First, when the smaller column parameters are sufficiently rare, the cluster evolves into an
approximately flat shape near the vertical axis. This behavior creates a flat segment in the boundary of the limit shape adjacent to the vertical axis, and has been observed earlier in [25, 60]. Second, the cluster can grow at distinct speeds across columns leading to persistent macroscopic variations in the height profile of the cluster. As a result, after a while the cluster visually resembles a structure with large crevices and spikes that do not disappear over time. Out of these features, the limit shape only remembers the maximal size of the spikes, and registers this information as a spike (line segment) along the vertical axis emanating from the vertical intercept of its boundary inside the quadrant. A systematic treatment of the formation of spikes and crevices in the CGM seems to be new.

In this paper, we obtain a complete and exact description for the macroscopic evolution of the cluster and elucidate the growth behavior outlined above. Our main result describes the first-order asymptotics of the growth process in terms of an explicit variational formula under a mild condition ensuring at least linear growth. With further reasonable assumptions, the formula leads to an exact description of the limit shape. In this model, the limit shape still controls the macroscopic growth asymptotically at sites increasingly away from both axes. The formula also yields the leading order growth of the cluster along a fixed set of columns or rows. This information is, in general, not encoded in the limit shape.

As an application of the results for the CGM, we also describe the macroscopic evolution of the particles in the associated disordered TASEP. In particular, we derive the flux function and limiting particle profile from the limit shape. Subsection 1.5 provides a more detailed account of our results.

It has come to our attention that a statement somewhat similar to our main result was conjectured by E. Rains in [51, Conjecture 5.2], which also contains analogous claims for various other integrable percolation models. Although peripheral to the present work, we reformulate and prove the part of the conjecture pertinent to our setting to highlight the connection.

A sequel [27] to the present paper will study geometric features such as Busemann limits, geodesics, and the competition interface in the inhomogeneous LPP model, and also apply these results to an inhomogeneous tandem of queues.

There is also some technical novelty in the treatment of the model. In the present setting, the existence of the limit shape does not follow from standard subadditive arguments and takes up a significant part of the paper to establish. We attain this through concentration bounds for the growth process, development of which utilizes explicit increment-stationary versions of the process. The arguments can likely be adapted to prove similar results for the geometric counterpart of the current model.

As proved in [43], the CGM studied here is connected to Schur measures [50] and thereby possesses a determinantal structure. In particular, the one-point distribution of the growth process can be written in terms of a Fredholm determinant with an explicit kernel. We take advantage of one feature that follows from this representation, namely, the distributional invariance of the growth process under permutations of columns and rows (stated in Lemma 4.4). Apart from this point, our methodology (described in Section 1.6) does not rely on integrable probability.

1.2. Limit shape in the CGM. The general two-dimensional CGM consists of a given collection of nonnegative real-valued random waiting times \( \omega(i, j) : i, j \in \mathbb{Z}_{>0} \) and a corner growth process \( \{G(i, j) : i, j \in \mathbb{Z}_{>0}\} \) defined through the recursion

\[
G(i, j) = \max\{1_{i>1}G(i-1, j) + 1_{j>1}G(i, j-1)\} + \omega(i, j) \quad \text{for } i, j \in \mathbb{Z}_{>0}.
\]
This process represents a randomly growing cluster in the first quadrant of the plane, given at time \( t \in \mathbb{R}_{\geq 0} \) by
\[
R(t) = \{(x, y) \in \mathbb{R}^2_{\geq 0} : G([x], [y]) \leq t\}.
\]
In other words, the unit square \((i-1, i] \times (j-1, j]\) is added to the cluster at time \( t = G(i, j) \) for \( i, j \in \mathbb{Z}_{> 0} \). The closure of (1.2) in \( \mathbb{R}^2_{\geq 0} \) is given by
\[
\overline{R(t)} = \{(x, y) \in \mathbb{R}^2_{\geq 0} : G([x] + 1_{(x=0)}, [y] + 1_{(y=0)}) \leq t\} \quad \text{for} \quad t \in \mathbb{R}_{\geq 0}.
\]
The limit shape of the cluster is defined as the limiting set
\[
\mathcal{R} = \lim_{t \to \infty} t^{-1}\overline{R(t)},
\]
with respect to the Hausdorff metric (on nonempty, closed, bounded subsets of \( \mathbb{R}^2_{\geq 0} \), see Appendix A.4) provided that the limit exists.

The first instance of the CGM in the literature had i.i.d. exponential waiting times and appeared in connection with a fundamental interacting particle system, TASEP, in a pioneering work [51] of H. Rost. Recall that the standard TASEP [62] is a continuous-time Markov process on particle configurations on \( \mathbb{Z} \) that permit at most one particle per site (exclusion), and evolves as follows: Each particle independently attempts to jump at a common rate \( c > 0 \) to the next site to its right. Per the exclusion rule, the jump is allowed only if the next site is vacant. The dynamics is unambiguously defined since simultaneous jump attempts a.s. never happen. To connect with the CGM, start the TASEP from the step initial condition meaning that the particles occupy the sites of \( \mathbb{Z}_{\leq 0} \) at time zero. Label the particles with positive integers from right to left such that particle \( j \) is initially at site \( -j + 1 \) for \( j \in \mathbb{Z}_{> 0} \). Let \( T(i, j) \) denote the time of the \( i \)th jump of particle \( j \), and write
\[
\omega'(i, j) = T(i, j) - \max\{1_{(i>1)}T(i-1, j), 1_{(j>1)}T(i, j-1)\} \quad \text{for} \quad i, j \in \mathbb{Z}_{> 0}.
\]
By the strong Markov property, \( \omega'(i, j) \sim \text{Exp}(c) \) and are jointly independent for \( i, j \in \mathbb{Z}_{> 0} \). Then, since the recursions in (1.1) and (1.5) are the same, the T-process is equal in distribution to the G-process defined with i.i.d. Exp(\( c \))-distributed waiting times.

A celebrated result in [54], based on the above correspondence with TASEP, identifies the limit shape of the CGM with i.i.d. \( \text{Exp}(c) \) waiting times as the parabolic region given by
\[
\mathcal{R} = \{(x, y) \in \mathbb{R}^2_{\geq 0} : \sqrt{x} + \sqrt{y} \leq \sqrt{c}\}.
\]
If the waiting times are i.i.d. and geometrically distributed, \( \mathcal{R} \) is also explicitly known as a certain elliptic region [15, 37, 57]. More generally, for i.i.d. waiting times subject to mild conditions, the limit in (1.4) still exists and is a concave region with the boundary inside \( \mathbb{R}^2_{\geq 0} \) extending continuously to the axes [47]. Furthermore, the limit can be characterized in terms of variational formulas over certain infinite dimensional spaces [31]. However, these formulas presently do not yield detailed geometric information about the limit shape except in the above exactly solvable cases. For example, it is unclear precisely when the limit shape has flat segments in the boundary. If the waiting times attain their maxima frequently enough to create an infinite cluster of oriented percolation, the boundary of the limit shape becomes flat in a cone symmetric around the diagonal of the plane [31]. In the context of undirected

---

1The definition of the cluster in some literature can differ slightly from (1.2). For example in [37], the growth process lives on \( \mathbb{Z}^2_{\geq 0} \) and the cluster at a given time is defined as a closed subset of \( \mathbb{R}^2_{\geq 0} \) with the floor function instead of the ceiling function. These variations do not have any impact on the limit shape.
first-passage percolation, this phenomenon goes back to the classic paper of R. Durrett and T. Liggett [22], and was subsequently studied in [2] [46]. It is not known whether this is the only mechanism to produce flat segments with i.i.d. waiting times. Due to the limited knowledge in the general i.i.d. case, a natural starting point as a homogeneous setting for our study into the effects of inhomogeneity is the i.i.d. exponential model.

1.3. Simulations of flat segments, spikes and crevices. Varying the rates of the exponential waiting times can create flat spots, spikes and crevices in the evolving shape of the cluster. Let us illustrate these features through some simulations of the CGM deferring their rigorous discussion to Subsections 3.6 and 3.7.

The simulations below share a common sample of independent $\text{Exp}(1)$-distributed waiting times $\{\omega(i, j) : i, j \in [N]\}$ where $N = 4000$. Each simulation constructs waiting times with specific rates $\lambda_{m,n}(i,j) > 0$ by setting

$$
(1.7) \quad \omega_{m,n}(i,j) = \frac{\omega(i,j)}{\lambda_{m,n}(i,j)} \sim \text{Exp}(\lambda_{m,n}(i,j)) \quad \text{for } m,n \in [N], i \in [m], j \in [n].
$$

The value $G(m, n)$ of the growth process at each site $(m, n) \in [N]^2$ is then computed through (1.1) with $\omega_{m,n}(i,j)$ in place of $\omega(i,j)$ for $i \in [m], j \in [n]$. Finally, the cluster $R(t)$ is computed from (1.2) at time $t = 1000$.

Figure 1.1 depicts a realization of $R(t)$ together with the boundary of the limit shape approximation $tR$ in four cases. For comparison, Figure 1.1a covers the homogeneous case where the rates are 1 and $R$ is given by (1.6) with $c = 1$. In the remaining cases, $R$ is the subset of $\mathbb{R}^2_{\geq 0}$ given by

$$
(1.8) \quad R = \{x \geq y \text{ and } \sqrt{x} + \sqrt{y} \leq 1\} \cup \{x \leq y \text{ and } 2(x + y) \leq 1\} \cup \{(0, y) : 1/2 \leq y \leq 1\},
$$

as can be seen Theorem 3.10. The justification for the asserted asymptotic sizes of the spikes and crevices below is in Subsection 3.7.

In Figure 1.1b the rates along column $i = 100$ are altered to 0.5. Then the cluster becomes approximately flat above the diagonal to the right of column 100. This results in the flat segment between $(0,1)$ and $(0.25, 0.25)$ in the boundary of $R$. To the strictly left of column 100, the cluster develops tall (order $t$) spikes relative to the boundary of $tR$. The spikes persist in the long time limit leaving a trace in the limit shape in the form of the vertical segment from $(0,0.5)$ to $(0,1)$. The length of this segment indicates the asymptotic length of the maximal vertical spike in the cluster. In this example, all spikes are of the same length $0.5t$ asymptotically although this is not visible at time $t = 1000$.

The rates are further altered along column 50 to 0.75 in Figure 1.1c. As before, spikes appear strictly to the left of column 100. However, the spikes on the first 49 columns are now larger (order $0.5t$) than the ones between columns 50 and 100 (order $0.25t$). The cluster’s true order of growth on columns with smaller spikes is not recorded in the limit shape.

The rates in Figure 1.1d are modified from the homogeneous case as follows: When computing the growth process in the first 99 columns, the rates on column 50 are taken as 0.25. For the remaining values of the G-process, the rates are set to 0.50 on column 100. Deep crevices now form between columns 50 and 100 where the height of the cluster is order $0.25t$ below the boundary of $tR$. The limit shape retains no information about these features.

1.4. Exponential CGM with inhomogeneous rates. In the basic version of our setting, $\omega(i, j) \sim \text{Exp}(a_i + b_j)$ for $i, j \in \mathbb{Z}_{>0}$ for some real parameter sequences $\mathbf{a} = (a_i)_{i \in \mathbb{Z}_{>0}}$ and
Figure 1.1. The cluster $R(t)$ (red) and the boundary of the region $tR$ (blue) at time $t = 1000$ in four simulations of CGM with indicated rates. (a) Homogeneous case. $R$ is given by (1.6) with $c = 1$. (b) Flat spot above the diagonal (dashed gray) to the right of column 100 (dashed green) and spikes to the left of column 100. $R$ is given by (1.8) in this and subsequent cases. (c) Larger spikes to the left of column 50 (dashed purple) and smaller spikes between columns 50 and 100. (d) Crevices between columns 50 and 100.
\( b = (b_j)_{j \in \mathbb{Z}_{>0}} \). To have positive rates the parameters are assumed to satisfy \( a_i + b_j > 0 \) for \( i, j \in \mathbb{Z}_{>0} \).

The earliest appearances of the above CGM were perhaps in \([13, 39]\). The model arises via a limit transition from the CGM considered earlier in \([38]\). The latter has independent geometric waiting times with multiplicatively separable inhomogeneity in fail parameters and comes from a Schur measure \([50]\). As proved in \([13]\) [Theorem 1], the present model is closely linked to the complex Wishart ensemble (also known as Laguerre ensemble) in the sense that the square root of the largest singular value of a natural generalization of an \( m \times n \) sized realization of this ensemble has the same distribution as \( G(m, n) \) for \( m, n \in \mathbb{Z}_{>0} \). This correspondence was observed earlier in \([5, \text{Proposition 6.1}]\) when \( a \) or \( b \) is a constant sequence, and generalized later to the process level in \([20]\).

The model can also be naturally motivated as a TASEP with the step initial condition, and particlewise and holewise disorder. The disorder in rates translates to the feature that the square root of the largest singular value of a natural generalization of an \( m \times n \) sized realization of this ensemble has the same distribution as \( G(m, n) \) for \( m, n \in \mathbb{Z}_{>0} \). This correspondence was observed earlier in \([5, \text{Proposition 6.1}]\) when \( a \) or \( b \) is a constant sequence, and generalized later to the process level in \([20]\).

In this paper, we consider the following slightly more general setting that will permit us to simultaneously treat the models alluded to in items (i)-(vi) in Section 1.1. Fix two collections of real parameters

\[
(1.9) \quad \mathbf{a} = \{a_m(i) : m \in \mathbb{Z}_{>0} \text{ and } i \in \{m]\} \quad \text{and} \quad \mathbf{b} = \{b_n(j) : n \in \mathbb{Z}_{>0} \text{ and } j \in \{n]\}.
\]

Abbreviate \( a_m = (a_m(i))_{i \in [m]} \) and \( b_n = (b_n(j))_{j \in [n]} \) for \( m, n \in \mathbb{Z}_{>0} \). Assume that

\[
(1.10) \quad a_m(i) + b_n(j) > 0 \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ and } i \in [m], j \in [n]
\]

or, equivalently,

\[
(1.11) \quad \min a_m + \min b_n > 0 \quad \text{for } m, n \in \mathbb{Z}_{>0}.
\]

For each \( m, n \in \mathbb{Z}_{>0} \), let

\[
(1.12) \quad \omega_{m,n}^{a,b}(i, j) \sim \exp(a_m(i) + b_n(j)) \quad \text{and jointly independent for } i \in [m] \text{ and } j \in [n],
\]

and define \( G^{a,b}(m, n) \) from these waiting times by (1.1). Then, for \( t \in \mathbb{R}_{>0} \), define the region \( R_t^{a,b} \) from the growth process \( \{G^{a,b}(m, n) : m, n \in \mathbb{Z}_{>0}\} \) by (1.12). A few points worth emphasizing: The \( G^{a,b} \)-process itself does not necessarily satisfy the recursion (1.1) because the waiting times in (1.12) are allowed to vary with \( m, n \). By the same token, \( G^{a,b} \)-process need not be coordinatewise nondecreasing. Therefore, \( R_t^{a,b} \) may no longer be a connected subset of \( \mathbb{R}^2_{>0} \) although we shall continue to call it a cluster.

As corollaries we obtain results for the height process and cumulative particle current (flux process) of TASEP. In terms of the CGM these are defined respectively by

\[
(1.13) \quad H^{a,b}(n, t) = \max\{\sup\{m \in \mathbb{Z}_{>0} : G^{a,b}(m, n) \leq t\}, 0\}
\]

\[
(1.14) \quad F^{a,b}(m, t) = \max\{\sup\{n \in \mathbb{Z}_{>0} : G^{a,b}(m + n - 1, n) \leq t, 0\}
\]

for \( m, n \in \mathbb{Z}_{>0} \) and \( t \in \mathbb{R}_{>0} \). In the absence of \( m, n \)-dependence in (1.12) for \( m, n \in \mathbb{Z}_{>0} \), (1.13) gives the number of jumps executed by particle \( n \) by time \( t \) and also the height (namely,
length) of the \( n \)th row of the cluster at time \( t \), while (1.14) counts the number of particles that have jumped from site \( m - 1 \) to site \( m \) by time \( t \). See Subsection 2.4 for more details. These interpretations, although not valid in the full generality of (1.12), justify the names of the processes in (1.13)–(1.14).

1.5. Discussion of the main results. The main contributions of this paper are exact first-order asymptotics of the growth process that lead to fairly explicit descriptions of the limit shape and the limiting flux function. Precise results are stated in Section 3. For the moment, we summarize some key points.

An explicit centering for the growth process (Theorem 3.2). The central result of the paper computes an explicit, deterministic approximation to the first order (a centering for short, see Definition 3.1 below for the precise meaning) for the growth process under a mild growth condition on the means of the waiting times. More specifically, assuming that \( \min a_m + \min b_n \) does not decay too fast as \( m + n \) grows, \( G^{a,b}(m,n) \) is a.s. approximately equal to

\[
\inf_{-\min a_m < z < \min b_n} \left\{ \frac{1}{m} \sum_{i=1}^{m} a_m(i) + z + \frac{1}{n} \sum_{j=1}^{n} b_n(j) - z \right\}
\]

provided that \( m + n \) is sufficiently large. Here, \( z \) serves as a convenient parameter indexing the increment-stationary versions of the growth process. This result is obtained by first developing summable concentration bounds for the growth process.

Resolution of a conjecture due to E. Rains (Theorem 3.4). A formula similar to (1.15) appeared in [51] within the continuous counterpart of Conjecture 5.2, which is not stated explicitly but can be discerned from the context. We state and prove the part of the conjecture related to the present model again by means of concentration bounds.

Shape function (Theorem 3.6). Assume further that the running minima \( \min a_n \) and \( \min b_n \) converge to some \( a, b \in \mathbb{R} \cup \{\infty\} \) with \( a + b > 0 \), respectively, and the empirical distributions associated with \( a_n \) and \( b_n \) converge vaguely to some subprobability measures \( \alpha \) and \( \beta \), respectively, on \( \mathbb{R} \) as \( n \to \infty \). Then (1.15) leads to the simpler a.s. approximation

\[
\inf_{-a < z < b} \left\{ m \int_{\mathbb{R}} \frac{\alpha(da)}{a + z} + n \int_{\mathbb{R}} \frac{\beta(db)}{b - z} \right\}
\]

for \( G^{a,b}(m,n) \) when both \( m \) and \( n \) are sufficiently large. The centering in (1.16) is unique with the property that it extends to a positive-homogeneous and continuous function on \( \mathbb{R}_{\geq 0}^2 \). This extension is the shape function (see Definition 3.5) of the growth process. In many variants of the CGM from the literature, the shape function can be either represented as or derived from (1.16). Subsection 3.9 records numerous corollaries to this effect.

Theorem 3.6 is a considerable strengthening of [25, Theorem 2.1] which derived the approximation (1.16) as \( m, n \) grow large along a fixed direction and in the special where the parameters in (1.9) are not \( m, n \)-dependent and are randomly chosen subject to a joint ergodicity condition. This condition enabled [25] to utilize subadditive ergodic theory to obtain the existence of the shape function and then compute it through convex analysis from the shape functions of the increment-stationary growth processes. An obstruction to implementing the above approach in the present setting is that the waiting times in (1.12) are not stationary with respect to lattice translations and, therefore, the existence of the shape function is no longer guaranteed by standard subadditive ergodic theory.
Growth near the axes (Theorem 3.7). Another consequence of (1.15) is that $G_{a,b}^{m,n}$ is a.s. approximately

$$
\begin{cases}
  n \int_{\mathbb{R}} (b + \min a_m)^{-1}\beta(db) & \text{when } n \text{ is large and } m/n \text{ is small} \\
  m \int_{\mathbb{R}} (a + \min b_n)^{-1}\alpha(da) & \text{when } m \text{ is large and } n/m \text{ is small}
\end{cases}
$$

provided that $\inf a + \inf b > 0$ and the appropriate half of the vague convergence assumption above holds. In particular, (1.17) describes the asymptotics of the growth process along a fixed column or row. The result demonstrates the possibility of macroscopically uneven growth in the cluster, for example, across columns and reveals the underlying reason for this as the variations in the $\min a_m$ sequence. Near the axes, (1.16) is approximately given by

$$
\begin{cases}
  n \int_{\mathbb{R}} (b + a)^{-1}\beta(db) & \text{when } n \text{ is large and } m/n \text{ is small} \\
  m \int_{\mathbb{R}} (a + b)^{-1}\alpha(da) & \text{when } m \text{ is large and } n/m \text{ is small}
\end{cases}
$$

in contrast with (1.17). Discrepancies in these approximations are manifested as macroscopic spikes and crevices in the cluster relative to the boundary of the limit shape near the axes as shown in Figure 1.2. See Subsection 3.7 for a precise calculation in support of the figure.

![Figure 1.2](image-url)

**Figure 1.2.** An illustration of the cluster along column $m \in \mathbb{Z}_{>0}$ and after columns with much larger indices at time $t$ (red) in the case $\min a_n \neq a$. The lines $y \int_{\mathbb{R}} (b + a)^{-1}\beta(db) = t$ (blue) and $y \int_{\mathbb{R}} (b + \min a_m)^{-1}\beta(db) = t$ (purple) are shown. (a) A spike forms when $\min a_m > a$ (b) A crevice forms when $\min a_m < a$.

Limit shape (Theorem 3.10). With the aid of (1.16)-(1.17) and assuming $\alpha, \beta \neq 0$, the limit shape (in the sense of (1.4)) can be identified as the union of the sublevel set

$$
\left\{(x,y) \in \mathbb{R}^2_+: \inf_{z \in (-a,b)} \left\{ x \int_{\mathbb{R}} \frac{\alpha(da)}{a+z} + y \int_{\mathbb{R}} \frac{\beta(db)}{b-z} \right\} \leq 1 \right\}
$$
of the shape function, and the line segments

\[
(1.20) \quad \left\{ (x, 0) \in \mathbb{R}^2_\geq : x \int_{\mathbb{R}} \frac{\alpha(da)}{a + \mathfrak{A}} \leq 1 \right\} \quad \text{and} \quad \left\{ (0, y) \in \mathbb{R}^2_\geq : y \int_{\mathbb{R}} \frac{\beta(db)}{b + \mathfrak{A}} \leq 1 \right\},
\]

where \( \mathfrak{A} = \sup_{m \in \mathbb{Z}_{>0}} \min_{a_m} a_m \) and \( \mathfrak{B} = \sup_{m \in \mathbb{Z}_{>0}} \min_{b_m} b_m \). See Figure 1.3 for an illustration. (When \( \alpha = 0 \) or \( \beta = 0 \), the above set is unbounded but can still be viewed as the limit shape in a truncated sense, see Subsection 3.5). Computations behind the subsequent discussion are either omitted or postponed to Subsections 3.5-3.6. The statements pertinent to the vertical axis have obvious analogues for the horizontal axis.

![Figure 1.3. An illustration of the boundary of the limit shape (blue) and the boundary of the region (1.22) (dashed gray). The strictly concave part and the (possibly empty) flat segments and spikes of the limit shape are indicated.](image)

The boundary of the limit shape inside \( \mathbb{R}^2_{\geq 0} \) connects to the axes at the points

\[
(1.21) \quad \left( \left\{ \int_{\mathbb{R}} \frac{\alpha(da)}{a + b} \right\}^{-1}, 0 \right) \quad \text{and} \quad \left( 0, \left\{ \int_{\mathbb{R}} \frac{\beta(db)}{b + a} \right\}^{-1} \right).
\]

Comparing with (1.20) shows that the limit shape has a vertical spike, namely, a vertical line segment above the second intercept in (1.21), if and only if \( \mathfrak{A} > a \). The latter is the precise condition for the occurrence of a vertical spike in the cluster. Thus, the limit shape retains some residual memory of the spikes in the cluster by encoding their maximal size (to the first-order asymptotics) as the lengths of its spikes. However, the crevices and non-maximal spikes of the cluster, despite being persistent macroscopic scale structures, are not visible in the limit shape.

The boundary of the limit shape can be explicitly parametrized. It is curved (strictly concave) inside the nonempty conic region given by

\[
(1.22) \quad \left\{ (x, y) \in \mathbb{R}^2_{\geq 0} : x \int_{\mathbb{R}} \frac{\alpha(da)}{(a - a)^2} > y \int_{\mathbb{R}} \frac{\beta(db)}{(b + a)^2} \quad \text{and} \quad x \int_{\mathbb{R}} \frac{\alpha(da)}{(a + b)^2} < y \int_{\mathbb{R}} \frac{\beta(db)}{(b - b)^2} \right\},
\]
and is flat elsewhere. In particular, the boundary has a flat segment inside \( \mathbb{R}^2_{>0} \) adjacent to the vertical axis if and only if \( \int_{\mathbb{R}} \alpha_a(a - a)^{-2} \alpha(a) da < \infty \). This condition indicates that the small parameters in \( \mathbf{a}_m \) become sufficiently infrequent as \( m \to \infty \). It holds precisely when \( a < \inf \text{supp} \alpha \) or \( \int_{\mathbb{R}} (a - \inf \text{supp} \alpha)^{-2} \alpha(a) da < \infty \) since \( a \leq \inf \text{supp} \alpha \). The formation of flat segments can be understood geometrically in terms of the coalescence of geodesics in the associated LPP model, which we leave to the sequel [27].

Formulas (1.19)-(1.20) illuminate how the inhomogeneity introduced through the parameters \( \mathbf{a} \) and \( \mathbf{b} \) at the microscopic scale propagates to the limit shape. This happens by means of three partially independent mechanisms: the limiting empirical measures \( \alpha, \beta \), the limiting running minima \( \mathbf{a}, \mathbf{b} \) and the maximal running minima \( \mathbf{A}, \mathbf{B} \). The dependence on the running minima implies that changing the means of the waiting times in a single column or row can alter the limit shape. This feature is reminiscent of the sensitivity of the flux function to a slow bond in TASEP [8].

The limiting height and flux functions (Theorem 3.11). The knowledge of the shape function also leads to explicit centerings for the height and flux processes. \( H^{a,b}(n,t) \) and \( F^{a,b}(m,t) \) are a.s. approximately equal to

\[
\begin{align*}
(1.23) & \quad \max \left\{ \sup_{z \in (-a, b)} \left\{ \frac{t - n \int_{\mathbb{R}} (b - z)^{-1} \beta(db)}{\int_{\mathbb{R}} (a + z)^{-1} \alpha(da)}, 0 \right\} \right. \\
(1.24) & \quad \max \left\{ \sup_{z \in (-a, b)} \left\{ \frac{t - m \int_{\mathbb{R}} (a + z)^{-1} \alpha(da)}{\int_{\mathbb{R}} (a + z)^{-1} \alpha(da) + \int_{\mathbb{R}} (b - z)^{-1} \beta(db)} \right\}, 0 \right\},
\end{align*}
\]

respectively, for sufficiently large \( m, n \) and all \( t \). The formulas above are obtained from (1.16) assuming further that the measures \( \alpha, \beta \) are nonzero. We shall refer to (1.23) and (1.24) as the limiting height and flux functions, respectively.

Height of a fixed row (Theorem 3.12). In the case of spikes/crevices near the horizontal axis, (1.23) can be a poor approximation of the height of a fixed row. In fact, a correct centering for \( H^{a,b}(n,t) \) is

\[
t \left\{ \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_m} \right\}^{-1}
\]

for fixed \( n \) and sufficiently large \( t \). This result is derived from the behavior of the growth process near the axes.

1.6. Methodology. We study the growth process \( G^{a,b} \) through couplings with its increment-stationary versions \( \hat{G}^{a,b,z} \) indexed by the \( z \)-parameter in (1.15). The horizontal \( \hat{G}^{a,b,z} \) increments are independent along any row and exponentially distributed with explicit rates that are invariant under vertical translations, and an analogous statement holds for the vertical increments. This feature is sometimes referred to as the Burke property in reference to Burke’s theorem from queueing theory since the increments correspond to inter-arrival/departure times of customers in an interpretation of the CGM as M/M/1 queues in tandem. The details can be found, for example, in [38 Section 7].

Due to the distributional structure of the increments, concentration bounds for sums of independent exponentials show that the \( \hat{G}^{a,b,z} \)-process concentrates around the expression inside the infimum in (1.15) with overwhelming probability. Utilizing the coupling with \( z \) chosen as the unique minimizer \( \zeta = \zeta^{a,b}(m,n) \) in (1.15), which exists due to strict convexity, we then derive similar concentration bounds for the \( G \)-process. The right tail bound comes
easily since the $G^{a,b}$-process is dominated by the $\hat{G}^{a,b,z}$-process for each $z$. For the left tail bound, we first show that in the LPP representation of $\hat{G}^{a,b,z}$ the geodesic from the origin to $(m,n)$ exits the boundary close to the origin with overwhelming probability assuming monotonicity of the parameters. In this case, a left tail bound for $G^{a,b}(m,n)$ can be extracted from that of $\hat{G}^{a,b,z}$ since the two quantities are close. On the other hand, the distributional invariance of the $G^{a,b}(m,n)$ under permutations of the parameters $a_m$ and $b_n$ implies that the bound continues to hold without the monotonicity condition. The bounds obtained in this manner are not sharp but suffice for the purposes of first-order asymptotics.

In the context of percolation and directed polymer models, the idea of coupling with increment-stationary processes to compute limit shapes dates back to [57].

An alternative path to the results proved in this work is to utilize the determinantal structure in the model. For example, formula (1.15) can be predicted from the correlation kernel.

The remainder of this text is organized as follows. Section 2 casts the growth process near the axes. Section 9 computes the limit shape. Section 10 computes the limiting tail bounds for the growth process are developed in Section 4. The centerings (1.15) and (1.16) are derived in Sections 5 and 7, respectively. Section 8 obtains approximations to the growth process. The main results are formulated precisely in Section 3. Concentration bounds for the growth process are developed in Section 4. The centerings (1.15) and (1.16) are derived in Sections 5 and 7, respectively. Section 8 obtains approximations to the growth process near the axes. Section 9 computes the limit shape. Section 10 computes the limiting flux and height functions for the disordered TASEP. Section 11 contains the proofs of various applications of the main results. Some standard and auxiliary facts are recorded in Appendix A.

1.8. Notation and conventions. Let $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ denote the spaces of integers, rational, real and complex numbers, respectively. For $a \in \mathbb{R}$, define $\mathbb{Z}_{\geq a} = \{ i \in \mathbb{Z} : i \geq a \}$ and make analogous definitions if the set is replaced with $\mathbb{R}$ or the subscript is replaced with $> a$, $\leq a$ or $< a$. Write $\emptyset$ for the empty set. For $n \in \mathbb{Z}_{>0}$, $[n] = \{ 1, 2, \ldots, n \}$ with the convention that $[n] = \emptyset$ for $n \in \mathbb{Z}_{\leq 0}$. For $x \in \mathbb{R}$, write $[x] = \inf \mathbb{Z}_{\geq x}$ and $x_+ = \max \{ x, 0 \}$.

For a real sequence $(c_i)_{i \in \mathbb{Z}_{>0}}$, write $c_{p,n}^{\min} = \min \{ c_i : i \in [n] \setminus \{ p - 1 \} \}$ for $n \in \mathbb{Z}_{>0}$ and $p \in [n]$, and abbreviate $c_{1,n}^{\min} = c_n^{\min}$ for $n \in \mathbb{Z}_{>0}$. For $k \in \mathbb{Z}_{>0}$, denote with $\tau_k$ the shift map $(c_i)_{i \in \mathbb{Z}_{>0}} \mapsto (c_{i+k})_{i \in \mathbb{Z}_{>0}}$. A function $f : \mathbb{R}_{>0}^2 \to \mathbb{R}$ is positive-homogeneous if $f(cx, cy) = cf(x, y)$ for $x, y, c > 0$. Being an increasing or decreasing function is understood in the strict sense.

For any space $X$ and subset $A \subset X$, write $1_A$ for the indicator function of $A$ that equals 1 on $A$ and 0 on the complement $X \setminus A$. For any function $f : A \to \mathbb{R} \cup \{ \infty, -\infty \}$, the product $1_A f$ denotes the function that equals $f$ on $A$ and 0 on $X \setminus A$. If $X$ is a topological space, $\overline{A}$ denotes the closure of $A$ in $X$.

The support of a Borel measure $\mu$ on $\mathbb{R}$ is the set supp $\mu = \mathbb{R} \setminus U$ where $U \subset \mathbb{R}$ is the largest open set with $\mu(U) = 0$.

For $\lambda \in \mathbb{R}_{>0}$, the exponential distribution with rate $\lambda$, denoted $\text{Exp}(\lambda)$, is the Borel measure on $\mathbb{R}$ with density $x \mapsto 1_{\{x > 0\}} \lambda e^{-\lambda x}$. Its mean and variance are $\lambda^{-1}$ and $\lambda^{-2}$, respectively. The statement $X \sim \text{Exp}(\lambda)$ means that the random variable $X$ is $\text{Exp}(\lambda)$-distributed.

For $x \in \mathbb{R}$, the Dirac measure $\delta_x$ is the Borel probability measure on $\mathbb{R}$ such that $\delta_x \{ x \} = 1$. 
A sequence of events \((E_n)_{n \in \mathbb{Z}_{>0}}\) in a probability space occurs with overwhelming probability if for any \(p \in \mathbb{Z}_{>0}\) the probability of \(E_n\) is at least \(1 - C_p n^{-p}\) for \(n \in \mathbb{Z}_{>0}\) for some constant \(C_p > 0\) dependent only on \(p\).

2. LPP with inhomogeneous exponential weights

We study the corner growth process through its usual LPP representation. In this section, we reintroduce the model from the percolation perspective and discuss its special features due to the exponential weights (waiting times) that contribute to our analysis. We also discuss the disordered TASEP associated with the growth process and introduce several related quantities that will be of interest in the sequel.

2.1. Last-passage times, geodesics and exit points. Let \(\Omega = \mathbb{R}^{\mathbb{Z}_{>0}}\) and \(\hat{\Omega} = \mathbb{R}^{\mathbb{Z}_{>0}}\). Each \(\omega = \{\omega(i, j) : i, j \in \mathbb{Z}_{>0}\} \in \Omega\) represents a weight configuration on the bulk sites \(\mathbb{Z}_{>0}\) while each \(\hat{\omega} = \{\hat{\omega}(i, j) : i, j \in \mathbb{Z}_{>0}\} \in \hat{\Omega}\) represents a weight configuration on the bulk sites plus the boundary sites \(\mathbb{Z}_{>0} \times \{0\} \cup \{0\} \times \mathbb{Z}_{>0}\).

A finite sequence \(\pi = (\pi_i)_{i \in [p]}\) in \(\mathbb{Z}^2\) is an up-right path if \(\pi_i - \pi_{i-1} \in \{(1, 0), (0, 1)\}\) for \(1 < i < p\). For \(k, l, m, n \in \mathbb{Z}\), write \(\Pi_{k,l}^{m,n}\) for the set of all up-right paths with \(\pi_1 = (k, l)\) and \(\pi_p = (m, n)\).

Define the last-passage times on \(\Omega\) by

\[
(2.1) \quad G_{k,l}(m, n) = \max_{\pi \in \Pi_{k,l}^{m,n}} \sum_{(i,j) \in \pi} \omega(i, j) \quad \text{for } m, n, k, l \in \mathbb{Z}_{>0} \text{ and } \omega \in \Omega,
\]

and on \(\hat{\Omega}\) by

\[
(2.2) \quad \hat{G}_{k,l}(m, n) = \max_{\pi \in \Pi_{k,l}^{m,n}} \sum_{(i,j) \in \pi} \hat{\omega}(i, j) \quad \text{for } k, l, m, n \in \mathbb{Z}_{>0} \text{ and } \hat{\omega} \in \hat{\Omega}.
\]

We work with \(k \leq m\) and \(l \leq n\) in the sequel, in which case \(\Pi_{k,l}^{m,n}\) is nonempty and the maxima above are finite. Any maximizer \(\pi \in \Pi_{k,l}^{m,n}\) in \((2.1)\) or \((2.2)\) is called a geodesic. Being finite and nonempty, \(\Pi_{k,l}^{m,n}\) contains at least one geodesic.

We abbreviate \(G(m, n) = G_{1,1}(m, n)\) (consistently with \((1.1)\)) and \(\hat{G}(m, n) = \hat{G}_{0,0}(m, n)\). For \(m, n \in \mathbb{Z}_{>0}, k, l \in \mathbb{Z}_{>0}\) with \(k \leq m\) and \(l \leq n\), define the horizontal and vertical exit points by

\[
(2.3) \quad \hat{H}_k(m, n) = \max\{i \in \mathbb{Z}_{>0} : k \leq i \leq m\} \quad \text{and} \quad \hat{G}_{k,0}(m, n) = \hat{G}_{k,0}(i, 0) + \hat{G}_{i,1}(m, n),
\]

\[
(2.4) \quad \hat{V}_l(m, n) = \max\{j \in \mathbb{Z}_{>0} : l \leq j \leq n\} \quad \text{and} \quad \hat{G}_{0,l}(m, n) = \hat{G}_{0,l}(0, j) + \hat{G}_{1,j}(m, n),
\]

respectively. \(\hat{H}_k(m, n)\) is the maximal \(i \in \{k, \ldots, m\}\) such that \((i, 0) \in \pi\) for some geodesic \(\pi \in \Pi_{k,0}^{m,n}\), and then \((i, 0)\) is the site where \(\pi\) exits the horizontal boundary \(\mathbb{Z}_{>0} \times \{0\}\). Likewise, \(\hat{V}_l(m, n)\) is the maximal \(j \in \{l, \ldots, n\}\) such that there exists a geodesic in \(\Pi_{0,l}^{n,n}\) that exits the vertical boundary \(\{0\} \times \mathbb{Z}_{>0}\) at site \((0, j)\). We abbreviate \(\hat{H}(m, n) = \hat{H}_0(m, n)\) and \(\hat{V}(m, n) = \hat{V}_0(m, n)\).
2.2. Bulk LPP process. Let $P$ denote the Borel probability measure on $\Omega$ under which

\begin{equation}
\{\omega(i, j) : i, j \in \mathbb{Z}_{>0}\} \text{ are independent and } \omega(i, j) \sim \text{Exp}(1) \text{ for } i, j \in \mathbb{Z}_{>0}.
\end{equation}

Write $E$ for the corresponding expectation. For $m, n \in \mathbb{Z}_{>0}$, let $\{\omega_{m,n}(i, j) : (i, j) \in [m] \times [n]\}$ be a collection of independent $\text{Exp}(1)$-distributed random variables on the probability space $(\Omega, P)$. No assumption is made about the joint distribution of $\omega_{m,n}(i, j)$ and $\omega_{m',n'}(i', j')$ if $(m, n) \neq (m', n')$.

Introduce inhomogeneity (disorder) through real parameters in $[1.9]$ assumed to satisfy $[1.10]$. A weight (waiting time) process with property $[1.12]$ can be defined on $(\Omega, P)$ by setting

\begin{equation}
\omega_{m,n}^{a,b}(i, j) = \frac{\omega_{m,n}(i, j)}{a_n(i) + b_n(j)} \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ and } i \in [m], j \in [n].
\end{equation}

Let $P_{m,n}^{a,b}$ denote the distribution of the weights $\{\omega_{m,n}^{a,b}(i, j) : i \in [m], j \in [n]\}$ under $P$ for $m, n \in \mathbb{Z}_{>0}$. In other words, $P_{m,n}^{a,b}$ is the Borel probability measure on $\mathbb{R}^{[m] \times [n]}$ under which

\begin{equation}
\{\omega(i, j) : (i, j) \in [m] \times [n]\} \text{ are independent and } \omega(i, j) \sim \text{Exp}(a_{m}(i) + b_{n}(j)) \text{ for } (i, j) \in [m] \times [n].
\end{equation}

Define the bulk LPP process via $[2.1]$ using the weights in $[2.6]$. Namely, the value of the process at site $(m, n)$ is given by

\begin{equation}
G_{m,n}^{a,b}(m, n) = \max_{\pi \in \Pi_{m,n}^{1,1}} \sum_{(i,j) \in \pi} \omega_{m,n}^{a,b}(i, j) \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ and } i \in [m], j \in [n].
\end{equation}

This is a particular construction of the corner growth process discussed in Subsection $[1.4]$.

Consider the special case

\begin{equation}
\omega_{m,n}(i, j) = \omega(i, j), \ a_n(i) = a \text{ and } b_n(j) = b \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ and } i, j \in [m] \times [n]
\end{equation}

for some $a, b > 0$ with $c = a + b > 0$. This recovers the LPP process with i.i.d. $\text{Exp}(c)$ weights. Let us call the corresponding CGM/LPP model homogeneous. In this case, we will often replace the superscript $a, b$ with $c$, for example, writing $P^c$ for the distribution of the bulk weights.

2.3. Stationary last-passage increments. The horizontal and vertical $\hat{G}$-increments are defined by

\begin{align}
\hat{I}(m, n) &= \begin{cases} \hat{G}(m, n) - \hat{G}(m - 1, n) & \text{if } m > 0 \\ 0 & \text{otherwise} \end{cases} \\
\hat{J}(m, n) &= \begin{cases} \hat{G}(m, n) - \hat{G}(m, n - 1) & \text{if } n > 0 \\ 0 & \text{otherwise,} \end{cases}
\end{align}

respectively, for $m, n \in \mathbb{Z}_{>0}$. From the definitions, $\hat{I}(m, 0) = \hat{\omega}(m, 0)$ and $\hat{J}(0, n) = \hat{\omega}(0, n)$ for $m, n \in \mathbb{Z}_{>0}$.

Let $I_{m,n}^{a,b} = (\min a_m, \min b_n)$ for $m, n \in \mathbb{Z}_{>0}$ with the convention $\min a_0 = \min b_0 = \infty$. For $m, n \in \mathbb{Z}_{>0}$ and $z \in I_{m,n}^{a,b}$, let $P_{m,n}^{a,b,z}$ denote the Borel probability measure on
\( \mathbb{R}([n] \cup \{0\}) \times ([n] \cup \{0\}) \) under which
\[
\{\hat{\omega}(i, j) : i \in [m] \cup \{0\}, j \in [n] \cup \{0\}\} \text{ are independent, } \hat{\omega}(0, 0) \overset{a.s.}{=} 0, \text{ and }
(2.12)
\]
for \( i \in [m], j \in [n] \), \( \hat{\omega}(i, j) \sim \text{Exp}(a_m(i) + b_n(j)) \),
\( \hat{\omega}(i, 0) \sim \text{Exp}(a_m(i) + z) \) and \( \hat{\omega}(0, j) \sim \text{Exp}(b_n(j) - z) \).

Under \( \hat{\Phi}_{m,n}^{a,b} \), the bulk weights \( \{\hat{\omega}(i, j) : i \in [m], j \in [n]\} \) have distribution \( P_{m,n}^{a,b} \) described in \( (2.17) \) and \( G \)-increments are stationary in the sense that
\[
\{\hat{I}(i, n) : i \in [m]\} \text{ are independent with } \hat{I}(i, n) \sim \text{Exp}(a_m(i) + z) \\
(2.13)
\]
and \( \{\hat{J}(m, j) : j \in [n]\} \) are independent with \( \hat{J}(m, j) \sim \text{Exp}(b_n(j) - z) \).

A stronger version of this property is in \([6, \text{Lemma 4.2}]\) for constant parameters. The extension to the general case is sketched in \([25]\).

We study the bulk LPP process mainly through the coupling \( \omega(i, j) = \hat{\omega}(i, j) \) for \( i, j \in \mathbb{Z}_{>0} \). Then \( G_{k,l}(m, n) = \hat{G}_{k,l}(m, n) \) for \( m, n, k, l \in \mathbb{Z}_{>0} \), and
\[
\hat{G}(m, n) = \begin{cases} 
\hat{G}(\hat{H}(m, n), 0) + G_{\hat{H}(m, n), 1}(m, n), & \text{if } \hat{H}(m, n) > 0 \\
\hat{G}(0, \hat{V}(m, n)) + G_{0,\hat{V}(m, n)}(m, n), & \text{if } \hat{V}(m, n) > 0
\end{cases}
(2.14)
\]
for \( m, n \in \mathbb{Z}_{>0} \) follows from definitions \( (2.3) - (2.4) \). Utilizing the stationarity and the independence structure of \( \hat{G} \)-increments, we establish sufficient control over the exit points and then gain access to the bulk LPP process via \( (2.14) \).

### 2.4. TASEP with particlewise and holewise disorder.

Assume now that \( \omega(i, j) \geq 0 \) for \( i, j \in \mathbb{Z}_{>0} \). Define the height of an interface over site \( n \in \mathbb{Z}_{>0} \) at time \( t \in \mathbb{R}_{>0} \) by
\[
H(n, t) = \max\{\sup\{m \in \mathbb{Z}_{>0} : G(m, n) \leq t\}, 0\}.
(2.15)
\]
Since the weights are nonnegative, \( G \) is coordinatewise nondecreasing. Hence, \( H(n, t) \) is nonincreasing in \( n \) and nondecreasing in \( t \). Note that \( H(n, t) \) also measures the width of the cluster in \( (1.2) \) at level \( n \) and time \( t \).

The height variables also represent evolving configurations of particles on \( Z \) as follows: The position of particle \( n \in \mathbb{Z}_{>0} \) at time \( t \in \mathbb{R}_{>0} \) is given by
\[
\sigma(n, t) = H(n, t) - n + 1.
(2.16)
\]
Since \( \sigma(n, t) \) is decreasing in \( n \) and nonincreasing in \( t \), the particles move right over time retaining their order. In particular, each site is occupied by at most one particle at any time. Assume further that \( \omega(i, j) > 0 \) for \( i, j \in \mathbb{Z}_{>0} \). Then each particle jumps one step at a time and the particles start from the step initial condition i.e. \( \sigma(n, 0) = -n + 1 \) for \( n \in \mathbb{Z}_{>0} \).

Define the (total) flux over the time interval \([0, t]\) through site \( i \in \mathbb{Z}_{>0} \) by
\[
F(i, t) = \sup\{j \in \mathbb{Z}_{>0} : G(i + j - 1, j) \leq t\}, 0\}.
(2.17)
\]
Note from definitions \( (2.15) \) and \( (2.16) \) that
\[
\{j \in \mathbb{Z}_{>0} : G(i + j - 1, j) \leq t\} = \{j \in \mathbb{Z}_{>0} : H(j, t) \geq j + i - 1\} = \{j \in \mathbb{Z}_{>0} : \sigma(j, t) \geq i\}.
\]
Since the particles are initially at negative sites, it follows that \( F(i, t) \) counts the number of particles that have jumped from \( i - 1 \) to \( i \) by time \( t \).

Define the height process \( \{H^{a,b}(n, t) : n \in \mathbb{Z}_{>0}, t \in \mathbb{R}_{>0}\} \), the particle process \( \{\sigma^{a,b}(n, t) : n \in \mathbb{Z}_{>0}, t \in \mathbb{R}_{>0}\} \) and the flux process \( \{F^{a,b}(m, t) : m \in \mathbb{Z}_{>0}, t \in \mathbb{R}_{>0}\} \) through \( (2.15), (2.16) \).
and (2.17), respectively, using the bulk LPP process \(G^{a,b}\) in place of \(G\). We will provide first-order approximations to these processes.

The disordered TASEP arises in the special case \(a_m(i) = a_i\) and \(b_n(j) = b_j\) for \(m, n \in \mathbb{Z}_{>0}, i \in [m], j \in [n]\).

3. Main results

We state our main results in this section. Throughout, fix two collections of real parameters \(a = \{a_m(i) : m \in \mathbb{Z}_{>0}, i \in [m]\}\) and \(b = \{b_n(j) : n \in \mathbb{Z}_{>0}, j \in [n]\}\) subject to condition (1.10).

3.1. An explicit centering for the LPP process.

**Definition 3.1.** We call a (deterministic) function \(F: \mathbb{Z}_{>0}^2 \to \mathbb{R}\) a centering for the \(G^{a,b}\)-process if for any \(\epsilon > 0\), \(\mathbb{P}\)-a.s., there exists a random \(L \in \mathbb{Z}_{>0}\) such that

\[
|G^{a,b}(m, n) - F(m, n)| \leq \epsilon(m + n) \quad \text{for } m, n \in \mathbb{Z}_{>0}.
\]

The definition does not determine \(F\) uniquely since, for any function \(f: \mathbb{Z}_{>0}^2 \to \mathbb{R}\) with

\[
\lim_{l \to \infty} \sup_{m, n \in \mathbb{Z}_{>0}\infty} \frac{f(m, n)}{m + n} = 0,
\]

the function \(F + f\) also satisfies (3.1). The results of this subsection provide an explicit centering under a mild condition on the parameters.

Condition (1.10) implies that the interval \(I_{m,n} = (-\min a_m, \min b_n)\) (with the convention \(\min a_0 = \min b_0 = \infty\)) is nonempty for \(m, n \in \mathbb{Z}_{>0}\). When \(m, n \in \mathbb{Z}_{>0}\), the length \(|I_{m,n}| = \min a_m + \min b_n\) of this interval equals the reciprocal of the maximal mean of the weights in the rectangle \([m] \times [n]\):

\[
|I_{m,n}|^{-1} = \max_{i \in [m], j \in [n]} E[\omega_{m,n}^{a,b}(i, j)] \quad \text{for } m, n \in \mathbb{Z}_{>0}.
\]

Define

\[
M^{a,b,z}(m, n) = \sum_{i=1}^{m} \frac{1}{a_m(i) + z} + \sum_{j=1}^{n} \frac{1}{b_n(j) - z} \quad \text{for } m, n \in \mathbb{Z}_{>0}
\]

and \(z \in \mathbb{C} \setminus \{-a_m(i) : i \in [m]\} \cup \{b_n(j) : j \in [n]\}\). When \(z \in I_{m,n}^{a,b}\), (3.2) gives the mean of \(\hat{G}(m, n)\) under \(\hat{P}^{a,b,z}_{m,n}\) as can be seen from (2.10), (2.11) and (2.13). Next define

\[
\mathcal{M}^{a,b}(m, n) = \inf_{z \in I_{m,n}^{a,b}} M^{a,b,z}(m, n) \quad \text{for } m, n \in \mathbb{Z}_{>0}.
\]

Our first result bounds the difference \(G^{a,b}(m, n) - \mathcal{M}^{a,b}(m, n)\) with error terms that are of smaller order than \(m + n\) provided that \(|I_{m,n}^{a,b}|\) does not decay too quickly. Note that the bounds require only one of \(m\) and \(n\) to be sufficiently large.

**Theorem 3.2.** Let \(p > 0\). Then, \(\mathbb{P}\)-a.s., there exists a random \(L \in \mathbb{Z}_{>0}\) such that

\[
G^{a,b}(m, n) \leq \mathcal{M}^{a,b}(m, n) + |I_{m,n}^{a,b}|^{-1}(m + n)^{1/2+p}
\]

\[
G^{a,b}(m, n) \geq \mathcal{M}^{a,b}(m, n) - |I_{m,n}^{a,b}|^{-1}(m + n)^{9/10+p}
\]

for \(m, n \in \mathbb{Z}_{>0}\) with \(m + n \geq L\).

In particular, (3.3) is a centering for the \(G^{a,b}\)-process under a mild condition.
Corollary 3.3. Assume that, for some $c > 0$ and $\eta > 0$,
\begin{equation}
|I_{m,n}^{a,b}| \geq c(m + n)^{-1/10 + \eta} \quad \text{for } m, n \in \mathbb{Z}_{>0}.
\end{equation}

Let $\epsilon > 0$. Then, $\mathbb{P}$-a.s., there exists (random) $L \in \mathbb{Z}_{>0}$ such that
\begin{equation}
|G^{a,b}(m, n) - \mathcal{M}^{a,b}(m, n)| \leq \epsilon(m + n) \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ with } m + n \geq L.
\end{equation}

Remark 3.3.1. Assumption (3.4) is not claimed to be sharp. The result does fail if $|I_{m,n}^{a,b}|$ is allowed to decay too fast. For example, let $a_i(i) = b_j(i) = 2^{-i}$ for $n \in \mathbb{Z}_{>0}$ and $i \in [n]$. Then $\mathcal{M}^{a,b}(n, n) \leq \mathcal{M}^{a,b,0}(n, n) = 2 \sum_{i=1}^{n} 2^i \leq 2^{n+2}$, while $G(n, n) \geq \omega(n, n) \geq 100 \cdot 2^n$ happens with at least probability $e^{-200}$ for each $n$.

Remark 3.3.2. One would expect that the analogous estimates hold in the LPP with independent, $\mathbb{Z}_{>0}$-valued, geometrically distributed weights. The weight at site $(i, j)$ has fail parameter $a_i b_j$ for $i, j \in \mathbb{Z}_{>0}$ for some $\mathbb{R}_{>0}$-valued sequences $(a_i)_{i \in \mathbb{Z}_{>0}}$ and $(b_j)_{j \in \mathbb{Z}_{>0}}$ subject to $a_i b_j < 1$ for $i, j \in \mathbb{Z}_{>0}$. This model was introduced in [38]. For the precise geometric analogue of the present setting, fix positive real parameters $a$ and $b$ as in (1.9) but now subject to
\begin{equation}
a_i(i) b_j(j) < 1 \quad \text{for } m, n \in \mathbb{Z}_{>0}, \text{ and } i \in [m], j \in [n].
\end{equation}

For each $m, n \in \mathbb{Z}_{>0}$, consider independent weights on $(\Omega, \mathbb{P})$ such that
\begin{equation}
\mathbb{P}(\omega_{m,n}^{a,b}(i, j) \geq k) = (a_i(i) b_j(j))^k \quad \text{for } k \in \mathbb{Z}_{>0}, i \in [m] \text{ and } j \in [n].
\end{equation}

Then, in analogy with Theorem 3.2, a centering of the corresponding $G^{a,b}$-process should be of the form (3.3) with $I_{m,n}^{a,b} = (\max a_m, (\max b_n)^{-1})$ and
\begin{equation}
\mathcal{M}^{a,b,z}(m, n) = \sum_{i=1}^{m} \frac{a_i(i)}{z} - \frac{a_i(i)}{z} + \sum_{j=1}^{n} \frac{b_j(j)}{1 - b_j(j) z} \quad \text{for } m, n \in \mathbb{Z}_{>0},
\end{equation}

and $z \in \mathbb{C} \setminus \{\{a_m(i) : i \in [m]\} \cup \{b_n(j) : j \in [n]\}\}$. This can likely be obtained adapting the proof of Theorem 3.2. In a random parameter setting, a similar centering appeared in [24]. Formula (3.7) can be obtained from the mean of the explicit increment-stationary version of the $G^{a,b}$-process.

3.2. A conjecture due to E. Rains. The next result can be viewed as a variant of Corollary 3.3 on account of the similarity of the centering (3.3) to the limit (3.10) below. The statement is a reformulation of a conjecture due to E. Rains [51].

Theorem 3.4. Let $a = (a_i)_{i \in \mathbb{Z}_{>0}}$ and $b = (b_j)_{j \in \mathbb{Z}_{>0}}$ be real sequences subject to
\begin{equation}
\inf a + \inf b > 0,
\end{equation}
\begin{equation}
\mathcal{M}^{a,b}(\infty, \infty) = \sum_{i=1}^{\infty} \frac{1}{a_i + z} + \sum_{j=1}^{\infty} \frac{1}{b_j - z} < \infty \quad \text{for } -\inf a < z < \inf b,
\end{equation}
where the equality is a definition. Also define
\begin{equation}
\mathcal{M}^{a,b}(\infty, \infty) = \inf_{\text{inf }a < z < \text{inf }b} \mathcal{M}^{a,b,z}(\infty, \infty).
\end{equation}

On $(\Omega, \mathbb{P})$, consider the weights
\begin{equation}
\omega_n(i, j) = \frac{\omega(i, j)}{a_{i/n} + b_{j/n}} \quad \text{for } i, j, n \in \mathbb{Z}_{>0}.
\end{equation}
For each \( n \in \mathbb{Z}_{>0} \), define the last-passage times \( \{G_n(i,j) : i,j \in \mathbb{Z}_{>0}\} \) via (2.1) from the weights \( \{\omega_n(i,j) : i,j \in \mathbb{Z}_{>0}\} \). Then, \( P \)-a.s.,

\[
\lim_{n \to \infty} n^{-1} \sup_{i,j \in \mathbb{Z}_{>0}} G_n(i,j) = M^{a,b}(\infty, \infty).
\]

Remark 3.4.1. Since the conjecture addressed above is somewhat dispersed within the text of [51], we explain how to locate it. The statement is a special case of the continuous analogue of Conjecture 5.2. To obtain it, replace \( m(p, \alpha, p) \) in (5.5) with \( m(c, \rho, \rho) \) from (5.29) and set \( u = 0 \). The parameters \( \rho \) and \( \alpha \) play the role of \( a \), \( b \) and \( z \) in our setting. Assumptions (2.14)–(2.15) there correspond to our (3.8)–(3.9). The infimum in (5.5) is now to be taken over \( z \in \mathbb{R} \). In direct analogy with (5.7), the weights are chosen as in (3.11). Finally, the quantity \( \lambda_1 \) in (5.5) is precisely \( \sup_{i,j \in \mathbb{Z}_{>0}} G_n(i,j) \), which can be inferred from the discussion preceding [51, Theorem 2.4].

3.3. Shape function.

Definition 3.5. We call a deterministic function \( \gamma : \mathbb{R}^2_{>0} \to \mathbb{R}_{\geq 0} \) the shape function of the \( G^{a,b} \)-process if \( \gamma \) is coordinatewise nondecreasing, positive-homogeneous (see Subsection 1.8) and its restriction to \( \mathbb{Z}^2_{>0} \) is a centering for \( G^{a,b} \) in the sense of Definition 3.1. Definition (3.5) is consistent with the notion of shape function from earlier literature, see Remark 3.6.6 below. It follows from the definition and Lemmas A.6–A.7 that the shape function, if it exists, is necessarily unique and continuous. (The uniqueness also comes from (3.28) below). This subsection provides an explicit formula for the shape function under some natural sufficient conditions for its existence.

Let \( a \) and \( b \) be finite, nonnegative Borel measures on \( \mathbb{R} \). Introduce the functions

\[
A^\alpha(z) = \int_{\mathbb{R}} \frac{\alpha(da)}{a + z} \quad \text{for } z \in \mathbb{C} \setminus (-\text{supp } \alpha),
\]

\[
B^\beta(z) = \int_{\mathbb{R}} \frac{\beta(db)}{b - z} \quad \text{for } z \in \mathbb{C} \setminus \text{supp } \beta.
\]

The integrals above are well-defined, and \( A^\alpha \) and \( B^\beta \) are holomorphic functions. For each \( z \in \mathbb{C} \setminus ((-\text{supp } \alpha) \cup \text{supp } \beta) \), define

\[
\Gamma^{\alpha,\beta}(x,y) = x A^\alpha(z) + y B^\beta(z) = x \int_{\mathbb{R}} \frac{\alpha(da)}{a + z} + y \int_{\mathbb{R}} \frac{\beta(db)}{b - z} \quad \text{for } x,y > 0.
\]

As recorded in the last case of Corollary 3.16 below, the shape function (defined as in Definition (3.5) but with \( \mathbb{Z}_{>0} \) in place of \( \mathbb{Z}_{>0} \)) of the increment-stationary LPP process can be given in the form (3.14). This fact will not be used in the sequel, however.

Assume that

\[
\inf \text{supp } \alpha + \inf \text{supp } \beta > 0.
\]

Zero measures are acceptable here: if \( \alpha = 0 \) then \( \inf \text{supp } \alpha = \infty \) and the same for \( \beta \). Let \( a, b \in \mathbb{R} \cup \{\infty\} \) satisfy

\[
a + b > 0
\]

\[
a \leq \inf \text{supp } \alpha \text{ and } b \leq \inf \text{supp } \beta.
\]
Then the intervals \((-a, \infty)\) and \((-\infty, b)\) are contained in the domains of (3.12) and (3.13), respectively. In particular, each \(z \in (-a, b)\) is a legitimate parameter in (3.14). Therefore, the following definition is sensible:

\[
\gamma_{\alpha,\beta,a,b}^\alpha(x, y) = \inf_{z \in (-a, b)} \Gamma_{z}^{\alpha,\beta}(x, y) \quad \text{for} \quad x, y \in \mathbb{R}_{>0}.
\]

As will be made precise with Lemma 7.2 below, one can view (3.18) as the continuous analogue of (3.3) obtained after letting \(m, n \to \infty\). From (3.14), (3.16) and (3.18) it follows that the function \(\gamma_{\alpha,\beta,a,b}^\alpha\) is nonnegative, concave, finite, coordinatewise nondecreasing and positive-homogeneous.

The next result shows that the shape function of the \(G_{a,b}\)-process exists and can be represented in the form (3.18) under mild conditions. In the statement,

\[
\alpha_m^a = \frac{1}{m} \sum_{i=1}^{m} \delta_{a_m(i)} \quad \text{and} \quad \beta_n^b = \frac{1}{n} \sum_{j=1}^{n} \delta_{b_n(j)} \quad \text{for} \quad n \in \mathbb{Z}_{>0}
\]

denote the empirical distributions associated with the parameters \(a\) and \(b\), respectively. For the definition of vague convergence, see Appendix A.2

**Theorem 3.6.** Assume that

\[
\lim_{n \to \infty} \alpha_m^a = \alpha \quad \text{and} \quad \lim_{n \to \infty} \beta_n^b = \beta \quad \text{in the vague topology}
\]

\[
\lim_{m \to \infty} \min \alpha_m = a \quad \text{and} \quad \lim_{n \to \infty} \min \beta_n = b
\]

for some subprobability measures \(\alpha, \beta\) on \(\mathbb{R}\) and \(a, b \in \mathbb{R} \cup \{\infty\}\) such that (3.16) is satisfied. Then for any \(\epsilon > 0\), \(P\)-a.s., there exists a random \(L \in \mathbb{Z}_{>0}\) such that

\[
|G_{a,b}(m, n) - \gamma_{\alpha,\beta,a,b}(m, n)| \leq \epsilon(m + n) \quad \text{for} \quad m, n \in \mathbb{Z}_{>L}.
\]

**Remark 3.6.1.** Assumptions (3.20), (3.21) imply (3.17). Hence, the shape function in the theorem given by (3.18) makes sense.

**Remark 3.6.2.** The condition \(m, n \geq L\) can be weakened to \(m + n \geq L\) if and only if

\[
A^\alpha(\min \beta_n) = A^\alpha(b) \quad \text{and} \quad B^\beta(\min a_m) = B^\beta(-a) \quad \text{for} \quad m, n \in \mathbb{Z}_{>0}.
\]

This is recorded in Corollary 3.9 below. Condition (3.22) is equivalent to

\[
\text{min} \alpha_m = a \quad \text{for} \quad m \in \mathbb{Z}_{>0} \quad \text{when} \quad \beta \neq 0 \quad \text{and} \quad \text{min} \beta_n = b \quad \text{for} \quad n \in \mathbb{Z}_{>0} \quad \text{when} \quad \alpha \neq 0
\]

by the strict monotonicity of \(A^\alpha\) and \(B^\beta\).

**Remark 3.6.3.** When either \(\alpha\) or \(\beta\) is the zero measure, \(\gamma\) becomes a one-variable function and can be readily computed from (3.18) by monotonicity.

\[
\gamma_{\alpha,\beta,a,b}^\alpha(x, y) = \begin{cases} xA^\alpha(b) & \text{if} \quad \beta = 0 \\ yB^\beta(-a) & \text{if} \quad \alpha = 0 \end{cases} \quad \text{for} \quad x, y > 0.
\]

Hence, the shape function is identically zero in three cases:

\[
\gamma_{\alpha,\beta,a,b}^\alpha = 0 \quad \text{if} \quad a = \infty \quad \text{or} \quad b = \infty \quad \text{or} \quad \alpha = \beta = 0.
\]

If none of the conditions in (3.25) holds then the shape function is nonzero on \(\mathbb{R}_{>0}^2\) since

\[
\gamma_{\alpha,\beta,a,b}^\alpha(x, y) \geq xA^\alpha(b) + yB^\beta(-a) \geq \max\{xA^\alpha(b), yB^\beta(-a)\} \quad \text{for} \quad x, y > 0.
\]
Remark 3.6.4. Assuming \( \alpha, \beta \neq 0 \), there exists a unique minimizer \( \zeta^{\alpha, \beta, a, b}(x, y) \) in (3.18) for each \((x, y) \in \mathbb{R}^2_0\), see Section 7. It can be seen from (3.18) that \( \zeta^{\alpha, \beta, a, b} \) is a continuous function of \((x, y) \in \mathbb{R}^2_0\) and a decreasing function of the slope \( y/x \). Furthermore, \( \zeta^{\alpha, \beta, a, b} \) is continuously differentiable with gradient given by

\[
\nabla \zeta^{\alpha, \beta, a, b}(x, y) = (A^{\alpha}(\zeta^{\alpha, \beta, a, b}(x, y)), B^{\beta}(\zeta^{\alpha, \beta, a, b}(x, y))) \quad \text{for } x, y \in \mathbb{R}_{>0}.
\]

The details, being similar to the proof of [25 Corollary 2.3], are omitted.

Remark 3.6.5. The hypotheses of the theorem can be motivated from the following statement that holds under the weaker assumption \((3.8)\):

Let \( (m_i)_{i \in \mathbb{Z}_{>0}} \) and \( (n_j)_{j \in \mathbb{Z}_{>0}} \) be increasing sequences in \( \mathbb{Z}_{>0} \). By the (sequential) compactness of \([-\infty, \infty]\) and the space of subprobability measures (see Lemma A.4), there exist increasing sequences \( (k_i)_{i \in \mathbb{Z}} \) and \( (l_j)_{j \in \mathbb{Z}_{>0}} \) in \( \mathbb{Z}_{>0} \) such that

\[
\lim_{i \to \infty} a_{m_{k_i}} = \alpha \quad \text{and} \quad \lim_{j \to \infty} b_{n_{l_j}} = \beta
\]

in the vague topology

\[
\lim_{i \to \infty} \min a_{m_{k_i}} = a \quad \text{and} \quad \lim_{j \to \infty} \min b_{n_{l_j}} = b
\]

for some subprobability measures \( \alpha, \beta \) on \( \mathbb{R} \) and \( a, b \in \mathbb{R} \setminus \{0\} \) with (3.10). Repeating the argument in Section 7 with \( m = m_{k_i} \) and \( n = n_{l_j} \) yields that for any \( \epsilon > 0 \), \( P \)-a.s., there exists a random \( L \in \mathbb{Z}_{>0} \) such that

\[
|G^{a, b}(m_{k_i}, n_{l_j}) - \zeta^{\alpha, \beta, a, b}(m_{k_i}, n_{l_j})| \leq \epsilon(m_{k_i} + n_{l_j}) \quad \text{for } i, j \in \mathbb{Z}_{>0} \text{ with } i, j \geq L.
\]

Remark 3.6.6. Theorem 3.6 together with positive-homogeneity and continuity of the shape function implies that there exists a single \( P \)-a.s. event on which

\[
\lim_{k \to \infty} k^{-1} G^{a, b}(m_{k_i} x, n_{l_j} y) = \zeta^{\alpha, \beta, a, b}(x, y)
\]

holds for all choices of \( x, y > 0 \) and all sequences \( \{m_{k_i}, n_{l_j}\}_{k \in \mathbb{Z}_{>0}} \subset \mathbb{Z}_{>0} \) such that \( m_{k_i}/k \to x \) and \( n_{l_j}/k \to y \) as \( k \to \infty \). In literature, (3.28) with \( m_{k_i} = [kx] \) and \( n_{l_j} = [ky] \) is often taken as the definition of the shape function [18, 58].

Remark 3.6.7. Unlike the usual sequence of arguments, we do not first establish the a.s. limit in (3.28) to obtain Theorem 3.6. Instead, we derive Theorem 3.6 from Corollary 3.3 by approximating the centering (3.3) by the shape function.

3.4. Growth near the axes. The next theorem provides uniform approximations to the growth process at sites where one coordinate is large and the other is relatively small. In particular, the result describes the asymptotics along a fixed column or row.

Theorem 3.7. Let \( S \subset \mathbb{Z}_{>0} \) and \( \epsilon > 0 \).

(a) Assume that the first limit in (3.20) holds, and \( \inf a + \inf \min b_n > 0 \). Then, \( P \)-a.s., there exists a deterministic \( \delta > 0 \) and a random \( K \in \mathbb{Z}_{>0} \) such that

\[
|G^{a, b}(m, n) - mA^{\alpha}(\min b_n)| \leq \epsilon m \quad \text{for } m \in \mathbb{Z}_{>K} \text{ and } n \in S \text{ with } n \leq \delta m.
\]

(b) Assume that the second limit in (3.20) holds, and \( \inf b + \inf \min a_m > 0 \). Then, \( P \)-a.s., there exists a deterministic \( \delta > 0 \) and a random \( K \in \mathbb{Z}_{>0} \) such that

\[
|G^{a, b}(m, n) - nB^{\beta}(\min a_m)| \leq \epsilon n \quad \text{for } n \in \mathbb{Z}_{>K} \text{ and } m \in S \text{ with } m \leq \delta n.
\]
With the assumptions of Theorem 3.6, the approximations in Theorem 3.7 can be replaced with simpler one-dimensional linear functions at sites where both coordinates are large but one is small relative to the other.

**Corollary 3.8.** Assume (3.16), (3.20) and (3.21). Let $\epsilon > 0$. Then, $P$-a.s., there exist a deterministic $\delta > 0$ and a random $L \in \mathbb{Z}_{>0}$ such that the following hold for $m, n \in \mathbb{Z}_{>L}$.

(a) $|G^{a,b}(m,n) - mA^\alpha(b)| \leq \epsilon m$ if $n \leq \delta m$.

(b) $|G^{a,b}(m,n) - nB^\beta(-a)| \leq \epsilon n$ if $m \leq \delta n$.

The next corollary justifies the claim made in Remark 3.6.2.

**Corollary 3.9.** Assume (3.16), (3.20) and (3.21). Let $\epsilon > 0$.

(a) Assume that

$$\min a_m \geq a \text{ for } m \in \mathbb{Z}_{>0} \text{ when } \beta \neq 0 \text{ and } \min b_n \geq b \text{ for } n \in \mathbb{Z}_{>0} \text{ when } \alpha \neq 0.$$  

Then, $P$-a.s., there exists a random $L \in \mathbb{Z}_{>0}$ such that

$$G^{a,b}(m,n) \leq \gamma^{a,b}(m,n) + \epsilon(m+n) \text{ for } m, n \in \mathbb{Z}_{>0} \text{ with } m + n \geq L.$$  

(b) Assume that

$$\min a_m \leq a \text{ for } m \in \mathbb{Z}_{>0} \text{ when } \beta \neq 0 \text{ and } \min b_n \leq b \text{ for } n \in \mathbb{Z}_{>0} \text{ when } \alpha \neq 0.$$  

Then, $P$-a.s., there exists a random $L \in \mathbb{Z}_{>0}$ such that

$$G^{a,b}(m,n) \geq \gamma^{a,b}(m,n) - \epsilon(m+n) \text{ for } m, n \in \mathbb{Z}_{>0} \text{ with } m + n \geq L.$$  

(c) Fix $n \in \mathbb{Z}_{>0}$. Assume that $\alpha \neq 0$ and $\min b_n \neq b$. Then, $P$-a.s., there exists a random $K \in \mathbb{Z}_{>0}$ such that

$$\frac{G^{a,b}(m,n) - \gamma^{a,b}(m,n)}{A^\alpha(\min b_n) - A^\alpha(b)} \geq (1-\epsilon)m \text{ for } m \in \mathbb{Z}_{>K}.$$  

(d) Fix $m \in \mathbb{Z}_{>0}$. Assume that $\beta \neq 0$ and $\min a_m \neq a$. Then, $P$-a.s., there exists a random $K \in \mathbb{Z}_{>0}$ such that

$$\frac{G^{a,b}(m,n) - \gamma^{a,b}(m,n)}{B^\beta(-\min a_m) - B^\beta(-a)} \geq (1-\epsilon)n \text{ for } n \in \mathbb{Z}_{>K}.$$  

3.5. **Limit shape.** Denote the growing cluster associated with the bulk LPP process by

$$(3.31) \quad R_t^{a,b} = \{(x,y) \in \mathbb{R}_{>0}^2 : G^{a,b}([x],[y]) \leq t\} \quad \text{for } t \in \mathbb{R}_{>0}.$$  

Our purpose is to describe the limit shape, namely, the linear scaling limit of (3.31) with respect to the Hausdorff metric $d_{H}$ (constructed from the Euclidean metric on $\mathbb{R}_{>0}^2$), see Appendix A.4. To this end, define

$$\mathcal{R}^{a,b} = \{(x,y) \in \mathbb{R}_{>0}^2 : \gamma^{a,b}(x,y) \leq 1\}$$

(3.32)  

$\mathcal{I}^{a,b,w,z} = \{(x,0) : x \in \mathbb{R}_{>0} \text{ and } xA^\alpha(w) \leq 1\} \cup \{(0,y) : y \in \mathbb{R}_{>0} \text{ and } yB^\beta(z) \leq 1\}$

(3.33)  

for $\alpha, \beta, a, b$ subject to (3.15)–(3.17), $w > - \inf \sup \alpha$ and $z < \inf \sup \beta$.

Part (a) of the following result identifies the limit shape in terms of (3.32)–(3.33). Parts (b) and (c) describe precisely when the rescaled cluster is a.s. eventually squeezed between given scaling perturbations of (3.32). The statements involve truncations that restrict to a bounded set when the limit shape is unbounded. The result should be compared with limit shape statements in case of i.i.d. weights, see [37, Theorem 5.1(i)], where the limit shape is the closure of (3.32) in $\mathbb{R}_{>0}^2$. 

Theorem 3.10. Assume (3.16), (3.20) and (3.21). Let $0 < \epsilon < 1$. Let $C > 0$ and

$$S = \left\{ (x, y) \in \mathbb{R}^2_{\geq 0} : x \leq \frac{C}{1\{a=0\} \cup \{b=\infty\}} \text{ and } y \leq \frac{C}{1\{a=0\} \cup \{a=\infty\}} \right\}$$

with the convention $1/0 = \infty$.

(a) $P$-a.s.,

$$\lim_{t \to \infty} d_{H}(S \cap t^{-1}R_{t}^{ab}, S \cap (\mathcal{R}^{\alpha,\beta,ab} \cup \mathcal{T}^{\alpha,\beta,ab})) = 0,$$

where

$$\mathcal{A} = \sup_{m \in \mathbb{Z} > 0} \min a_m \text{ and } \mathcal{B} = \sup_{m \in \mathbb{Z} > 0} \min b_m.$$

(b) If (3.29) holds then, $P$-a.s., there exists a random $T > 0$ such that

$S \cap (1 - \epsilon)\mathcal{R}^{\alpha,\beta,ab} \subset S \cap t^{-1}R_{t}^{ab}$ for $t \geq T$.

If (3.29) does not hold then there exist $\epsilon_0 > 0$ and $C_0 > 0$ such that if $C \geq C_0$ and $\epsilon \leq \epsilon_0$ then, $P$-a.s., there exists a random $T_0$ such that

$$S \cap ((1 - \epsilon)\mathcal{R}^{\alpha,\beta,ab} \setminus t^{-1}R_{t}^{ab}) \neq \emptyset \text{ for } t \geq T_0.$$

(c) If (3.30) holds then, $P$-a.s., there exists a random $T > 0$ such that

$S \cap t^{-1}R_{t}^{ab} \subset S \cap (1 + \epsilon)\mathcal{R}^{\alpha,\beta,ab}$ for $t \geq T$.

If (3.30) does not hold then there exist $\epsilon_0 > 0$ and $C_0 > 0$ such that if $C \geq C_0$ and $\epsilon \leq \epsilon_0$ then, $P$-a.s., there exists a random $T_0$ such that

$$S \cap (t^{-1}R_{t}^{ab} \setminus (1 + \epsilon)\mathcal{R}^{\alpha,\beta,ab}) \neq \emptyset \text{ for } t \geq T_0.$$

Remark 3.10.1. It follows from (3.26) and Lemma 8.1 below that

$$\lim_{t \to 0} \gamma^{\alpha,\beta,ab}(x, t) = x\mathcal{A}(\mathbf{b}) \text{ and } \lim_{t \to 0} \gamma^{\alpha,\beta,ab}(t, y) = y\mathcal{B}(-\mathbf{a}) \text{ for } x, y \in \mathbb{R}_{>0}.$$

These limits imply that the closure of $\mathcal{R}^{\alpha,\beta,ab}$ in $\mathbb{R}^2_{\geq 0}$ is $\overline{\mathcal{R}^{\alpha,\beta,ab}} = \mathcal{R}^{\alpha,\beta,ab} \cup \mathcal{T}^{\alpha,\beta,ab}$. When $\mathcal{R}^{\alpha,\beta,ab}$ is bounded, $\overline{\mathcal{R}^{\alpha,\beta,ab}}$ coincides with the limit shape in part (c) if and only if (3.30) holds.

3.6. Flat segments. To describe the finer structure of the limit shape, define the regions

$$\mathcal{V}^{\alpha,\beta,ab} = \left\{ (x, y) \in \mathbb{R}^2_{\geq 0} : x \int_{\mathbb{R}} \frac{\alpha(da)}{(a - \mathbf{a})^2} \leq y \int_{\mathbb{R}} \frac{\beta(db)}{(b + \mathbf{b})^2} \right\}$$

$$\mathcal{H}^{\alpha,\beta,ab} = \left\{ (x, y) \in \mathbb{R}^2_{\geq 0} : x \int_{\mathbb{R}} \frac{\alpha(da)}{(a + \mathbf{b})^2} \geq y \int_{\mathbb{R}} \frac{\beta(db)}{(b - \mathbf{b})^2} \right\}$$

$$\mathcal{S}^{\alpha,\beta,ab} = \mathbb{R}^2_{\geq 0} \setminus (\mathcal{H}^{\alpha,\beta,ab} \cup \mathcal{V}^{\alpha,\beta,ab}).$$

To avoid trivialities, assume that $\alpha$ and $\beta$ are both nonzero. In particular, $a, b < \infty$. The regions $\mathcal{H}^{\alpha,\beta,ab}$, $\mathcal{V}^{\alpha,\beta,ab}$ and $\mathcal{S}^{\alpha,\beta,ab}$ are pairwise disjoint. Note that

$$\mathcal{V}^{\alpha,\beta,ab} \neq \emptyset \text{ if and only if } \int_{\mathbb{R}} \frac{\alpha(da)}{(a - \mathbf{a})^2} < \infty$$

$$\mathcal{H}^{\alpha,\beta,ab} \neq \emptyset \text{ if and only if } \int_{\mathbb{R}} \frac{\beta(db)}{(b - \mathbf{b})^2} < \infty.$$
(The other two integrals in (3.37)–(3.38) are finite by (3.16)). Also, \( S^{\alpha,\beta,a,b} \neq \emptyset \) since
\[
\int_R \alpha(da) \int_R (a + b)^2 \beta(db) < \int_R \alpha(da) \int_R (b - a)^2 \beta(db),
\]
where the inequality is strict by (3.16).

The justification for the following assertions can be seen from (7.1) below and Remark 3.6.4. The function \( \gamma^{\alpha,\beta,a,b} \) is affine on the regions \( \mathcal{H}^{\alpha,\beta,a,b} \) and \( \mathcal{Y}^{\alpha,\beta,a,b} \), and is given by
\[
\gamma^{\alpha,\beta,a,b}(x,y) = \left\{ \begin{array}{ll}
\frac{\alpha(da)}{a - a} + y \frac{\beta(db)}{b + a} & \text{for } (x,y) \in \mathcal{Y}^{\alpha,\beta,a,b} \\
\frac{\alpha(da)}{a + b} + y \frac{\beta(db)}{b - b} & \text{for } (x,y) \in \mathcal{H}^{\alpha,\beta,a,b}.
\end{array} \right.
\]

Hence, the boundaries (inside \( \mathbb{R}^2_{>0} \)) of the regions \( \mathcal{R}^{\alpha,\beta,a,b} \cap \mathcal{Y}^{\alpha,\beta,a,b} \) and \( \mathcal{R}^{\alpha,\beta,a,b} \cap \mathcal{H}^{\alpha,\beta,a,b} \) are flat segments. On the other hand, the function \( \gamma^{\alpha,\beta,a,b} \) is strictly concave on \( S^{\alpha,\beta,a,b} \), and the boundary of the region \( \mathcal{R}^{\alpha,\beta,a,b} \cap S^{\alpha,\beta,a,b} \) is curved (non-flat). The entire boundary of \( \mathcal{R}^{\alpha,\beta,a,b} \) is the image of a continuously differentiable curve and does not have any corners.

While the curved part is nonempty with the hypotheses of Theorem 3.6 it is also possible to generate completely flat limit shapes as in Corollary 3.19 below.

The boundary of the limit shape admits an exact parametrization. Indeed, the curve
\[
\Phi(z) = \frac{(\partial B^\beta(z), -\partial A^\alpha(z))}{A^\alpha(z)\partial B^\beta(z) - B^\beta(z)\partial A^\alpha(z)} \quad \text{for } z \in (-a, b)
\]
parametrizes the curved part since \( \gamma^{\alpha,\beta,a,b}(\Phi(z)) = 1 \) (because \( \zeta^{\alpha,\beta,a,b}(\partial B^\beta(z), -\partial A^\alpha(z)) = z \), see (7.1) below) and \( \Phi(z) \notin \mathcal{Y}^{\alpha,\beta,a,b} \cup \mathcal{H}^{\alpha,\beta,a,b} \) for \( z \in (-a, b) \). The flat boundaries inside \( \mathbb{R}^2_{>0} \) are the line segments from \( (0, B^\beta(-a)^{-1}) \) to \( \Phi(-a) \), and from \( (A^\alpha(b)^{-1}, 0) \) to \( \Phi(b) \). Finally, the boundary along the axes are the line segments from the origin to \( (0, B^\beta(-a)^{-1}) \) and \( (A^\alpha(b)^{-1}, 0) \).

3.7. Spikes and crevices. In the absence of condition (3.23), large (in macroscopic scale) spikes/crevices form near the axes that are not visible in the limit shape. To demonstrate this, consider the case \( \beta = 0 \) and \( \min a_m \neq a \) for some \( m \in \mathbb{Z}_{>0} \), namely, that the first part of (3.23) fails. The other case is analogous. The precise claim is that, for any \( \epsilon > 0 \) with \( 2\epsilon < |B^\beta(-\min a_m)^{-1} - \min a_m|/2 \), \( \mathbf{P} \)-a.s., there exists a random \( T > 0 \) such that
\[
\left\{ \frac{m}{t} \right\} \times \left[ \frac{1}{B^\beta(-a)} + \epsilon, \frac{1}{B^\beta(-\min a_m)} - \epsilon \right] \subset t^{-1} R_t a,b \ \mathcal{R}^{\alpha,\beta,a,b} \quad \text{if } \min a_m > a
\]
\[
\left\{ \frac{m}{t} \right\} \times \left[ \frac{1}{B^\beta(-\min a_m)} + \epsilon, \frac{1}{B^\beta(-a)} - \epsilon \right] \subset \mathcal{R}^{\alpha,\beta,a,b} \triangle t^{-1} R_t a,b \quad \text{if } \min a_m < a.
\]
for \( t \geq T \). The line segments in (3.42) and (3.43) can be visualized as a vertical spike or crevice, respectively, in the rescaled cluster near the vertical axis.

To verify (3.42) for example, pick \( 0 < \delta < B^\beta(-a) \) such that
\[
u = \frac{1}{B^\beta(-a)} - \delta \quad \text{and} \quad \nu = \frac{1}{B^\beta(-\min a_m)} + \delta \quad \text{such that} \quad \frac{1}{B^\beta(-a)} - \delta \leq \frac{1}{B^\beta(-\min a_m)} + \delta.
\]
By Theorem 3.7, P-a.s., there exists a random $K \in \mathbb{Z}_{>0}$ such that $G^{a,b}(m, n) \leq n(v + \delta)^{-1}$ for $n \in \mathbb{Z}_{>K}$. Therefore, $K \leq n \leq t(v + \delta)$ implies that $(m, n) \in R_{t}^{a,b}$. Consequently,

$$\{t^{-1}m\} \times [t^{-1}K, v] \subset t^{-1}R_{t}^{a,b} \quad \text{for } t \geq T = \max\{Kv^{-1}, \delta^{-1}\}.$$ 

On the other hand, by (3.36), the shape function $\gamma^{a,b}(t^{-1}m, u) \rightarrow uB^{\beta}(-a) > 1$. Hence,

$$\{t^{-1}n\} \times [u, v] \subset t^{-1}R_{t}^{a,b} \subset \mathcal{R}^{a,b} \quad \text{for } t \geq T$$

after increasing $T$ if necessary.

3.8. **Centerings for the height and flux processes.** The limit shape for the bulk LPP process leads to the following explicit centerings for the height and flux processes, respectively, discussed in Subsection 2.4. Assuming (3.16), (3.17) and that $\alpha, \beta \neq 0$, introduce the limiting height and flux functions by

$$h^{a,b}(y, t) = \max\left\{ \sup_{x \in (-a, b)} \left\{ \frac{t - yB^{\beta}(z)}{A^{\alpha}(z)} \right\}, 0 \right\} \quad \text{for } (y, t) \in \mathbb{R}_{\geq 0}^{2}$$

$$f^{a,b}(x, t) = \max\left\{ \sup_{x \in (-a, b)} \left\{ \frac{t - xA^{\alpha}(z)}{A^{\alpha}(z) + B^{\beta}(z)} \right\}, 0 \right\} \quad \text{for } (x, t) \in \mathbb{R}_{\geq 0}^{2},$$

respectively.

**Theorem 3.11.** Assume (3.16), (3.20), (3.21) and $\alpha, \beta \neq 0$. Let $\epsilon > 0$. Then, P-a.s., there exists a (random) $L \in \mathbb{Z}_{>0}$ such that

$$|H^{a,b}(n, t) - 1^{a,b}(n, t)| \leq \epsilon(t + n), \quad |\alpha^{a,b}(n, t) - 1^{a,b}(n, t) + n| \leq \epsilon(t + n)$$

for $m, n \in \mathbb{Z}_{>L}$ and $t \in \mathbb{R}_{\geq 0}$.

**Remark 3.11.1.** It can be seen from (3.18) that the height function is also given by

$$h^{a,b}(y, t) = \begin{cases} 0 & \text{if } t \leq yB^{\beta}(-a) \\ \{ \text{the unique } x \in (0, t/A^{\alpha}(b) \} \end{cases}$$

such that $\gamma^{a,b}(x, y) = t$ otherwise.

The partial derivatives can be computed as

$$\partial_{y}h = -\frac{B^{\beta}(\xi(h, y))}{A^{\alpha}(\xi(h, y))} \quad \text{and} \quad \partial_{t}h = \frac{1}{A^{\alpha}(\xi(h, y))} \quad \text{for } (y, t) \in \mathbb{R}^{2}_{\geq 0} \text{ with } t > yB^{\beta}(-a),$$

where $h = h^{a,b}(y, t)$ and $\xi = \xi^{a,b}$. Hence, the height function satisfies the Hamilton-Jacobi equation

$$\partial_{t}h = v(\partial_{y}h) \quad \text{for } (y, t) \in \mathbb{R}^{2}_{\geq 0} \text{ with } t > yB^{\beta}(-a),$$

where the speed function $v$ is implicitly defined on the interval $I = (B^{\beta}/A^{\alpha})(-a, b)$ by

$$v\left(\frac{B^{\beta}(z)}{A^{\alpha}(z)}\right) = \frac{1}{A^{\alpha}(z)} \quad \text{for } z \in (-a, b).$$

Similarly, the flux function can be alternatively given by

$$f^{a,b}(x, t) = \begin{cases} 0 & \text{if } t \leq xA^{\alpha}(b) \\ \{ \text{the unique } y \in (0, t/\gamma^{a,b}(1, 1) \} \end{cases}$$

such that $\gamma^{a,b}(x + y, y) = t$ otherwise.
The partial derivatives of \( f = f^{a,\beta,a,b}(x,t) \) read
\[
\partial_x f = -\frac{A^\alpha(\zeta(x+f,t))}{A^\alpha(\zeta(x,f)) + B^\beta(\zeta(x+f,t))} \quad \text{and} \quad \partial_t f = \frac{1}{A^\alpha(\zeta(x+f,t)) + B^\beta(\zeta(x+f,t))}
\]
for \((x,t) \in \mathbb{R}^2_+\) with \(t > xA^\alpha(b)\). The functions \( \rho = -\partial_x f \) and \( j = \partial_t f \) represent macroscopic density and current of the particles, respectively. A brief computation verifies that the density satisfies the conservation law
\[
\partial_t \rho + \partial_x \left\{ \rho v \left( \frac{1 - \rho}{\rho} \right) \right\} = 0 \quad \text{for} \quad (x,t) \in \mathbb{R}^2_+ \quad \text{with} \quad t > xA^\alpha(b).
\]

For TASEP with particlewise random disorder, variational representations of the height and density functions, and PDEs (3.46) and (3.47) appeared in [60, (16), (25)]. For discrete-time TASEP with step initial condition and particlewise macroscopic disorder, a formula for the height function is included in [43, (2.10)] as a special case, see Remark 3.20.3 below.

Remark 3.11.2. In the homogeneous case (2.9), various quantities in Remark 3.11.1 can be computed explicitly as
\[
h^c(y,t) = (\sqrt{ct} - y)^2, \quad f^c(x,t) = \frac{(ct - x)^2}{4ct}, \quad \rho^c(x,t) = \frac{(ct - x) + 2ct}{2ct} \quad \text{and} \quad j^c(x,t) = c\rho(1 - \rho)
\]
for \(x, y, t \in \mathbb{R}_+\), which were first obtained in [54].

The next result approximates the location of particle with a fixed label after a long time.

Theorem 3.12. Assume the first limits in (3.20), (3.21) and that \( \alpha \neq 0 \). Fix \( n \in \mathbb{Z}_+ \) and assume that \( a + \min b_n > 0 \). Then, \( P \)-a.s., there exists a (random) \( T \in \mathbb{Z}_+ \) such that
\[
\left| H^{a,b}(n,t) - \frac{t}{A^\alpha(\min b_n)} \right| \leq ct \quad \text{and} \quad \left| \sigma^{a,b}(n,t) - \frac{t}{A^\alpha(\min b_n)} + n \right| \quad \text{for} \quad t \geq T.
\]

3.9. Applications of the shape theorem. We record special cases and applications of Theorem 3.6 and connect them with earlier literature. Recall Definition (3.5) for the shape function.

Fixed rates. First, consider the case where the parameters \( a \) and \( b \) come from two fixed sequences, i.e. no \( m, n \)-dependence in the terms.

Corollary 3.13. Let \( a = (a_i)_{i \in \mathbb{Z}_+} \) and \( b = (b_j)_{j \in \mathbb{Z}_+} \) be real sequences subject to (3.8) and (3.20). Then the shape function exists and is given by \( \gamma^{a,\beta,\inf a,\inf b} \).

Periodic rates. A further special case is the one with periodic rates.

Corollary 3.14. Let \( k, l \in \mathbb{Z}_+ \). Let \( a = (a_i)_{i \in \mathbb{Z}_+} \) and \( b = (b_j)_{j \in \mathbb{Z}_+} \) be real sequences subject to \( a_k^{\min} + b_l^{\min} > 0 \), and with periods \( k \) and \( l \), respectively, i.e. \( a_i = a_{i+k} \) and \( b_j = b_{j+l} \) for \( i, j \in \mathbb{Z}_+ \). Then the shape function exists and is given by
\[
\gamma(x,y) = \inf_{z \in (-a_k^{\min}, b_l^{\min})} \left\{ x \sum_{i=1}^{k} \frac{1}{a_i + z} + y \sum_{j=1}^{l} \frac{1}{b_j - z} \right\} \quad \text{for} \quad x, y \in \mathbb{R}_+.
\]

Remark 3.14.1. For the homogeneous case (2.9), the preceding infimum can be computed explicitly to recover Rost’s shape function [51] given by
\[
\gamma^c(x,y) = \frac{1}{c} (\sqrt{x} + \sqrt{y})^2 \quad \text{for} \quad x, y > 0.
\]
Random rates. The following application to the random parameter setting improves [25, Theorem 2.1] by strengthening directional limits (of the kind in (3.28)) to a shape theorem and by eliminating the joint ergodicity assumptions therein.

**Corollary 3.15.** Let \( a = (a_i)_{i \in \mathbb{Z}_+} \) and \( b = (b_j)_{j \in \mathbb{Z}_+} \) be individually ergodic sequences with marginal distributions \( a_i \sim \alpha \) and \( b_j \sim \beta \) that satisfy (3.15). Then, for almost every realization of the parameters \( a \) and \( b \), the shape function exists and is given by \( \gamma_{\alpha,\beta,\inf \sup \alpha,\inf \sup \beta} \).

Boundary rates on one or two sides. Another application of Theorem 3.6 reveals the shape functions of the LPP processes with one-sided and two-sided boundaries. To define these processes, introduce the Borel probability measure \( \hat{P} \) on \( \Omega \) under which

\[
\{\hat{w}(i,j) : i,j \in \mathbb{Z}_+\} \text{ is independent and } \hat{w}(i,j) \sim \text{Exp}(1) \text{ for } i,j \in \mathbb{Z}_+.
\]

For \( m, n \in \mathbb{Z}_+ \), let \( \{\hat{w}_{m,n}(i,j) : i \in [m] \cup \{0\}, j \in [n] \cup \{0\}\} \) be jointly independent and \( \text{Exp}(1) \)-distributed random variables on \( (\Omega, \hat{P}) \). Define the weights

\[
\hat{w}_{m,n}(i,j) = \hat{w}_{m,n}(i,j) \left( \frac{1_{\{i,j>0\}}}{a_m(i) + b_n(j)} + \frac{1_{\{i>0,j=0\}}}{a_m(i) + b_n(j)} + \frac{1_{\{i=0,j>0\}}}{a_m(i) + z} \right)
\]

for \( m,n,i,j \in \mathbb{Z}_+ \) with \( i \leq m \) and \( j \leq n \), \( w > -\min a_m \) and \( z < \min b_n \). Abbreviate \( w, z \) in the superscript as \( z \) when \( z = w \). For \( m,n \in \mathbb{Z}_+ \), the joint distribution of \( \{\hat{w}_{m,n}(i,j) : i \in [m] \cup \{0\}, j \in [n] \cup \{0\}\} \) is precisely \( \hat{P}_{m,n}^{a,b,z} \) defined at (2.12). Now define three LPP processes

\[
\{\hat{G}_{1,0}^{a,b,w}(m,n), \hat{G}_{0,1}^{a,b,z}(m,n) \text{ and } \hat{G}_{a,b,w,z}^{a,b}(m,n) : m,n \in \mathbb{Z}_+\}
\]

for each \( w > -\min a_m \) and \( z < \min b_n \) via formula (2.2) using the weights in (3.50). The first two processes see the boundary weights only one one axis while the last process sees boundaries on both axes. For the last case in the theorem below, recall definition (3.14).

**Corollary 3.16.** Assume (3.16), (3.20) and (3.21). Let \( w, z \in (-a, b) \) and \( \epsilon > 0 \). Then \( \hat{P}-a.s. \), there exists a (random) \( L \in \mathbb{Z}_+ \) such that, for \( m,n \in \mathbb{Z}_+ \) with \( m,n \geq L \),

\[
|\hat{G}_{1,0}^{a,b,w}(m,n) - \gamma_{\alpha,\beta,\alpha,w}(m,n+1)| \leq \epsilon (m+n)
\]

\[
|\hat{G}_{0,1}^{a,b,z}(m,n) - \gamma_{\alpha,\beta,-z,b}(m+1,n)| \leq \epsilon (m+n)
\]

\[
|\hat{G}_{a,b,w,z}^{a,b}(m,n) - \max\{\gamma_{\alpha,\beta,\alpha,w}(m,n+1), \gamma_{\alpha,\beta,-z,b}(m+1,n)\}| \leq \epsilon (m+n)
\]

Remark 3.16.1. In case of homogeneous bulk weights as in (2.9), LPP processes with one-sided boundaries were considered in [5] (also see Remark 3.17.1 below) while the version with two-sided boundary appeared in [6, 10]. Note that the more general model with thickened boundaries as in [10, 41]) is also included in (3.50).

Remark 3.16.2. If (3.16), (3.20) and (3.21) hold then the parameters \( \tilde{a} = \{a_m(m+1-i) : m \in \mathbb{Z}_+, i \in [m]\} \) and \( \tilde{b} = \{b_n(n+1-j) : n \in \mathbb{Z}_+, j \in [n]\} \) also satisfy these conditions with the same \( \alpha, \beta, a \) and \( b \). Therefore, the conclusion of Corollary 3.16 remain true with \( \tilde{a}, \tilde{b} \) in place of \( a, b \). The processes in (3.51) computed with parameters \( \tilde{a}, \tilde{b} \) can viewed as LPP processes with boundary weights on north and/or east sides as in [59, (4.29)–(4.30)]. Hence, Corollary 3.16 implies [59, Lemma 4.8].
Defective rates along a few rows and columns. The next corollary records the shape function in the perturbations of the homogeneous model obtained by modifying the parameters on a fixed set of defective rows and columns. The law of large numbers and fluctuations of this variant of LPP (with defective columns) was studied in [5]. The model is interesting because, with careful tuning of the parameters, it exhibits a transition between Tracy-Widom and Gaussian type fluctuations, now known as Baik-BenArous-Péché (BBP) transition. Here, we obtain the LLN part of their result without resorting to the integrable probability techniques.

Corollary 3.17. Fix $k, l \in \mathbb{Z}_{>0}$ and sequences $(a_i)_{i \in [k]}$ and $(b_j)_{j \in [l]}$ in $\mathbb{R}_{>\frac{1}{2}}$ that satisfy $a_k^\text{min} + b_l^\text{min} > 0$. For $m, n \in \mathbb{Z}_{>0}$, $i \in [m]$, and $j \in [n]$ define rate parameters

$$a_m(i) = a_i 1_{i \leq k} + \frac{1}{2} 1_{i > k} \quad \text{and} \quad b_n(j) = b_j 1_{j \leq l} + \frac{1}{2} 1_{j > l}.$$

Then the shape function exists and is given by

$$\gamma(x, y) = \begin{cases} x(1/2 + a_k^\text{min})^{-1} + y(1/2 - b_l^\text{min})^{-1} & \text{if } \sqrt{x} - \sqrt{y} \geq 2b_l^\text{min}(\sqrt{x} + \sqrt{y}) \\ x(1/2 - a_k^\text{min})^{-1} + y(1/2 + a_k^\text{min})^{-1} & \text{if } \sqrt{x} - \sqrt{y} \leq -2a_k^\text{min}(\sqrt{x} + \sqrt{y}) \\ (\sqrt{x} + \sqrt{y})^2 & \text{otherwise.} \end{cases}$$

Remark 3.17.1. Set $k = 0$ and $b_j = b - 1/2$ for $j \in [r]$ and $b_j > b - 1/2$ for $j \in [l] \setminus [r]$ for some $b > 0$ and $r \in [l] \cup \{0\}$. Corollary 3.17 then yields

$$\gamma(x, y) = \begin{cases} xb^{-1} + y(b + 1)^{-1} & \text{if } \sqrt{x} \geq b(\sqrt{x} + \sqrt{y}) \\ (\sqrt{x} + \sqrt{y})^2 & \text{otherwise.} \end{cases}$$

The last formula implies [5 Corollary 1.1]

Convergent rates. The next corollary shows that if the parameters $(a_i)_{i \in \mathbb{Z}_{>0}}$ and $(b_j)_{j \in \mathbb{Z}_{>0}}$ converge uniformly as $m, n \to \infty$, then the shape function is the same as in the model with limiting parameters.

Corollary 3.18. Let $(a_i)_{i \in \mathbb{Z}_{>0}}$ and $(b_j)_{j \in \mathbb{Z}_{>0}}$ be real sequences subject to (3.8) and (3.20). Assume that

$$\max_{i \in \mathbb{Z}_{>0}} |a_i| \to 0 \quad \text{and} \quad \max_{j \in \mathbb{Z}_{>0}} |b_j| \to 0.$$

Then the shape function exists and is given by $\gamma^{a,b}$ where $a = \inf(a_i)_{i \in \mathbb{Z}_{>0}}$ and $b = \inf(b_j)_{j \in \mathbb{Z}_{>0}}$.

Remark 3.18.1. The corollary covers the following type of model, the discrete version of which was considered in [17 Corollary 2.11]: Let $k, l \in \mathbb{Z}_{>0}$, and $x_i, y_j \in \mathbb{R}$ for $i \in \mathbb{Z}_{k}$ and $j \in \mathbb{Z}_{l}$. Let $\eta > 0$ and $a, b \in \mathbb{R}$ with $c = a + b > 0$. Let $p_m \in [m - k]$ and $q_n \in [n - l]$ for $m, n \in \mathbb{Z}_{>0}$. Assume that

$$a_m(i) = a + 1_{i \leq p_m[k]} \frac{x_i}{m\eta} \quad \text{for } m \in \mathbb{Z}_{>0} \text{ and } i \in \mathbb{Z}_{k}$$

$$b_n(j) = b + 1_{j \leq q_n[l]} \frac{y_j}{n\eta} \quad \text{for } n \in \mathbb{Z}_{>0} \text{ and } j \in \mathbb{Z}_{l}.$$

Then the shape function is given by (3.48).

The shape function can still be computed if (3.8) is weakened to conditions (3.53) and (3.54) below.
Consider the LPP process \( t(x,y) \).

Remark 3.19.2. Define the parameters \( a \) and \( b \) by

\[
\begin{align*}
\omega_N(i,j) &= \frac{\omega(i,j)}{\lambda(i/N,j/N)} & \text{for } i,j \in \mathbb{Z}_{>0}.
\end{align*}
\]

Now fix \( j \) for some \( k,l \).

Remark 3.19.1. If \( a_0 + b_0 > 0 \) then the conclusion also follows from Corollary 3.18. The interesting case is \( a_0 + b_0 = 0 \), in which case (3.53) implies that \( a_i + b_j = 0 \) for some \( i \in [k] \) and \( j \in [l] \). Then \( \Gamma_{a_0} = \Gamma_{b_0} \) is finite because (3.20) and (3.53) imply that \( -a_0 = b_0 \in (-a_k,b_l) \subset (\inf \text{supp } a, \inf \text{supp } b) \). The shape function is linear in this case.

Remark 3.19.2. It can be deduced from the corollary that the shape function in the LPP model studied in [13] is (3.48). To see this, let \( \eta > 0, a,b \in \mathbb{R}_{>0}, k,l \in \mathbb{Z}_{\geq 0} \), and pick \( x_m(i) \in \mathbb{R}_{>0}, y_n(j) \in \mathbb{R}_{>0} \) with \( x_m(i) + y_n(j) > 0 \) and \( |x_m(i)|, |y_n(j)| \leq C \) for \( m,n \in \mathbb{Z}_{\geq 0}, i \in [k], j \in [l] \) for some constant \( C > 0 \). Consider the rates

\[
\begin{align*}
a_m(i) &= 1_{(i > k)}a + \frac{x_m(i)}{m^\eta}1_{(i \leq k)} & \text{for } m \in \mathbb{Z}_{\geq 0} \text{ and } i \in [k],
\end{align*}
\]

\[
\begin{align*}
b_n(j) &= 1_{(j > l)}b + \frac{y_n(j)}{n^\eta}1_{(j \leq l)} & \text{for } n \in \mathbb{Z}_{\geq 0} \text{ and } j \in [l].
\end{align*}
\]

Condition (3.8) fails for these rates but the hypotheses of Corollary 3.19 hold. Hence, the shape function is given by

\[
\gamma(x,y) = \frac{x}{a} + \frac{y}{b} & \text{ for } x,y \in \mathbb{R}_{>0}.
\]

Now fix \( x,y > 0 \) and choose \( a = \sqrt{x} (\sqrt{x} + \sqrt{y})^{-1}, b = \sqrt{y} (\sqrt{x} + \sqrt{y})^{-1} \). Then (3.56) coincides with (3.48) with \( c = 1 \), which agrees with the centering in [13 Theorem 2].

Macroscopically inhomogeneous rates. Given a speed function \( \lambda : \mathbb{R}_{>0}^2 \to \mathbb{R}_{>0} \), a scaling parameter \( N \in \mathbb{Z}_{>0} \) and the weights in (2.5), define

\[
\omega_N(i,j) = \frac{\omega(i,j)}{\lambda(i/N,j/N)} & \text{ for } i,j \in \mathbb{Z}_{>0}.
\]

Consider the LPP process \( \{G_N^t(i,j) : i,j \in \mathbb{Z}_{>0}\} \) computed from these weights via (2.1) with the initial point at site \((1,1)\). This variant of LPP was introduced in [53] with a continuous speed function and subsequently studied in more generality in [14], [29] and [30]. The weights in (3.57) can be emulated in our setup when the speed function is additively separable. The next lemma describes the shape function in this special case under further mild conditions.

Corollary 3.20. Let \( A,B : [0,1] \to \mathbb{R} \) be Riemann integrable functions such that

\[
\inf A + \inf B > 0.
\]

Define the parameters \( a \) and \( b \) by

\[
\begin{align*}
a_m(i) &= A(i/m) & \text{and } b_n(j) &= B(j/n) & \text{for } m,n \in \mathbb{Z}_{>0}, i \in [m], j \in [n].
\end{align*}
\]
Let \( A, B \). Remark 3.2.0.2 \( \lambda \) given by \( A, B \) applied with the functions \( \inf \). Interestingly, the speed function is assumed to be lower semicontinuous in \( \inf \) and \( \inf \). For any \( x, y \in \mathbb{Z}_+^2 \) with \( x \geq x_0 \) and \( y \geq y_0 \), the corollary applied with the functions \( t \to A(tx) \) and \( t \to B(ty) \) for \( t \in [0, 1] \) gives

\[
\lim_{N \to \infty} N^{-1} G_N^\lambda(Nx, Ny) \overset{\text{P-a.s.}}{=} \inf_{x \in (-a, b)} \left\{ x \int_{[0,1]} \frac{dt}{A(t) + z} + y \int_{[0,1]} \frac{dt}{B(t) - z} \right\}
\]

\[
= \inf_{x \in (-a, b)} \left\{ \int_{[0,x]} \frac{dt}{A(t) + z} + \int_{[0,y]} \frac{dt}{B(t) - z} \right\}
\]

The right-hand side defines the shape function \( U : \mathbb{R}_+^2 \to \mathbb{R}_+^2 \) (notation from \( \mathbb{R}_+^2 \)) for the model in \( \mathbb{R}_+^2 \). The directional limits above can be upgraded to a shape theorem via standard arguments using monotonicity and positive-homogeneity. An omitted computation verifies that \( U \) is precisely the solution of the boundary value problem in \( \mathbb{R}_+^2 \) and, equivalently, satisfies \( \mathbb{R}_+^2 \) (17).

Remark 3.2.0.3. We formally link Theorem \( \mathbb{R}_+^2 \) with the limit shape in \( \mathbb{R}_+^2 \). The following derivation can likely be made rigorous. Under suitable assumptions analogous to \( \mathbb{R}_+^2 \), \( \mathbb{R}_+^2 \) and \( \mathbb{R}_+^2 \), the shape function corresponding to the geometric model from Remark \( \mathbb{R}_+^2 \) should be given by

\[
\gamma^{\alpha, \beta, a, b}(x, y) = \inf_{a \in \mathbb{R}^+} \left\{ x \int_{\mathbb{R}^+} \frac{da}{z - a} + y \int_{\mathbb{R}^+} \frac{dz}{1 - b z} \right\} \quad \text{for} \quad x, y > 0,
\]

where \( \max a_m \to \mathbb{R}^+ \) and \( \max b_n \to \mathbb{R}^+ \). This formula appears in \( \mathbb{R}^+ \). Theorem 2.1 in the case of random parameters. Now, for each \( N \in \mathbb{R}_+^2 \), consider independent, \( \mathbb{Z}_+^2 \)-valued weights \( \{ \omega_N(i,j) : i, j \in \mathbb{Z}_+^2 \} \) such that

\[
\mathbb{P} \{ \omega_N(i,j) \geq k \} = (A(i/N)B(j/N))^k \quad \text{for} \quad i, j, k \in \mathbb{Z}_+^2,
\]

where \( A, B : \mathbb{R}_+^2 \to \mathbb{R}_+^2 \) are given continuous functions with \( \sup A \sup B < 1 \). The shape function for this model deduced from \( \mathbb{R}_+^2 \) in analogy with the computation in Remark \( \mathbb{R}_+^2 \) reads

\[
\gamma(x, y) = x + y + \inf_{z \in (\sup A, 1/\sup B)} \left\{ \int_0^x \frac{A(s)}{z - A(s)} ds + \int_0^y \frac{B(s)z}{1 - B(s)z} ds \right\} \quad \text{for} \quad x, y > 0.
\]

The term \( x + y \) in \( \mathbb{R}_+^2 \) comes because the geometric weights in \( \mathbb{R}_+^2 \) are supported on \( \mathbb{R}_+^2 \) unlike \( \mathbb{R}_+^2 \). Now specialize to \( A = 1 \), introduce \( \tilde{B} = 1/B - 1 \), replace \( z \) with \( z - 1 \) and rearrange terms in \( \mathbb{R}_+^2 \) to obtain

\[
\gamma(x, y) = \inf_{0 < \inf \tilde{B}} \left\{ \frac{x(1 + z)}{z} + \int_0^y \frac{\tilde{B}(s) + 1}{\tilde{B}(s) - z} ds \right\} \quad \text{for} \quad x, y > 0.
\]
This is the shape function for a special case of the model in [33] Section 2.4 (with \( a_i = \tilde{B}(i/N) \), \( \nu_i = -a_i \), and after interchanging the roles of columns/rows). The limiting height function can be obtained from the shape function in analogy with (3.44) as

\[
(3.65) \quad h(t, y) = \max \left\{ \sup_{z \in (0, \inf B)} \left\{ \frac{z}{1 + z} \left( t - \int_0^y \frac{\tilde{B}(s) + 1}{\tilde{B}(s) - z} \, ds \right) , 0 \right\} \right\} \quad \text{for } t, y > 0,
\]

which is in agreement with [33] (2.10).

Growing rates. When the \( G^{a,b} \)-process grows sublinearly, the shape function is trivial and does not capture the order of growth. This is the case, for example, if \( a \) and \( b \) are unbounded increasing sequences. However, the precise first-order asymptotics can still be deduced from Theorem 3.2 in some cases. The next corollary illustrates this with a model taken from [39].

Corollary 3.21. Let \( \eta \in (0, 1) \) and assume that \( a_m(i) = \iota^n \) and \( b_n(j) = j^n \) for \( m, n \in \mathbb{Z}_{>0}, i \in [m], j \in [n] \). Let \( \epsilon > 0 \). Then, \( \mathbb{P} \)-a.s., there exists a (random) \( L \in \mathbb{Z}_{>0} \) such that

\[
|G^{a,b}(m, n) - (1 - \eta)^{-1}(m^{1-\eta} + n^{1-\eta})| \leq \epsilon \cdot (m^{1-\eta} + n^{1-\eta}) \quad \text{for } m, n \in \mathbb{Z}_{\geq L}.
\]

4. Concentration bounds for the last-passage times

As a main step towards the proof of Theorem 3.2 we begin to derive concentration bounds for \( G(m, n) \) around \( \mathcal{M}^{a,b}(m, n) \) under \( P_{m,n}^{a,b} \) for each site \( (m, n) \in \mathbb{Z}^2_{>0} \).

Writing \( \partial_z \) for the \( z \)-derivative note that, for \( m, n \in \mathbb{Z}_{\geq 0} \),

\[
(4.1) \quad \partial_z \mathcal{M}^{a,b,z}(m, n) = -\sum_{i=1}^{m} \frac{1}{(a_m(i) + z)^2} + \sum_{j=1}^{n} \frac{1}{(b_n(j) - z)^2}
\]

\[
(4.2) \quad \partial_z^2 \mathcal{M}^{a,b,z}(m, n) = \sum_{i=1}^{m} \frac{2}{(a_m(i) + z)^3} + \sum_{j=1}^{n} \frac{2}{(b_n(j) - z)^3}
\]

If \( m \) or \( n \) is nonzero then the function \( z \mapsto \mathcal{M}^{a,b,z}(m, n) \) is strictly convex on \( I_{m,n}^{a,b} \) due to the strict positivity of (4.2). Also, if \( m, n > 0 \) then \( \mathcal{M}^{a,b,z}(m, n) \to \infty \) as \( z \) approaches the boundary values \( \{-\min a_m, \min b_n\} \) within \( I_{m,n}^{a,b} \). Hence, there exists a unique minimizer \( \zeta = \zeta^{a,b}(m, n) \) in (4.3). This is the unique \( z \in I_{m,n}^{a,b} \) that satisfies the implicit equation

\[
(4.3) \quad \sum_{i=1}^{m} \frac{1}{(a_m(i) + z)^2} = \sum_{j=1}^{n} \frac{1}{(b_n(j) - z)^2}.
\]

Note from definition (2.12) that the sums in (4.3) are precisely the variances of \( \hat{G}(m, 0) \) and \( \hat{G}(0, n) \), respectively, under \( P_{m,n}^{a,b,z} \). Thus, \( \zeta \) is the unique \( z \)-value for which \( \hat{G}(m, 0) \) and \( \hat{G}(0, n) \) have the same variance given by

\[
(4.4) \quad \mathcal{C}^{a,b}(m, n) = \sum_{i=1}^{m} \frac{1}{(a_m(i) + \zeta)^2} = \sum_{j=1}^{n} \frac{1}{(b_n(j) - \zeta)^2}.
\]

The deviations of \( G(m, n) \) from the centering \( \mathcal{M}^{a,b}(m, n) \) are naturally expressed below in terms of this variance.

For brevity, introduce the functions

\[
(4.5) \quad A^a_z(m) = \mathcal{M}^{a,b,z}(m, 0) = \sum_{i=1}^{m} \frac{1}{a_m(i) + z} \quad \text{for } m \in \mathbb{Z}_{\geq 0} \text{ and } z \in \mathbb{C} \setminus \{-a_m(i) : i \in [m]\},
\]
\begin{equation}
B_{z}(n) = M^{a, z}(0, n) = \sum_{j=1}^{n} \frac{1}{b_{n}(j) - z} \quad \text{for } n \in \mathbb{Z}_{\geq 0} \text{ and } z \in \mathbb{C} \setminus \{b_{n}(j) : j \in [n]\}
\end{equation}

with the convention that $A_{z}^{a}(0) = B_{z}(0) = 0$ for $z \in \mathbb{C}$. Because the concentration bounds below for site $(m, n) \in \mathbb{Z}_{\geq 0}^{2}$ depend on the parameters $a$ and $b$ only through $a_{m}$ and $b_{n}$, it causes no loss in generality to assume in this section that

\[ a_{m}(i) = a_{i} \quad \text{and} \quad b_{n}(j) = b_{j} \quad \text{for } m, n \in \mathbb{Z}_{\geq 0} \text{ and } i \in [m], j \in [n] \]

for some real sequences $(a_{i})_{i \in \mathbb{Z}_{\geq 0}}$ and $(b_{j})_{j \in \mathbb{Z}_{\geq 0}}$.

We first record a concentration bound for $\hat{G}(m, n)$ around $M^{a, b}(m, n)$ under $\hat{P}^{a, b, \zeta}_{m, n}$.

**Lemma 4.1.** Let $m, n \in \mathbb{Z}_{\geq 0}$ and $\zeta = \zeta^{a, b}(m, n)$. Let $s > 0$ and $p \in \mathbb{Z}_{\geq 0}$. Then there exists a constant $C_{p} > 0$ (depending only on $p$) such that

\[ \hat{P}^{a, b, \zeta}_{m, n}\{|\hat{G}(m, 0) - A_{\zeta}^{a}(m)| + |\hat{G}(m, n) - \hat{G}(m, 0) - B_{\zeta}^{b}(n)| \geq s\sqrt{C}\} \leq C_{p}s^{-p}. \]

**Proof.** Abbreviate $C = C^{a, b}(m, n)$. By the triangle inequality, a union bound and (2.13), the probability in the statement is at most

\[ \hat{P}^{a, b, \zeta}_{m, n}\{|\hat{G}(m, 0) - A_{\zeta}^{a}(m)| + |\hat{G}(m, n) - \hat{G}(m, 0) - B_{\zeta}^{b}(n)| \geq s\sqrt{C}\} \leq \hat{P}^{a, b, \zeta}_{m, n}\{|\hat{G}(m, 0) - A_{\zeta}^{a}(m)| \geq \frac{s}{2}\sqrt{C}\} + \hat{P}^{a, b, \zeta}_{m, n}\{|\hat{G}(m, n) - \hat{G}(m, 0) - B_{\zeta}^{b}(n)| \geq \frac{s}{2}\sqrt{C}\} \]

Now the result readily follows from definition (4.4) and Lemma A.2 \qed

An immediate consequence is the next right tail bound.

**Lemma 4.2.** Let $m, n \in \mathbb{Z}_{\geq 0}$. Let $s > 0$ and $p \in \mathbb{Z}_{\geq 0}$. Then there exists a constant $C_{p} > 0$ (depending only on $p$) such that

\[ \hat{P}^{a, b}_{m, n}\{G(m, n) - M^{a, b}(m, n) \geq s(C^{a, b}(m, n))^{1/2}\} \leq C_{p}s^{-p}. \]

**Proof.** Write $\zeta = \zeta^{a, b}(m, n)$. Since $P^{a, b}_{m, n}$ is a projection of $P^{a, b, \zeta}_{m, n}$ and $G(m, n) \leq \hat{G}(m, n)$ a.s. under $P^{a, b, \zeta}_{m, n}$, the result follows from Lemma 4.1 \qed

We now turn to developing a corresponding left tail bound. To this end, first note the following right tail bound for the last-passage times defined on paths constrained to enter the bulk at a specific boundary site.

**Lemma 4.3.** Let $m, n \in \mathbb{Z}_{\geq 0}$ and $\zeta = \zeta^{a, b}(m, n)$. Let $k \in [m], l \in [n], s > 0$ and $p \in \mathbb{Z}_{\geq 0}$. Then there exists a constant $C_{p} > 0$ (depending only on $p$) such that

\[ \hat{P}^{a, b, \zeta}_{m, n}\{\hat{G}(k, 0) + G_{k, 1}(m, n) \geq M^{a, b}(m - k + 1, n) + A_{\zeta}^{a}(k) + s(C^{a, b}(m, n))^{1/2}\} \leq C_{p}s^{-p} \]

\[ \hat{P}^{a, b, \zeta}_{m, n}\{\hat{G}(0, l) + G_{1, l}(m, n) \geq M^{a, b}(m, n - l + 1) + B_{\zeta}^{b}(l) + s(C^{a, b}(m, n))^{1/2}\} \leq C_{p}s^{-p}. \]

**Proof.** By Lemma A.2 and since $\sum_{i=1}^{b} (a_{i} + \zeta)^{-2} \leq C^{a, b}(m, n)$,

\[ \hat{P}^{a, b, \zeta}_{m, n}\{\hat{G}(k, 0) - A_{\zeta}^{a}(k) \geq s(C^{a, b}(m, n))^{1/2}\} \leq C_{p}s^{-p}. \]
Write \( \tilde{\zeta} = \zeta_{r_k-1,a,b}(m - k + 1, n) \). The ordering \( \tilde{\zeta} \leq \zeta \) is clear from definition (4.3). Then
\[
C_{r_k-1,a,b}(m - k + 1, n) = \sum_{j=1}^{n} \frac{1}{(b_j - \tilde{\zeta})^2} \leq \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} = C_{a,b}(m, n).
\]
Hence, by Lemma 4.2,
\[
P_{a,b}(m, n) - M_{r_k-1,a,b}(m - k + 1, n) \geq s(C_{a,b}(m, n))^{1/2} \leq C_p s^{-p}.
\]
The first of the claimed bounds now follows from the triangle inequality and a union bound. The proof of the second bound is analogous.

Some of the statements below require an ordering condition on the parameters \( a \) and \( b \). This does not limit the scope of the tail bounds of \( G \), however, because the distribution of \( G \) is invariant under permutations of the parameters as stated in the next lemma.

Lemma 4.4. Let \( m, n \in \mathbb{Z}_{>0} \). Let \( \sigma, \tau \) be permutations on \( [m] \) and \( [n] \), respectively. Then, for \( x \in \mathbb{R} \),
\[
P_{a,b}(m, n) \leq x = P_{a,\tau b}(m, n) \leq x.
\]

Proof. One can readily observe this from the formula (13) (12)] for the distribution of \( G \).

Next comes a comparison of \( M_{a,b} \) with essentially (up to a single boundary term) the centering for the LPP values considered in Lemma 4.3. Denote the distance from the minimizer \( \zeta \) to the boundary of \( I_{m,n} \) by
\[
\Delta_{a,b}(m, n) = \min\{a_m^{\min} + \zeta, b_n^{\min} - \zeta\}.
\]

Lemma 4.5. Let \( m, n \in \mathbb{Z}_{>0} \), \( \zeta = \zeta_{a,b}(m, n), \ C = C_{a,b}(m, n) \) and \( \Delta = \Delta_{a,b}(m, n) \). There exists an absolute constant \( c > 0 \) such that the following statements hold.

(a) Let \( k \in [m] \). If \( (a_i)_{i \in [m]} \) is nondecreasing then
\[
A^a_k(k - 1) + M_{r_k-1,a,b}(m - k + 1, n) - M_{a,b}(m, n) \leq -c\Delta C\left(\frac{k - 1}{m}\right)^2.
\]

(b) Let \( l \in [n] \). If \( (b_j)_{j \in [n]} \) is nondecreasing then
\[
B^b_\zeta(l - 1) + M_{r_l-1,a,b}(m, n - l + 1) - M_{a,b}(m, n) \leq -c\Delta C\left(\frac{l - 1}{n}\right)^2.
\]

Proof. We prove only (a) since the proof of (b) is similar. For \( z \in I_{m,n} \), note the identities
\[
M_{a,b,z}(m, n) - M_{a,b}(m, n) = \sum_{i=1}^{m} \frac{1}{a_i + z} - \frac{1}{a_i + \zeta} + \sum_{j=1}^{n} \frac{1}{b_j - z} - \frac{1}{b_j - \zeta}
\]
\[
= (z - \zeta) \left\{ - \sum_{i=1}^{m} \frac{1}{(a_i + z)(a_i + \zeta)} + \sum_{j=1}^{n} \frac{1}{(b_j - z)(b_j - \zeta)} \right\}
\]
\[
= (z - \zeta)^2 \left\{ - \sum_{i=1}^{m} \frac{1}{(a_i + z)(a_i + \zeta)^2} + \sum_{j=1}^{n} \frac{1}{(b_j - z)(b_j - \zeta)^2} \right\}.
\]
The last equality is obtained by adding \( \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} - \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} = 0 \) to the previous line.

Next note that, for any \( z \in (-a_{k,m}^{\min}, t_{n}^{\min}) \),

\[
A_{\zeta}^a(k - 1) + \mathcal{M}_{k-1}^{a,b}(m - k + 1, n) \leq A_{\zeta}^a(k - 1) + \mathcal{M}_{k-1}^{a,b,z}(m - k + 1, n) \\
= A_{\zeta}^a(k - 1) - A_{\zeta}^a(k - 1) + \mathcal{M}_{a,b,z}(m, n) \\
= -\sum_{i=1}^{k-1} \frac{\zeta - z}{(a_i + \zeta)(a_i + z)} + \mathcal{M}_{a,b}(m, n) \\
+ (\zeta - z)^2 \left( \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2(a_i + z)} + \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2(b_j - z)} \right).
\]

Set \( z = \zeta - \frac{c(k-1)\Delta}{m} \) for some absolute constant \( c \in (0, 1/2) \) to be selected below. This is a legitimate value for \( z \) since \( k \leq m \) and \( \Delta \leq a_{m}^{\min} + \zeta \). Then, using the monotonicity of \((a_i)_{i \in [m]}\) and bounding term by term, one obtains that

\[
A_{\zeta}^a(k - 1) + \mathcal{M}_{k-1}^{a,b}(m - k + 1, n) - \mathcal{M}_{a,b}(m, n) \\
\leq -\frac{k-1}{m} \sum_{i=1}^{m} \frac{\zeta - z}{(a_i + \zeta)(a_i + z)} + (\zeta - z)^2 \left( \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2(a_i + z)} + \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2(b_j - z)} \right) \\
\leq -\left( \frac{k-1}{m} \right)^2 \frac{c\Delta}{m} \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} + \left( \frac{k-1}{m} \right)^2 \frac{c^2\Delta}{m} \left( \sum_{i=1}^{m} \frac{2}{(a_i + \zeta)^3} + \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^3} \right) \\
\leq -\left( \frac{k-1}{m} \right)^2 \frac{c\Delta}{m} \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} + \left( \frac{k-1}{m} \right)^2 \frac{c^2\Delta}{m} \left( \frac{2}{(a_i + \zeta)^2} + \frac{m}{(b_j - \zeta)^2} \right) \\
= -\left( \frac{k-1}{m} \right)^2 (c - 3c^2)\Delta \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} \leq \left( \frac{k-1}{m} \right)^2 (c - 3c^2)\Delta C.
\]

The second inequality above uses \( a_i + z \geq \frac{1}{2}(a_i + \zeta) \), which follows from \( c \leq 1/2 \) in the choice of \( z \). The subsequent steps use \([4.4]\). Let \( c < 1/3 \) and rename \( c - 3c^2 \) as \( c \).

With the aid of the preceding estimates, one can derive the upper bounds below for the exit probabilities.

**Lemma 4.6.** Let \( m, n \in \mathbb{Z}_{\geq 0} \), \( \zeta = \zeta_{a,b}(m, n) \), \( C = C_{a,b}(m, n) \) and \( \Delta = \Delta_{a,b}(m, n) \). Let \( s > 0 \) and \( p \in \mathbb{Z}_{\geq 0} \). Then there exist an absolute constant \( s_0 > 0 \) and a constant \( C_p > 0 \) (depending only on \( p \)) such that the following bounds hold subject to the indicated further assumptions.

(a) Let \( k \in \mathbb{Z} \). Assume that \((a_i)_{i \in [m]}\) is nondecreasing, \( s \geq s_0 \) and \( k \geq 1 + \frac{sm}{\Delta^{1/2}C^{1/4}} \). Then

\[
\tilde{P}_{m,n}^{a,b,\zeta}(\tilde{H}(m, n) \geq k) \leq C_p ms^{-p}.
\]

(b) Let \( l \in \mathbb{Z} \). Assume that \((b_j)_{j \in [n]}\) is nondecreasing, \( s \geq s_0 \) and \( l \geq 1 + \frac{sn}{\Delta^{1/2}C^{1/4}} \). Then

\[
\tilde{P}_{m,n}^{a,b,\zeta}(\tilde{V}(m, n) \geq l) \leq C_p ns^{-p}.
\]
Proof. We prove only (a) since the proof of (b) is analogous. One may assume that \( k \leq m \) since the probability is zero otherwise. Set \( s_0 = 2c^{-1/2} \) where \( c > 0 \) is the absolute constant in Lemma 4.5(a). Then, by the lemma,

\[
M^{a,b}(m, n) - M^{k-1,a,b}(m - k + 1, n) - A^a(k) \geq c\Delta C\left(\frac{k-1}{m}\right)^2 - \frac{1}{a_k + \zeta} > cs^2\sqrt{C} - \sqrt{C} \geq \frac{1}{2}cs^2\sqrt{C}.
\]

Then a union bound combined with the tail bounds in Lemmas 4.1 and 4.3 yields

\[
\hat{P}_{m,n}^{a,b,\zeta}\{\hat{H}(m, n) = k\} = \hat{P}_{m,n}^{a,b,\zeta}\{\hat{G}(m, n) = \hat{G}(k, 0) + G_{k,1}(m, n)\}
\leq \hat{P}_{m,n}^{a,b,\zeta}\{\hat{G}(m, n) \leq M^{a,b}(m, n) - \frac{cs^2}{4}\sqrt{C}\}
+ \hat{P}_{m,n}^{a,b,\zeta}\{\hat{G}(k, 0) + G_{k,1}(m, n) \geq A^a(k + M^{k-1,a,b}(m - k + 1, n) + \frac{cs^2}{4}\sqrt{C}\}
\leq Cpms^{-2p}.
\]

Now applying the last inequality with another union bound results in

\[
\hat{P}_{m,n}^{a,b,\zeta}\{\hat{H}(m, n) \geq k\} \leq \sum_{i=k}^{m} \hat{P}_{m,n}^{a,b,\zeta}\{\hat{H}(m, n) = i\} \leq C_pms^{-2p},
\]
which implies the claim in (a).

The next lemma is a provisional left tail bound for the last-passage times.

Lemma 4.7. Let \( m, n \in \mathbb{Z}_{>0} \), \( \zeta = \zeta^{a,b}(m, n) \), \( C = C^{a,b}(m, n) \) and \( \Delta = \Delta^{a,b}(m, n) \). Let \( s > 0 \) and \( p \in \mathbb{Z}_{>0} \). Then there exist an absolute constant \( s_0 > 0 \) and a constant \( C_p > 0 \) (depending only on \( p \)) such that

\[
P_{m,n}^{a,b}\{G(m, n) \leq M^{a,b}(m, n) - s\Delta^{-1/4}C^{3/8}(m + n)^{1/2}\} \leq C_p(m + n)s^{-p} \quad \text{for } s \geq s_0.
\]

Proof. Let \( k, l \in \mathbb{Z}_{>0} \) and \( x \in \mathbb{R} \). Note from the definitions (2.3)–(2.4) that, on the event \( \hat{H}(m, n) \leq k \) and \( \hat{V}(m, n) \leq l \), the inequality

\[
G(m, n) \geq \hat{G}(m, n) - \hat{G}(k, 0) - \hat{G}(0, l)
\]
holds. Using this with the union bound leads to

\[
P_{m,n}^{a,b}\{G(m, n) \leq x\} = \hat{P}_{m,n}^{a,b,\zeta}\{G(m, n) \leq x\}
= \hat{P}_{m,n}^{a,b,\zeta}\{\hat{H}(m, n) \geq k + 1\} + \hat{P}_{m,n}^{a,b,\zeta}\{\hat{V}(m, n) \geq l + 1\}
+ \hat{P}_{m,n}^{a,b,\zeta}\{\hat{G}(m, n) - \hat{G}(k, 0) - \hat{G}(0, l) \leq x\}.
\]

Let \( s \geq \sqrt{s_0} \) where \( s_0 > 0 \) denotes the constant from Lemma 4.6. Choose \( k = \min\{\lfloor ms^2\Delta^{-1/4}C^{1/4}\rfloor, m\} \) and \( l = \min\{\lfloor ns^2\Delta^{-1/2}C^{-1/4}\rfloor, n\} \).

By virtue of Lemma 4.4, the sequences \((a_i)_{i \in [n]}\) and \((b_j)_{j \in [n]}\) are both nondecreasing without loss of generality. Also since \( s^2 \geq s_0 \), in the case \( s^2\Delta^{-1/2}C^{-1/4} \leq 1 \), Lemma 4.6 gives

\[
m^{a,b}(m, n) - y \quad \text{where } y = \ldots
\]
for some constant \( C_p > 0 \). The last bound also holds trivially in the case \( s^2\Delta^{-1/2}C^{-1/4} > 1 \) because then (4.9) = 0 since \( k = m \) and \( l = n \). Set \( x = M^{a,b}(m, n) - y \) where \( y = \ldots
\]
Assume that the first inequality is by the assumption. It reveals that \( r \). We only verify (a) since (b) is entirely analogous. A moment of inspecting (4.3) provided that \( c \). Also, if \( b \) then \( \int_{1}^{2} \). Hence, \( \int_{1}^{2} \). This implies the claim upon replacing \( s \) with \( s/c \) throughout.

We next derive a nontrivial left tail bound that does not depend on the location of the minimizer. One ingredient in our argument is the following set of elementary estimates on the minimizer with shifted parameters.

**Lemma 4.8.** Let \( m, n \in \mathbb{Z}_{>0} \) and \( \zeta = \zeta^{a,b}(m, n) \).

(a) Assume that \( m > 1 \) and write \( \tilde{\zeta} = \zeta^{a,b}(m - 1, n) \). If \( a_{1} = a_{m}^{\min} \) then \( a_{2,m}^{\min} + \tilde{\zeta} \geq \frac{a_{1} + \zeta}{\sqrt{2}} \).

Also, if \( b_{n}^{\min} - \zeta \leq \frac{a_{1} + \zeta}{\sqrt{2}} \), then \( b_{n}^{\min} - \tilde{\zeta} \leq \sqrt{2}(b_{n}^{\min} - \zeta) \).

(b) Assume that \( n > 1 \) and write \( \tilde{\zeta} = \zeta^{a,b}(m, n - 1) \). If \( b_{1} = b_{n}^{\min} \) then \( b_{2,n}^{\min} - \tilde{\zeta} \geq \frac{b_{1} - \zeta}{\sqrt{2}} \).

Also, if \( a_{m}^{\min} + \zeta \leq \frac{b_{1} - \zeta}{\sqrt{2}} \), then \( a_{m}^{\min} + \tilde{\zeta} \leq \sqrt{2}(a_{m}^{\min} + \zeta) \).

**Proof.** We only verify (a) since (b) is entirely analogous. A moment of inspecting (4.3) reveals that \( \tilde{\zeta} \leq \zeta \). Hence, the second and last inequalities in the following derivation. The first inequality is by the assumption \( a_{1} \leq a_{2,m}^{\min} \), and the equality comes again from (4.3).

\[
\frac{2}{(a_{1} + \zeta)^{2}} - \frac{1}{(a_{2,m}^{\min} + \zeta)^{2}} \geq \frac{1}{(a_{1} + \zeta)^{2}} + \frac{1}{(a_{2,m}^{\min} + \zeta)^{2}} - \frac{1}{(a_{2,m}^{\min} + \zeta)^{2}}
\]
\[ \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} - \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} = \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} - \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} \geq 0. \]

Hence, \( a_{2,m}^{\min} + \tilde{\zeta} \geq \frac{a_1 + \zeta}{\sqrt{2}} \) as claimed. Using \( \tilde{\zeta} \leq \zeta \) and (4.3) also yields
\[
\frac{1}{(a_1 + \zeta)^2} + \frac{1}{(b_{1,m}^{\min} - \zeta)^2} - \frac{1}{(b_{1,m}^{\min} - \zeta)^2} \geq \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} - \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} \geq 0.
\]

Now if \( \frac{b_{1,m}^{\min} - \zeta}{a_1 + \zeta} \leq \frac{1}{\sqrt{2}} \) then \( b_{1,m}^{\min} - \tilde{\zeta} \leq \sqrt{2}(b_{1,m}^{\min} - \zeta) \). \qed

**Lemma 4.9.** Let \( m, n \in \mathbb{Z}_{>0} \) and \( C = C^{a,b}(m, n) \). Let \( p \in \mathbb{Z}_{>0} \). Then there exist absolute constants \( s_0, s_1 > 0 \) and a constant \( C_p > 0 \) (depending only on \( p \)) such that
\[
P_{m,n}(G(m, n) \leq M^{a,b}(m, n) - sC^{1/2}(m + n)^{2/5}) \leq C_p s^{-p}
\]
provided that \( s_0 \leq s \leq s_1(a_{m}^{\min} + b_{m}^{\min})C^{1/2}(m + n)^{-2/5} \).

**Proof.** Introduce a threshold \( 0 < \delta \leq (a_{m}^{\min} + b_{m}^{\min})/2 \) to be determined later. Let
\[
K = \min\{k \in [m] : \zeta^{a_{k-1},b_{k+1}}(m - k + 1, n) \leq b_{n}^{\min} - \delta \}
\]
\[
L = \min\{l \in [n] : \zeta^{a_{m-1},b_{n-1}}(m, n - l + 1) \geq -a_{m}^{\min} + \delta \}.
\]
Both sets above are nonempty because
\[
\zeta^{a_{m-1},b_{1}}(1, n) \leq b_{n}^{\min} - (a_{m}^{\min} + b_{m}^{\min})/2 \leq b_{n}^{\min} - \delta
\]
\[
\zeta^{a_{1},b_{m-1}}(m, 1) \geq -a_{m}^{\min} + (a_{m}^{\min} + b_{m})/2 \geq -a_{m}^{\min} + \delta,
\]
where the first inequalities on both lines can be readily seen from definition (4.3). Also, since the intersection \((-a_{m}^{\min}, -a_{m}^{\min} + \delta) \cap (b_{n}^{\min} - \delta, b_{n}^{\min})\) is empty, the inequalities \( K > 1 \) and \( L > 1 \) cannot both hold. Appealing to the row-column symmetry, let us assume that \( K = 1 \) for concreteness.

On account of Lemma 4.4, without loss in generality, the parameters \( (a_i)_{i \in [m]} \) and \( (b_j)_{j \in [n]} \) can be reordered to be nondecreasing. Work with
\[
\delta \leq (\sqrt{2} - 1)(a_1 + b_1)
\]
here on. Abbreviate \( \zeta_L = \zeta^{a_{m-1},b_{n-1}}(m, n - l + 1) \) for \( l \in [L] \). **Claim:**
\[
\Delta^{a_{m-1},b_{n-1}}(m, n - L + 1) = \min\{a_1 + \zeta_L, b_L - \zeta_L\} \geq \delta.
\]
The inequality \( a_1 + \zeta_L \geq \delta \) holds by definition (4.13). If \( L = 1 \) then \( b_L - \zeta_L = b_1 - \zeta_1 \geq \delta \) since \( K = 1 \). Now consider the case \( L > 1 \). Then \( a_1 + \zeta_{L-1} < \delta \) and
\[
b_{L-1} - \zeta_{L-1} \geq b_1 - \zeta_{L-1} = (a_1 + b_1) - (a_1 + \zeta_{L-1}) \geq (a_1 + b_1) - \zeta_{L-1} - \delta \geq \sqrt{2}\delta \geq \sqrt{2}(a_1 + \zeta_{L-1}).
\]
Hence, invoking Lemma 4.8(b) with the parameters \( a, \tau_{L-2}b \) and the lattice coordinates \( m \) and \( n - L + 2 \) yields
\[
b_L - \zeta_L \geq \frac{b_{L-1} - \zeta_{L-1}}{\sqrt{2}} \geq \delta \quad \text{and} \quad a_1 + \zeta_L \leq \sqrt{2}(a_1 + \zeta_{L-1}) \leq \sqrt{2}\delta.
\]
The first inequality above completes the verification of (4.15).

Write $\Delta = \Delta^{a,b}(m, n)$. One can read off from definition (4.3) that the shifted minimizer $\zeta_{\tau_k} - 1^{a,b}(m - k + 1, n - l + 1)$ is nonincreasing in $k \in [m]$ and nondecreasing in $l \in [n]$. Hence, the inequality below.

$$C = \sum_{i=1}^{m} \frac{1}{(a_i + \zeta_{L})^2} \geq \sum_{i=1}^{m} \frac{1}{(a_i + \zeta_{L})^2} = C^{a,\tau_{L^{-1}}b}(m, n - L + 1).$$

Now conclude from Lemma 4.7 and the bounds in (4.15) and (4.17) that

$$P^{a,b}_{m,n}\{ G_{1,L}(m, n) \leq M^{a,\tau_{L^{-1}}b}(m, n - L + 1) - u\delta^{-1/4}C^{3/8}(m + n)^{1/2} \}
\leq C_p(m + n)u^{-p}$$

whenever $u \geq u_0$ for some constants $u_0, C_p > 0$. Let $v > 0$ and $q \in \mathbb{Z}_{\geq 0}$. By virtue of Lemma A.2 and since

$$C = \sum_{j=1}^{n} (b_j - \zeta_{1})^{-2} \geq \sum_{j=1}^{n} (a_1 + b_j)^{-2},$$

one also has

$$P^{a,b}_{m,n}\{ G(1, L - 1) \leq B^{b}_{-a_1}(L - 1) - v\sqrt{C} \} \leq C_q v^{-q}$$

for some constant $C_q > 0$. Here, interpret $G(1, 0) = 0$ that arises in the case $L = 1$.

The next task is to establish that

$$M^{a,b}(m, n) \leq M^{a,\tau_{L^{-1}}b}(m, n - L + 1) + B^{b}_{-a_1}(L - 1) + 4\delta C.$$  

Assume that $L > 1$ since (4.21) holds trivially otherwise. One obtains from the second set of inequalities in (4.16) that

$$b_1 - \zeta_{L} = (a_1 + b_1) - (a_1 + \zeta_{L}) \geq (a_1 + b_1) - \sqrt{2}\delta \geq (\sqrt{2} - 1)(a_1 + b_1) \geq \delta > 0.$$  

Thus, $\zeta_{L} \in (-a_1, b_1)$ is an admissible $z$-parameter in the next derivation. Furthermore,

$$\frac{b_j - \zeta_{L}}{a_1 + b_j} \geq \frac{b_1 - \zeta_{L}}{a_1 + b_1} \geq \sqrt{2} - 1 \quad \text{for } j \in [n]$$

by (4.22) and the monotonicity of $(b_j)_{j\in[n]}$. One now develops from definition (3.3), the second bound in (4.16) and estimates (4.19) and (4.23) that

$$M^{a,b}(m, n) - M^{a,\tau_{L^{-1}}b}(m, n - L + 1) = M^{a,b}(m, n) - M^{a,\tau_{L^{-1}}b,\zeta_{L}}(m, n - L + 1)
\leq M^{a,b,\zeta_{L}}(m, n) - M^{a,\tau_{L^{-1}}b,\zeta_{L}}(m, n - L + 1) = B^{b}_{\zeta_{L}}(L - 1)
= B^{b}_{-a_1}(L - 1) + \sum_{j=1}^{L-1} \frac{a_1 + \zeta_{L}}{(a_1 + b_j)(b_j - \zeta_{L})}
\leq B^{b}_{-a_1}(L - 1) + \sqrt{2}\delta \sum_{j=1}^{L-1} \frac{1}{(a_1 + b_j)(b_j - \zeta_{L})}
\leq B^{b}_{-a_1}(L - 1) + 4\delta \sum_{j=1}^{L-1} \frac{1}{(a_1 + b_j)^2}
\leq B^{b}_{-a_1}(L - 1) + 4\delta C,$$
which verifies the claim in (4.21).

Now combine (4.18) and (4.20) with a union bound, and then use (4.21) and that $G(m, n) \overset{a.s.}{=} G(1, L - 1) + G_{1,L}(m, n)$ to arrive at
\begin{equation}
\mathbf{P}_{m,n}^{a,b}(G(m, n) \leq \mathcal{M}^{a,b}(m, n) - y) \leq C_p(m + n)u^{-p} + C_qv^{-q},
\end{equation}
where $y = u\delta^{-1/4}C^{3/8}(m + n)^{1/2} + vC^{1/2} + 4\delta C$. The terms on the right-hand side become comparable upon setting $\delta = sC^{-1/2}(m + n)^{2/5}$ and $v = s(m + n)^{2/5}$ where $s = u^{4/5}$. Thus, $s_0$ can be chosen as $u_0^{4/5}$. For the choice of $\delta$ to meet condition (4.14), it suffices to have $s \leq (\sqrt{2} - 1)(a_1 + b_1)C^{1/2}(m + n)^{-2/5}$. With the preceding choices, $y = 6sC^{1/2}(m + n)^{2/5}$ and the bound in (4.24) reads
\[ C_p(m + n)s^{-5p/4} + C_q s^{-q}(m + n)^{-2q/5}. \]
Enlarging $p$ by a factor 5/4 and choosing $q \geq 5p/4$ makes the first term more dominant than the second and results in the bound
\begin{equation}
\mathbf{P}_{m,n}^{a,b}(G(m, n) \leq \mathcal{M}^{a,b}(m, n) - 6sC^{1/2}(m + n)^{2/5}) \leq C_p(m + n)s^{-p}.
\end{equation}
Redefining $s$ to be $s/6$ and adjusting the constant completes the proof. \hfill \Box

5. \textbf{PROOF OF THEOREM 3.2}

\textbf{Proof of Theorem 3.2}. Let $0 < q < p$. A Borel-Cantelli argument and Lemma 4.2 imply that, $\mathbf{P}$-a.s., there exists a random $M \in \mathbb{Z}_{>0}$ such that
\begin{equation}
\mathcal{G}^{a,b}(m, n) \leq \mathcal{M}^{a,b}(m, n) + (m + n)^q(C^{a,b}(m, n))^{1/2} \quad \text{whenever} \quad m + n \geq M.
\end{equation}
Since $\zeta$ is at least $\frac{1}{2}|I_{m,n}^{a,b}|$ away from one of the endpoints of $I_{m,n}^{a,b} = (-\min a_m, \min b_n)$, one concludes from definition (4.4) the trivial bound
\begin{equation}
C^{a,b}(m, n) \leq 4 \max\{m, n\}|I_{m,n}^{a,b}|^{-2}.
\end{equation}
Inserting this into (5.1) yields
\begin{equation}
\mathcal{G}^{a,b}(m, n) \leq \mathcal{M}^{a,b}(m, n) + 2(m + n)^{q+1/2}|I_{m,n}^{a,b}|^{-1} \quad \text{whenever} \quad m + n \geq M.
\end{equation}
Since $q < p$, the upper bound in the theorem follows.

Now the lower bound. Since $G \overset{a.s.}{=} 0$, it suffices to consider $m, n \in \mathbb{Z}_{>0}$ such that
\begin{equation}
\mathcal{M}^{a,b}(m, n) \geq |I_{m,n}^{a,b}|^{-1}(m + n)^{9/10+p}.
\end{equation}
Then, by the Cauchy-Schwarz inequality,
\begin{align}
C^{a,b}(m, n) &= \frac{1}{2} \left( \sum_{i=1}^{m} \frac{1}{(a_i + \zeta)^2} + \sum_{j=1}^{n} \frac{1}{(b_j - \zeta)^2} \right) \\
&= \frac{\mathcal{M}^{a,b}(m, n)^{2}}{2(m + n)} \geq \frac{1}{2} |I_{m,n}^{a,b}|^{-2}(m + n)^{4/5+2p},
\end{align}
where $\zeta = \zeta^{a,b}(m, n)$. Hence,
\begin{equation}
|I_{m,n}^{a,b}|C^{1/2}(m + n)^{-2/5} \geq \frac{1}{\sqrt{2}} (m + n)^p.
\end{equation}
Let $s_0, s_1 > 0$ denote the absolute constants in Lemma 4.9. By (5.6) and since $0 < q < p$,
\begin{equation}
s_0 \leq (m + n)^q \leq s_1 |I_{m,n}^{a,b}|C^{1/2}(m + n)^{-2/5} \quad \text{whenever} \quad m + n \geq N_0
\end{equation}
for some sufficiently large constant $N_0 \in \mathbb{Z}_{>0}$. Also, by (5.2),
\begin{equation}
C^{1/2}(m + n)^{2/5} \leq 2|I_{m,n}^{a,b}|^{-1}(m + n)^{9/10}.
\end{equation}

Let $u > 0$. By (5.8) and an application of Lemma 4.9 with $s = (m + n)^q$, one obtains that
\begin{equation}
\mathbb{P}\{G^{a,b}(m,n) \leq \mathcal{M}^{a,b}(m,n) - 2|I_{m,n}^{a,b}|^{-1}(m + n)^{9/10+q}\}
\leq \mathbb{P}\{G^{a,b}(m,n) \leq \mathcal{M}^{a,b}(m,n) - (m + n)^q(C^{1/2}(m + n)^{2/5})\} \leq \frac{C}{(m + n)^q u}
\end{equation}
whenever $m + n \geq N_0$ and for some constant $C > 0$ dependent only on $u$. The last bound
is summable over $\mathbb{Z}_{>0}^2$ provided that $u$ is sufficiently large. Hence, by the Borel-Cantelli
argument, $\mathbb{P}$-a.s., there exists a random $N \geq N_0$ such that
\begin{equation}
G^{a,b}(m,n) \geq \mathcal{M}^{a,b}(m,n) - 2|I_{m,n}^{a,b}|^{-1}(m + n)^{9/10+q}
\end{equation}
whenever $m + n \geq N$.

This implies the claimed lower bound since $q \leq p$. \hfill \Box

6. PROOF OF THEOREM 3.4

Proof of Theorem 3.4. Fix $n \in \mathbb{Z}_{>0}$ for the moment. Since the weights in (3.11) are a.s.
nonnegative, the $G_n$-process is a.s. coordinatewise nondecreasing. Therefore, $\mathbb{P}$-a.s.,
\begin{equation}
\sup_{i,j \in \mathbb{Z}_{>0}} G_n(i,j) = \sup_{l \in \mathbb{Z}_{>0}} G_n(ln,ln) = \lim_{l \to \infty} G_n(ln,ln) = \mathcal{G}_n
\end{equation}
where the last equality defines $\mathcal{G}_n$.

Consider real parameters $\tilde{a}^n$ and $\tilde{b}^n$ subject to (1.10) (with $a = \tilde{a}^n$ and $b = \tilde{b}^n$) that also satisfies
\begin{equation}
\tilde{a}^n_l(i) = a_{[i/n]} \quad \text{and} \quad \tilde{b}^n_l(i) = b_{[i/n]} \quad \text{for } l \in \mathbb{Z}_{>0} \text{ and } i \in [ln].
\end{equation}

Then $\omega_n(i,j) = \tilde{a}^n_{ln,i} \tilde{b}^n_{ln,j}$ for $i,j \in [ln]$ where the right-hand side is given by (2.6) (with $\omega_{m,n}(i,j) = \omega(i,j)$). Hence,
\begin{equation}
G_n(ln,ln) = G^{\tilde{a}^n,\tilde{b}^n}(ln,ln) \quad \text{for } l \in \mathbb{Z}_{>0}.
\end{equation}

From definition (3.3), one has
\begin{equation}
\mathcal{M}^{\tilde{a}^n,\tilde{b}^n}(ln,ln) = n \inf_{z \in (-a_{l}^{\min,b_{l}^{\min}})} \left\{ \sum_{i=1}^{l} \frac{1}{a_i + z} + \sum_{j=1}^{l} \frac{1}{b_j - z} \right\} = n \mathcal{M}^{a,b}(l,l).
\end{equation}

Similarly, by definition (4.4),
\begin{equation}
G^{\tilde{a}^n,\tilde{b}^n}(ln,ln) = nG^{a,b}(l,l) \quad \text{for } l \in \mathbb{Z}_{>0}.
\end{equation}

Since $(-a_{l}^{\min,b_{l}^{\min}}) \supset (-\inf a,\inf b)$, it is clear from (3.10) that
\begin{equation}
\mathcal{M}^{a,b}(l,l) \leq \mathcal{M}^{a,b}(\infty,\infty) \quad \text{for } l \in \mathbb{Z}_{>0}.
\end{equation}

Write $z_0 = (\inf a - \inf b)/2$ and $\zeta_l = \zeta^{a,b}(l,l)$ for $l \in \mathbb{Z}_{>0}$. Recalling definitions (4.4) and
(4.7), note also that
\begin{equation}
\Delta^{a,b}(l,l)^{-2} = \max\{(a_l^{\min} + \zeta_l)^{-2},(b_l^{\min} - \zeta_l)^{-2}\} \leq C^{a,b}(l,l) = \sum_{i=1}^{l} \frac{1}{(a_i + \zeta_l)^2} = \sum_{j=1}^{l} \frac{1}{(b_j - \zeta_l)^2}
\end{equation}
The first term equals \( (6.8) \) and inequality uses that \( (6.6) \). Combining with (6.5), one concludes that

\[
(6.11) \quad \inf_{z \in l} \mathcal{M}^{a,b}(\varnothing, \infty) \leq \inf_{z \in l} \mathcal{M}^{a,b}(l, l) + \sum_{i=1}^{\infty} \frac{1}{z_i} a_i \inf_{z \in l} \mathcal{M}^{a,b}(l, l) + \sum_{j=1}^{\infty} \frac{1}{z_j} b_j \inf_{z \in l} \mathcal{M}^{a,b}(l, l)
\]

The first term equals \( \mathcal{M}^{a,b}(l, l) \) for \( l \geq L_0 \) while both series vanish as \( l \to \infty \) in (6.8). Combining with (6.5), one concludes that

\[
(6.9) \quad \lim_{l \to \infty} \mathcal{M}^{a,b}(l, l) = \mathcal{M}^{a,b}(\varnothing, \infty).
\]

Let \( p > 0 \). Apply Lemma 4.2 using (6.5) and (6.7) to obtain

\[
P \{ \mathcal{G}_n(l, n) \geq n \mathcal{M}^{a,b}(\varnothing, \infty) + s \delta \}
\]

\[
\leq P \{ \mathcal{G}_n(l, n) \geq n \mathcal{M}^{a,b}(l, l) + s (C^{a,b}(l, l))^{1/2 + n} \} \leq C_p s^{-p} \quad \text{for } s > 0
\]

for some constant \( C_p > 0 \) depending only on \( p \). Passing to the limit \( l \to \infty \) results in

\[
(6.10) \quad P \{ \mathcal{G}_n > n \mathcal{M}^{a,b}(\varnothing, \infty) + s \delta \} \leq C_p s^{-p} \quad \text{for } s > 0
\]

on account of (6.1). Let \( \eta > 0 \). By (6.10) and the Borel-Cantelli argument, \( P \)-a.s., there exists a random \( L_1 \in \mathbb{Z} \) such that

\[
\mathcal{G}_n \leq n \mathcal{M}^{a,b}(\varnothing, \infty) + n^{1/2 + \eta} \quad \text{for } n \geq L_1.
\]

In particular, with \( \eta < 1/2 \),

\[
(6.11) \quad \limsup_{n \to \infty} n^{-1} \mathcal{G}_n \leq \mathcal{M}^{a,b}(\varnothing, \infty).
\]

Note from the bounds culminating in (6.7) that

\[
\max \{ \Delta^{a,b}(l, l)^{-2}, C^{a,b}(l, l) \} \leq c_0 \quad \text{for } l \in \mathbb{Z},
\]

which justifies the first step in the next derivation.

\[
P \{ \mathcal{G}_n(l, n) \leq n \mathcal{M}^{a,b}(l, l) - s \Delta^{a,b}(l, l)^{-1/2} \}
\]

\[
\leq P \{ \mathcal{G}_n(l, n) \leq n \mathcal{M}^{a,b}(l, l) - s (\Delta^{a,b}(l, l))^{3/8} l^{1/2} n^{1/2} \}
\]

\[
= P \{ \mathcal{G}^{a,b} \leq n \mathcal{M}^{a,b}(l, l) - s (\Delta^{a,b}(l, l))^{3/8} l^{1/2} n^{1/2} \}
\]

\[
\leq C_p \ln s^{-p} \quad \text{for } s > s_0.
\]
The second step is by (6.2)-(6.4). The final bound is an application of Lemma 4.7 and \( s_0 > 0 \) denotes the absolute constant from there. Hence, by the Borel-Cantelli, \( \mathbb{P}\text{-a.s.}, \)
\[
\mathcal{G}_n \geq G_n(l, ln) \geq n\mathcal{M}^{a,b}(l, l) - l^{1/2+\eta}n^{7/8+\eta} \quad \text{whenever } l + n \geq L_1
\]
and that \( \mathcal{G}_n \) after increasing \( L_1 \) if necessary. With \( \eta < 1/8 \), one obtains
\[
(6.12) \quad \lim_{n \to \infty} n^{-1}\mathcal{G}_n \geq \mathcal{M}^{a,b}(l, l)
\]
By (6.9), letting \( l \to \infty \), the lower bound in (6.12) matches the upper bound in (6.11). \( \Box \)

7. PROOF OF THEOREM 3.6

The proof is based on Corollary 3.3 and an approximation of the centering \( \mathcal{M}^{a,b} \) by the shape function.

Let \( \alpha \) and \( \beta \) be finite, nonnegative Borel measures on \( \mathbb{R} \). Fix \( x, y > 0 \). The derivatives of (3.14) are given by
\[
\delta_z^\alpha \Gamma_z(x, y) = x(-1)^n n! \int_{\mathbb{R}} \frac{\alpha(da)}{(a + z)^{n+1}} + y n! \int_{\mathbb{R}} \frac{\beta(db)}{(b - z)^{n+1}} \quad \text{for } z \in \mathbb{C} \setminus (-\text{supp } \alpha \cup \text{supp } \beta)
\]
on account of (A.5). Assume that \( \alpha \) and \( \beta \) are nonzero, that (3.15) holds, and suppose \( a, b \in \mathbb{R} \) satisfy (3.16) and (3.17). Then \( \delta_z^\alpha \Gamma_z(x, y) > 0 \) for \( z \in (-a, b) \). Hence, the function \( z \mapsto \Gamma_z(a, b)(x, y) \) is strictly convex on \( (-a, b) \). Consequently, there exists a unique z-value, denoted with \( \zeta^\alpha,\beta,a,b(x, y) \), in the closed interval \([ -a, b ]\) such that the infimum in (3.18) is given by \( \gamma^\alpha,\beta,a,b(x, y) = \Gamma_z^\alpha,\beta(x, y) \). Examining the sign of the first derivative reveals that
\[
(7.1) \quad \zeta^\alpha,\beta,a,b(x, y) = \begin{cases} 
-a & \text{if } x \int_{\mathbb{R}} \frac{\alpha(da)}{(a - b)^2} \leq y \int_{\mathbb{R}} \frac{\beta(db)}{(b + a)^2} \\
b & \text{if } x \int_{\mathbb{R}} \frac{\alpha(da)}{(a + b)^2} \geq y \int_{\mathbb{R}} \frac{\beta(db)}{(b - b)^2} \\
\text{otherwise, the unique } z \text{-value with } x \int_{\mathbb{R}} \frac{\alpha(da)}{(a + z)^2} = y \int_{\mathbb{R}} \frac{\beta(db)}{(b - z)^2}.
\end{cases}
\]

Recall the definition of \( \zeta^{a,b}(m, n) \) as the unique minimizer in (3.3), described in (4.3).

Lemma 7.1. Assume (3.16), (3.20), (3.21) and that \( \alpha \) and \( \beta \) are not zero measures. Let \( \epsilon > 0 \). Then there exists \( L \in \mathbb{Z}_{>0} \) such that
\[
|\zeta^{a,b}(m, n) - \zeta^{\alpha,\beta,a,b}(m, n)| < \epsilon \quad \text{whenever } m, n \geq L.
\]

Proof. Note that \( a, b < \infty \) since \( \alpha, \beta \neq 0 \). Pick \( \delta > 0 \) such that \( 2\delta < a + b \). Then the interval \([ -a + \delta, b - \delta ]\) is nonempty. By (3.21), there exists \( L \in \mathbb{Z}_{>0} \) such that
\[
|\min a_m - a| < \delta \quad \text{and} \quad |\min b_n - b| < \delta \quad \text{for } m, n \geq L.
\]
In particular, \([ -a + \delta, b - \delta ] \subset I_{m,n}^{a,b} \) for \( m, n \geq L \). Hence, it follows from assumption (3.20) and Lemma A.5 that
\[
\lim_{m \to \infty} \frac{1}{m} \sum_{i=1}^{m} \frac{1}{a_m(i) + z} = \int_{\mathbb{R}} \frac{\alpha(da)}{a + z} \quad \text{and} \quad \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \frac{1}{b_n(j) - z} = \int_{\mathbb{R}} \frac{\beta(db)}{b - z}.
\]
Lemma 7.1 is complete. □

The second inequality is monotonicity, and the last inequality comes from choosing
such that
\[ f(z) = g(z) = \int R (b - z)^k \]
uniformly in \( z \in [-a + \delta, b - \delta] \). Increase \( L \in \mathbb{Z}_{>0} \) if necessary to have
\[
\sum_{i=1}^{m} \frac{1}{(a_m(i) + z)^2} - m \int R \frac{\alpha(da)}{(a + z)^2} < m\epsilon
\]
(7.2)
\[
\text{and} \quad \sum_{j=1}^{n} \frac{1}{(b_n(j) - z)^2} - n \int R \frac{\beta(db)}{(b - z)^2} < n\epsilon
\]
whenever \( m, n \geq L \) and \( z \in [-a + \delta, b - \delta] \), where \( c > 0 \) is a constant to be chosen below.

Work with \( m, n \geq L \) below. To prove the claim of the lemma, argue by contradiction. Consider the case \( \zeta^{a,b}(m, n) \geq \zeta^{a,\alpha,b}(m, n) + \epsilon \) first. Put \( z = \zeta^{a,\alpha,b}(m, n) + \epsilon/2 \). Then \( z \geq -a + \epsilon/2 \) and \( z \leq \zeta^{a,b}(m, n) - \epsilon/2 \leq \min b_n - \epsilon/2 \leq b + \delta - \epsilon/2 \). Therefore, \( z \in [-a + \delta, b - \delta] \) provided that \( \delta \leq \epsilon/4 \). Recalling (4.3), \( z \leq \zeta^{a,b}(m, n) \) and (7.2) imply that
\[
0 \geq -\sum_{i=1}^{m} \frac{1}{(a_m(i) + z)^2} + \sum_{j=1}^{n} \frac{1}{(b_n(j) - z)^2}
\]
(7.3)
\[
\geq -m \int R \frac{\alpha(da)}{(a + z)^2} + n \int R \frac{\beta(db)}{(b - z)^2} - c\epsilon(m + n).
\]
The function \( f : [\zeta^{a,\alpha,b}(m, n), z] \to \mathbb{R} \) given by
\[
f(s) = \partial_s \Gamma_s^{a,b}(m, n) = -m \int R \frac{\alpha(da)}{(a + s)^2} + n \int R \frac{\beta(db)}{(b - s)^2}
\]
is differentiable in the interior and continuous up to the boundary of its domain. Continuity at the endpoint \( \zeta^{a,\alpha,b}(m, n) \) holds even when \( \zeta^{a,\alpha,b}(m, n) = -a \) because then \( \int R (a - a)^{-2} \alpha(da) < \infty \), see (7.1). By the mean-value theorem, there exists \( s \in (\zeta^{a,\alpha,b}(m, n), z) \) such that
\[
f(z) = f(\zeta^{a,\alpha,b}(m, n)) + \frac{1}{2} \epsilon f'(s) \geq m\epsilon \int R \frac{\alpha(da)}{(a + s)^3} + n\epsilon \int R \frac{\beta(db)}{(b - s)^3}
\]
\[
\geq m\epsilon \int R \frac{\alpha(da)}{(a + b)^3} + n\epsilon \int R \frac{\beta(db)}{(b + a)^3} \geq 2c\epsilon(m + n).
\]
The first inequality above holds because \( f(\zeta^{a,\alpha,b}(m, n)) = 0 \) if \( \zeta^{a,\alpha,b}(m, n) \in (-a, b) \), and \( f(\zeta^{a,\alpha,b}(m, n)) \geq 0 \) if \( \zeta^{a,\alpha,b}(m, n) = -a \). Note that \( \zeta^{a,\alpha,b}(m, n) < b \) in the present case. The second inequality is monotonicity, and the last inequality comes from choosing \( c > 0 \) small enough. Combining this with (7.3) gives the contradiction
\[
0 \geq f(z) - c\epsilon(m + n) \geq c\epsilon(m + n).
\]

Likewise, the case \( \zeta^{a,b}(m, n) \leq \zeta^{a,\alpha,b}(m, n) - \epsilon \) results in a contradiction. The proof of Lemma 7.1 is complete. □
Lemma 7.2. Assume \((3.16), (3.20)\) and \((3.21)\). Let \(\epsilon > 0\). Then there exists \(L \in \mathbb{Z}_{>0}\) such that
\[
|\mathcal{M}^{a,b}(m,n) - \gamma^{a,b,a,b}(m,n)| \leq \epsilon (m+n) \quad \text{whenever } m,n \in \mathbb{Z}_{\geq L}.
\]

Proof. Abbreviate \(\zeta = \zeta^{a,b}(m,n)\) and \(\xi = \xi^{a,b,a,b}(m,n)\). Assume further that \(a,b < \infty\). As in the preceding proof, pick \(\delta > 0\) and \(L \in \mathbb{Z}_{>0}\) such that \(2\delta < a + b\) and \([-a+\delta, b - \delta) \subset \mathcal{I}^{a,b}_{m,n}\) for \(m,n \geq L\). Let \(z \in (-a+\delta, b - \delta)\). By \((3.21)\), after increasing \(L\) if necessary,
\[
a_m(i) + z \geq \delta \quad \text{and} \quad b_n(j) - z \geq \delta \quad \text{for } m,n \geq L \text{ and } i \in [m], j \in [n].
\]
Hence, using definition \((4.4)\), identity \((4.8)\) and bound \((5.2)\), one obtains that
\[
0 \leq M^{a,b,z}(m,n) - \mathcal{M}^{a,b}(m,n)
\]
\[
= (z - \zeta)^2 \left\{ \sum_{i=1}^{m} \left( a_m(i) + z \right) (a_m(i) + \zeta)^2 + \sum_{j=1}^{n} \left( b_n(j) - z \right) (b_n(j) - \zeta)^2 \right\}
\]
\[
\leq 2\delta^{-1} (z - \zeta)^2 c^{a,b}(m,n)
\]
(6) \[
\leq \frac{8(z - \zeta)^2 (m+n)}{\delta (\inf a + \inf b)^2}.
\]
The denominator is nonzero by \((3.16)\) and \((3.21)\). Analogously one derives
\[
0 \leq \Gamma^{a,b,z}(m,n) - \gamma^{a,b,a,b}(m,n)
\]
\[
= (z - \zeta)^2 \left\{ m \int_{\mathbb{R}} \frac{\alpha(da)}{(a+z)(a+\zeta)^2} + n \int_{\mathbb{R}} \frac{\beta(db)}{(b-z)(b-\zeta)^2} \right\}
\]
\[
\leq 2\delta^{-1} (z - \zeta)^2 \left\{ m \int_{\mathbb{R}} \frac{\alpha(da)}{(a+\zeta)^2} + n \int_{\mathbb{R}} \frac{\beta(db)}{(b-\zeta)^2} \right\}
\]
\[
\leq \frac{8(z - \zeta)^2 (m+n)}{\delta (\inf a + \inf b)^2}.
\]
The second inequality above uses \((\inf \supp \alpha) + z \geq \delta\) and \((\inf \supp \beta) - z \geq \delta\), which comes from combining \((7.4)\) with \((3.17), (3.20)\) and \((3.21)\). For the last inequality, observe from \((7.1)\) that
\[
\int_{\mathbb{R}} \frac{\alpha(da)}{(a+\zeta)^2} + \int_{\mathbb{R}} \frac{\beta(db)}{(b-\zeta)^2} \leq 2 \left( 1 \{ \zeta \leq \frac{b-a}{2} \} \int_{\mathbb{R}} \frac{\beta(db)}{(b-\zeta)^2} + 1 \{ \zeta > \frac{b-a}{2} \} \int_{\mathbb{R}} \frac{\alpha(da)}{(a+\zeta)^2} \right) \leq \frac{8}{(a+b)^2}.
\]
To verify the claim of the lemma, first consider the case that \(\alpha\) and \(\beta\) are not zero measures. Choose \(\delta\) sufficiently small such that
\[
40\delta (\inf a + \inf b)^{-2} < \epsilon/2.
\]
Then pick \(L \in \mathbb{Z}_{>0}\) sufficiently large such that
\[
|\zeta - \zeta| \leq \delta \quad \text{and} \quad |M^{a,b,z}(m,n) - \Gamma^{a,b,z}(m,n)| \leq \frac{1}{2} \epsilon (m+n)
\]
whenever \(m,n \geq L\) and \(z \in [-a+\delta, b - \delta]\). Such \(L\) exists by virtue of Lemmas 7.1 and A.5.

Set \(z = \min \{ \max \{ \zeta, -a+\delta \}, b - \delta \} \). Then \(z \in [-a+\delta, b - \delta]\) and \(|z - \zeta| \leq \delta\). Furthermore, \(|z - \zeta| \leq |z - \zeta| + |\zeta - \zeta| \leq 2\delta\) if \(m,n \geq L\). Now putting together \((7.5)-(7.9)\) via the triangle inequality leads to
\[
|\mathcal{M}^{a,b}(m,n) - \gamma^{a,b,a,b}(m,n)| \leq |\mathcal{M}^{a,b,z}(m,n) - \mathcal{M}^{a,b}(m,n)| + |\Gamma^{a,b,z}(m,n) - \gamma^{a,b,a,b}(m,n)| + |M^{a,b,z}(m,n) - \Gamma^{a,b,z}(m,n)|
\]
By another appeal to Lemma A.5, increase \( L \) \((7.11)\). For the second-last inequality, first use \( a \)

The first inequality above is by definition \((3.3)\). The next two inequalities are due to \((7.10)\)-\((7.11)\), where we invoke Lemma A.5 again. Then, for \( m,n \geq L \).

Then \( M^{a,b}(m,n) \geq \sum_{i=1}^{m} \alpha_m(i) + \min b_n \geq \sum_{i=1}^{m} \frac{1}{\alpha_m(i) + b + \delta} \geq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \delta} - \frac{\epsilon m}{2} \)

for \( m,n \geq L \). The second-last inequality comes from \( \inf a \leq \inf \supp \alpha \) and \( \inf b \leq \min b_n \rightarrow b \).

For the complementary bound, choose \( L \) larger if necessary such that

\[
\min b_n \in [b - \delta/2, b + \delta/2] \quad \text{and} \quad \sum_{j=1}^{n} \frac{1}{b_n(j) - b + \delta/2} \leq \frac{\epsilon n}{2} \quad \text{for } n \geq L
\]

(7.10)  
\[
\sum_{i=1}^{m} \frac{1}{\alpha_m(i) + b - \delta/2} - m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \delta} \leq \frac{\epsilon m}{2} \quad \text{for } m \geq L,
\]

(7.11)  
where we invoke Lemma A.5 again. Then, for \( m,n \geq L \), one obtains that

\[
M^{a,b}(m,n) \leq \sum_{i=1}^{m} \frac{1}{\alpha_m(i) + \min b_n - \delta} + \sum_{j=1}^{n} \frac{1}{b_n(j) - \min b_n + \delta}
\]

\[
\leq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \delta} + \frac{\epsilon}{2} (m + n)
\]

\[
= \gamma^{a,b}(m,n) + \frac{3\delta m}{2} \int_{\mathbb{R}} \frac{\alpha(da)}{(a + b)(a + b - 3\delta/2)} + \frac{\epsilon}{2} (m + n)
\]

\[
\leq \gamma^{a,b}(m,n) + \frac{6\delta m}{(\inf a + \inf b)^2} + \frac{\epsilon}{2} (m + n) \leq \gamma^{a,b}(m,n) + \epsilon (m + n).
\]

The first inequality above is by definition \((3.3)\). The next two inequalities are due to \((7.10)-(7.11)\). For the second-last inequality, first use \( a \geq \inf \supp \alpha \geq a \) and \( \delta \leq a + b \), and then
recall \( a + b \geq \inf a + \inf b \). This completes the case \( \beta = 0 \). The case \( \alpha = 0 \) is handled similarly.

The preceding paragraph also includes the cases \( a = \infty, b < \infty \) and \( a < \infty, b = \infty \). Therefore, the only remaining case is \( a = b = \infty \) which implies that \( \gamma^{\alpha,\beta,a,b} = 0 \). Pick any \( z_0 \in (-\inf a, \inf b) \). Since \( \alpha, \beta = 0 \) now, by Lemma \[A.5\]
\[
\mathcal{M}^{a,b}(m,n) \leq \mathcal{M}^{a,b,z_0}(m,n) \leq \epsilon (m+n) \quad \text{for } m,n \geq L
\]
after increasing \( L \) if necessary. This completes the proof.

\[\square\]

**Proof of Theorem 3.6.** This is immediate from Theorem 3.2 and Lemma 7.2.

\[\square\]

8. Proofs of Theorem 3.7 and Corollaries 3.8 and 3.9

**Proof of Theorem 3.7.** Due to the symmetry, only (a) is proved below. Write \( P = \inf_{n \in S} \min b_n \).

Introduce a small parameter \( \eta > 0 \) such that \( 2\eta < \inf a + p \). Since \( |J_{m,n}^{a,b}| = \min a_m + \min b_n \geq \inf a + p > \eta \) for \( m \in \mathbb{Z}_{>0} \) and \( n \in S \), it follows from Theorem 3.2 that, \( \mathbb{P} \)-a.s., there exists a random \( L \in \mathbb{Z}_{>0} \) such that

\[
|G^{a,b}(m,n) - \mathcal{M}^{a,b}(m,n)| \leq \epsilon (m+n) \quad \text{for } m \in \mathbb{Z}_{>0} \text{ and } n \in S \text{ with } m+n \geq L.
\]

By the first limit in (3.20) and Lemma \[A.5\] there exists \( K \in \mathbb{Z}_{>0} \) such that

\[
\left| \sum_{i=1}^{m} \frac{1}{a_m(i) + z} - \frac{1}{a + z} \right| \leq \epsilon m \quad \text{whenever } m \geq K \text{ and } z \in [p-\eta, p+4\epsilon^{-1}].
\]

The range of \( z \) in (8.2) can be extended to \([p-\eta, \infty)\) since the terms \((a_m(i) + z)^{-1}\) for \( i \in [m]\) and the integrand \((a+z)^{-1}\) are bounded from above by \((\inf a + z)^{-1}\) which is less than \(\epsilon/4\) for \( z \geq p + 4/\epsilon \).

Choose \( K \geq L \), take \( m \geq K \) and \( n \in S \) below. Write \( \zeta = \zeta^{a,b}(m,n) \). By definition (3.3), (8.2) and since \( \max \{ \zeta, p \} \leq \min b_n \), one has the lower bound

\[
\mathcal{M}^{a,b}(m,n) \geq \sum_{i=1}^{m} \frac{1}{a_m(i) + \zeta} \geq \sum_{i=1}^{m} \frac{1}{a_m(i) + \min b_n} \geq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n} - \epsilon m.
\]

For a complementary upper bound, noting that \( \min b_n - \eta \in J_{m,n}^{a,b} \), develop

\[
\mathcal{M}^{a,b}(m,n) \leq \mathcal{M}^{a,b,\min b_n - \eta}(m,n) = \sum_{i=1}^{m} \frac{1}{a_m(i) + \min b_n - \eta} + \frac{1}{\min b_n - \eta} \left( \sum_{j=1}^{n} \frac{1}{b_n(j) - \min b_n + \eta} \right)
\]

\[
\leq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n - \eta} + \epsilon m + \frac{n}{\eta}
\]

\[
= m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n} + m\eta \int_{\mathbb{R}} \frac{\alpha(da)}{(a + \min b_n)(a + \min b_n - \eta)} + \epsilon m + \frac{n}{\eta}
\]

\[
\leq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n} + 2m\eta \int_{\mathbb{R}} \frac{\alpha(da)}{(a + \min b_n)^2} + \epsilon m + \frac{n}{\eta}.
\]

The first two inequalities above come again from (3.3) and (8.2). The last inequality comes from \( 2\eta < \inf a + \min b_n \leq \inf \supp a + \min b_n \) where we appealed to the assumption that the first limit in (3.20) holds. With \( \eta \leq \epsilon \) and \( n \leq \epsilon m \), one then has

\[
\mathcal{M}^{a,b}(m,n) \leq m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n} + C\epsilon m,
\]
where \( C = 2 + 2 \int_{\mathbb{R}} (a + \min b_n)^{-2} \alpha(da) \).

Choose \( \delta = \min \{1, \eta\} \). Combining the bounds from (8.1), (8.3) and (8.4) with the triangle inequality results in

\[
\left| G^{a,b}(m, n) - m \int_{\mathbb{R}} \frac{\alpha(da)}{a + \min b_n} \right| \leq \epsilon(m + n) + C \epsilon m \leq \epsilon m (1 + \delta + C) \leq \epsilon (2 + C) m
\]

for \( m \in \mathbb{Z}_{\geq K} \) and \( n \in S \) with \( n \leq \delta m \). The result follows upon replacing \( \epsilon \) with \( \epsilon (2 + C)^{-1} \) throughout.

**Proof of Corollary 3.8** Assumptions (3.16) and (3.21) imply that \( \inf a + \inf b > 0 \). Since (3.20) is also assumed, both parts of Theorem 3.7 hold with \( S = \mathbb{Z}_{>0} \). The conclusion then follows from (3.21) and the continuity of \( A^\alpha \) and \( B^\beta \).

For the proof of Corollary 3.9, we record the following upper bounds matching (3.26) close to the axes.

**Lemma 8.1.** Let \( \gamma^{\alpha,\beta,a,b} \) denote the function in (3.18). Let \( \epsilon > 0 \). Then there exists \( \delta > 0 \) such that

\[
\gamma^{\alpha,\beta,a,b}(x, y) \leq x A^\alpha(b) + x \epsilon \quad \text{for } x, y > 0 \text{ with } y \leq \delta x
\]

\[
\gamma^{\alpha,\beta,a,b}(x, y) \leq y B^\beta(-a) + y \epsilon \quad \text{for } x, y > 0 \text{ with } x \leq \delta y.
\]

**Proof.** If \( b < \infty \) then, by continuity of \( A^\alpha \), there exists \( 0 < \eta < (a + b)/2 \) such that

\[
A^\alpha(b - \eta) \leq A^\alpha(b) + \epsilon/2.
\]

The last bound also holds if \( b = \infty \). Then, by definition (3.18),

\[
\gamma^{\alpha,\beta,a,b}(x, y) \leq \Gamma^{\alpha,\beta}_{b-\eta}(x, y) = x A^\alpha(b - \eta) + y B^\beta(b - \eta) \leq x A^\alpha(b) + \frac{x \epsilon}{2} + \frac{y}{\eta}
\]

(8.5)

\[
\leq x A^\alpha(b) + x \epsilon \quad \text{for } x, y > 0 \text{ with } y \leq \frac{x \epsilon \eta}{2}.
\]

For the third step above, \( (b - b + \eta)^{-1} \leq \eta^{-1} \) for \( b \geq \inf \text{supp} \beta \) due to the second inequality in (3.17). Hence, the first claimed bound holds with \( \delta = \frac{\epsilon \eta}{2} \). The second bound follows similarly.

**Proof of Corollary 3.9** By Theorem 3.6 \( \mathbb{P} \)-a.s., there exists a random \( L \in \mathbb{Z}_{>0} \) such that

\[
|G^{a,b}(m, n) - \gamma^{\alpha,\beta,a,b}(m, n)| \leq \epsilon(m + n) \quad \text{for } m, n \in \mathbb{Z}_{\geq L}.
\]

Note that the assumptions of Theorem 3.7 hold with \( S = \mathbb{Z}_{>0} \). Therefore, \( \mathbb{P} \)-a.s., there exist a random \( K \in \mathbb{Z}_{>0} \) and a deterministic \( \delta > 0 \) such that

\[
|G^{a,b}(m, n) - A^\alpha(\min b_n)| \leq \frac{\epsilon m}{2} \quad \text{for } m \in \mathbb{Z}_{\geq K} \text{ and } n \in \mathbb{Z}_{>0} \text{ with } n \leq \delta m
\]

\[
|G^{a,b}(m, n) - B^\beta(-\min a_m)| \leq \frac{\epsilon n}{2} \quad \text{for } n \in \mathbb{Z}_{\geq K} \text{ and } m \in \mathbb{Z}_{>0} \text{ with } m \leq \delta n.
\]

By Lemma 8.1 and (3.26), choosing \( \delta \) smaller and \( K \) larger if necessary,

\[
0 \leq \gamma^{\alpha,\beta,a,b}(x, y) - x A^\alpha(b) \leq \frac{\epsilon x}{2} \quad \text{for } x, y \in \mathbb{R}_{>0} \text{ with } y \leq \delta x
\]

\[
0 \leq \gamma^{\alpha,\beta,a,b}(x, y) - y B^\beta(-a) \leq \frac{\epsilon y}{2} \quad \text{for } x, y \in \mathbb{R}_{>0} \text{ with } x \leq \delta y.
\]
Pick $\delta < 1$ and set $N = (1 + \delta^{-1}) \max\{K, L\}$. Claim: If (3.29) holds then
\begin{equation}
G^{a,b}(m, n) \leq \gamma^{a,\beta,a,b}(m, n) + \epsilon(m + n) \quad \text{for } m, n \in \mathbb{Z}_{\geq 0} \text{ with } m + n \geq N.
\end{equation}
This is clear from the choice of $L$ if $m, n \geq L$. If $n < L$ then $m \geq K$ and $n \leq \delta m$, and it follows from the triangle inequality, $A^\alpha(\min b_n) \leq A^\alpha(b)$ and the choices of $K$ and $\delta$ that
\begin{equation}
G^{a,b}(m, n) - \gamma^{a,\beta,a,b}(m, n) = (G^{a,b}(m, n) - mA^\alpha(b)) + (\gamma^{a,\beta,a,b}(m, n) - mA^\alpha(b))
\leq (G^{a,b}(m, n) - mA^\alpha(\min b_n)) + (\gamma^{a,\beta,a,b}(m, n) - mA^\alpha(b))
\leq \frac{em}{2} + \frac{em}{2} = em.
\end{equation}
The case $m < L$ is similar. This gives (a), and (b) follows similarly.

To prove (c), assume that $A^\alpha(\min b_n) > A^\alpha(b)$ since the other case is similar. Then, for $m \in \mathbb{Z}_{\geq K}$ and $n \in \mathbb{Z}_{>0}$ with $n \leq m\delta$, one has
\begin{align*}
G^{a,b}(m, n) - \gamma^{a,\beta,a,b}(m, n) &= m(A^\alpha(\min b_n) - A^\alpha(b)) - (\gamma^{a,\beta,a,b}(m, n) - mA^\alpha(b)) \\
&\quad + (G^{a,b}(m, n) - mA^\alpha(\min b_n)) \\
&\geq m(A^\alpha(\min b_n) - A^\alpha(b)) - em.
\end{align*}
The proof of (d) is similar. \hfill \Box

9. PROOF OF THEOREM 3.10

Lemma 9.1. Assume (3.15) and (3.17). Then
(a) $R^{a,\beta,a,b} \subset \{(x, y) \in \mathbb{R}^2 : xA^\alpha(b) \leq 1 \text{ and } yB^\beta(a) \leq 1\}$
(b) $R^{a,\beta,a,b} \supset \{(x, y) \in \mathbb{R}^2 : 2(x + y) \leq a + b\}$.

Proof. (3.26) implies (a). If $a, b < \infty$ then taking $z = \frac{1}{2}(b - a)$ in (3.18) gives
\begin{equation}
\gamma^{a,\beta,a,b}(x, y) \leq \frac{2(x + y)}{a + b} \quad \text{for } x, y \in \mathbb{R}_{>0}.
\end{equation}
This bound also trivially holds if $a = \infty$ or $b = \infty$ by (3.25). Hence, (b). \hfill \Box

Lemma 9.2. Assume (3.16), (3.20) and (3.21). Let $S$ denote the set from (3.34), and $\mathfrak{A}$ and $\mathfrak{B}$ be given by (3.35). Then there exists a constant $C_0 > 0$ such that the following hold.
(a) $S \cap (R^{a,\beta,a,b} \cup T^{a,\beta,a,b}) \subset [0, C_0]^2$.
(b) $P$-a.s., $S \cap t^{-1}\mathbb{R}^{a,b}_t \subset (0, \max\{C_0, Kt^{-1}\}]^2$ for $t > 0$ and some random $K \in \mathbb{Z}_{>0}$.

Proof. Let $t > 0$ and $(x, y) \in S \cap (R^{a,\beta,a,b} \cup T^{a,\beta,a,b} \cup t^{-1}\mathbb{R}^{a,b}_t)$. By symmetry, it suffices to bound $x$ from above assuming $x \geq y$. If $\alpha = 0$ or $b = \infty$ then $x \leq C$ by definition (3.34). Assume now that $\alpha \neq 0$ and $b < \infty$. The latter implies that $\mathfrak{B} < \infty$ in view of (3.21). This and monotonicity give $0 < A^\alpha(\mathfrak{B}) \leq A^\alpha(b)$. If $(x, y) \in R^{a,\beta,a,b}$ then, by Lemma 9.1(a), $x \leq A^\alpha(b)^{-1} < \infty$. If $(x, y) \in T^{a,\beta,a,b}$ then $x \leq A^\alpha(\mathfrak{B})^{-1} < \infty$ by definition (3.33). Hence, (a).

Turn to the remaining case $(x, y) \in t^{-1}\mathbb{R}^{a,b}_t$. Let $\eta > 0$ to be chosen below. By Theorems 3.6 and 3.7, $P$-a.s., there exist random $K, L \in \mathbb{Z}_{>0}$ with $K \geq L$ such that
\begin{align*}
G^{a,b}(m, n) &\geq \gamma^{a,\beta,a,b}(m, n) + \eta(m + n) \quad \text{for } m, n \in \mathbb{Z}_{\geq L} \\
G^{a,b}(m, n) &\geq mA^\alpha(\min b_n) + \eta m \quad \text{for } m \in \mathbb{Z}_{\geq K} \text{ and } n \in [L].
\end{align*}
To prove (b), one may assume that $tx > K$. If $ty > L$ then, by monotonicity, homogeneity, (9.1) and since $x \geq y$,
\begin{align}
\gamma^{\alpha,\beta,a,b}(x, y) = t^{-1}\gamma^{\alpha,\beta,a,b}(tx, ty) \leq t^{-1}\gamma^{\alpha,\beta,a,b}([tx], [ty]) \leq t^{-1}\{G^{a,b}([tx], [ty]) + \eta([tx] + [ty])\}
\end{align}
(9.3) 
\begin{align}
&\leq 1 + \eta(1 + 1/L)(x + y) \leq 1 + 4\eta x.
\end{align}
Combining the last bound with (3.26) and using monotonicity yield
\begin{align}
xA^\alpha(\mathcal{B}) \leq xA^\alpha(b) \leq 1 + 4\eta x.
\end{align}
If $ty \leq L$ then, by monotonicity and (9.2),
\begin{align}
xA^\alpha(\mathcal{B}) \leq t^{-1}[tx]A^\alpha(\min_b \{1, [ty]\}) \leq t^{-1}G^{a,b}([tx], [ty]) + \eta t^{-1}[tx] \leq 1 + 2\eta x.
\end{align}
Since $A^\alpha(\mathcal{B}) > 0$, one then has $x \leq 2A^\alpha(\mathcal{B})^{-1}$ in both cases upon taking $\eta$ sufficiently small. Hence, (b). \hfill \Box

**Lemma 9.3.** Assume (3.16), (3.20) and (3.21). Let $S$ be given by (3.34), and define $S_t = S \cap \mathbb{R}_t^2$ for $t > 0$. Let $0 < \epsilon < 1$. Then, $\mathbf{P}$-a.s., there exists a random $L \in \mathbb{Z}_{>0}$ such that
\begin{align}
S_{L/t} \cap (1 - \epsilon)\mathcal{R}^{\alpha,\beta,a,b} \subset S_{L/t} \cap t^{-1}\mathcal{R}^{a,b} \subset S_{L/t} \cap (1 + \epsilon)\mathcal{R}^{\alpha,\beta,a,b} \quad \text{for } t \in \mathbb{R}_t>0.
\end{align}

**Proof.** Introduce $\delta > 0$ to be tuned later. By Theorem 3.6 $\mathbf{P}$-a.s., there exists a random $L \in \mathbb{Z}_{>0}$ such that
\begin{align}
|G^{a,b}(m, n) - \gamma^{\alpha,\beta,a,b}(m, n)| \leq \delta(m + n) \quad \text{for } m, n \in \mathbb{Z}_{\geq L}.
\end{align}
(9.6)
Fix $t \in \mathbb{R}_t>0$. Assume that $(x, y) \in S_{L/t} \cap (1 - \epsilon)\mathcal{R}^{\alpha,\beta,a,b}$. Choosing $L$ large enough, one has $x, y \leq C_0$ where $C_0 > 0$ is the constant from Lemma 9.2. By (9.6), monotonicity, homogeneity and that $L/t \leq x, y \leq C_0$,
\begin{align}
G^{a,b}([tx], [ty]) \leq \gamma^{\alpha,\beta,a,b}([tx], [ty]) + \delta([tx] + [ty]) \leq t(1 + 1/L)(\gamma^{\alpha,\beta,a,b}(x, y) + \delta(x + y))
\end{align}
\begin{align}
&\leq t(1 + 1/L)(1 - \epsilon + 2\delta C_0) \leq t.
\end{align}
The last line inequality holds provided that $\delta$ is sufficiently small and $L$ is sufficiently large. Hence, $(x, y) \in S_{L/t} \cap t^{-1}\mathcal{R}^{a,b}$. Assuming this and arguing as in (9.3) also lead to
\begin{align}
\gamma^{\alpha,\beta,a,b}(x, y) \leq 1 + \delta(1 + 1/L)(x + y) \leq 1 + 4\delta C_0 \leq 1 + \epsilon
\end{align}
for sufficiently small $\delta$. Hence, $(x, y) \in S_{L/t} \cap (1 + \epsilon)\mathcal{R}^{\alpha,\beta,a,b}$. \hfill \Box

**Lemma 9.4.** Assume (3.16), (3.20) and (3.21). Let $S$, $\mathcal{A}$ and $\mathcal{B}$ be given by (3.34) and (3.35). Let $0 < \epsilon < 1$. Then, $\mathbf{P}$-a.s., there exist deterministic $M, N \in \mathbb{Z}_{>0}$ and random $K \in \mathbb{Z}_{>0}$, $T \in \mathbb{R}_{>0}$ such that the following hold for $(x, y) \in \mathbb{R}_t^2$ and $t \in \mathbb{R}_T^2$.
\begin{enumerate}
\item [(a)] If $(x, y) \in S \cap t^{-1}\mathcal{R}^{a,b}$ and $ty \leq K$ then $xA^\alpha(\mathcal{B}) \leq 1 + \epsilon$. If $xA^\alpha(\mathcal{B}) \leq 1 - \epsilon$ and $x1\{\alpha=0\} \cup \{\beta=\infty\} \leq C$ then $(x, Nt^{-1}) \in S \cap t^{-1}\mathcal{R}^{a,b}$.
\item [(b)] If $(x, y) \in S \cap t^{-1}\mathcal{R}^{a,b}$ and $tx \leq K$ then $yB^\beta(-\mathcal{A}) \leq 1 + \epsilon$. If $yA^\alpha(\mathcal{B}) \leq 1 - \epsilon$ and $y1\{\beta=0\} \cup \{\alpha=\infty\}$ then $(Mt^{-1}, y) \in S \cap t^{-1}\mathcal{R}^{a,b}$.
\end{enumerate}

**Proof.** Due to the symmetry, we only prove (a). Let $\eta > 0$ to be chosen below. By Theorem 3.7 and Corollary 3.8 $\mathbf{P}$-a.s., there exist a deterministic $0 < \delta \leq 1$ and a random $K \in \mathbb{Z}_{>0}$ such that
\begin{align}
|G^{a,b}(m, n) - mA^\alpha(\min_b \{1, n\})| \leq \eta m \quad \text{for } m \in \mathbb{Z}_{\geq K}, n \in \mathbb{Z}_{>0} \text{ with } n \leq \delta m
\end{align}
(9.8)
\begin{align}
|G^{a,b}(m, n) - nB^\beta(\min_a m)| \leq \eta n \quad \text{for } n \in \mathbb{Z}_{\geq K}, m \in \mathbb{Z}_{>0} \text{ with } m \leq \delta n.
\end{align}
(9.9)
Fix $t \in \mathbb{R}_{\geq T}$. Assume that $(x, y) \in S \cap t^{-1} R_{t}^{a, b}$ and $ty \leq K$. Let $C_0 > 0$ denote the constant from Lemma 9.2. If $\delta x \geq K$ then, by (9.8) and arguing as in (9.5),
\begin{align}
(9.10) \quad xA_{o}(B) & \leq 1 + 2\eta x \leq 1 + 2\eta C_0 \leq 1 + \epsilon
\end{align}
for sufficiently large $K$ and sufficiently small $\eta$.

To prove the second claim in (a), assume now that $xA_{o}(B) \leq 1 - \epsilon$ and $x1_{\{a(\alpha) = \beta(b) = \gamma\}} \leq C$. The assumptions again imply that $x \leq C_0$ by Lemma 9.2. By continuity, there exists $N \in \mathbb{Z}_{>0}$ such that $A_{o}(\min b_N) \leq A_{o}(B) + \eta$. Work with $K \geq N$. If $\delta x \geq K$ then
\begin{align*}
G_{a,b}(\{tx\}, N) & \leq [tx]A_{o}(\min b_N) + \eta[tx] \leq (1 + 1/K)tx(A_{o}(\min b_N) + \eta) \\
& \leq (1 + 1/K)tx(A_{o}(B) + 2\eta) \leq (1 + 1/K)(1 - \epsilon + 2\eta C_0).
\end{align*}
After choosing $\eta$ sufficiently small and $K$ sufficiently large, the last term is at most $t$. If $\delta x < K$ then $x \leq K\delta - 1t^{-1} \leq K\delta - T^{-1} \leq t \leq t$ upon taking $T$ sufficiently large.

**Proof of Theorem 3.10.** Corresponding to the given $\epsilon > 0$, $P$-a.s., there exist $L \in \mathbb{Z}_{>0}$ as in Lemma 9.3 and $K, M, N \in \mathbb{Z}_{>0}, T \in \mathbb{R}_{>0}$ as in Lemma 9.4. Take $t \geq T$ below. Let $C_0 > 0$ denote the constant from Lemma 9.2. To prove (a), it suffices to show that
\begin{align}
(9.11) \quad d_{H}(S \cap t^{-1} R_{t}^{a, b}, S \cap (R_{a,b}^{\alpha, \beta, a} \cup T^{a, \beta, a, \theta})) & \leq \epsilon C_0
\end{align}
for sufficiently large $T$. The arguments in (9.11) are closed subsets of $\mathbb{R}_{\geq 0}$. The second argument is nonempty and bounded by Lemmas 9.2(b) and 9.2(a). The same is true for the first argument with large enough $T$ by Lemma 9.2(b) and the first containment in Lemma 9.3. Hence, the left-hand side in (9.11) makes sense per definition of the Hausdorff metric in Subsection A.4.

To obtain (9.11), first pick $(x, y) \in S \cap t^{-1} R_{t}^{a, b}$. Put
\begin{align*}
x' = (1 + \epsilon)^{-1}x1_{\{tx \geq K\}} \quad \text{and} \quad y' = (1 + \epsilon)^{-1}y1_{\{ty \geq K\}}.
\end{align*}
If $tx, ty \geq K$ then Lemma 9.3 implies that $(x', y') \in S \cap R_{a,b}^{\alpha, \beta, a}$. If $tx < K$ or $ty < K$ then Lemma 9.4 yields $(x', y') \in S \cap T_{a,b}^{\alpha, \beta, a, \theta}$. Furthermore, $0 \leq x - x', y - y' \leq \epsilon C_0$. Assume now that $(x, y) \in S \cap (R_{a,b}^{\alpha, \beta, a} \cup T_{a,b}^{\alpha, \beta, a, \theta})$. Put
\begin{align*}
x' = (1 - \epsilon)x1_{\{tx \geq K\}} + \frac{M}{t}1_{\{tx < K\}} \quad \text{and} \quad y' = (1 - \epsilon)y1_{\{ty \geq K\}} + \frac{N}{t}1_{\{ty < K\}}.
\end{align*}
Then $(x', y') \in S \cap t^{-1} R_{t}^{a, b}$ by Lemma 9.3 if $tx, ty \geq K$ with $K \geq (1 - \epsilon)L$ and by Lemma 9.4 otherwise. Furthermore, $|x - x'|, |y - y'| \leq \epsilon C_0$ by taking $T$ large enough. Hence, (9.11) is proved.

Turn to (b) now. Let $\delta > 0$ to be chosen later. By Lemma A.6 and uniform continuity, there exists $\eta > 0$ such that
\begin{align}
(9.12) \quad |\gamma_{a,b,\alpha, \beta}(u, v) - \gamma_{a,b,\alpha, \beta}(u', v')| & \leq \delta
\end{align}
for $(u, v), (u', v') \in [0, 2]^2$ with max$\{|u - u'|, |v - v'|\} \leq \eta$.

Let $(x, y) \in S \cap (1 - \epsilon)R_{a,b}^{\alpha, \beta, a}$. If (3.29) holds then, by Corollary 3.9(a), there exists a random $L > 0$ such that
\begin{align}
G_{a,b}(m, n) - \gamma_{a,b,\alpha, \beta}(m, n) & \leq \delta(m + n) \quad \text{for } m, n \in \mathbb{Z}_{>0} \text{ with } m + n \geq L.
\end{align}
Choose $T \geq \max_{i,j\in[L]} G^a,b(i,j)$, and take $t \geq T$ below. If $t(x+y) \geq L$ then, by (9.12)-(9.13), monotonicity, homogeneity and because $x,y \leq C_0$, one obtains that
\[
G^a,b([tx],[ty]) \leq \gamma^{\alpha,\beta,a,b}(tx,ty) + \delta(tx + ty) \leq \gamma^{\alpha,\beta,a,b}(tx + 1,ty + 1) + 2\delta(tx + ty)
\]
\[
\leq t(x+y) \left( \gamma^{\alpha,\beta,a,b}\left( \frac{x}{x+y} + \frac{1}{L}, \frac{y}{x+y} + \frac{1}{L} \right) + 2\delta \right)
\]
\[
\leq t\gamma^{\alpha,\beta,a,b}(x,y) + 3t\delta(x+y) \leq t(1 + \epsilon + 6\delta C_0) \leq t
\]
providing that $L$ is sufficiently large and $\delta$ is sufficiently small. The last bound also holds if $t(x+y) < L$ by the choice of $T$. Hence, $(x,y) \in S \cap t^{-1}R^a,b$ as claimed.

Suppose now that (3.29) fails. Consider the case $\alpha,\beta \not= 0$ and $\min a_m < a$ for some $m \in \mathbb{Z}_{\geq 0}$. With $\epsilon \leq \epsilon_0 = \frac{1}{2}(B^\beta(-a) - 1) - B^\beta(-\min a_m)^{-1}$, one has
\[
v = \frac{1 - 2\epsilon}{B^\beta(-a)} > \frac{1}{B^\beta(-\min a_m)}.
\]
It then follows from (3.43) that, P-a.s., there exists a random $T_0 > 0$ such that $(mt^{-1},v) \not= t^{-1}R^a,b_t$ for $t \geq T_0$. Since $\lim_{t \to \infty} \gamma^{\alpha,\beta,a,b}(mt^{-1},v) = 1 - 2\epsilon$ by (3.36), after increasing $T_0$ if necessary, one also has $(mt^{-1},v) \in (1-\epsilon)\mathcal{R}^{\alpha,\beta,a,b}$. Finally, with $C \geq B^\beta(-a)$ and taking $T_0 \geq mB^\beta(-a)$, one has $(mt^{-1},v) \in S$. The case $\alpha \not= 0$ and $\min b_n < b$ for some $n \in \mathbb{Z}_{\geq 0}$ is treated similarly. The proof of (b) is now complete.

The proof of (c) is analogous. 

\[\square\]

10. Proofs of Theorems 3.11 and 3.12

\textbf{Proof of Theorem 3.11.} We prove only the estimate for the flux process. The estimate for the height process can be obtained in the same manner, and then the estimate for the particle locations is immediate.

Introduce a constant $c > 0$ to be chosen later. By Theorem 3.6, P-a.s., there exists $L_0 \in \mathbb{Z}_{\geq 0}$ such that
\[
|G^{a,b}(m,n) - \gamma^{\alpha,\beta,a,b}(m,n)| \leq c(m+n) \quad \text{for } m,n \in \mathbb{Z}_{\geq L_0}.
\]

Choose $L \in \mathbb{Z}_{\geq 0}$ with $L > 2L_0 \max\{1,\epsilon^{-1}\}$. Fix $m \geq L$ and $t \in \mathbb{R}_{\geq 0}$ below. Consider $j \in \mathbb{Z}_{\geq 0}$ with $j > \gamma^{\alpha,\beta,a,b}(m,t) + \epsilon(m+t)$. Then, by definition of the flux process and rearranging terms,
\[
(m+j)A^\alpha(z) + jB^\beta(z) > t + \epsilon(A^\alpha(z) + B^\beta(z))(t+j) \quad \text{for } z \in (-a,b).
\]

In particular, $t < c_0(m+j)$ for some constant $c_0 > 0$. Now setting $z = \zeta^{\alpha,\beta,a,b}(m+j,j)$ in (10.2), using monotonicity of $A^\alpha$ and $B^\beta$ and the bound on $t$, one obtains that
\[
\gamma^{\alpha,\beta,a,b}(m+j,j) > (m+j)A^\alpha(\zeta) + jB^\beta(\zeta) > t + \epsilon(A^\alpha(b) + B^\beta(-a))(c_0(m+j) + j)
\]
\[
> t + c_1\epsilon(m+2j)
\]
for some constant $c_1 > 0$. Since $j \geq L_0$, choosing $c \leq c_1$ yields
\[
G^{a,b}(m+j,j) \geq \gamma^{\alpha,\beta,a,b}(m+j,j) - c_1\epsilon(m+2j) > t
\]
in view of (10.1). Then it follows from the choice of $m$ that
\[
F^{a,b}(m,t) \leq \gamma^{\alpha,\beta,a,b}(m+t) + \epsilon(m+t).
\]
For the lower bound, it suffices to consider the case \( f_{\alpha,\beta,\lambda}(m, t) \geq \epsilon(m + t) \) since the flux process is nonnegative. Now consider \( j \in Z_{>0} \) with \( L_0 \leq j < f_{\alpha,\beta,\lambda}(m, t) - \epsilon(m + t)/2 \). Such \( j \) exists since the right-hand side is greater than \( L_0 \). By definition \( (3.44) \), there exists \( z \in (-a, b) \) such that
\[
(m + j)A^\alpha(z) + jB^\beta(z) < t - \frac{\epsilon}{2}(A^\alpha(z) + B^\beta(z))(t + j).
\]
In particular, \( t \geq j(A^\alpha(z) + B^\beta(z)) \geq j(A^\alpha(b) + B^\beta(-a)) \). Then, by \( (10.4) \)
\[
\gamma_{\alpha,\beta,\lambda}(m + j, j) < t - c_2\epsilon(m + 2j)
\]
for some constant \( c_2 > 0 \). Now choosing \( c \leq c_2 \) yields
\[
G^\alpha_{a,b}(m + j, j) \leq \gamma_{\alpha,\beta,\lambda}(m + j, j) + c_2\epsilon(m + 2j) < t.
\]
One then concludes from the choice of \( m \) that
\[
F_{a,b}(m, t) \geq f_{\alpha,\beta,\lambda}(m, t) - \frac{\epsilon}{2}(m + t).
\]

Proof of Theorem 3.12. Abbreviate \( A = A^\alpha(\min b) \). Assume that \( \epsilon \leq 1 \) and let \( 0 < c < \min\{A, A^2\} \). By Theorem 3.7, there exists \( K \in Z_{>0} \) such that
\[
|G^\alpha_{a,b}(m, n) - mA| \leq cem \quad \text{for} \ m \geq Z_{>K}.
\]
Pick \( T \geq K/\epsilon \) and let \( t \geq T \) below.

If \( m \in Z_{>0} \) with \( m \geq t(1/A + \epsilon) \) then \( m \geq K \) and, by \( (10.7) \),
\[
G^\alpha_{a,b}(m, n) \geq m(A - c) > t(\epsilon + 1/A)(A - c) = t + \epsilon(A - c/A - c) > t
\]
Hence, \( H^\alpha_{a,b}(n, t) \leq t(1/A + \epsilon) \). Now assuming \( 2\epsilon < 1/A \), let \( m \in Z_{>K} \) with \( m \leq t(1/A - \epsilon) \) noting that the right-hand side is at least \( K \). Therefore, by \( (10.7) \),
\[
G^\alpha_{a,b}(m, n) \leq m(A + c) < t(1/A - \epsilon)(A + c) = t - \epsilon(A - c/A - c) < t.
\]
Hence, \( H^\alpha_{a,b}(n, t) \geq t(1/A - \epsilon) \).

11. Proofs of Corollaries 3.13-3.21

Proof of Corollary 3.13. Conditions \( (3.16) \) and \( (3.21) \) hold with \( a = \inf a \) and \( b = \inf b \).

Proof of Corollary 3.14. By periodicity, \( (3.8) \) holds since \( \inf a = a_k^{\min} \) and \( \inf b = b_k^{\min} \). Also, \( (3.20) \) holds with the empirical measures \( \alpha = a_k \) and \( \beta = b_k^{\sup} \) defined at \( (3.19) \). Hence, Corollary 3.13 applies.

Proof of Corollary 3.15. The ergodic theorem implies that \( (3.16), (3.20) \) and \( (3.21) \) hold with measures \( \alpha, \beta \) and \( a = \inf \sup \alpha, b = \inf \sup \beta \).

Proof of Corollary 3.16. By \( (3.21) \), for sufficiently large \( m, n \in Z_{>0} \), one has \( z, w \in I_{m,n} \) and the last-passage times in the claimed bounds make sense. Define two collections of parameters \(-za\) and \( wb\) by
\[
(-za)_m(i) = -z1_{i=1} + 1_{i=1}(a_m(i - 1) \quad \text{and} \quad (wb)_n(j) = w1_{j=1} + 1_{j=1}(b_n(j - 1)
\]
for \( m, n \in Z_{>0} \) and \( i \in [m], j \in [n] \). Observe that \( \{G_{a,b,w}^\alpha(m, n - 1) : m, n \in Z_{>0} \} \) and \( \{G_{a,b,w}^\alpha(m - 1, n) : m, n \in Z_{>0} \} \) can be regarded as bulk LPP process with parameters \( (a, wb) \) and \( (-za, b) \), respectively. By \( (3.20) \), the limiting empirical measures for \(-za\) and \( wb\) are \( \alpha \) and \( \beta \), respectively. Furthermore, \( \min(-za)_m = -z \) and \( \min(wb)_n = w \). Finally, since
$w, z \in (-a, b)$, one has $\min\{a + w, -z + b\} > 0$. Hence, the first two bounds are consequences of Theorem 3.6. Since
\[\hat{G}^{a,b,w,z}(m, n) = \max\{\hat{G}^{a,b,w}_{1,0}(m, n), \hat{G}^{a,b,z}_{0,1}(m, n)\}\]
due to $\hat{w}_{0,0}^{a,b,w,z}(m, n) = 0$, the third inequality also follows. To see the last inequality, note from definitions (3.14), (3.18), continuity and convexity (noted in Section 7) that
\[\max\{\alpha, \beta, a, z(x, y), \gamma(x, y)\} = \max\{\inf_{a < s < b} \Gamma_{a,s}^{\alpha,\beta}(x, y), \inf_{z < s < b} \Gamma_{z,s}^{\alpha,\beta}(x, y)\}
= \Gamma_{z,s}^{\alpha,\beta}(x, y).\]

Proof of Corollary 3.17. Conditions (3.16), (3.20) and (3.21) hold with $\alpha = \beta = \delta_{1/2}$, $a = \min\{a_{k}^{\min}, 1/2\}$ and $b = \min\{b_{l}^{\min}, 1/2\}$. Hence, the shape function exists and is given by
\[\gamma(x, y) = \inf_{a < s < b} \left\{ \frac{x}{1/2 + z} + \frac{y}{1/2 - z} \right\}.\]
An elementary computation then yields the claimed formula. \hfill \Box

Proof of Corollary 3.18. Let $\epsilon > 0$. By uniform convergence, there exists $M \in \mathbb{Z}_{>0}$ such that
\[(11.1)\]
\[\left| a_{m}(i) - a_{i} \right| \leq \epsilon \quad \text{for} \quad m \in \mathbb{Z}_{\geq M} \quad \text{and} \quad i \in [m].\]
This implies that $\min a_{m} - a_{\min}^{m} \leq \epsilon$ for $m \in \mathbb{Z}_{\geq M}$. Since $a_{\min}^{m} \rightarrow a = \inf\{a_{i}\}_{i \in \mathbb{Z}_{>0}}$ and $\epsilon$ is arbitrary, $\min a_{m} \rightarrow a$. Similarly, $\min b_{n} \rightarrow b$. Hence, (3.16) and (3.21) hold with $a$ and $b$. To verify (3.20), let $f$ be a continuous function vanishing at infinity. Pick $A > 0$ large such that $f < \epsilon$ on $\mathbb{R} \setminus [-A, A]$. By uniform continuity and vague convergence, one can increase $M$ if necessary to have
\[(11.2)\]
\[\sup_{i \in [m]} \left| f(a_{m}(i)) - f(a_{i}) \right| 1_{\{a_{i} \leq A + 1\}} \leq \epsilon\]
\[(11.3)\]
\[\left| \frac{1}{m} \sum_{i=1}^{m} f(a_{i}) - \int_{\mathbb{R}} f(a) \alpha(da) \right| \leq \epsilon \quad \text{for} \quad m \in \mathbb{Z}_{\geq M}.\]
Assuming $\epsilon \leq 1$, $|a_{i}| \geq A + 1$ implies that $a_{m}(i) \geq A$ for $m \in \mathbb{Z}_{\geq M}$ and $i \in [m]$. Therefore,
\[(11.4)\]
\[\sup_{i \in [m]} \left| f(a_{m}(i)) - f(a_{i}) \right| 1_{\{|a_{i}| > A + 1\}} \leq 2\epsilon \quad \text{for} \quad m \in \mathbb{Z}_{\geq M}.\]
Putting together (11.2) \text{--} (11.4) via the triangle inequality yields
\[\left| \frac{1}{m} \sum_{i=1}^{m} f(a_{m}(i)) - \int_{\mathbb{R}} f(a) \alpha(da) \right| \leq 4\epsilon \quad \text{for} \quad m \in \mathbb{Z}_{\geq M}.\]
This shows that $a_{m}^{\alpha} \rightarrow \alpha$ vaguely. Similarly, $b_{n}^{\beta} \rightarrow \beta$ vaguely. Hence, (3.20) holds with measures $\alpha$ and $\beta$. The claim then follows from Theorem 3.6. \hfill \Box

Proof of Corollary 3.19. Since the weights are $P$-a.s. nonnegative,
\[\max\{G_{k+1,1}^{a,b}(m, n), G_{l+1,1}^{a,b}(m, n)\} \leq G^{a,b}(m, n) \leq \max\{G_{k+1,1}^{a,b}(m, n), G_{l+1,1}^{a,b}(m, n)\}\]
\[(11.5)\]
\[\sum_{(i,j) \in [k] \times [l]} \omega(i,j) \frac{a_{m}(i) + b_{n}(j)}{a_{m}(i) + b_{n}(j)} \]
for $m \in \mathbb{Z}_{>k}$, $n \in \mathbb{Z}_{>l}$. Theorem 3.6 applies to the LPP processes with initial points at $(k+1, 1)$ and $(l, l+1)$. Assumption (3.54) implies that the sum in (11.5) divided by $m + n$
can be made arbitrarily close to zero by taking \( m, n \) sufficiently large. Therefore, the shape function of \( G^{a, b} \)-process is given by

\[
(11.6) \quad \max\{\gamma^{\alpha, \beta, a_k, b_0}, \gamma^{\alpha, \beta, a_0, b_j}\} = \max\left\{ \inf_{z \in (-a_k, b_0)} \Gamma_{\alpha, \beta}^z, \inf_{z \in (-a_0, b_j)} \Gamma_{\alpha, \beta}^z \right\}.
\]

To see that the last expression agrees with (3.55), consider cases: If \( \alpha = 0 \) or \( \beta = 0 \) then the claim can be seen from (3.24). Assume now that \( \alpha, \beta \neq 0 \). Then \( z \to \Gamma_{\alpha, \beta}^z \) is strictly convex on \((-a, b)\) where \( a = \inf \text{supp} \alpha \) and \( b = \inf \text{supp} \beta \), see Section 7. Let \( \xi = \xi^{\alpha, \beta, a, b} \) denote the unique minimizer on \([-a, b]\). Note that the right-hand side of (11.6) can be written as

\[
1_{\{\xi < a\}} \Gamma_{\alpha, \beta}^a + 1_{\{\xi \in [-a, b]\}} \Gamma_{\xi}^{\alpha, \beta} + 1_{\{\xi > b\}} \Gamma_{b}^{\alpha, \beta} = 1_{\{a_0 + b_0 > 0\}} \gamma^{\alpha, \beta, a, b} + 1_{\{a_0 + b_0 = 0\}} \Gamma_{-a_0}^{\alpha, \beta}.
\]

Proof of Corollary 3.21. Let \( \alpha \) and \( \beta \) denote the Borel probability measures on \( \mathbb{R} \) induced by the uniform measure on \([0, 1]\) via the restrictions of \( A \) and \( B \), respectively, to \([0, 1]\). Let \( f \) be a continuous function on \( \mathbb{R} \) vanishing at infinity. By the continuity of \( f \) and the Riemann integrability of \( A \), the composition \( f \circ A \) is also Riemann integrable on \([0, 1]\) [55, Theorem 6.11]. Hence,

\[
(11.7) \quad \frac{1}{m} \sum_{i=1}^{m} f(a_m(i)) = \frac{1}{m} \sum_{i=1}^{m} f(A(i/m)) \xrightarrow{m \to \infty} \int_{0}^{1} f(A(t)) dt = \int_{\mathbb{R}} f(a) \alpha(da),
\]

Since \( f \) is arbitrary, (11.7) implies that \( \alpha_{m} \to \alpha \) vaguely. Similarly, \( \beta_{n} \to \beta \) vaguely. Hence, (3.20) holds with \( \alpha \) and \( \beta \). Since (3.21) is already assumed, and (3.16) holds due to (3.58), the result comes from Theorem 3.6. \(\square\)

Proof of Corollary 3.21. From definition (3.3),

\[
\mathcal{M}^{a, b}(m, n) = \inf_{-1 < z < 1} \left\{ \sum_{i=1}^{m} \frac{1}{i^\eta + z} + \sum_{j=1}^{n} \frac{1}{j^\eta - z} \right\} \quad \text{for } m, n \in \mathbb{Z}_{> 0},
\]

which leads to the bounds

\[
\sum_{i=1}^{m} \frac{1}{i^\eta} + \sum_{j=1}^{n} \frac{1}{j^\eta} \geq \mathcal{M}^{a, b}(m, n) \geq \sum_{i=1}^{m} \frac{1}{i^\eta + 1} + \sum_{j=1}^{n} \frac{1}{j^\eta + 1} \quad \text{for } m, n \in \mathbb{Z}_{> 0}.
\]

Both bounds differ from \((m^{1-\eta} + n^{1-\eta})\int_{0}^{1} \frac{dx}{x^\eta} = \frac{m^{1-\eta} + n^{1-\eta}}{1-\eta} \) by at most \( \epsilon(m^{1-\eta} + n^{1-\eta}) \) provided that \( m, n \) are sufficiently large. The result then follows from Corollary 3.3. \(\square\)

**Appendix A.**

A.1. Concentration bounds for sums of independent exponential random variables.

**Lemma A.1.** Let \( m, p \in \mathbb{Z}_{> 0} \) and \( x_1, \ldots, x_m > 0 \). Then

\[
\sum_{(k_1, \ldots, k_m) \in \mathbb{Z}_{> 0}^m} \prod_{i \in [m]} x_{i}^{k_i} \leq 2^p \left( \sum_{i \in [m]} x_i^2 \right)^p.
\]
Proof. For \( n \in \mathbb{Z}_{>0} \), write \( S_n \) for the set of all \( k = (k_1, \ldots, k_m) \in \mathbb{Z}_{\geq 0}^m \) such that \( \sum_{i \in [m]} k_i = n \). Let \( S'_n \) denote the set of all \( k \in S_n \) with \( k_i \neq 1 \) for \( i \in [m] \). Define two maps \( f, g : S'_{2p} \rightarrow S_p \) as follows: For each \( k \in S'_{2p} \), there is an even number \( 2l \) of indices \( i \in [m] \) for which \( k_i \) is odd. Let \( i_1 < \cdots < i_{2l} \) denote these indices. Define \( f(k) \in S_p \) and \( g(k) \in S_p \) by setting

\[
\begin{align*}
  f(k)_i & = \begin{cases} 
    (k_i + 1)/2 & \text{if } i = i_s \text{ for some } s \in [l] \\
    (k_i - 1)/2 & \text{if } i = i_s \text{ for some } s \in [2l] \setminus [l] \\
    k_i/2 & \text{otherwise.}
  \end{cases} \\
  g(k)_i & = \begin{cases} 
    (k_i - 1)/2 & \text{if } i = i_s \text{ for some } s \in [l] \\
    (k_i + 1)/2 & \text{if } i = i_s \text{ for some } s \in [2l] \setminus [l] \\
    k_i/2 & \text{otherwise.}
  \end{cases}
\end{align*}
\]

The inequality \( 2 \leq t + 1/t \) applied with \( t = \prod_{i=s+1}^l x_{i_s} \prod_{i=1}^{2l} 1/x_{i_s} \) yields

\[
2 \sum_{i \in [m]} x_i^{k_i} \leq \left( \sum_{i \in [m]} x_i^{2f(k)_i} + \sum_{i \in [m]} x_i^{2g(k)_i} \right) \leq 3^p \sum_{u=(u_1, \ldots, u_m) \in S_p} \prod_{i \in [m]} x_i^{2u_i} \leq 3^p \left( \sum_{i \in [m]} x_i^2 \right)^p.
\]

An application of the preceding lemma yields the concentration inequality below.

**Lemma A.2.** Let \( X_i \sim \text{Exp}(\lambda_i) \) be mutually independent exponential random variables. Then for each \( p \in \mathbb{Z}_{\geq 0} \) there exists a constant \( C_p > 0 \) (depending only on \( p \)) such that, for all \( s > 0 \) and \( n \in \mathbb{Z}_{\geq 0} \),

\[
\mathbf{P}\left\{ \left| \sum_{i=1}^n X_i - \frac{1}{\lambda_i} \right| \geq s \sqrt{\sum_{i=1}^n \frac{1}{\lambda_i^2}} \right\} \leq \frac{C_p}{s^p}.
\]

**Proof.** With \( S = \sum_{i=1}^n X_i \) the claimed inequality is

(A.1) \[
\mathbf{P}\{|S - \mathbb{E}S| \geq s\sqrt{\text{Var}S}\} \leq C_p s^{-p}.
\]

For \( i \in [n] \) and \( q \in \mathbb{Z}_{\geq 0} \), a brief computation gives the \( q \)th central moment of \( X_i \) as

\[
\mathbf{E}[(X_i - \lambda_i^{-1})^q] = c_q \lambda_i^{-q} \quad \text{where} \quad c_q = q! \sum_{l=0}^{q} \frac{(-1)^l}{l!}.
\]
From this, the multinomial theorem and independence,

\[ E[|S - ES|^{2p}] = E \left[ \left( \sum_{i=1}^{n} X_i - \sum_{i=1}^{n} \frac{1}{\lambda_i^2} \right)^{2p} \right] = \sum_{u_1, \ldots, u_n \in \mathbb{Z}_{\geq 0}} \frac{(2p)!}{\prod_{i=1}^{n} u_i!} \prod_{i=1}^{n} \frac{c_{u_i}}{\lambda_i^{u_i}} \]

Since \( c_1 = 0 \), the condition \( u_i \neq 1 \) for \( i \in [k] \) can be skipped into the outer sum without breaking the equality. Then, by virtue of Lemma A.1 and since \( 0 \leq c_{u_i} \leq u_i! \), the right-hand side of (A.2) is at most

\[ (2p)! \sum_{\sum_i u_i = 2p, u_i \neq 1, i \in [n]} \prod_{i=1}^{n} \frac{1}{\lambda_i^{u_i}} \leq (2p)! 3^p \left( \sum_{i=1}^{n} \frac{1}{\lambda_i^2} \right)^p = C_p (\text{Var}S)^p, \]

where \( C_p = (2p)! 3^p \). By Markov’s inequality,

\[ P\{|S - ES| \geq s \sqrt{\text{Var}S}\} \leq \frac{E[|S - ES|^{2p}]}{s^{2p} (\text{Var}S)^p} \leq \frac{C_p}{s^{2p}}, \]

which implies (A.1) if \( s \geq 1 \). Since \( C_p > 1 \), (A.1) also trivially holds if \( s < 1 \).

A.2. Vague convergence. For convenience, we recall the definition of and some standard facts about the vague convergence of real-valued Borel measures on the real line. These can be found for example in [21] and [28].

Let \( \mathcal{M}(\mathbb{R}) \) and \( C_0(\mathbb{R}) \), respectively, denote the spaces of real-valued Borel measures on \( \mathbb{R} \) and real-valued, continuous functions on \( \mathbb{R} \) vanishing at infinity. The vague topology on \( \mathcal{M}(\mathbb{R}) \) is the minimal topology such that the maps \( \mu \mapsto \int f d\mu \) for \( f \in C_0(\mathbb{R}) \) are continuous. With this definition, a sequence \((\mu_n)_{n \in \mathbb{Z}_{>0}}\) in \( \mathcal{M}(\mathbb{R}) \) converges to \( \mu \in \mathcal{M}(\mathbb{R}) \) in the vague topology (vaguely) if and only if \( \int f d\mu_n \to \int f d\mu \) as \( n \to \infty \) for any \( f \in C_0(\mathbb{R}) \).

Lemma A.3. Let \((\mu_n)_{n \in \mathbb{Z}_{>0}}\) be a sequence in \( \mathcal{M}(\mathbb{R}) \) such that \( \mu_n \to \mu \) vaguely as \( n \to \infty \) for some \( \mu \in \mathcal{M}(\mathbb{R}) \). Then there exists \( C > 0 \) such that \( \mu_n(\mathbb{R}) \leq C \) for \( n \in \mathbb{Z}_{>0} \).

Denote the subspace of subprobability measures on \( \mathbb{R} \) by

\[ \mathcal{M}^+_{<1}(\mathbb{R}) = \{ \mu \in \mathcal{M}(\mathbb{R}) : \mu \geq 0 \text{ and } \mu(\mathbb{R}) \leq 1 \}. \]

Lemma A.4. For any sequence \((\mu_n)_{n \in \mathbb{Z}_{>0}}\) in \( \mathcal{M}^+_{<1}(\mathbb{R}) \), there exists a subsequence \((\mu_{n_k})_{k \in \mathbb{Z}_{>0}}\) in \( \mathcal{M}^+_{<1}(\mathbb{R}) \) and \( \mu \in \mathcal{M}^+_{<1}(\mathbb{R}) \) such that \( \mu_{n_k} \to \mu \) vaguely as \( k \to \infty \).

A.3. Cauchy transform. This subsection derives a uniform strengthening of the continuity of the Cauchy transform (also known as the Stieltjes or Cauchy-Stieltjes transform) with respect to the vague topology.

Write \( \mathcal{M}^+(\mathbb{R}) \) for the space of \( \mathbb{R}_{>0} \)-valued Borel measures on \( \mathbb{R} \). Let \( \mu \in \mathcal{M}^+(\mathbb{R}) \) and \( D = \mathbb{C} \setminus \text{supp} \mu \). The Cauchy transform of \( \mu \) is defined as the convolution

\[ C_\mu(z) = \int_{\mathbb{R}} \frac{\mu(dt)}{z - t} \quad \text{for } z \in D. \]

The integral is well-defined since \( \mu(\mathbb{R}) < \infty \), \( \mu(\mathbb{R} \setminus \text{supp} \mu) = 0 \) and the distance \( \Delta(z) = \inf_{t \in \text{supp} \mu} |z - t| > 0 \) for \( z \in D \), the latter due to \( \text{supp} \mu \) being closed. By direct computation,

\[ |C_\mu(z) - C_\mu(w)| = |(w - z) \int_{\mathbb{R}} \frac{\mu(dt)}{(z - t)(w - t)}| \leq \frac{|z - w| \mu(\mathbb{R})}{\Delta(z) \Delta(w)} \quad \text{for } z, w \in D, \]
and $C_\mu$ is holomorphic on $D$ with
\begin{equation}
\partial_z^n C_\mu(z) = (-1)^n n! \int_\mathbb{R} \frac{\mu(dt)}{(z - t)^{n+1}} \quad \text{for } z \in D \text{ and } n \in \mathbb{Z}_{\geq 0}.
\end{equation}

**Lemma A.5.** Let $\mu \in \mathcal{M}^+(\mathbb{R})$ and $(\mu_n)_{n \in \mathbb{Z}_{>0}}$ be a sequence in $\mathcal{M}^+(\mathbb{R})$ such that $\lim_{n \to \infty} \mu_n = \mu$ vaguely. Let $S \subset \mathbb{C}$ denote the closure of $\text{supp} \mu \cup \bigcup_{n \in \mathbb{Z}_{>0}} \text{supp} \mu_n$. Let $K \subset \mathbb{C} \setminus S$ be compact. Then, for any $\varepsilon > 0$, there exists $n_0 \in \mathbb{Z}_{>0}$ such that
\[ |C_{\mu_n}(z) - C_\mu(z)| < \varepsilon \quad \text{for all } n \geq n_0 \text{ and } z \in K. \]

**Proof.** Since the real and imaginary parts of the integrand in (A.3) belong to $C_0(\mathbb{R})$, it is immediate from the definition of vague convergence that $C_{\mu_n}(z) \to C_\mu(z)$ as $n \to \infty$ pointwise for $z \in \mathbb{C} \setminus S$. To upgrade to uniform convergence, first pick a constant $C > 0$ as in Lemma A.3 such that $\mu_n(\mathbb{R}) \leq C$ for $n \in \mathbb{Z}_{>0}$. Also, since $K$ is compact, $S$ is closed and $K \cap S = \emptyset$, there exists $\delta > 0$ such that $|z - x| \geq \delta$ for $z \in K$ and $x \in S$. Hence, it follows from (A.4) that
\[ |C_{\mu_n}(z) - C_{\mu_n}(w)| \leq \frac{C}{\delta^2}|z - w| \quad \text{for } z, w \in K \text{ and } n \in \mathbb{Z}_{>0}. \]

In particular, the sequence of functions $(C_{\mu_n})_{n \in \mathbb{Z}_{>0}}$ is equicontinuous on $K$. This property together with the pointwise convergence on the compact set $K$ implies that $C_{\mu_n}(z) \to C_\mu(z)$ uniformly in $z \in K$ as $n \to \infty$.

**A.4. Hausdorff metric.** We include the definition of the Hausdorff metric given for example in [55, p. 280]. Let $(X, d)$ be a metric space. For any $\varepsilon > 0$ and $A \subset X$, denote the $\varepsilon$-fattening of $A$ by $A^\varepsilon = \{x \in X : d(x, y) < \varepsilon \text{ for some } y \in A\}$. Let $\mathcal{X}$ denote the space of nonempty, bounded, closed subsets of $X$. The Hausdorff metric on $\mathcal{X}$ is defined by
\begin{equation}
d_H(A, B) = \inf \{\varepsilon > 0 : A \subset B^\varepsilon \text{ and } B \subset A^\varepsilon\} \quad \text{for } A, B \in \mathcal{X}.
\end{equation}

**A.5. Positive-homogeneous, monotone functions.**

**Lemma A.6.** Let $f : \mathbb{R}_{\geq 0}^2 \to \mathbb{R}_{\geq 0}$ be a positive-homogeneous and coordinatewise nondecreasing function. Then $f$ has a continuous extension to $\mathbb{R}_{\geq 0}^2$.

**Proof.** By positive-homogeneity and coordinatewise monotonicity,
\[ |f(x, y) - f(\tilde{x}, \tilde{y})| \leq f(\max\{x, \tilde{x}\}, \max\{y, \tilde{y}\}) - f(\min\{x, \tilde{x}\}, \min\{y, \tilde{y}\}) \]
\[ \leq \left( \max\left\{ \begin{array}{c} \max\{x, \tilde{x}\} - \min\{x, \tilde{x}\} \\ \max\{y, \tilde{y}\} - \min\{y, \tilde{y}\} \end{array} \right\} - 1 \right) f(\min\{x, \tilde{x}\}, \min\{y, \tilde{y}\}) \]
\[ \leq \left( \begin{array}{c} \max\{\max\{x, \tilde{x}\}, \max\{y, \tilde{y}\}\} - 1 \\ \min\{\min\{x, \tilde{x}\}, \min\{y, \tilde{y}\}\} - 1 \end{array} \right) f(x, y) \quad \text{for } x, y, \tilde{x}, \tilde{y} \in \mathbb{R}_{\geq 0}. \]

In particular, $f$ is continuous on $\mathbb{R}_{\geq 0}^2$. Extend $f$ to a function $\mathbb{R}_{\geq 0}^2 \to \mathbb{R}_{\geq 0}$ by setting
\begin{equation}
f(x, 0) = \inf_{t > 0} f(x, t) = \lim_{t \to 0^+} f(x, t) \quad \text{and} \quad f(0, y) = \inf_{t > 0} f(t, y) = \lim_{t \to 0^+} f(t, y)
\end{equation}
for $x, y \in \mathbb{R}_{\geq 0}$, and $f(0, 0) = 0$. The extension is also positive-homogeneous and coordinatewise nondecreasing. Then $f(x, y) \leq \max\{x, y\} f(1, 1)$ and, consequently, $f$ is continuous at $(0, 0)$. $f$ is also continuous on the horizontal axis by (A.7) and on account of the bound
\[ |f(x, 0) - f(\tilde{x}, \tilde{y})| \leq |xf(1, 0) - \tilde{x}f(1, \tilde{y}/\tilde{x})| \leq x(f(1, \tilde{y}/\tilde{x}) - f(1, 0)) + |x - \tilde{x}|f(1, \tilde{y}/\tilde{x}) \]
\[ \leq x(f(1, 2\tilde{y}/x) - f(1, 0)) + |x - \tilde{x}|f(1, 2\tilde{y}/x) \]
for $x, \tilde{x} \in \mathbb{R}_{>0}$ with $\tilde{x} \geq x/2$ and $\tilde{y} \in \mathbb{R}_{>0}$. The continuity on the vertical axis follows similarly.

**Lemma A.7.** Let $f, g: \mathbb{R}_{>0}^2 \to \mathbb{R}_{>0}$ be positive-homogeneous and coordinatewise nondecreasing functions such that, for any $\epsilon > 0$, there exists $L \in \mathbb{Z}_{>0}$ such that

\[
|f(m, n) - g(m, n)| \leq \epsilon(m + n) \quad \text{for } m, n \geq L.
\]

Then $f = g$ on $\mathbb{R}_{>0}^2$.

**Proof.** Let $\epsilon > 0$ and choose $L \in \mathbb{Z}_{>0}$ such that (A.8) holds. Let $p, q \in \mathbb{Q}_{>0}$. Then, by positive-homogeneity,

\[
|f(p, q) - g(p, q)| = n^{-1}|f(np, nq) - g(np, nq)| \leq \epsilon(p + q)
\]

for $n \in \mathbb{Z}_{>0}$ such that $np, nq \in \mathbb{Z}_{>0}$. Since $\epsilon > 0$ is arbitrary, it follows that $f = g$ on $\mathbb{Q}_{>0}^2$. Also, $f$ and $g$ are continuous on $\mathbb{R}_{>0}^2$ by Lemma A.6. Hence, $f = g$ on $\mathbb{R}_{>0}^2$. □
