THE FOUNDATIONS OF SPECTRAL COMPUTATIONS VIA THE SOLVABILITY COMPLEXITY INDEX HIERARCHY: PART I

M. J. COLBROOK AND A. C. HANSEN

ABSTRACT. Given the many applications in the physical sciences, the problem of computing spectra of operators is arguably one of the most investigated areas of computational mathematics over the last half-century. As well as computing the spectrum, scientists may want to determine if there is a spectral gap, compute geometric features of the spectrum, compute isolated eigenvalues and their multiplicities etc. Despite substantial interest in these problems, the fundamental questions on whether algorithms exist for these quantities remain open, even for the spectrum. Establishing the foundations of spectral computations is very much related to Smale’s comprehensive program on the foundations of computational mathematics initiated in the 1980s. What makes spectral problems particularly delicate is that many of the problems can only be computed using several limits, a phenomenon also shared in the foundations of polynomial root finding with rational maps as proved by McMullen.

This paper, the first of a two-part series, has three purposes. First, we establish answers to many of the long-standing open questions on the existence of algorithms via the Solvability Complexity Index (SCI) hierarchy, a classification tool determining the boundaries of what computers can achieve in computational mathematics. For instance, we show that for a large class of partial differential operators, the spectrum can be computed with error control from point sampling the coefficients of the operator. Second, these classifications determine which types of problems can be used in computer-assisted proofs. The theory for this is virtually non-existent, and we provide some of the first results in this infinite classification theory. Third, our proofs are constructive, yielding a library of new algorithms for problems that before were out of reach. We show several examples on contemporary problems in the physical sciences.

1. INTRODUCTION

The problem of computing spectra of operators has fascinated and frustrated mathematicians for several decades since the 1950s. Indeed, W. Arveson pointed out in the nineties, "Unfortunately, there is a dearth of literature on this basic problem, and so far as we have been able to tell, there are no proven techniques" [5]. The reason why there have been no known general techniques has recently been resolved and is due to classification results in the newly established Solvability Complexity Index (SCI) hierarchy [8, 34, 65]. The fact that algorithms were not found for the general computational spectral problem has a potentially surprising cause: one needs several limits in the computation. Traditional approaches have been dominated by techniques based on one limit, and this is the reason behind Arveson’s observation. Moreover, the fact that several limits are required is a phenomenon that is shared by other areas of computational mathematics. For example, the problem of root-finding of polynomials with rational maps initiated by S. Smale [95] is also subject to the issue of requiring several limits. This was established by C. McMullen [75, 76] and P. Doyle & C. McMullen in [44], and their results become classification results in the SCI hierarchy.

The recent results in [8, 33, 34, 65] establishing the SCI hierarchy reveal that the computational spectral problem becomes an infinite classification theory. Hence, there is an infinite well of open problems, some of which have been open for decades. The main topic of this paper is to provide solutions to many of these open problems, and this program has two main motivations:

(I) Classifications and new algorithms: Sharp classifications of problems in the SCI hierarchy establish the boundaries of what computers can achieve. Constructive classifications, which we always provide in this paper, provide algorithms that achieve the boundary of what computers can do. Moreover, with new classifications, such algorithms will solve problems in the sciences that before were not possible. We provide several examples in this paper.

(II) Computer-assisted proofs: Computer-assisted proofs, where computers are used to solve numerical problems rigorously, have become essential in modern mathematics. What may be surprising is that undecidable or non-computable problems can be used in computer-assisted proofs. Indeed, the recent proof of Kepler’s conjecture (Hilbert’s 18th problem) [61, 62], led by T. Hales, on optimal packings of 3-spheres, relies on such undecidable problems. Moreover, the Dirac–Schwinger conjecture on the asymptotic behaviour of ground states of certain Schrödinger operators, was proven in a series of papers by C. Fefferman and L. Seco [47–55] using computer assistance. Fascinatingly, this proof also relies on computing non-computable problems. This may seem like a paradox, but can indeed be explained by the SCI hierarchy. In particular, it is the $\Sigma_1^A$ class described below that is crucial. In fact, Hales, Fefferman and Seco implicitly prove $\Sigma_1^A$ classifications in the SCI hierarchy in their papers.

Our classifications of spectral problems provide new results regarding which spectral problems can be used in computer-assisted proofs.

1.1. Main problems. In this paper we consider the following four main open problems.

(i) Computing spectra of differential operators. There is a rich literature on how to compute spectra of differential operators on bounded domains that is intimately linked to computational PDE theory. The computation is often done with finite element, finite difference or spectral methods by discretising the operator on a suitable finite-dimensional space and then using algorithms for finite-dimensional matrix eigenvalue problems on the discretised operator [2, 14, 16, 26, 29, 32, 82, 83, 107]. However, it is in general unknown how to compute spectra of differential operators on unbounded
domains (some specific examples do exist, for instance, see [72] for a particular truncation method). Our results can be summarised as follows.

1. We provide a sharp solution to this problem for large classes of differential operators, meaning that we achieve the boundary of what computers can achieve on these problems. In particular, we demonstrate that many of these problems are in $\Sigma^A_1$ in the SCI hierarchy (see §1.2). This means that one can have error control in the following form. There exist convergent algorithms that are guaranteed to only produce output that is in the spectrum (up to an arbitrarily small error).

2. The new algorithms that yield the $\Sigma^A_1$ results suggest a potential change of paradigm in spectral computation, not only on unbounded domains, but also on bounded domains. Indeed, whilst standard algorithms for computing spectra of differential operators on bounded domains often have results on qualitative rates of convergence, they do not have the above feature of error control and it is not clear in general what portion of the computation can be trusted. This is a well-known problem, see for example [106], which occurs even if the algorithm is convergent. This means that such algorithms can never be used for computer-assisted proofs. In the language of the SCI hierarchy, these standard algorithms provide, at best, $\Delta^A_2$ classifications of the problems, and not the correct $\Sigma^A_1$ classification. In other words, the standard algorithms fail to reach the boundary of what algorithms can actually do. Hence, we can draw the following conclusion:

Computing spectra of differential operators through discretisation of the operator that yield a finite-dimensional matrix, for which one computes its eigenvalues, is typically not an optimal method. Such methods will never provide certainty about the output. However, there do exists algorithms that are optimal in the way that they provide error control and certainty about the computed output.

Remark 1.1 (Classical discretisation and new approaches). It is important to emphasise that what causes classical approaches to become suboptimal is the usual final step of computing eigenvalues of the finite-dimensional discrete differential operator matrix. The new approach used in this paper circumvents this. However, this does not mean that classical discretisation techniques, such as finite element methods, cannot be used in connection with the new approach. To the contrary, much of the classical research in finite element and spectral methods can be changed only slightly, with the new set-up, and will then yield the optimal $\Sigma^A_1$ classification, with algorithms with error control, that are guaranteed never to make a mistake, and always provide elements in the spectrum (see Remark 2.6). Such algorithms can then be used in computer-assisted proofs.

(ii) Computing spectra of unbounded operators on graphs. Operators on graphs are ubiquitous in mathematical physics. We establish sharp classifications of spectral problems with such operators, and in many cases, we establish $\Sigma^A_1$ classification that yields the desired error control and algorithms with guaranteed output in the spectrum.

(iii) The spectral gap problem; determine if there is a gap between the lowest element in the spectrum and the next element. We show why this problem is notoriously difficult, as this problem is higher up in the SCI hierarchy, in particular $\Sigma^A_2$, even for the simplest operators. This means that no algorithm can provide verifiable results on a digital computer, and hence these problems cannot be used in computer-assisted proofs. However, the $\Sigma^A_2$ classification suggests that given an analogue device that could compute a limit process, the problem will be verifiable, if there is a spectral gap, but not if there is no gap.
Computing discrete spectra and multiplicities. We demonstrate why this is also a notoriously difficult problem when we establish the correct classification high up in the SCI hierarchy. This means that no algorithm on a digital computer can provide reliable results. This can, in certain cases, only be done if one could find a device that could compute a limit process.

The fundamental notion of the SCI hierarchy is that of a computational problem. The SCI of a class of computational problems is the smallest number of limits needed in order to compute the solution to the problem.

The basic objects of a computational problem are: \( \Omega \), called the domain, \( \Lambda \) a set of complex valued functions on \( \Omega \), called the evaluation set, \( \mathcal{M} \) a metric space, and \( \Xi : \Omega \rightarrow \mathcal{M} \) the problem function. The set \( \Omega \) is the set of objects that give rise to our computational problems. The problem function \( \Xi : \Omega \rightarrow \mathcal{M} \) is what we are interested in computing. Finally, the set \( \Lambda \) is the collection of functions that provide us with the information we are allowed to read as input to the algorithm. This leads to the following definition:

**Definition 1.2 (Computational Problem).** Given a domain \( \Omega \), an evaluation set \( \Lambda \), a metric space \( \mathcal{M} \) and a problem function \( \Xi : \Omega \rightarrow \mathcal{M} \), we call the collection \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \} \) a computational problem.

The definition of a computational problem is deliberately general in order to capture any computational problem in the literature. However, the set-up of this paper has the following typical form: \( \Omega \) will be a class of operators on a separable Hilbert space \( \mathcal{H} \), \( \Xi(A) = \text{Sp}(A) \) (the spectrum or other related maps), \( \mathcal{M} \) is the collection of closed subsets of \( \mathbb{C} \) with an appropriate generalisation of the Hausdorff metric (see (3.1) and (3.2)), and finally \( \Lambda \) may be the set of complex functions that could provide the matrix elements of \( A \in \Omega \) given some orthonormal basis \( \{ e_j \} \) of \( \mathcal{H} \). In particular, \( \Lambda \) consists of \( f_{i,j} : A \mapsto \langle Ae_j, e_i \rangle \), \( i, j \in \mathbb{N} \), which provide the entries of the matrix representation of \( A \) with respect to the basis. Moreover, \( \Lambda \) could be the collection of functions providing point samples of a potential function of a Schrödinger or more general partial differential operator.

1.2. The SCI hierarchy. In words, the SCI hierarchy \([8, 65]\) for spectral problems can be informally described as follows, and for decision problems, the description is similar (see \([3]\) for the formal definitions).

(i) \( \Delta^0_\alpha = \Pi^0_\alpha = \Sigma^0_\alpha \) is the set of problems that can be solved in finite time.
(ii) \( \Delta^1_\alpha \) is the set of problems that can be computed by passing to one limit, moreover, one has error control and knows a bound on the error committed.
(iii) \( \Sigma^1_\alpha \) is the set of problems that can be computed by passing to one limit. Error control may not be possible, however, what the algorithm produces is included in the true solution (up to a controlled error).
(iv) \( \Pi^1_\alpha \) is the set of problems that can be computed by passing to one limit. Error control may not be possible, however, what the algorithm produces includes the true solution (up to a controlled error).
(v) \( \Delta^2_\alpha \) is the set of problems that can be computed by passing to one limit, however, error control may not be possible.
(vi) \( \Delta^m_{\alpha+1} \) is the set of problems that can be computed by passing to \( m \) limits.
(vii) \( \Sigma^m_\alpha \) is the set of problems that can be computed by passing to \( m \) limits, and computing the \( m \)-th limit is a \( \Sigma^1_\alpha \) problem.
(viii) \( \Pi^m_\alpha \) is the set of problems that can be computed by passing to \( m \) limits, and computing the \( m \)-th limit is a \( \Pi^1_\alpha \) problem.

Schematically, the SCI hierarchy can be viewed in the following way.
Note that the $\Sigma^0_k$ and $\Pi^0_k$ classes become crucial in computer-assisted proofs, see §1.3.

**Remark 1.3** (The model of computation $\alpha$). The $\alpha$ in the superscript indicates the model of computation, which is described in §3. For $\alpha = G$, the underlying algorithm is general and can use any tools at its disposal. The reader may think of a Blum–Shub–Smale (BSS) machine or a Turing machine with access to any oracle, although a general algorithm is even more powerful. However, for $\alpha = A$ this means that only arithmetic operations and comparisons are allowed. In particular, if rational inputs are considered, the algorithm is a Turing machine, and in the case of real inputs, a BSS machine. Hence, a result of the form

$$\notin \Delta^G_k$$ is stronger than $$\notin \Delta^A_k.$$ Indeed, a $\notin \Delta^G_k$ result is universal and holds for any model of computation. Moreover,

$$\in \Delta^A_k$$ is stronger than $$\in \Delta^G_k,$$

and similarly for the $\Pi_k$ and $\Sigma_k$ classes. The main results are sharp classification results in this hierarchy that are summed up in Table 1.

1.3. The SCI hierarchy and computer-assisted proofs. Note that $\Delta^A_k$ is the class of problems that are computable according to Turing’s definition of computability. In particular, there exists an algorithm such that for any $\epsilon > 0$ the algorithm can produce an $\epsilon$-accurate output. Most spectral problems, except the finite-dimensional ones, are $\notin \Delta^A_1$. The simplest way to see this is to consider the problem of computing spectra of infinite diagonal matrices. Since this problem is the simplest of the infinite computational spectral problems and does not lie in $\Delta^A_1$, very few interesting infinite spectral problems are actually in $\Delta^A_1$. This is why most of the literature on spectral computations provides algorithms that yield $\Delta^A_2$ classification results. In particular, an algorithm will converge, but error control may be impossible.

Problems that are not in $\Delta^A_1$ are computed daily in the sciences, simply because numerical simulations may be suggestive rather than providing a rock-solid truth. Moreover, the lack of error control may be compensated for by comparing with experiments. However, this is not possible in computer-assisted proofs, where 100% rigour is the only approach accepted. It may, therefore, be surprising that there are examples of famous conjectures that have been proven with numerical calculations of problems that are not in $\Delta^A_1$ or non-computable according to Turing. The proof of Kepler’s conjecture [61, 62] is a striking example where the decision problems computed are not in $\Delta^A_1$. The decision problems are of the form of deciding feasibility of linear programs given irrational inputs, as shown in [7] these problems are not in $\Delta^G_1$. Similarly, the problem of obtaining the asymptotics of the ground state of the operator

$$H_{dZ} = \sum_{k=1}^{d} (-\Delta x_k - Z|x_k|^{-1}) + \sum_{1 \leq j \leq k \leq N} |x_j - x_k|^{-1},$$
as $Z \to \infty$ was obtained by computer-assisted proof [47–55] by Fefferman and Seco that relied on problem that were not in $\Delta^A_1$. These paradoxical phenomena can be described by the SCI hierarchy.
1.3.1. The $\Sigma^A_1$ and $\Pi^A_1$ classes. The key to the paradoxical phenomena lies in the $\Sigma^A_1$ and $\Pi^A_1$ classes. These classes of problems are larger than $\Delta^A_1$, but can still be used in computer-assisted proofs. Indeed, if we consider computational spectral problems that are in $\Sigma^A_1$ then there is an algorithm that will never provide incorrect output. The output may not include the whole spectrum, but it is always sound. Thus, conjectures about operators never having spectra in a certain area could be disproved by a computer-assisted proof. Similarly, $\Pi^A_1$ problems would always be approximated from above, and thus conjectures on the spectrum being in a certain area could be disproved by computer simulations.

The computational problems in both examples of computer-assisted proofs given above can be shown to be in $\Sigma^A_1$.

Remark 1.4 (Classifications of problems for computer-assisted proofs). Classifying all computational problems that are in either $\Sigma^A_1$ or $\Pi^A_1$ becomes, of course, an infinite classification theory. In an ideal world, mathematicians wanting to enquire whether a computational problem that is needed for a computational proof is in $\Sigma^A_1$ or $\Pi^A_1$ should have a lookup table. Such a lookup table would have to be infinite. However, that should not stop the mathematics community from forming a long, ever-growing table containing classifications. Table 1 is an example of the beginning of this lookup table.

Remark 1.5 (Connection to previous work). The field of spectral computations is vast and we can only discuss a fraction of the results in this paper. However, the reader is invited to consult $\S 2.5$ for a detailed and thorough account of the many results that have been inspiring for - and direct influence on - our contributions. We want to point out that the SCI hierarchy may be viewed as a continuation of Smale’s program [90,94,96] on the foundations of computational mathematics. In particular, the results by C. McMullen [75,76,97] and P. Doyle & C. McMullen in [44], answering some of the fundamental questions asked by Smale, become classification results in the SCI hierarchy.

2. MAIN RESULTS

The main results are sharp classifications in the SCI hierarchy with corresponding algorithms that settle some of the many open classification problems in computational spectral theory. We are concerned with the following basic problem:

Given a computational spectral problem, where is it in the SCI hierarchy?

In addition to the spectrum, we also consider the pseudospectrum defined by

$$Sp_\epsilon(A) := \text{cl}\{z \in \mathbb{C} : \|(A - zI)^{-1}\| > 1/\epsilon\}, \quad \epsilon > 0.$$ 

All our upper bounds are constructed with easy to use algorithms. We have included routines for the main algorithms in $\S 8$, where we demonstrate examples from the physical sciences. All the constructed towers can be modified to work (recursively) with inexact input and restricted to arithmetic operations and comparisons on $\mathbb{Q}$ (see Appendix $A$). As a consequence, the SCI classification of the problems discussed in this paper is completely independent of the model of computation.

The problem of computing spectra of arbitrary infinite matrices acting as bounded operators on $l^2(\mathbb{N})$ is $\not\in \Delta^G_1$. Thus, the question above is really about what type of assumptions are needed to lower the computational spectral problem in the SCI hierarchy.

2.1. Spectra of unbounded operators on graphs. Consider a possibly unbounded operator $A$ with domain $\mathcal{D}(A) \subset l^2(\mathbb{N})$ and non-empty spectrum. We consider the problems of computing

$$\Xi_1(A) = Sp(A), \quad \Xi_2(A) = Sp_\epsilon(A).$$

To define the computational problem we have to define the domain $\Omega$ as well as $\Lambda$, the set of evaluation functions. Let $\mathcal{C}(l^2(\mathbb{N}))$ denote the set of closed, densely defined operators on $l^2(\mathbb{N})$, and consider the following assumptions.

Table 1. Summary of the main results. Bounded dispersion roughly means that there is some off-diagonal decay on the matrix elements in the matrix representation of the operator, see (2.1). Also, known resolvent bound means control of the growth of the resolvent, see (2.2).

1. The subspace $\text{span}\{e_n : n \in \mathbb{N}\}$ forms a core for $A$ and $A^*$, where $\{e_j\}_{j \in \mathbb{N}}$ is the canonical basis for $l^2(\mathbb{N})$.
2. Given any $f : \mathbb{N} \to \mathbb{N}$ with $f(n) \leq n$ define

\[
D_{f,n}(A) := \max \left\{ \| (I - P_{f(n)})AP_n \|, \| (I - P_{f(n)})A^*P_n \| \right\},
\]

where $P_n$ is the projection onto the span of $\{e_1, \ldots, e_n\}$ of the canonical basis. We say that an operator has bounded dispersion with respect to $f$ if $\lim_{n \to \infty} D_{f,n}(A) = 0$. We will assume knowledge of a sequence $\{e_n\}_{n \in \mathbb{N}} \subset \mathbb{Q}$ with $D_{f,n}(A) \leq e_n$.
3. We assume knowledge of a sequence $\{g_m\}$ of strictly increasing continuous functions $g_m : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ vanishing only at 0 and diverging at $\infty$ such that

\[
g_m(\text{dist}(z, \text{Sp}(A))) \leq \| R(z, A) \|^{-1}, \quad \forall z \in B_m(0).
\]

In this case we say that $A$ has resolvent bounded by $\{g_m\}$. Note that this implicitly assumes the spectrum is non-empty.

Remark 2.1. Note that the concept of bounded dispersion in (2.1) generalises the notion of a banded matrix. Moreover, given any operator with assumption (1) there exists an $f$ such that $\lim_{n \to \infty} D_{f,n}(A) = 0$. The theorem we prove is for the class of operators that have $\lim_{n \to \infty} D_{f,n}(A) = 0$ given a fixed $f$. In order to handle non-self-adjoint operators we need to be able to control the resolvent as in (2.2). Without such
control, the spectral problem is still not in $\Delta_1^G$. If $A$ has $\text{Sp}(A) \neq \emptyset$, then a simple compactness argument implies the existence of such a sequence of continuous functions. We may not be able to control the growth of the resolvent across the whole complex plane by a single function, but for convergence of our algorithms, it is enough to control the resolvent on compact balls.

2.1.1. Defining $\Omega$ and $\Lambda$. Let $f$ be as described in (2), and $\hat{\Omega}$ to be the class of all $A \in C(\ell^2(\mathbb{N}))$ such that (1) and (2) hold and such that the spectrum is non-empty. Given a sequence as described in (3) let $\Omega_\delta$ be the class of all $A \in \hat{\Omega}$ such that (2.2) holds. We also let $\Omega_{D}$ denote the operators in $\hat{\Omega}$ that are diagonal.

Operators on graphs. For operators on graphs, consider any connected, undirected graph $G$, such the set of vertices $V = V(G)$ is countably infinite. We consider operators on $\ell^2(V)$ that are closed, densely defined and of the form

$$A = \sum_{v,w \in V} \alpha(v,w) |v\rangle \langle w|,$$

for some $\alpha : V \times V \to \mathbb{C}$. We have also used the classical Dirac notation in (2.3) and identified any $v \in V$ by the element in $\psi_v \in \ell^2(V)$ such that $\psi_v(v) = 1$ and $\psi_v(w) = 0$ for $w \neq v$. When writing this, we assume that the linear span of such vectors forms a core of both $A$ and its adjoint. We also assume that for any $v \in V$, the set of vertices $w$ with $\alpha(v,w) \neq 0$ or $\alpha(w,v) \neq 0$ is finite. We then let $\Omega_D^G$ the class of all such $A$ with non-empty spectrum and $\Omega_\delta^G$ operators in $\Omega_D^G$ of known $\{g_m\}$ such that (2.2) holds. We also assume that with respect to some given enumeration $v_1, v_2, \ldots$ of $V$, we have access to a function $S : \mathbb{N} \to \mathbb{N}$ such that if $m > S(n)$ then $\alpha(v_n, v_m) = \alpha(v_m, v_n) = 0$.

Remark 2.2 (Defining $\Lambda$). For operators on $\ell^2(\mathbb{N})$, $\Lambda$ contains the collection of matrix value evaluation functions, the functions describing the dispersion and the family of the functions $g_m$ controlling the growth of the resolvent. For operators on $\ell^2(V)$, $\Lambda$ contains the functions $\alpha$, the function $S$ and, in the case of $\Omega_D^G$, the family $g_m$ for $m \in \mathbb{N}$.

We can now state our main result in this section:

**Theorem 2.3.** Let $\Xi_1$ be the problem function $\text{Sp}(\cdot)$ and $\Xi_2$ be the problem function $\text{Sp}_\alpha(\cdot)$ for $\epsilon > 0$, where these map into the metric space $(\text{Cl}(\mathbb{C}), d_{\text{AW}})$. Then

$$\Delta_1^G \not= \{\Xi_1, \Omega_D\} \in \Sigma_1^A, \quad \Delta_1^G \not= \{\Xi_1, \Omega_\delta\} \in \Sigma_1^A, \quad \Delta_1^G \not= \{\Xi_1, \Omega_D^G\} \in \Sigma_1^A,$$

$$\Delta_1^G \not= \{\Xi_2, \Omega_D\} \in \Sigma_1^A, \quad \Delta_1^G \not= \{\Xi_2, \Omega_\delta\} \in \Sigma_1^A, \quad \Delta_1^G \not= \{\Xi_2, \Omega_D^G\} \in \Sigma_1^A.$$

Furthermore the routines $\text{CompSpecUB}$ and $\text{PseudoSpecUB}$ in [8] realise the sharp $\Sigma_1^A$ inclusions, and in the case of $\Xi_2$, the output is guaranteed to be inside the true pseudospectrum.

The algorithm used to compute the pseudospectrum can be applied to cases where the spectrum or pseudospectrum are empty and we provide a numerical example of this below. Finally, we consider two discrete problems which also include the case when the spectrum may be empty. Let $K$ be a non-empty and compact set in $\mathbb{C}$ and denote the collection of such subsets by $K(\mathbb{C})$. Consider

$$\Xi_3 : (A, K) \to \text{"Is } \text{Sp}(A) \cap K = \emptyset?\text{"},$$

$$\Xi_4 : (A, K) \to \text{"Is } \text{Sp}_\alpha(A) \cap K = \emptyset?\text{"}.$$}

More precisely, the information we consider available to the algorithms in the $\ell^2(\mathbb{N})$ ($\ell^2(V(G))$) case are the matrix elements of $A$ (the functions $\alpha$), the dispersion function $f$ and dispersion bounds $\{e_n\}$ (the finite sets $S_n$) and a sequence of finite sets $K_n \subset \mathbb{Q} + i\mathbb{Q}$, with the property that $d_{\text{H}}(K_n, K) \leq 2^{-(n+1)}$ [6]. Although the pseudospectrum is easier to compute as a whole, the following shows that this is not the case for testing on a given set. We also see that these discrete problems are harder than computing the spectrum.

---

1This is an example where functions in $\Lambda$ take values in $\mathbb{C}^2$ - for a given $n$ the first coordinate tells us how many points are in $K_n$. then we can use a bijection $\mathbb{C}^{|K_n|} \leftrightarrow \mathbb{C}$ to encode the set $K_n$ in the second coordinate.
Theorem 2.4. We have the following classifications for \( j = 3, 4 \):

\[
\Delta_2^G \notin \{ \Xi, \Omega \times K(\mathbb{C}) \} \in \Pi_2^4, \quad \Delta_2^G \notin \{ \Xi, \Omega_D \times K(\mathbb{C}) \} \in \Pi_2^4, \\
\Delta_2^G \notin \{ \Xi, \Omega^G \times K(\mathbb{C}) \} \in \Pi_2^4.
\]

The routines TestSpec and TestPseudoSpec, used for \( \Xi_3 \) and \( \Xi_4 \) respectively, realise the sharp \( \Pi_2^4 \) classifications. Furthermore, the proof will make clear that the lower bounds also hold when we restrict the allowed compact sets to any fixed compact subset of \( \mathbb{R} \).

Remark 2.5. By considering singletons \( K = \{ z \} \), we can test whether a point lies in the spectrum or pseudospectrum. Even when restricting to such \( K \), the proof makes clear that the classification remains the same.

2.2. Spectra of differential operators. In this section, we provide classification results for general classes of differential operators. What may be surprising is that with very general assumptions we obtain \( \Sigma_1^4 \) classifications for the spectrum. This means that despite these operators being hard to analyse for spectral theoretical purposes, the problem of computing their spectra is not harder than computing the spectra of diagonal matrices. Moreover, the computational problem can also be used for computer-assisted proofs. Finally, we establish how the problem makes a jump in the SCI hierarchy. In particular, with slightly weaker assumptions the spectral problem \( \notin \Sigma_1^4 \cup \Pi_1^4 \), and hence, typically, computer-assisted proofs become impossible.

For \( N \in \mathbb{N} \), consider the operator formally defined on \( L^2(\mathbb{R}^d) \) by

\[
Tu(x) = \sum_{k \in \mathbb{Z}_d^N, |k| \leq N} a_k(x) \partial^k u(x),
\]

where throughout we use multi-index notation with \( |k| = \max\{|k_1|, \ldots, |k_d|\} \) and \( \partial^k = \partial_{x_1}^{k_1} \partial_{x_2}^{k_2} \cdots \partial_{x_d}^{k_d} \). We will assume that the coefficients \( a_k(x) \) are complex-valued measurable functions on \( \mathbb{R}^d \). Suppose also that \( T \) can be defined on an appropriate domain \( D(T) \) such that \( T \) is closed and has a non-empty spectrum. Our aim is to compute the spectrum and \( \epsilon \)-pseudospectrum from the functions \( a_k \). We consider two cases. First, the algorithm can access point samples of the functions, and second, the algorithm can access coefficients in the series expansion of the functions in the case that the \( a_k \) are analytic. Note that these are very different computational problems.

Remark 2.6. Though we have chosen \( \mathbb{R}^d \) as the geometrical domain of our operators, the proof will make clear that other domains (and correspondingly other discretisations) can also be treated, yielding a \( \Sigma_1 \) classification. Indeed, the results can be extended to any domain where we can build a suitable basis to represent the operator, such as the half-line for radially symmetric Dirac operators in quantum chemistry, intervals using orthogonal polynomial series or products of any of the above geometries. It is also possible to extend our results to more complicated domains using finite elements, non-orthogonal bases and generalised pencil eigenvalue problems, but this will be the topic of future work. This justifies Remark 2.1.

2.2.1. The set-up. To make our problems well defined we let \( \Omega \) consist of all such \( T \) such that the following assumptions hold:

1. The set \( C_0^{\infty}(\mathbb{R}^d) \) of smooth, compactly supported functions forms a core of \( T \) and its adjoint \( T^* \).
2. The adjoint operator \( T^* \) can be initially defined on \( C_0^{\infty}(\mathbb{R}^d) \) via

\[
T^* u(x) = \sum_{k \in \mathbb{Z}_d^N, |k| \leq N} \tilde{a}_k(x) \partial^k u(x),
\]

where \( \tilde{a}_k(x) \) are complex-valued measurable functions on \( \mathbb{R}^d \).
3. For each of the functions \( a_k(x) \) and \( \tilde{a}_k(x) \), there exists a positive constant \( A_k \) and an integer \( B_k \) such that

\[
|a_k(x)|, |\tilde{a}_k(x)| \leq A_k \left( 1 + |x|^{2B_k} \right),
\]
almost everywhere on \( \mathbb{R}^d \), that is, we have at most polynomial growth.

(4) As in the case of (2.1) we have access to functions \( \{ g_m \} \) (see 2.2) and the assumptions on \( \{ g_m \} \) such that
\[
g_m(\text{dist}(z, \text{Sp}(T))) \leq \| R(z, T) \|^{-1}, \quad \forall z \in B_m(0).
\]

(5) \( \text{Sp}(T) \) (and hence \( \text{Sp}_p(T) \)) is non-empty.

Hence we consider the operator \( T \) defined as the closure of \( T \) acting on \( C_0^\infty(\mathbb{R}^d) \). The initial domain \( C_0^\infty(\mathbb{R}^d) \) is commonly encountered in applications, and it is straightforward to adapt our methods to other initial domains such as Schwartz space.

**Remark 2.7** (The open problem of computing spectra of differential operators). There is no existing theory guaranteeing even a finite SCI for this problem even when each \( a_k \) is a polynomial. For simple polynomials such as the ones giving Schrödinger operators, the standard procedure is to discretise the differential operator via finite differences, truncate the resulting infinite matrix and then handle the finite matrix with standard algorithms designed for finite-dimensional problems. Such an approach would at best give a \( \Delta^2 \) classification, and in general, this approach may not always converge, thus not even providing a \( \Delta^2 \) classification. Despite this, we prove below that one can actually achieve \( \Sigma^4 \) classification for a large class of operators.

In the numerical applications, we will demonstrate this on anharmonic oscillators of the form
\[
H = -\Delta + \sum_{j=1}^d (a_jx_j + b_jx_j^2) + \sum_{|\alpha| \leq M} c(\alpha)x^\alpha,
\]
where \( a_j, b_j, c(\alpha) \in \mathbb{R} \). The multi-indices \( \alpha \) are chosen such that \( \sum_{|\alpha| \leq M} c(\alpha)x^\alpha \) is bounded from below.

To the best of our knowledge our algorithm is the first that computes the spectrum of such operators with error control in the sense of \( \Sigma^4 \). As described, this has a wide number of applications and the problem has received a lot of attention [11][12][56][104].

**Remark 2.8.** Throughout this section, the functions \( \{ g_m \} \) are not needed to compute the pseudospectrum.

### 2.2.2. General Case with Function Evaluations.

In this section we consider the computation of the spectra/pseudospectra of operators \( T \in \Omega \) from evaluations of the functions \( a_k \) and \( \tilde{a}_k \). For dimension \( d \) and \( r > 0 \) consider the space
\[
A_r = \{ f \in M([-r, r]^d) : \| f \|_{\infty} + \text{TV}_{[-r, r]^d}(f) < \infty \},
\]
where \( M([-r, r]^d) \) denotes the set of measurable functions on the hypercube \([-r, r]^d\) and \( \text{TV}_{[-r, r]^d} \) the total variation norm in the sense of Hardy and Krause (see [77]). This space becomes a Banach algebra when equipped with the norm
\[
\| f \|_{A_r} = \| f \|_{\infty} + \sigma \text{TV}_{[-r, r]^d}(f)
\]
with \( \sigma = 3^d + 1 \) (see [13]). We will assume that each of the (appropriate restrictions of) \( a_k \) and \( \tilde{a}_k \) lie in \( A_r \) for all \( r > 0 \) and that we are given a sequence of positive numbers such that
\[
\| a_k \|_{A_n}, \| \tilde{a}_k \|_{A_n} \leq c_n, \quad c_n > 0, \quad n \in \mathbb{N}, |k| \leq N.
\]

The extra readable information is completely analogous to using bounded dispersion for matrix problems, and we shall see that it cannot be omitted if one wishes to gain error control in the sense of \( \Sigma_1 \). Let
\[
\Omega_{TV}^1 = \{ T \in \Omega \mid \text{ such that (1) \& (5) and (2.6) hold} \}.
\]

In this case we let \( \Lambda^1 \) contain functions that allow us to access sample of the functions \( \{ g_m \}_{m \in \mathbb{N}}, \{ a_k, \tilde{a}_k \}_{|k| \leq N} \) and the constants \( \{ A_k, B_k \}_{|k| \leq N} \) \( \{ c_n \}_{n \in \mathbb{N}} \). Consider the weaker assumption on \( \Lambda^1 \) that we can evaluate \( b_n > 0 \) (not the \( A_k, B_k \)'s and the \( c_n \)'s) such that
\[
\sup_{n \in \mathbb{N}} \max_{|k| \leq N} \left\{ \frac{\| a_k \|_{A_n}, \| \tilde{a}_k \|_{A_n}}{b_n} : |k| \leq N \right\} < \infty.
\]
With a slight abuse of notation we use $\Omega^2_{TV}$ to denote the class of problems where we have this weaker requirement. We can now define the mappings

$$
\Xi^j_j, \Xi^2_j : \Omega^1_{TV}, \Omega^2_{TV} \ni T \mapsto \begin{cases} 
\text{Sp}(T) \in \mathcal{M}_{AW}, & j = 1 \\
\text{Sp}_c(T) \in \mathcal{M}_{AW}, & j = 2,
\end{cases}
$$

and state the first theorem.

**Theorem 2.9.** Let $\Xi^j_j, \Xi^2_j, \Omega^1_{TV}$, and $\Omega^2_{TV}$ be as above. Then for $j = 1, 2$

$$
\Delta^G_1 \neq (\Xi^j_j, \Omega^2_{TV}) \in \Sigma^G_1,
\Sigma^G_1 \cup \Pi^G_1 \neq (\Xi^2_j, \Omega^2_{TV}) \in \Delta^G_2.
$$

The proof also shows the stronger result that even if we had included the information $\{A_k, B_k\}_{|k| \leq N}$ for operators in $\Omega^2_{TV}$, we would still have $(\Xi^2_j, \Omega^2_{TV}) \notin \Sigma^G_1 \cup \Pi^G_1$.

**Remark 2.10.** This result is of interest since it gives a computational problem where no $\Sigma$ or $\Pi$ error control is available in its $\Delta$ (SCI) class.

2.2.3. Analytic coefficients. In this section we assume that the functions $a_k$ and $\tilde{a}_k$ are analytic. In particular, we assume we can evaluate $\{c_j\}_{j \in \mathbb{N}}$, an enumeration (where we know the ordering) of the coefficients $b_k^j$ where $a_k(x) = \sum_{j=1}^{\infty} b_k^j x^j$. In this special case, we can compute the corresponding coefficients of the $\tilde{a}_k(x)$ using finitely many arithmetic operations on $\{c_j\}$. We will assume that as well as the information $\{g_m\}, \{c_j\}$ and $\{A_k, B_k\}$ our algorithms can read the following information. Given

$$
a_k(x) = \sum_{m \in (\mathbb{Z}_{\geq 0})^d} a_k^m x^m, \quad \tilde{a}_k(x) = \sum_{m \in (\mathbb{Z}_{\geq 0})^d} \tilde{a}_k^m x^m,
$$

for each $n \in \mathbb{N}$ we know a constant $d_n$ such that

$$
|a_k^m|, |\tilde{a}_k^m| \leq d_n(n+1)^{|m|}, \quad \forall m \in (\mathbb{Z}_{\geq 0})^d, |k| \leq N.
$$

It is straightforward to show that such a $d_n$ must exist using the fact that the power series converges absolutely on the whole of $\mathbb{R}^d$. Let

$$
\Omega^1_{AN} = \{ T \in \Omega \mid \text{such that (1) – (5), the functions } a_k \text{ are analytic and (2.8) hold}\}.
$$

Moreover, in this case we let $\Lambda^1$ contain functions that allow us to access sample of the functions $\{g_m\}_{m \in \mathbb{N}}$, the constants $\{A_k, B_k\}_{|k| \leq N}, \{c_n\}_{n \in \mathbb{N}}$, and $\{d_n\}_{n \in \mathbb{N}}$. As the proof makes clear, the information $d_n$ can be replaced by any suitable information that allows us to control the remainder term in the truncated Taylor series uniformly on compact subsets of $\mathbb{R}^d$. For example, we could use Cauchy’s formula, together with bounds on the functions $a_k$ on compact subsets of $\mathbb{C}^d$. One could consider a weaker requirement on $\Lambda^1$ by replacing knowledge of $A_k, B_k$ and $d_n$ by some sequence of positive numbers $b_n$ with

$$
\sup_{n \in \mathbb{N}} \sup_{m \in (\mathbb{Z}_{\geq 0})^d} \max \{|a_k^m|/(n+1)^{|m|}, |\tilde{a}_k^m|/(n+1)^{|m|} : |k| \leq N\} < \infty.
$$

With a slight abuse of notation we use $\Omega^2_{AN}$ to denote the class of problems where we have this weaker requirement. Moreover, let $\Omega_\rho$ denote the class of operators in $\Omega^2_{AN}$ such that each $a_k$ is a polynomial (where we can let $b_n$ be $n!$ say). We can now define the mappings

$$
\Xi^3_j, \Xi^4_j : \Omega^1_{AN}, \Omega^2_{AN}, \Omega_\rho \ni T \mapsto \begin{cases} 
\text{Sp}(T) \in \mathcal{M}_{AW}, & j = 1 \\
\text{Sp}_c(T) \in \mathcal{M}_{AW}, & j = 2,
\end{cases}
$$

and state the second theorem.
Theorem 2.11. Let $\Xi^j_1, \Xi^j_2, \Omega_{AN}^1, \Omega_{AN}^2$ and $\Omega_p$ be as above. Then for $j = 1, 2$
\[
\Delta_1^G \not\in \{\Xi^j_1, \Omega_{AN}^1\} \in \Sigma_1^4, \quad \Sigma_1^G \cup \Pi_1^G \not\in \{\Xi^j_1, \Omega_{AN}^1\} \in \Delta_1^A, \quad \Sigma_1^G \cup \Pi_1^G \not\in \{\Xi^j_2, \Omega_p\} \in \Delta_2^A.
\]

2.3. The spectral gap problem. The spectral gap problem has a long tradition and is linked to many important conjectures and problems such as the Haldane conjecture \[60]\ or the Yang-Mills mass gap problem in quantum field theory \[17]. The spectral gap question is indeed fundamental to physicists, and in the seminal paper by Cubitt, Perez-Garcia and Wolf \[35\] it was shown that the spectral gap problem is undecidable when considering the thermodynamic limit of finite-dimensional Hamiltonians.

In this paper, we consider the general infinite-dimensional problem. The question can be formulated in the following way. Let $\tilde{\Omega}_{SA}$ be the set of all bounded below, self-adjoint operators $A$ on $l^2(\mathbb{N})$, for which the linear span of the canonical basis form a core of $A$ (we do not assume $A$ is bounded above) and such that one of the following cases occur:

1. The minimum of the spectrum, $a$, is an isolated eigenvalue with multiplicity one.
2. There is some $\epsilon > 0$ such that $[a, a + \epsilon] \subset \text{Sp}(A)$.

In the former case, we say the spectrum is gapped, whereas in the latter we say it is gappless. Note that because we have restricted ourselves to the class where either (1) or (2) must hold, our problem is well defined as a decision problem. Moreover, this definition is in line with the definitions in \[35\] and the physics literature. We also let $\tilde{\Omega}_D$ denote the operators in $\tilde{\Omega}_{SA}$ that are diagonal and define

\[(2.9) \quad \Xi_{\text{gap}} : \tilde{\Omega}_{SA}, \tilde{\Omega}_D \ni A \mapsto \text{Is the spectrum of } A \text{ gapped?}\]

Theorem 2.12 (Spectral gap). Let $\Xi_{\text{gap}}$ be as in \[(2.9)\] and $\tilde{\Omega}_{SA}, \tilde{\Omega}_D$ as above. Then
\[
\Delta_2^G \not\in \{\Xi_{\text{gap}}, \tilde{\Omega}_{SA}\} \in \Sigma_2^4, \quad \Delta_2^G \not\in \{\Xi_{\text{gap}}, \tilde{\Omega}_D\} \in \Sigma_2^4.
\]

In particular, the routine SpecGap described in the proof realises the sharp $\Sigma_2^A$ inclusions.

Remark 2.13 (Diagonal vs. full matrix). It is worth noting that Theorem 2.12 shows that there is no difference in the classification of the spectral gap problem between the set of diagonal matrices and the collection of full matrices.

The above spectral gap problem can also be extended as follows. Let $\tilde{\Omega}_{SA}^f$ denote the class of operators that are bounded below, self-adjoint, for which the linear span of the canonical basis form a core, and that have (known) bounded dispersion with respect to the function $f$. Let $a(A) = \inf\{x : x \in \text{Sp}(A)\}$ and consider the following four cases

1. $a(A)$ lies in the discrete spectrum and has multiplicity 1,
2. $a(A)$ lies in the discrete spectrum and has multiplicity $> 1$,
3. $a(A)$ lies in the essential spectrum but is an isolated point of the spectrum,
4. $a(A)$ is a cluster point of $\text{Sp}(A)$.

We will consider the classification problem $\Xi_{\text{class}}$ which maps $\tilde{\Omega}_{SA}^f$ (or relevant subclasses) to the discrete space $\{1, 2, 3, 4\}$ (with the natural order). We denote by $\tilde{\Omega}_D$ the class of diagonal operators in $\tilde{\Omega}_{SA}^f$.

Theorem 2.14 (Spectral Classification). Let $\Xi_{\text{class}}, \tilde{\Omega}_{SA}^f$ and $\tilde{\Omega}_D$ be as above. Then
\[
\Delta_2^G \not\in \{\Xi_{\text{class}}, \tilde{\Omega}_{SA}^f\} \in \Pi_2^4, \quad \Delta_2^G \not\in \{\Xi_{\text{class}}, \tilde{\Omega}_D\} \in \Pi_2^4.
\]

In particular, SpecClass realises the sharp $\Pi_2^A$ inclusions.
2.4. Computing discrete spectra and multiplicities. Let $\Omega^d_N$ denote the class of bounded normal operators on $l^2(\mathbb{N})$ with (known) bounded dispersion and with non-empty discrete spectrum, and denote by $\Omega^d_D$ the class of bounded diagonal self-adjoint operators in $\Omega^d_N$. For a normal operator $A$, there is a simple decomposition of $\text{Sp}(A)$ into the discrete spectrum and the essential spectrum, denoted by $\text{Sp}_d(A)$ and $\text{Sp}_{ess}(A)$ respectively. The discrete spectrum consists of isolated points of the spectrum that are eigenvalues of finite multiplicity. The essential spectrum has numerous definitions in the non-normal case, but for the normal case is defined as the set of $z$ such that $A - zI$ is not a Fredholm operator. Define the problem function

$$
(2.10)\quad \Xi^d_1 : \Omega^d_N, \Omega^d_D \ni A \mapsto \overline{\text{Sp}_d(A)}.
$$

We have taken the closure and restricted to operators with non-empty discrete spectrum since we want convergence with respect to the Hausdorff metric. However, the algorithm we build, $\Gamma_{n_2, n_1}$, has the property that $\lim_{n_1 \to \infty} \Gamma_{n_2, n_1}(A) \subset \text{Sp}_d(A)$, so this is not restrictive in practice.

**Theorem 2.15.** Let $\Xi^d_1$, $\Omega^d_N$, and $\Omega^d_D$, be as above. Then,

$$
\Delta^G \not\subset \{ \Xi^d_1, \Omega^d_N \} \in \Sigma^A_2, \quad \Delta^G \not\subset \{ \Xi^d_1, \Omega^d_D \} \in \Sigma^A_2.
$$

In particular, the routine $\text{DiscreteSpec}$ realises the sharp $\Sigma^A_2$ inclusions.

The constructed algorithm $\Gamma_{n_2, n_1}$ (routine $\text{DiscreteSpec}$) has the property that given $A \in \Omega^d_N$ and $z \in \text{Sp}_d(A)$, the following holds. If $\epsilon > 0$ is such that $\text{Sp}(A) \cap B_\epsilon(z) = \{ z \}$ then there is at most one point in $\Gamma_{n_2, n_1}(A)$ that also lies in $B_\epsilon(z)$. Furthermore, the limit $\lim_{n_1 \to \infty} \Gamma_{n_2, n_1}(A) = \Gamma_{n_2}(A)$ is contained in the discrete spectrum and increases to $\text{Sp}_d(A)$ in the Hausdorff metric. In other words, a given point of $\text{Sp}_d(A)$ has at most one point in $\Gamma_{n_2, n_1}(A)$ approximating it.

We also want to compute multiplicities. Suppose that we have $z_{n_2, n_1} \in \Gamma_{n_2, n_1}(A)$ with

$$
\lim_{n_2 \to \infty} z_{n_2, n_1} = z_{n_2} = z \in \text{Sp}_d(A)
$$

(the limit independent of $n_2$). Our tower also computes a function $h_{n_2, n_1}(A, \cdot)$ over the output $\Gamma_{n_2, n_1}(A)$ such that

$$
\lim_{n_2 \to \infty} \lim_{n_1 \to \infty} h_{n_2, n_1}(A, z_{n_2, n_1}) = h(A, z)
$$

(where $h(A, z)$ denotes the multiplicity of the eigenvalue $z$) in $\mathbb{Z}_{\geq 0}$ with the discrete metric. The routine $\text{Multipliicty}$ in [8] computes $h_{n_2, n_1}$.

**Remark 2.16.** It was shown in [8] that computing $\text{Sp}_{ess}(A)$ in the Hausdorff metric for $A \in \Omega^d_N$ has SCI = 2, so it is not surprising that the index is at least two for the discrete spectrum. What is surprising is that it is not more difficult to compute the discrete spectrum and multiplicities together than, either the essential spectrum, or the discrete spectrum. Even more surprising is that it is no more difficult than doing so for diagonal operators.

**Remark 2.17.** Suppose that we equip $\mathbb{N} \cup \{ +\infty \}$ with the metric inherited from the natural compactification of $\mathbb{R}_{\geq 0}$. One can alter the proof slightly to show that we can compute $h_{n_2, n_1}$ such that

$$
\lim_{n_1 \to \infty} h_{n_2, n_1}(A, z_{n_2, n_1}) =: h_{n_2}(A, z) \geq h(A, z),
$$

with convergence monotonic from above, thus generalising the notion of $\Pi^A_1$ to the multiplicity problem.

An easy corollary of the proof of Theorem 2.15 is as follows. Let $\Omega^d_C$ denote the class of bounded normal operators with (known) bounded dispersion with respect to the function $f$. Let $\Omega^d_D$ denote the class of bounded self-adjoint diagonal operators and consider the following discrete problem function

$$
(2.11)\quad \Xi^d_1 : \Omega^d_C, \Omega^d_D \ni A \mapsto \text{Sp}_d(A) \not\subset \emptyset?
$$
Corollary 2.18. Let \( \Xi^d_2 \), \( \Omega^d_2 \), and \( \Omega_D \) be as above. Then,

\[
\Delta^G_2 \not\subseteq \{ \Xi^d_2, \Omega^d_2 \} \subseteq \Sigma^A_2, \quad \Delta^G_2 \not\subseteq \{ \Xi^d_2, \Omega_D \} \subseteq \Sigma^A_2.
\]

Finally, we comment on using the routine ApproxEigenvector in [8.3] to approximate eigenvectors. For simplicity we shall stick to eigenspaces of multiplicity 1 but note that these ideas can be easily extended to higher multiplicities to approximate the whole eigenspace. The question is whether, given a \( \sigma \) where

\[
\sigma = \Gamma_n, \quad \text{output} \quad E_n,
\]

we also have the computed bound (2.12), then we can compute a corresponding vector \( x_n \). Suppose \( \Gamma \) will be an approximate eigenvector sequence.

Theorem 2.19. Suppose \( A \in \Omega^d_N \). Let \( \delta > 0 \) and \( z_{n_1} \in \Gamma_{n_2,n_1}(A) \) such that \( z_{n_1} \to z \in \text{Sp}_d(A) \). Suppose we also have the computed bound (2.12), then we can compute a corresponding vector \( x_{n_1} \) (of finite support) satisfying

\[
\| (A - z_{n_1}I)x_{n_1} \| < \| x_{n_1} \| \left( E(n_1, z_{n_1}) + c_{n_1} + \delta \right) \quad \text{and} \quad 1 - \delta < \| x_{n_1} \| < 1 + \delta
\]

in finitely many arithmetic operations.

2.4.1. What happens when we cannot bound the dispersion? Whilst Theorem 2.15 shows that computing the discrete spectrum requires two limits, it is still useful since the constructed algorithm has

\[
\lim_{n_1 \to \infty} \Gamma_{n_2,n_1}(A) \subseteq \text{Sp}_d(A).
\]

This is reflected in Theorem 2.19 which shows that we can still effectively approximate eigenspaces with error control. But what happens if we do not know a dispersion function \( f \) as in (2.1) such that we may not have known bounded dispersion? To investigate this case we let \( \Omega^d_1 \) denote the class of bounded normal operators with non-empty discrete spectrum and \( \Omega^d_2 \) the class of bounded normal operators. As the next theorem reveals, we get a jump in the SCI hierarchy.

Theorem 2.20. Let \( \Xi^d_1 \) and \( \Omega^d_1 \) be as above. Then,

\[
\Delta^G_2 \not\subseteq \{ \Xi^d_1, \Omega^d_1 \} \subseteq \Sigma^A_2, \quad \Delta^G_2 \not\subseteq \{ \Xi^d_2, \Omega^d_1 \} \subseteq \Sigma^A_3.
\]

The proof also shows that without additional structure it requires three limits to compute the discrete spectrum of self-adjoint matrices. It also requires three limits to check if there are any isolated eigenvalues of finite multiplicity.

2.5. Connection to previous work. Due to the vast literature on spectral computation, we can only cite a small subset here that has been crucial for the developments in this paper. Note that the idea of using computational and algorithmic approaches to obtain spectral information dates back to work by E. Schrödinger [85]. Moreover, P. W. Anderson considered computational approximations in [1], and in [86] J. Schwinger introduced finite-dimensional approximations to quantum systems in infinite-dimensional spaces that allow for spectral computations. Schwinger’s ideas were already present in work H. Weyl [105]. In [42] T. Digerne, V. S. Varadarajan and S. R. S. Varadhan proved convergence of spectra of Schwinger’s finite-dimensional discretisation matrices for a specific class of Schrödinger operators with certain types of potential which yields \( \Delta^3 \) classification in the SCI hierarchy.

Note that Schwinger’s idea of approximating in a finite-dimensional subspace is similar to the finite-section method that has been intensely studied for spectral computation and has often been viewed in connection with Toeplitz theory. The reader may want to consult the pioneering work by A. Böttcher [18].
and A. Böttcher & B. Silberman [21, 22], see also A. Böttcher, H. Brunner, A. Iserles & S. Nørsett [20], M. Marletta [73] and M. Marletta & R. Scheichl [74]. The latter papers also discuss the failure of the finite section approach for certain classes of operators, see also [63, 64]. Another important result is that of E. Shargorodsky [89] demonstrating how second order spectra methods [36] (a variant of the finite section method) will never recover the whole spectrum.

E. Shargorodsky [89] demonstrating how second order spectra methods [36] (a variant of the finite section approach for certain classes of operators, see also [63, 64]. Another important result is that of M. Marletta [73] and M. Marletta & R. Scheichl [74]. The latter papers also discuss the failure of the finite section approach for certain classes of operators, see also [63, 64]. Another important result is that of E. Shargorodsky [89] demonstrating how second order spectra methods [36] (a variant of the finite section method) will never recover the whole spectrum.

There are important results on spectral computations with links to the $C^*$-algebra literature pioneered by W. Arveson and continued by Brown. In particular the results in [44, 55] are crucial, as well as their refinements by Brown in [23, 24], see also [25] where variants of finite section analysis is implicitly used. Arveson also considered spectral computation in terms of densities, which is related to Szego’s work [98] on finite section approximations. Similar results are also obtained by A. Laptev and Y. Safarov [70]. Typically, when applied to appropriate subclasses of operators, finite section approaches yield $\Delta^1_2$ classification results.

There are other approaches based on the infinite QR algorithm [33] in connection with Toda flows with infinitely many variables pioneered by Deift, Li and Tomei [29]. This approach has been continued and refined by Olver, Townsend and Webb, where they have provided a practical framework for infinite-dimensional linear algebra and foundational results on computations with infinite data structures [78–81, 103].

The pioneering work by Fefferman and Seco [47–55] on proving the Dirac–Schwinger conjecture is a striking example of computations used in order to obtain complete information about the asymptotical behaviour of the ground state of a family of Schrödinger operators. The fascinating computer-assisted proof implicitly proves $\Sigma^1_1$ classifications in the SCI hierarchy. Moreover, the paper [46] by Fefferman is based on similar approaches. We also want to highlight the work by L. Demanet and W. Schlag [40] as well as P. Hertel, E. Lieb and W. Thirring [67]. Although Hale’s program on proving Kepler’s conjecture (Hilbert’s 18th problem) does not involve spectral computations, it may be of interest to the reader as it is based on computing problems that are in $\Sigma^1_1$ and not $\Delta^1_2$ (the class of problems that are defined as computable by Turing).

Finally, we would like to mention recent work by M. Zworski [108, 109] on computing resonances that can be viewed in terms of the SCI hierarchy. In particular, the computational approach [109] is based on expressing the resonances as limits of non-self-adjoint spectral problems, and hence the SCI hierarchy is inevitable, see also [93].

3. MATHEMATICAL PRELIMINARIES

In this section we formally define the SCI hierarchy. We have already presented the definition of a computational problem $\{\Xi, \Omega, M, \Lambda\}$. When computing the spectrum of bounded operators on $l^2(\mathbb{N})$, we let $(M, d)$ be the set of all non-empty compact subsets of $\mathbb{C}$ provided with the Hausdorff metric $d = d_H$:

$$d_H(X, Y) = \max \left\{ \sup_{x \in X} \inf_{y \in Y} d(x, y), \sup_{y \in Y} \inf_{x \in X} d(x, y) \right\},$$

where $d(x, y) = |x - y|$ is the usual Euclidean distance. In the case of unbounded operators we use the Attouch–Wets metric defined by

$$d_{AW}(C_1, C_2) = \sum_{n=1}^{\infty} 2^{-n} \min \{1, \sup_{|x| < n} |\text{dist}(x, C_1) - \text{dist}(x, C_2)|\},$$

for $C_1, C_2 \in \text{Cl}(\mathbb{C})$, where $\text{Cl}(\mathbb{C})$ denotes the set of closed non-empty subsets of $\mathbb{C}$. The goal is to find algorithms that approximate the function $\Xi$. More generally, the main pillar of our framework is the concept of a tower of algorithms, which is needed to describe problems that need several limits in the computation. However, first one needs the definition of a general algorithm.

Definition 3.1 (General Algorithm). Given a computational problem $\{\Xi, \Omega, M, \Lambda\}$, a general algorithm is a mapping $\Gamma : \Omega \to M$ such that for each $A \in \Omega$

(i) there exists a finite subset of evaluations $\Lambda_{\Gamma}(A) \subset \Lambda$,
Definition 3.2 (Tower of Algorithms). Given a computational problem \( \{\Xi, \Omega, \mathcal{M}, \Lambda\} \), a tower of algorithms of height \( k \) for \( \{\Xi, \Omega, \mathcal{M}, \Lambda\} \) is a family of sequences of functions

\[
\Gamma_{n_k} : \Omega \to \mathcal{M}, \quad \Gamma_{n_k,n_{k-1}} : \Omega \to \mathcal{M}, \ldots, \Gamma_{n_k,\ldots,n_1} : \Omega \to \mathcal{M},
\]

where \( n_k, \ldots, n_1 \in \mathbb{N} \) and the functions \( \Gamma_{n_k,\ldots,n_j} \) at the “lowest level” of the tower are general algorithms in the sense of Definition 3.1. Moreover, for every \( A \in \Omega \),

\[
\Xi(A) = \lim_{n_k \to \infty} \Gamma_{n_k}(A), \quad \Gamma_{n_k,\ldots,n_j+1}(A) = \lim_{n_j \to \infty} \Gamma_{n_k,\ldots,n_j}(A) \quad j = k - 1, \ldots, 1.
\]

In addition to a general tower of algorithms (defined above), we will focus on arithmetic towers.

Definition 3.3 (Arithmetic Tower). Given a computational problem \( \{\Xi, \Omega, \mathcal{M}, \Lambda\} \), an Arithmetic Tower of Algorithms of height \( k \) for \( \{\Xi, \Omega, \mathcal{M}, \Lambda\} \) is a tower of algorithms where the lowest level functions

\[
\Gamma = \Gamma_{n_k,\ldots,n_1} : \Omega \to \mathcal{M}
\]

satisfy the following: For each \( A \in \Omega \) the action of \( \Gamma \) on \( A \) consists of only finitely many arithmetic operations on \( \{A_f\}_{f \in \Lambda(A)} \), where we remind that \( A_f = f(A) \).

In other words one may say that for the finitely many steps of the computation of the lowest functions \( \Gamma = \Gamma_{n_k,\ldots,n_1} : \Omega \to \mathcal{M} \) only the arithmetic operations \(+,-,\cdot,/\) within the smallest (algebraic) field which is generated by the input \( \{A_f\}_{f \in \Lambda(A)} \) are allowed. We implicitly assume that any complex number can be decomposed into a real and an imaginary part, and moreover, we can determine whether \( a = b \) or \( a > b \) for all real numbers \( a, b \) which can occur during the computations.

Remark 3.4. In Appendix A we also briefly discuss the problem of inexact input, restricting computation to \( \mathbb{Q} \) and recursivity through the definition of a Turing tower. All of the results of this paper extend to this type of tower also.

Given the definitions above we can now define the key concept, namely, the Solvability Complexity Index:

Definition 3.5 (Solvability Complexity Index). A computational problem \( \{\Xi, \Omega, \mathcal{M}, \Lambda\} \) is said to have Solvability Complexity Index \( \text{SCI}(\Xi, \Omega, \mathcal{M}, \Lambda)_\alpha = k \), with respect to a tower of algorithms of type \( \alpha \), if \( k \) is the smallest integer for which there exists a tower of algorithms of type \( \alpha \) of height \( k \). If no such tower exists then \( \text{SCI}(\Xi, \Omega, \mathcal{M}, \Lambda)_\alpha = \infty \). If there exists a tower \( \{\Gamma_n\}_{n \in \mathbb{N}} \) of type \( \alpha \) and height one such that \( \Xi = \Xi_{n_1} \) for some \( n_1 < \infty \), then we define \( \text{SCI}(\Xi, \Omega, \mathcal{M}, \Lambda)_\alpha = 0 \). The type \( \alpha \) may be General, or Arithmetic, denoted respectively \( G \) and \( A \). We may sometimes write \( \text{SCI}(\Xi, \Omega)_\alpha \) to simplify notation when \( \mathcal{M} \) and \( \Lambda \) are obvious.

We will let \( \text{SCI}(\Xi, \Omega)_A \) and \( \text{SCI}(\Xi, \Omega)_G \) denote the SCI with respect to an arithmetic tower and a general tower, respectively. Note that a general tower means just a tower of algorithms as in Definition 3.2 where there are no restrictions on the mathematical operations. Thus, clearly \( \text{SCI}(\Xi, \Omega)_A \geq \text{SCI}(\Xi, \Omega)_G \). The definition of the SCI immediately induces the SCI hierarchy:
**Definition 3.6** (The Solvability Complexity Index Hierarchy). Consider a collection $C$ of computational problems and let $T$ be the collection of all towers of algorithms of type $\alpha$ for the computational problems in $C$. Define

\[
\Delta_0^{\alpha} := \{\{\Xi, \Omega\} \in C \mid \text{SCI}(\Xi, \Omega)_n = 0\} \\
\Delta_{m+1}^{\alpha} := \{\{\Xi, \Omega\} \in C \mid \text{SCI}(\Xi, \Omega)_n \leq m\}, \quad m \in \mathbb{N},
\]

as well as

\[
\Delta^{\alpha} := \{\{\Xi, \Omega\} \in C \mid \exists \{\Gamma_n\}_{n \in \mathbb{N}} \in T \text{ s.t. } \forall A \ d(\Gamma_n(A), \Xi(A)) \leq 2^{-n}\}.
\]

When there is extra structure on the metric space, such as in the spectral case when one considers the Attouch–Wets or the Hausdorff metric, one can extend the SCI hierarchy.

**Definition 3.7** (The SCI Hierarchy (Attouch–Wets/Hausdorff metric)). Given the set-up in Definition 3.6 and suppose in addition that $M$ is the Attouch–Wets or the Hausdorff metric space induced by another metric space $M'$. Define for $m \in \mathbb{N}$

\[
\Sigma_{0}^{\alpha} = \Pi_{0}^{\alpha} = \Delta_{0}^{\alpha}, \\
\Sigma_{1}^{\alpha} = \left\{\{\Xi, \Omega\} \in \Delta_{2} \mid \exists \Gamma_n \in \mathcal{T}, \tilde{\Gamma}_n(A) \in M \text{ s.t. } \Gamma_n(A) \subset \tilde{\Gamma}_n(A), \right. \\
\left. \lim_{n \to \infty} \Gamma_n(A) = \Xi(A), \ d(\tilde{\Gamma}_n(A), \Xi(A)) \leq 2^{-n} \forall A \in \Omega\right\},
\]

\[
\Pi_{1}^{\alpha} = \left\{\{\Xi, \Omega\} \in \Delta_{2} \mid \exists \Gamma_n \in \mathcal{T}, \tilde{\Gamma}_n(A) \in M \text{ s.t. } \Xi(A) \subset \tilde{\Gamma}_n(A), \right. \\
\left. \lim_{n \to \infty} \Gamma_n(A) = \Xi(A), \ d(\tilde{\Gamma}_n(A), \Gamma_n(A)) \leq 2^{-n} \forall A \in \Omega\right\},
\]

where $\subset$ means inclusion in the metric space $M'$. Moreover,

\[
\Sigma_{m+1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{m+2} \mid \exists \Gamma_{n_{m+1}, \ldots, n_1} \in \mathcal{T}, \tilde{\Gamma}_{n_{m+1}}(A) \in M \text{ s.t. } \Gamma_{n_{m+1}}(A) \subset \tilde{\Gamma}_{n_{m+1}}(A), \right. \\
\left. \lim_{n_{m+1} \to \infty} \Gamma_{n_{m+1}}(A) = \Xi(A), \ d(\tilde{\Gamma}_{n_{m+1}}(A), \Xi(A)) \leq 2^{-n_{m+1}} \forall A \in \Omega\right\},
\]

\[
\Pi_{m+1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{m+2} \mid \exists \Gamma_{n_{m+1}, \ldots, n_1} \in \mathcal{T}, \tilde{\Gamma}_{n_{m+1}}(A) \in M \text{ s.t. } \Xi(A) \subset \tilde{\Gamma}_{n_{m+1}}(A), \right. \\
\left. \lim_{n_{m+1} \to \infty} \Gamma_{n_{m+1}}(A) = \Xi(A), \ d(\tilde{\Gamma}_{n_{m+1}}(A), \Gamma_{n_{m+1}}(A)) \leq 2^{-n_{m+1}} \forall A \in \Omega\right\}.
\]

Note that to build a $\Sigma_1$ algorithm, it is enough by taking subsequences of $n$ to construct $\Gamma_n(A)$ such that $\Gamma_n(A) \subset \mathcal{N}_{E_n(A)}(\Xi(A))$ with some computable $E_n(A)$ that converges to zero. The same extension can be applied to the real line with the usual metric, or $\{0, 1\}$ with the discrete metric (where we interpret 1 as “Yes”).

**Definition 3.8** (The SCI Hierarchy (totally ordered set)). Consider the set-up in Definition 3.6 and suppose in addition that $M$ is a totally ordered set. Define

\[
\Sigma_{0}^{\alpha} = \Pi_{0}^{\alpha} = \Delta_{0}^{\alpha}, \\
\Sigma_{1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{2} \mid \exists \Gamma_n \in \mathcal{T}, \Gamma_n(A) \triangleright \Xi(A) \forall A \in \Omega\},
\]

\[
\Pi_{1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{2} \mid \exists \Gamma_n \in \mathcal{T}, \Gamma_n(A) \triangleright \Xi(A) \forall A \in \Omega\},
\]

where $\triangleright$ and $\triangleright$ denote convergence from below and above respectively, as well as, for $m \in \mathbb{N}$,

\[
\Sigma_{m+1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{m+2} \mid \exists \Gamma_{n_{m+1}, \ldots, n_1} \in \mathcal{T}, \Gamma_{n_{m+1}}(A) \triangleright \Xi(A) \forall A \in \Omega\},
\]

\[
\Pi_{m+1}^{\alpha} = \{\{\Xi, \Omega\} \in \Delta_{m+2} \mid \exists \Gamma_{n_{m+1}, \ldots, n_1} \in \mathcal{T}, \Gamma_{n_{m+1}}(A) \triangleright \Xi(A) \forall A \in \Omega\}.
\]

**Remark 3.9** ($\Delta_1^{\alpha} \subseteq \Sigma_1^{\alpha} \subseteq \Delta_0^{\alpha}$). Note that the inclusions are strict. For example if $\Omega_K$ consists of the set of compact infinite matrices acting on $l^2(\mathbb{N})$ and $\Xi(A) = \text{Sp}(A)$ (the spectrum of $A$) then $\Xi(\Omega_K) \in \Delta_0^{\alpha}$ but not in $\Sigma_1^{\alpha}$ or $\Pi_1^{\alpha}$ for $\alpha$ representing either towers of arithmetical or general type (see [9] for a proof). Moreover, as was demonstrated in [8], if $\Omega$ is the set of discrete Schrödinger operators on $l^2(\mathbb{Z})$, then $\Xi(\Omega) \in \Sigma_1^{\alpha}$ but not in $\Delta_1^{\alpha}$. 

The definition of a basic tower of algorithms is informally a tower of algorithms that provides the correct classification in the SCI Hierarchy. Thus, a basic tower of algorithms represents essentially the best possible tower one can find for the particular problem. More formally we have the following.

**Definition 3.10** (Basic Tower of Algorithms). A basic tower of algorithms is a tower that realises the correct classification in the SCI Hierarchy of a class of problems $\Theta$.

4. Proofs of Theorems on Unbounded Operators on Graphs

We will now prove the theorems in [21]. The following argument shows that it is sufficient to consider the $l^2(\mathbb{N})$ case. Given the graph $G$ and enumeration $v_1, v_2, \ldots$ of the vertices, consider the induced isomorphism $l^2(V(G)) \cong l^2(\mathbb{N})$. This induces a corresponding operator on $l^2(\mathbb{N})$ where the functions $\alpha$ now become matrix values. For the lower bounds, we can consider diagonal operators in $\Omega$ and $\Omega \neq l$ of operators on $l$ of the form $\{0\}$. For the upper bounds, the construction of algorithms for $l^2(\mathbb{N})$ can be computed via the above isomorphism using functions in $\Lambda$ for the relevant class of operators on $l^2(\mathbb{N})$. For instance, to evaluate matrix elements, we use $\alpha(v_i, v_j)$.

There is a useful characterisation of the Attouch–Wets topology. For any closed non-empty sets $A$ and $C$, the convergence $d_{AW}(C_n, C) \to 0$ holds if and only if $d_K(C_n, C) \to 0$ for any compact $K \subset C$ where

$$d_K(C_1, C_2) = \max \left\{ \sup_{a \in C_1 \cap K} \text{dist}(a, C_2), \sup_{b \in C_2 \cap K} \text{dist}(b, C_1) \right\},$$

with the convention that the supremum over the empty set is 0. This occurs if and only if for any $\delta > 0$ and $K$, there exists $N$ such that if $n > N$ then $C_n \cap K \subset C + B_\delta(0)$ and $C \cap K \subset C_n + B_\delta(0)$. Furthermore, it is enough to consider $K$ of the form $B_m(0)$, the closed ball of radius $m$ about the origin for $m \in \mathbb{N}$, for $m$ large. Throughout this section we take our metric space $(\mathcal{M}, d)$ to be $(\text{Cl}(\mathbb{C}), d_{AW})$.

**Remark 4.1** (A note on the empty set). There is a slight subtlety regarding the empty set. It could be the case that the output of our algorithm is the empty set and hence $\Gamma_n(A)$ does not map to the required metric space. However, the proofs will make clear that for large $n$, $\Gamma_n(A)$ is non-empty and we gain convergence. By successively computing $\Gamma_n(A)$ and outputting $\Gamma_{m(n)}(A)$ where $m(n) \geq n$ is minimal with $\Gamma_{m(n)}(A) \neq \emptyset$, we see that this does not matter for the classification, but the algorithm in this case is adaptive.

The following lemma is a useful criterion for determining $\Sigma^A_n$ error control in the Attouch–Wets topology and will be used in the proofs without further comment.

**Lemma 4.2.** Suppose that $\Xi : \Omega \to (\text{Cl}(\mathbb{C}), d_{AW})$ is a problem function and $\Gamma_n$ is a sequence of arithmetic algorithms with each output a finite set such that

$$\lim_{n \to \infty} d_{AW}(\Gamma_n(A), \Xi(A)) = 0, \quad \forall A \in \Omega.$$

Suppose also that there is a function $E_n$ provided by $\Gamma_n$ (and defined over the output of $\Gamma_n$), such that

$$\lim_{n \to \infty} \sup_{z \in \Gamma_n(A) \cap B_m(0)} E_n(z) = 0$$

for all $m \in \mathbb{N}$ and such that

$$\text{dist}(z, \Xi(A)) \leq E_n(z), \quad \forall z \in \Gamma_n(A).$$

Then:

1. For each $m \in \mathbb{N}$ and given $\Gamma_n(A)$, we can compute in finitely many arithmetic operations and comparisons a sequence of non-negative numbers $a_{nm}^m \to 0$ (as $n \to \infty$) such that

$$\Gamma_n(A) \cap B_{a_{nm}}(0) \subset \Xi(A) + B_{a_{nm}}(0).$$
(2) Given \( \Gamma_n(A) \), we can compute in finitely many arithmetic operations and comparisons a sequence of non-negative numbers \( b_n \to 0 \) such that
\[
\Gamma_n(A) \subset A_n
\]
for some \( A_n \in \text{Cl}(\mathbb{C}) \) with \( d_{\text{AW}}(A_n, \Xi(A)) \leq b_n \).

Hence we can convert \( \Gamma_n \) to a \( \Sigma^1_4 \) tower using the sequence \( \{b_n\} \) by taking subsequences if necessary.

**Proof.** For the proof of (1), we may take \( a_n^m = \sup \{ E_n(z) : z \in \Gamma_n(A) \cap B_m(0) \} \) and the result follows. Note that we need \( \Gamma_n(A) \) to be finite to be able to compute this number with finitely many arithmetic operations and comparisons. We next show (2) by defining
\[
B = \left( \Xi(A) + B_{A_m}^n(0) \right) \cap B_m(0) \cup \left( \Gamma_n(A) \cap \{ z : |z| \geq m \} \right).
\]
It is clear that \( \Gamma_n(A) \subset A_n^m \) and given \( \Gamma_n(A) \) we can easily compute a lower bound \( m_1 \) such that \( \Xi(A) \cap B_{m_1}(0) \neq \emptyset \). Compute this from \( \Gamma_1(A) \) and then fix it. Suppose that \( m \geq 4m_1 \), and suppose that \( |z| < [m/4] \). Then the points in \( A_n^m \) and \( \Xi(A) \) nearest to \( z \) must lie in \( B_m(0) \) and hence
\[
dist(z, A_n^m) \leq dist(z, \Xi(A)), \quad dist(z, \Xi(A)) \leq dist(z, A_n^m) + a_n^m.
\]
It follows that
\[
d_{\text{AW}}(A_n^m, \Xi(A)) \leq a_n^m + 2^{-[m/4]}.
\]
We now choose a sequence \( m(n) \) such that setting \( A_n = A_n^{m(n)} \) and \( b_n = a_n^{m(n)} + 2^{-[m(n)/4]} \) proves the result. Clearly it is enough to ensure that \( b_n \) is null. If \( n < 4m_1 \) then set \( m(n) = 4m_1 \), otherwise consider \( 4m_1 \leq k \leq n \). If such a \( k \) exists with \( a_k^{k_1} \leq 2^{-k} \) then let \( m(n) \) be the maximal such \( k \) and finally if no such \( k \) exists then set \( m(n) = 4m_1 \). For a fixed \( m, a_n^m \to 0 \) as \( n \to \infty \). It follows that for large \( n, a_n^{m(n)} \leq 2^{-m(n)} \) and that \( m(n) \to \infty \). \( \square \)

**Remark 4.3.** We will only consider algorithms where the output of \( \Gamma_n(A) \) is at most finite for each \( n \). Hence the above restriction does not matter in what follows.

In order to build our algorithms we will need to characterise the reciprocal of resolvent norm in terms of the injection modulus. For \( A \in \mathcal{C}(l^2(\mathbb{N})) \) define the injection modulus as
\[
\sigma_1(A) = \inf \{ \|Ax\| : x \in \mathcal{D}(A), \|x\| = 1 \},
\]
and define the function
\[
\gamma(z, A) = \min \{ \sigma_1(A - zI), \sigma_1(A^* - z^*I) \}.
\]

**Lemma 4.4.** For \( A \in \mathcal{C}(l^2(\mathbb{N})) \), \( \gamma(z, A) = 1/\|R(z, A)\| \), where \( R(z, A) \) denotes the resolvent \( (A - zI)^{-1} \) and we adopt the convention that \( 1/\|R(z, A)\| = 0 \) if \( z \in \text{Sp}(A) \).

**Proof.** We deal with the case \( z \notin \text{Sp}(A) \) first, where we prove \( \sigma(A - zI) = \sigma(A^* - z^*I) = 1/\|R(z, A)\| \). We show this for \( \sigma_1(A - zI) \) and the other case is similar using the fact that \( R(z, A)^* = R(\Xi, A^*) \) and \( \|R(z, A)\| = \|R(z, A)^*\| \). Let \( x \in \mathcal{D}(A) \) with \( \|x\| = 1 \) then
\[
1 = \|R(z, A)(A - zI)x\| \leq \|R(z, A)\| \| (A - zI)x \|
\]
and hence upon taking infimum, \( \sigma_1(A - zI) \geq 1/\|R(z, A)\| \). Conversely, let \( x_n \in l^2(\mathbb{N}) \) such that \( \|x_n\| = 1 \) and \( \|R(z, A)x_n\| \to \|R(z, A)\| \). It follows that
\[
1 = \| (A - zI)R(z, A)x_n \| \geq \sigma_1(A - zI) \| R(z, A)x_n \|.
\]
Letting \( n \to \infty \) we get \( \sigma_1(A - zI) \leq 1/\|R(z, A)\| \).

Now suppose that \( z \in \text{Sp}(A) \). If at least one of \( A - zI \) or \( A^* - z^*I \) is not injective on their respective domain then we are done, so assume both are one to one. Suppose also that \( \sigma_1(A - zI), \sigma_1(A^* - z^*I) > 0 \) otherwise we are done. It follows that \( \mathcal{R}(A - zI) \) is dense in \( l^2(\mathbb{N}) \) by injectivity of \( A^* - z^*I \) since
\( R(A - zI) = N(A^* - zI) \). It follows that we can define \((A - zI)^{-1}\), bounded on the dense set \( R(A - zI) \). We can extend this inverse to a bounded operator on the whole of \( l^2(\mathbb{N}) \). Closedness of \( A \) now implies that \((A - zI)(A - zI)^{-1} = I\). Clearly \((A - zI)^{-1}(A - zI)x = x\) for all \( x \in \mathcal{D}(A) \). Hence, \((A - zI)^{-1} = R(z, A) \in B(l^2(\mathbb{N}))\) so that \( z \notin \text{Sp}(A) \), a contradiction.

Suppose we have a sequence of functions \( \gamma_n(z, A) \) that converge uniformly to \( \gamma(z, A) \) on compact subsets of \( \mathbb{C} \). Define the grid
\[
\text{Grid}(n) = \frac{1}{n}(\mathbb{Z} + i\mathbb{Z}) \cap B_n(0).
\]
For an strictly increasing continuous function \( g : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0} \), with \( g(0) = 0 \) and diverging at infinity, for \( n \in \mathbb{N} \) and \( y \in \mathbb{R}_{\geq 0} \) define
\[
\text{CompInvg}(n, y, g) = \min\{k/n : k \in \mathbb{N}, g(k/n) > y\}.
\]
Note that \( \text{CompInvg}(n, y, g) \) can be computed from finitely many evaluations of the function \( g \). We now build the algorithm converging to the spectrum step by step using the functions in (2.2). For each \( z \in \text{Grid}(n) \), let
\[
\mathcal{T}_{n, z} = B_{\text{CompInvg}(n, \gamma_n(z, A), g(|z|))}(z) \cap \text{Grid}(n).
\]
If \( \gamma_n(z, A) > (|z|^2 + 1)^{-1} \) then set \( M_z = \emptyset \), otherwise set
\[
M_z = \{w \in \mathcal{T}_{n, z} : \gamma_n(w, A) = \min_{v \in \mathcal{T}_{n, z}} \gamma_n(v, A)\}.
\]
Finally define \( \Gamma_n(A) = \bigcup_{z \in \text{Grid}(n)} M_z \). It is clear that if \( \gamma_n(z, A) \) can be computed in finitely many arithmetic operations and comparisons from the relevant functions in \( A \) for each problem, then this defines an arithmetic algorithm. If \( A \in \mathcal{C}(l^2(\mathbb{N})) \) with non-empty spectrum then there exists \( z \in B_m(0) \) with \( \gamma(z, A) \leq (m^2 + 1)^{-1}/2 \) and, for large \( n \), \( z_n \in \text{Grid}(n) \) sufficiently close to \( z \) with \( \gamma(z_n, A) \leq (|z_n|^2 + 1)^{-1} \). Hence, by computing successive \( \Gamma_n(A) \), we can assume that \( \Gamma_n(A) \neq \emptyset \) without loss of generality (see Remark 4.1).

**Proposition 4.5.** Suppose \( A \in \mathcal{C}(l^2(\mathbb{N})) \) with non-empty spectrum and we have a function \( \gamma_n(z, A) \) that converges uniformly to \( \gamma(z, A) \) on compact subsets of \( \mathbb{C} \). Suppose also that (2.2) holds, namely
\[
g_m(\text{dist}(z, \text{Sp}(A))) \leq \|R(z, A)\|^{-1}, \quad \forall z \in B_m(0).
\]
Then \( \Gamma_n(A) \) converges in the Attouch–Wets topology to \( \text{Sp}(A) \) (assuming \( \Gamma_n(A) \neq \emptyset \) without loss of generality).

**Proof.** We use the characterisation of the Attouch–Wets topology. Suppose that \( m \in \mathbb{N} \) is large such that \( B_m(0) \cap \text{Sp}(A) \neq \emptyset \). We must show that given \( \delta > 0 \), there exists \( N \) such that if \( n > N \) then \( \Gamma_n(A) \cap B_m(0) \subset \text{Sp}(A) + B_\delta(0) \) and \( \text{Sp}(A) \cap B_m(0) \subset \Gamma_n(A) + B_\delta(0) \). Throughout the rest of the proof we fix such an \( m \). Let \( \epsilon_n = \|\gamma_n(\cdot, A) - \gamma(\cdot, A)\|_{\infty, B_{m+1}(0)} \), where the notation means the supremum norm over the set \( B_{m+1}(0) \).

We deal with the second inclusion first. Suppose that \( z \in \text{Sp}(A) \cap B_m(0) \), then there exists some \( w \in \text{Grid}(n) \) such that \(|w - z| \leq 1/n \). It follows that
\[
\gamma_n(w, A) \leq \gamma(w, A) + \epsilon_n \leq \text{dist}(w, \text{Sp}(A)) + \epsilon_n \leq \epsilon_n + 1/n.
\]
By choosing \( n \) large, we can ensure that \( \epsilon_n < (2m^2 + 2)^{-1} \) and that \( 1/n \leq (2m^2 + 2)^{-1} \) so that \( \gamma_n(w, A) < (|w|^2 + 1)^{-1} \). It follows that \( M_w \) is non-empty. If \( y \in M_w \) then
\[
|y - z| \leq |w - z| + |y - w| \leq 1/n + 1/n + g_m^{-1}(\gamma_n(w, A)).
\]
But the $g_k$'s are non-increasing in $k$, strictly increasing continuous functions with $g_k(0) = 0$. Since $\gamma_n(w, A) \leq \epsilon_n + 1/n$, it follows that

$$|y - z| \leq 2/n + g_{m+1}^{-1}(\epsilon_n + 1/n).$$

There exists $N_1$ such that if $n \geq N_1$ then (4.6) holds and $2/n + g_{m+1}^{-1}(\epsilon_n + 1/n) \leq \delta$ and this gives the second inclusion.

For the first inclusion, suppose for a contradiction that this is false. Then there exists $n_j \to \infty$, $\delta > 0$ and $z_{n_j} \in \Gamma_{n_j}(A) \cap B_m(0)$ such that $\text{dist}(z_{n_j}, \text{Sp}(A)) \geq \delta$. Then $z_{n_j} \in M_{w_{n_j}}$ for some $w_{n_j} \in \text{Grid}(n_j)$. Let

$$I(j) = B_{\text{comp}}(\omega, \gamma_{n_j}(A)(n_j)) (w_{n_j}) \cap \text{Grid}(n_j),$$

the set that we compute minima of $\gamma_{n_j}$ over. Let $y_{n_j} \in \text{Sp}(A)$ be of minimal distance to $w_{n_j}$ (such a $y_{n_j}$ exists since the spectrum restricted to any compact ball is compact). It follows that $|y_{n_j} - w_{n_j}| \leq g_{|w_{n_j}|}(\gamma(w_{n_j}, A))$. A simple geometrical argument (which also works when we restrict everything to the real line for self-adjoint operators), shows that there must be a $v_{n_j}$ in $I(j)$ so that

$$|v_{n_j} - y_{n_j}| \leq \frac{4}{n_j} + g_{|w_{n_j}|}^{-1}(\gamma(w_{n_j}, A)) - g_{|w_{n_j}|}^{-1}(\gamma_{n_j}(w_{n_j}, A)).$$

Since $z_{n_j}$ minimises $\gamma_{n_j}$ over $I(j)$ and $M_{w_{n_j}}$ is non-empty, it follows that

$$\gamma(z_{n_j}, A) \leq \gamma_{n_j}(z_{n_j}, A) + \epsilon_{n_j} \leq \min \left\{ \frac{1}{|w_{n_j}|^2 + 1}, \gamma_{n_j}(v_{n_j}, A) \right\} + \epsilon_{n_j}.$$

This implies that

$$\delta \leq \text{dist}(z_{n_j}, \text{Sp}(A)) \leq g_m^{-1}\left( \min \left\{ \frac{1}{|w_{n_j}|^2 + 1}, \gamma_{n_j}(v_{n_j}, A) \right\} + \epsilon_{n_j} \right),$$

where we recall that $g_m^{-1}$ is continuous. It follows that the $w_{n_j}$ must be bounded and hence so are the $v_{n_j}$. Due to the local uniform convergence of $\gamma_n$ to $\gamma$, it follows that

$$\frac{4}{n_j} + g_{|w_{n_j}|}^{-1}(\gamma(w_{n_j}, A)) - g_{|w_{n_j}|}^{-1}(\gamma_{n_j}(w_{n_j}, A)) \to 0, \quad \text{as } n_j \to \infty.$$

But then

$$\gamma(v_{n_j}, A) \leq \text{dist}(v_{n_j}, \text{Sp}(A)) \leq |v_{n_j} - y_{n_j}| \to 0.$$

Again the local uniform convergence implies that $\gamma_{n_j}(v_{n_j}, A) \to 0$, which contradicts (4.7) and completes the proof.

Next, given such a sequence $\gamma_n$, we would like to provide an algorithm for computing the pseudospectrum. However, care must be taken in the unbounded case since the resolvent norm can be constant on open subsets of $\mathbb{C}$ [68]. Simply taking

$$\text{Grid}(n) \cap \{ z : \gamma_n(z, A) \leq \epsilon \}$$

is not guaranteed to converge, as can be seen in the case that $\gamma_n$ is identically $\gamma$ and $A$ is such that $\|R(z, A)\|^{-1} = \epsilon$ has non-empty interior. To get around this, we will need an extra assumption on the functions $\gamma_n$.

**Lemma 4.6.** Suppose $A \in C^0(\mathbb{N})$ with non-empty spectrum and let $\epsilon > 0$. Suppose we have a sequence of functions $\gamma_n(z, A)$ that converge uniformly to $\|R(z, A)\|^{-1}$ on compact subsets of $\mathbb{C}$. Set

$$\Gamma_n^\epsilon(A) = \text{Grid}(n) \cap \{ z : \gamma_n(z, A) < \epsilon \}.$$

For large $n$, $\Gamma_n^\epsilon(A) \neq \emptyset$ so we can assume this without loss of generality. Suppose also $\exists N \in \mathbb{N}$ (possibly dependent on $A$ but independent of $z$) such that if $n \geq N$ then $\gamma_n(z, A) \geq \|R(z, A)\|^{-1}$. Then $d_{AW}(\Gamma_n^\epsilon(A), \text{Sp}_\epsilon(A)) \to 0$ as $n \to \infty$. 
Proof. Since the pseudospectrum is non-empty, for large \( n \), \( \Gamma_n'(A) \neq \emptyset \) so by our usual argument of computing successive \( \Gamma_n' \) (see Remark 4.1) we may assume that this holds for all \( n \) without loss of generality. We use the characterisation of the Attouch–Wets topology. Suppose that \( m \) is large such that \( B_m(0) \cap \text{Sp}_n(A) \neq \emptyset. \) \( \exists N \in \mathbb{N} \) such that if \( n \geq N \) then \( \gamma_n(z,A) \geq \|R(z,A)\|^{-1} \) and hence \( \Gamma_n'(A) \cap B_m(0) \subset \text{Sp}_n(A) \). Hence must show that given \( \delta > 0 \), there exists \( N_1 \) such that if \( n > N_1 \) then \( \text{Sp}_n(A) \cap B_m(0) \subset \Gamma_n'(A) + B_\delta(0) \). Suppose for a contradiction that this were false. Then there exists \( z_{n_j} \in \text{Sp}_n(A) \cap B_m(0), \delta > 0 \) and \( n_j \to \infty \) such that \( \text{dist}(z_{n_j}, \Gamma_n'(A)) \geq \delta \). Without loss of generality, we can assume that \( z_{n_j} \to z \in \text{Sp}_n(A) \cap B_m(0) \).

There exists some \( w \) with \( \|R(w,A)\|^{-1} < \epsilon \) and \( |z - w| \leq \delta/2 \). Assuming \( n_j > m + \delta \), there exists \( y_{n_j} \in \text{grid}(n_j) \) with \( |y_{n_j} - w| \leq 1/n_j \). It follows that

\[
\gamma_{n_j}(y_{n_j}, A) \leq |\gamma_{n_j}(y_{n_j}, A) - \gamma(y_{n_j}, A)| + |\gamma(w, A) - \gamma(y_{n_j}, A)| + \|R(w, A)\|^{-1}.
\]

But \( \gamma \) is continuous and \( \gamma_{n_j} \) converges uniformly to \( \gamma \) on compact subsets. Hence for large \( n_j \), \( \gamma_{n_j}(y_{n_j}, A) < \epsilon \) so that \( y_{n_j} \in \Gamma_n'(A) \). But \( |y_{n_j} - z| \leq |z - w| + |y_{n_j} - w| \leq \delta/2 + 1/n_j \), which is smaller than \( \delta \) for large \( n_j \). This gives the required contradiction. \( \square \)

Now suppose that \( \Lambda \in \Omega \) and let \( D_{f,n}(A) \leq c_n \). The following shows that we can construct the required sequence \( \gamma_n(z,A) \), each function output requiring finitely many arithmetic operations and comparisons of the corresponding input information.

**Theorem 4.7.** Let \( \Lambda \in \Omega \) and define the function

\[
\tilde{\gamma}_n(z,A) = \min\{\sigma_1(P_{f,n}(A - zI)P_{c}(I^2(n))), \sigma_1(P_{f,n}(A^* - zI)P_{c}(I^2(n)))\}.
\]

We can compute \( \tilde{\gamma}_n \) up to precision \( 1/n \) using finitely many arithmetic operations and comparisons. We call this approximation \( \hat{\gamma}_n \) and set

\[
\gamma_n(z,A) = \hat{\gamma}_n(z,A) + c_n + 1/n.
\]

Then \( \gamma_n(z,A) \) converges uniformly to \( \gamma(z,A) \) on compact subsets of \( \mathbb{C} \) and \( \gamma_n(z,A) \geq \gamma(z,A) \).

**Proof.** We will first prove that \( \sigma_1((A - zI)P_{c}(I^2(n))) \downarrow \sigma_1(A - zI) \) as \( n \to \infty \). It is trivial that \( \sigma_1((A - zI)P_{c}(I^2(n))) \geq \sigma_1(A - zI) \) and that \( \sigma_1((A - zI)P_{c}(I^2(n))) \) is non-increasing in \( n \). Using Lemma 4.4, let \( \epsilon > 0 \) and \( x \in D(A) \) such that \( \|x\| = 1 \) and \( \|A - zI\| \leq \sigma_1(A - zI) + \epsilon \). Since \( \text{span}\{e_n : n \in \mathbb{N}\} \) forms a core of \( A \), \( AP_{n_j}x_{n_j} \to Ax \) and \( P_{n_j}x_{n_j} \to x \) for some \( n_j \to \infty \) and some sequence of vectors \( x_{n_j} \) that we can assume have norm 1. It follows that for large \( n_j \)

\[
\sigma_1((A - zI)P_{n_j}(I^2(n))) \leq \frac{\|(A - zI)P_{n_j}x_{n_j}\|}{\|P_{n_j}x_{n_j}\|} \to \|(A - zI)x\| \leq \sigma_1(A - zI) + \epsilon.
\]

Since \( \epsilon > 0 \) was arbitrary, this shows the convergence of \( \sigma_1((A - zI)P_{c}(I^2(n))) \). The fact that \( \text{span}\{e_n : n \in \mathbb{N}\} \) forms a core of \( A^* \) can also be used to show that \( \sigma_1((A - zI)^*P_{c}(I^2(n))) \downarrow \sigma_1(A^* - zI) \).

Next we will use the assumption of bounded dispersion. For any bounded operators \( B, C \), it holds that \( |\sigma_1(A) - \sigma_1(B)| \leq \|A - B\| \). The definition of bounded dispersion now implies that

\[
|\hat{\gamma}_n(z,A) - \min\{\sigma_1((A - zI)P_{c}(I^2(n))), \sigma_1((A - zI)^*P_{c}(I^2(n)))\}| \leq c_n.
\]

The monotone convergence of \( \min\{\sigma_1((A - zI)P_{c}(I^2(n))), \sigma_1((A - zI)^*P_{c}(I^2(n)))\} \), together with Dini’s theorem, imply that \( \hat{\gamma}_n(z,A) \) converges uniformly to the continuous function \( \gamma(z,A) \) on compact subsets of \( \mathbb{C} \) with \( \hat{\gamma}_n(z,A) + c_n \geq \gamma(z,A) \).

The proof will be complete if we can show that we can compute \( \tilde{\gamma}_n(z,A) \) to precision \( 1/n \) using finitely many arithmetic operations and comparisons. To do this, consider the matrices

\[
B_n(z) = P_{n}(A - zI)^*P_{f,n}(A - zI)P_{n} \quad C_n(z) = P_{n}(A - zI)P_{f,n}(A - zI)^*P_{n}.
\]
By an interval search routine and Lemma 4.8 below, we can determine the smallest \( l \in \mathbb{N} \) such that at least one of \( B_n(z) - (l/n)^2 I \) or \( C_n(z) - (l/n)^2 I \) has a negative eigenvalue. We then output \( 1/n \) to get the \( 1/n \) bound.

Recall that every finite Hermitian matrix \( B \) (not necessarily positive definite) has a decomposition

\[
PBP^T = LDL^*,
\]

where \( L \) is lower triangular with 1’s along its diagonal, \( D \) is block diagonal with block sizes 1 or 2 and \( P \) is a permutation matrix. Furthermore, this decomposition can be computed with finitely many arithmetic operations and comparisons. Throughout, we will assume without loss of generality that \( P \) is the identity matrix.

**Lemma 4.8.** Let \( B \in \mathbb{C}^n \) be self-adjoint (Hermitian), then we can determine the number of negative eigenvalues of \( B \) in finitely many arithmetic operations and comparisons (assuming no round-off errors) on the matrix entries of \( B \).

**Proof.** We can compute the decomposition \( B = LDL^* \) in finitely many arithmetical operations and comparisons. By Sylvester’s law of inertia (the Hermitian version), \( D \) has the same number of negative eigenvalues as \( B \). It is then clear that we only need to deal with \( 2 \times 2 \) matrices corresponding to the maximum block size of \( D \). Let \( \lambda_1, \lambda_2 \) be the two eigenvalues of such a matrix, then we can determine their sign pattern from the trace and determinant of the matrix. \( \square \)

This lemma has a corollary that will be useful in [7].

**Corollary 4.9.** Let \( B \in \mathbb{C}^n \) be self-adjoint (Hermitian) and list its eigenvalues in increasing order, including multiplicity, as \( \lambda_1 \leq \lambda_2 \leq ... \leq \lambda_n \). In exact arithmetic, given \( \epsilon > 0 \), we can compute \( \lambda_1, \lambda_2, ..., \lambda_n \) to precision \( \epsilon \) using only finitely many arithmetic operations and comparisons.

**Proof.** Consider \( A(\lambda) = B - \lambda I \). We will apply Lemma 4.8 to \( A(\lambda) \) for various \( \lambda \). First by considering the sequences \(-1, -2, ... \) and \( 1, 2, ... \) we can find \( m_1 \in \mathbb{N} \) such that \( \text{Sp}(B) \subset (-m_1, m_1) \). Now let \( m_2 \in \mathbb{N} \) such that \( 1/m_2 < \epsilon \) and let \( a_j \) be the output of Lemma 4.8 applied to \( A(j/m_2) \) for \(-m_1 m_2 \leq j \leq m_1 m_2 \). Set

\[
\hat{\lambda}_k = \min \{ j : -m_1 m_2 \leq j \leq m_1 m_2, a_j \geq k \}, \quad k = 1, ..., n.
\]

If \( \hat{\lambda}_k \in \{ j/m_2, (j + 1)/m_2 \} \) then \( \hat{\lambda}_k = (j + 1)/m_2 \) and hence \( |\hat{\lambda}_k - \lambda_k| \leq 1/m_2 < \epsilon \). \( \square \)

Note that by taking successive minima, \( \nu_n(z, A) = \min_{1 \leq j \leq n} \gamma_n(z, A) \), we can obtain a sequence of functions \( \nu_n \) that converge uniformly on compact subsets of \( \mathbb{C} \) to \( \gamma(z, A) \) monotonically from above. Hence without loss of generality, we will always assume that \( \gamma_n \) have this property. We can now prove our main result.

**Proof of Theorem 2.3.** By considering bounded diagonal operators, it is straightforward to see that none of the problems lie in \( \Delta^0 \). We first deal with convergence of height one arithmetical towers. For the spectrum, we use the function \( \gamma_n \) described in Theorem 4.7 together with Proposition 4.5 and its algorithm. For the pseudospectrum, we use the same function \( \gamma_n \) described in Theorem 4.7 and convergence follows from using the algorithm in Proposition 4.4.

We are left with proving that our algorithms have \( \Sigma^4 \) error control. For any \( A \in \hat{\Omega} \), the output of the algorithm in Proposition 4.6 is contained in the true pseudospectrum since \( \gamma_n(z, A) \geq \gamma(z, A) = \| R(z, A) \|^{-1} \). Hence we need only show that the algorithm in Proposition 4.5 provides \( \Sigma^4 \) error control for input \( A \in \Omega_g \).

Denote the algorithm by \( \Gamma_n \) and set

\[
E_n(z) = \text{CompInvq}(n, \gamma_n(z, A), g_{\| z \|}^{-1})
\]
on $\Gamma_n(A)$ and zero on $\mathbb{C}\setminus\Gamma_n(A)$. Since $\gamma_n(z, A) \geq \|R(z, A)\|^{-1}$, the assumptions on $\{g_m\}$ imply that
$$\text{dist}(z, \text{Sp}(A)) \leq E_n(z), \quad \forall z \in \Gamma_n(A).$$

Suppose for a contradiction that $E_n$ does not converge uniformly to zero on compact subsets of $\mathbb{C}$. Then there exists some compact set $K$, some $\epsilon > 0$, a sequence $n_j \to \infty$ and $z_{n_j} \in K$ such that $E_{n_j}(z_{n_j}) \geq \epsilon$. It follows that $z_{n_j} \in \Gamma_{n_j}(A)$. Without loss of generality, $z_{n_j} \to z$. By convergence of $\Gamma_{n_j}(A)$, $z \in \text{Sp}(A)$ and hence $\gamma_{n_j}(z_{n_j}, A) \to \gamma(z, A) = 0$. Now choose $M$ large such that $K \subset B_M(0)$. But then
$$E_{n_j}(z_{n_j}) \leq g_n^{-1}(\gamma_{n_j}(z_{n_j}, A)) + \frac{1}{n_j} \to 0,$$
the required contradiction.

\[ \square \]

Remark 4.10. The above makes it clear that $E_n(z)$ converges uniformly to the function $g_n^{-1}(\gamma(z, A))$ as $n \to \infty$ on compact subsets of $\mathbb{C}$.

Finally, we consider the decision problems $\Xi_3$ and $\Xi_4$.

Proof of Theorem 4.2. It is clearly enough to prove the lower bounds for $\Omega_D \times K(\mathbb{C})$ and the existence of towers for $\hat{\Omega} \times K(\mathbb{C})$. The proof of lower bounds for $\Omega_D \times K(\mathbb{C})$ can also be trivially adapted to the more restrictive versions of the problem described in the theorem.

Step 1: $\{\Xi_3, \Omega_D \times K(\mathbb{C})\} \not\subset \Delta^G_2$. Suppose this where false, and $\Gamma_n$ is a height one tower solving the problem. For every $A$ and $n$ there exists a finite number $N(A, n) \in \mathbb{N}$ such that the evaluations from $\Lambda_{n,j}(A)$ only take the matrix entries $A_{ij} = (Ae_j, e_i)$ with $i, j \leq N(A, n)$ into account. Without loss of generality (by shifting our argument), we assume that $K \cap [0, 1] = \{0\}$. We will consider the operators $A_m = \text{diag}(1, 1/2, \ldots, 1/m) \in \mathbb{C}^{m \times m}$, $B_m = \text{diag}(1, 1, \ldots, 1) \in \mathbb{C}^{m \times m}$ and $C = \text{diag}(1, 1, \ldots)$. Set $A = \bigoplus_{m=1}^{\infty} (B_m \oplus A_m)$ where we choose an increasing sequence $k_m$ inductively as follows.

Set $k_1 = 1$ and suppose that $k_1, \ldots, k_m$ have been chosen. $\text{Sp}(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \{1, 1/2, \ldots, 1/m\}$ and hence
$$\Xi_3(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{No},$$
so there exists some $n_m \geq m$ such that if $n \geq n_m$ then
$$\Gamma_n(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{No}.$$

Now let $k_{m+1} = \max\{N(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C, n_m), k_m + 1\}$. By assumption (iii) in definition 3.3, it follows that $\Lambda_{n,m}(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \Lambda_{n,m}(A)$ and hence by assumption (ii) in the same definition that $\Gamma_{n,m}(A) = \Gamma_{n,m}(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{No}$. But $0 \notin \text{Sp}(A)$ and so must have $\lim_{n \to \infty} (\Gamma_n(A)) = \text{Yes}$, a contradiction.

Step 2: $\{\Xi_4, \Omega_D\} \not\subset \Delta^G_2$. The same proof as step 1, but replacing $A$ by $A + \epsilon I$ works in this case.

Step 3: $\{\Xi_3, \hat{\Omega} \times K(\mathbb{C})\} \in \Pi^G_3$. Recall that we can compute, with finitely many arithmetic operations and comparisons, a function $\gamma_n$ that converges monotonically down to $\|R(z, A)\|^{-1}$ uniformly on compacts. Set
$$\Gamma_{n_2, n_1}(A) = \text{"Does there exist some } z \in K_{n_2} \text{ such that } \gamma_{n_1}(z, A) < 1/2^{n_2}?".$$ It is clear that this is an arithmetic algorithm since each $K_n$ is finite and that
$$\lim_{n_1 \to \infty} \Gamma_{n_2, n_1}(A) = \text{"Does there exist some } z \in K_{n_2} \text{ such that } \|R(z, A)\|^{-1} < 1/2^{n_2}?" = \Gamma_{n_2}(A).$$

If $K \cap \text{Sp}(A) = \emptyset$, then $\|R(z, A)\|^{-1}$ is bounded below on the compact set $K$ and hence for large $n_2$, $\Gamma_{n_2}(A) = \text{No}$. However, if $z \in \text{Sp}(A) \cap K$ then let $z_{n_2} \in K_{n_2}$ minimise the distance to $z$. Then
$$\|R(z_{n_2}, A)\|^{-1} \leq \text{dist}(z_{n_2}, \text{Sp}(A)) < 1/2^{n_2}$$
and hence $\Gamma_{n_2}(A) = \text{Yes}$ for all $n_2$. This also shows the $\Pi^G_3$ classification.
Step 4: \( \{ \Xi_4, \hat{\Omega} \times \mathcal{K}(\mathbb{C}) \} \in \Pi_2^4 \). Set

\[
\Gamma_{n_2, n_1}(A) = \text{"Does there exist some } z \in K_{n_2} \text{ such that } \gamma_{n_1}(z, A) < 1/2^{n_2} + \epsilon^p?,
\]

then the same argument used in step 3 works in this case. \( \square \)

4.0.1. Examples of \( f \) used in the numerics. We end with some examples for the graph case \( l^2(V(G)) \). Suppose our enumeration of the vertices obeys the following pattern. \( v_1 \)’s neighbours (including itself) are \( S_1 = \{ v_1, v_2, ..., v_{q_1} \} \) for some finite \( q_1 \). The set of neighbors of these vertices is \( S_2 = \{ e_1, ..., e_{q_2} \} \) for some finite \( q_2 \) where we continue the enumeration of \( S_1 \) and this process continues inductively enumerating \( S_m \).

Example 4.11. Suppose that the bounded operator \( A \) can be written as

\[
A = \sum_{v \sim_k w} \alpha(v, w) |v\rangle \langle w| 
\]

for some \( k \in \mathbb{N} \) (we write \( v \sim_k w \) for two vertices \( v, w \in V \) if there is a path of at most \( k \) edges connecting \( v \) and \( w \), that is, \( A \) only involves \( k \)-th nearest neighbour interactions). Suppose also that the vertex degree of \( G \) is bounded by \( M \). It holds that \( v_n \in S_n \) and \( \{ w \in V : v \sim_k w \} \subset S_{n+k} \). Inductively \( |S_n| \leq (M+1)^n \) and hence we may take the upper bound

\[
S(n) = (M+1)^{n+k}.
\]

Example 4.12. Consider a nearest neighbour operator \( (k = 1 \text{ in } (4.8)) \) on \( l^2(\mathbb{Z}^d) \). It holds that \( |S_m| \sim \mathcal{O}(m^d) \) whilst \( |S_{m+1} - S_m| \sim \mathcal{O}(m^{d-1}) \) (think of the \( S_n \)’s as radial spheres). It is easy to see that we can choose a suitable \( S \) such that

\[
S(n) - n \sim \mathcal{O}(n^{d-1}),
\]

that is, \( S \) grows at most linearly.

5. PROOFS OF THEOREMS ON DIFFERENTIAL OPERATORS

Here we shall prove Theorems 2.9 and 2.11. The algorithms we construct involve technical error estimates with parameters depending on these estimates. However, the algorithms can be implemented using adaptations of the routines in the proofs in [4]. Hence we do not provide pseudocodes for these algorithms. In the construction of the algorithms, our strategy will be to reduce the problem to one handled by the proofs in [4]. In order to do so, we must first select a suitable basis and then compute matrix values. Recall that our aim is to compute the spectrum and pseudospectrum from the information given to us regarding the functions \( a_k \) and \( \hat{a}_k \) with the information we can evaluate made precise by the mappings \( \Xi_1, \Xi_2, \Xi_3, \Xi_4 \) and \( \Xi_5 \). We will start by constructing the algorithms used for the positive results in Theorems 2.9 and 2.11 and then prove the lower bounds.

5.1. Construction of Algorithms. We begin with the description for \( d = 1 \) and comment how this can easily be extended to arbitrary dimensions. As an orthonormal basis of \( L^2(\mathbb{R}) \) we choose the Hermite functions

\[
\psi_m(x) = (2^m m! \sqrt{\pi})^{-1/2} e^{-x^2/2} H_m(x), m \in \mathbb{Z}_{\geq 0},
\]

where \( H_n \) denotes the \( n \)-th (physicists’) Hermite polynomial defined by

\[
H_n(x) = (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).
\]

These obey the recurrence relations

\[
\psi'_m(x) = \sqrt{\frac{m}{2}} \psi_{m-1}(x) - \sqrt{\frac{m + 1}{2}} \psi_{m+1}(x)
\]
\[
x \psi'_m(x) = \sqrt{\frac{m}{2}} \psi_{m-1}(x) + \sqrt{\frac{m + 1}{2}} \psi_{m+1}(x).
\]
We let \( \mathcal{C}_H(\mathbb{R}) = \text{span}\{\psi_m : m \in \mathbb{Z}_{\geq 0}\} \). Note that since the Hermite functions decay like \( e^{-x^2/2} \) (up to polynomials) and the functions \( a_k \) and \( \tilde{a}_k \) can only grow polynomially, the formal differential operator \( T \) and its formal adjoint \( T^* \) make sense as operators from \( \mathcal{C}_H(\mathbb{R}) \) to \( L^2(\mathbb{R}) \). The next proposition says that we can use the chosen basis.

**Proposition 5.1.** Consider an operator \( T \in \Omega \). Then \( \mathcal{C}_H(\mathbb{R}) \) forms a core of both \( T \) and \( T^* \).

**Proof.** Let \( f \in \mathcal{C}_H(\mathbb{R}) \) and choose \( \phi \in C^\infty_0(\mathbb{R}) \) (the space of compactly supported smooth functions) bounded by 1 such that \( \phi(x) = 1 \) for all \( |x| \leq 1 \). It is straightforward using the fact that the \( a_k \)'s are polynomially bounded to show that

\[
\lim_{n \to \infty} \phi(x/n)f(x) = f(x), \quad \lim_{n \to \infty} T\phi(x/n)f(x) = (Tf)(x)
\]

in \( L^2(\mathbb{R}) \), where \( Tf \) is the formal differential operator applied to \( f \). The fact that \( T \) is closed implies that \( f \in \mathcal{D}(T) \). Let \( \tilde{T} \) denote the closure of the formal operator \( T \), acting on \( \mathcal{C}_H(\mathbb{R}) \), then we have shown that \( \tilde{T} \) exists with \( \tilde{T} \subset T \). Hence to show that \( \mathcal{C}_H(\mathbb{R}) \) forms a core of \( T \), we must show that \( \mathcal{C}_H^\infty(\mathbb{R}) \subset \mathcal{D}(\tilde{T}) \). Let \( g \in \mathcal{C}_H^\infty(\mathbb{R}) \) then in the \( L^2 \) sense write

\[
g = \sum_{m \geq 0} b_m \psi_m.
\]

Define \( g_n = \sum_{m=0}^{n} b_m \psi_m \) then, since \( \tilde{T} \) is closed, it is enough to show that \( \tilde{T}g_n \) converges as \( n \to \infty \). Let \( H \) denote the closure of the operator \(-d^2/dx^2 + x^2\) with initial domain \( \mathcal{C}_H^\infty(\mathbb{R}) \) then \( H\psi_m = (2m+1)\psi_m \) and \( H \) is self-adjoint. Note also that \( g \in \mathcal{D}(H^n) \) for any \( n \in \mathbb{N} \). But \( \langle Hg, \psi_m \rangle = (2m+1)\langle g, \psi_m \rangle = (2m+1)b_m \), so \( \{(2m+1)|b_m|\} \) is square summable. We can repeat this argument any number of times to get that the coefficients \( b_m \) decay faster than any inverse polynomial. To prove the required convergence, it is enough to consider one of the terms \( a_k(x)\partial^k \) that defines \( \tilde{T} \) acting on \( \mathcal{C}_H(\mathbb{R}) \). The coefficient \( a_k(x) \) is polynomially bounded almost everywhere, and for some \( A_k \) and \( B_k \)

\[
\langle a_k \partial^k \psi_m, a_k \partial^k \psi_m \rangle \leq A_k^2 \int_{\mathbb{R}} (1 + |x|^{2B_k})^2 \partial^k \psi_m(x) \partial^k \psi_m(x) dx.
\]

But we can use the recurrence relations for the derivatives of the Hermite functions and orthogonality to bound the right hand side by a polynomial in \( m \). The convergence now follows since \( \tilde{T}g_n \) is a Cauchy sequence due to the rapid decay of the \( \{|b_m|\} \). Exactly the same argument works for \( T^* \). \( \square \)

Clearly, all of the above analysis holds in higher dimensions by considering tensor products

\[
\mathcal{C}_H(\mathbb{R}^d) := \text{span}\{\psi_{m_1} \otimes \ldots \otimes \psi_{m_d} : m_1, \ldots, m_d \in \mathbb{Z}_{\geq 0}\}
\]

of Hermite functions. We will abuse notation and write \( \psi_m = \psi_{m_1} \otimes \ldots \otimes \psi_{m_d} \). It will be clear from the context when we are dealing with the multi-dimensional case. In order to build the required algorithms with \( \Sigma_d^\alpha \) error control, we need to select an enumeration of \( \mathbb{Z}_{\geq 0}^d \) in order to represent \( T \) as an operator acting on \( l^2(\mathbb{N}) \). A simple way to do this is to consider successive half spheres \( S_n = \{m \in \mathbb{Z}_{\geq 0}^d : |m| \leq n\} \). We list \( S_1 \) as \( \{e_1, \ldots, e_{r_1}\} \) and given an enumeration \( \{e_1, \ldots, e_{r_n}\} \) of \( S_n \), we list \( S_{n+1} \setminus S_n \) as \( \{e_{r_{n+1}}, \ldots, e_{r_{n+1}}\} \). We will then list our basis functions as \( \psi = \psi_{e_1} \otimes \ldots \otimes \psi_{e_m} \). In practice, it is often more efficient (especially for large \( d \)) to consider other orderings such as the hyperbolic cross [71]. Now that we have a suitable basis, the next question to ask is how to recover the matrix elements of \( T \). In [4] the key construction is a function, that can be computed from the information given to us, \( \gamma_n(z, T) \), which also converges uniformly from above to \( ||R(z, T)||^{-1} \) on compact subsets of \( C \). Such a sequence of functions is given by

\[
\Psi_n(z, T) := \min\{\sigma_1((T - zI)|_{P_n(\mathbb{Z}(\mathbb{N}))}), \sigma_1((T^* - zI)|_{P_n(\mathbb{Z}(\mathbb{N}))})\}
\]

as long as the linear span of the basis forms a core of \( T \) and \( T^* \). In [4] we used the notion of bounded dispersion to approximate this function. Here we have no such notion, but we can use the information given to us to replace this. It turns out that to approximate \( \gamma_n(z, T) \), it suffices to use the following.
Lemma 5.2. Let $\epsilon > 0$ and $n \in \mathbb{N}$, and suppose that we can compute, with finitely many arithmetic operations and comparisons, the matrices
\[
\begin{align*}
\{W_n(z)\}_{ij} &= \langle (T - zI) e_j, (T - zI) e_i \rangle + E_{ij}^{n,1}(z) \\
\{V_n(z)\}_{ij} &= \langle (T - zI)^* e_j, (T - zI)^* e_i \rangle + E_{ij}^{n,2}(z)
\end{align*}
\]
for $1 \leq i, j \leq n$ where the entrywise errors $E_{ij}^{n,1}$ and $E_{ij}^{n,2}$ have magnitude at most $\epsilon$. Then
\[
\min\{\sigma_1(W_n), \sigma_1(V_n)\} \leq 2n\epsilon.
\]
It follows that if $\epsilon$ is known, we can compute $\Psi_n(z, T)^2$ to within $2n\epsilon$. If $\epsilon$ is unknown, then for any $\delta > 0$, we can compute $\Psi_n(z, T)^2$ to within $n\epsilon + \delta$. (In each case with finitely many arithmetic operations and comparisons.)

Proof. Given $\{W_n(z)\}_{ij}$, note that $\{W_n(z) + W_n^*(z)\}_{ij}/2$ still has an entry-wise absolute error bounded by $\epsilon$. Hence without loss of generality we can assume that the approximations $W_n(z)$ and $V_n(z)$ are self-adjoint. Call the matrices with no errors $\tilde{W}_n(z)$ and $\tilde{V}_n(z)$ then note that
\[
\min\{\sigma_1((T - zI)P_n(z^2)), \sigma_1((T^* - zI)P_n(z^2))\}^2 = \min\{\sigma_1(\tilde{W}_n), \sigma_1(\tilde{V}_n)\}
\]
and
\[
(5.2) \quad \left| \min\{\sigma_1(\tilde{W}_n), \sigma_1(\tilde{V}_n)\} - \min\{\sigma_1(W_n), \sigma_1(V_n)\} \right| \leq \max \left\{ \|W_n - \tilde{W}_n\|, \|V_n - \tilde{V}_n\| \right\}.
\]
But for a finite matrix $M$, we can bound $\|M\|$ by its Frobenius norm $\sqrt{\sum |M_{ij}|^2}$. Hence the right hand side of (5.2) is at most $n\epsilon$. In order to use finitely many arithmetic operations and comparisons, we note that given a self-adjoint positive semi-definite matrix $M$, we can compute $\sigma_1(M)$ to arbitrary precision using finitely many arithmetic operations and comparisons via the argument in the proof of Theorem 4.7. The lemma now follows. $\square$

Finally, we will need some results from the subject of quasi-Monte Carlo numerical integration, which we use to build the algorithm. Note that given no prior information on the coefficients and for large $d$, this is the type of approach one would use in practice. We start with some definitions and theorems which we include here for completeness. An excellent reference for these results is [77].

Definition 5.3. Let $\{t_1, \ldots, t_d\}$ be a sequence in $[0, 1]^d$ and let $K$ denote all subsets of $[0, 1]^d$ of the form $\prod_{k=1}^d [0, y_k)$ for $y_k \in [0, 1]$. Then we define the star discrepancy of $\{t_1, \ldots, t_d\}$ to be
\[
D^*_s(\{t_1, \ldots, t_d\}) = \sup_{K \in \mathcal{K}} \left| \frac{1}{\sum_{k=1}^d \chi_K(t_j)} - |K| \right|,
\]
where $\chi_K$ denotes the characteristic function of $K$.

Theorem 5.4. If $\{t_k\}_{k \in \mathbb{N}}$ is the Halton sequence in $[0, 1]^d$ in the pairwise relatively prime bases $q_1, \ldots, q_d$, then
\[
D^*_s(\{t_1, \ldots, t_d\}) < \frac{d}{j} + \frac{1}{j} \prod_{k=1}^d \left( \frac{q_k - 1}{\log(q_k)} \log(j) + \frac{q_k + 1}{2} \right).
\]

Note that given $d$ (and suitable $q_1, \ldots, q_d$), we can easily compute in finitely many arithmetic operations and comparisons a constant $C(d)$ such that the above implies
\[
D^*_s(\{t_1, \ldots, t_d\}) < C(d) \frac{(\log(j) + 1)^d}{j}.
\]

The following theorem says why this is useful.
Lemma 5.6. Consider the tensor product
\[ TV \]
Then
\[ \int f(x) dx \leq TV[f]D^\prime_j(\{t_1, ..., t_j\}). \]

By re-scaling, if \( f \) has bounded variation \( TV[-r,r]^d(f) \) and \( s_k = 2rt_k - (r, r, ..., r)^T \) then we obtain
\[ (2r)^d \sum_{k=1}^j f(s_k) - \int_{[-r,r]^d} f(x) dx \leq (2r)^d \cdot TV[-r,r]^d(f)D^\prime_j(\{t_1, ..., t_j\}). \]

Finally, in order to deal with our choice of basis, we need the following.

Theorem 5.5 (Koksma-Hlawka inequality \[77\]). If \( f \) has bounded variation \( TV[0,1]^d(f) \) on the hypercube \([0,1]^d\) then for any \( t_1, ..., t_j \) in \([0,1]^d\)
\[
\frac{1}{j} \sum_{j=1}^J f(t_k) - \int_{[0,1]^d} f(x) dx \leq TV[0,1]^d(f)D^\prime_j(\{t_1, ..., t_j\}).
\]

Proof. We will use an alternative form of the total variation which holds for smooth enough functions and can be found in \[77\]:
\[
TV[-r,r]^d(\psi_m) = \sum_{k=1}^d \int_{-r}^r \left| \frac{\partial^k \psi_m}{\partial x_{i_1} \cdots \partial x_{i_k}}(x) \right| dx_{i_1} \cdots dx_{i_k},
\]
where \( x_j = x_j \) for \( j = i_1, ..., i_k \) and \( x_j = r \) otherwise. We can use the recurrence relations for Hermite functions as well as Cramér’s inequality (which bounds the one-dimensional Hermite functions \[69\]) to gain the bound
\[
\int_{-r}^r \left| \frac{\partial^k \psi_m}{\partial x_{i_1} \cdots \partial x_{i_k}}(x) \right| dx_{i_1} \cdots dx_{i_k} \leq \left( 2r \sqrt{2(|m|+1)} \right)^k.
\]
It follows that
\[
TV[-r,r]^d(\psi_m) \leq \sum_{k=1}^d \left( 2r \sqrt{2(|m|+1)} \right)^k \sum_{1 \leq i_1 < \cdots < i_k \leq d} 1
\]
\[
= \sum_{k=1}^d \left( 2r \sqrt{2(|m|+1)} \right)^k \binom{d}{k} = \left( 1 + 2r \sqrt{2(|m|+1)} \right)^d - 1.
\]

\[ \Box \]

Proposition 5.7. Given \( T \in \Omega^1_{TV} \) or \( T \in \Omega^1_{AN} \) and \( \epsilon > 0 \), we can approximate the matrix values
\[
\langle (T - zI)\psi_m, (T - zI)\psi_n \rangle \quad \text{and} \quad \langle (T - zI)^*\psi_m, (T - zI)^*\psi_n \rangle
\]
to within \( \epsilon \) using finitely many arithmetical operations and comparisons of the relevant information (captured by \( \Xi^1 \) and \( \Xi^1 \)) in \[2.2\] given to us in each class.

Proof. Let \( T \in \Omega^1_{TV} \) or \( T \in \Omega^1_{AN} \) and \( \epsilon > 0 \). Recall that
\[
T = \sum_{|k| \leq N} a_k(x) \partial^k, \quad T^* = \sum_{|k| \leq N} \bar{a}_k(x) \partial^k,
\]
so by expanding out the inner products and also considering the case \( a_k = 1 \), it is sufficient to approximate
\[
\langle a_k \partial^k \psi_m, a_j \partial^j \psi_n \rangle \quad \text{and} \quad \langle \bar{a}_k \partial^k \psi_m, \bar{a}_j \partial^j \psi_n \rangle
\]
for all relevant \( k, j \), \( m \) and \( n \). Due to the symmetry in the assumptions of \( T \) and \( T^* \), we only need to show that one can compute the first inner product, the proof for the second one is identical. Note that by the specific choice of the basis functions \( \psi_m \) it follows that \( \partial^k \psi_m \) can be written as a finite linear combination of tensor products of Hermite functions using the recurrence relations (the coefficients in the linear combinations are thus recursively defined as a function of \( k \)). Hence, in the inner product, we can assume that there are no
partial derivatives. In doing this, we have assumed that we can compute square roots of integers (which occur in the coefficients) to arbitrary precision (recall we want an arithmetic tower) which can be achieved by a simple interval bisection routine. It follows that we only need to consider approximations of inner products of the form $\langle a_k \psi_m, a_j \psi_n \rangle$.

To do so let $R > 1$ then, by Hölder’s inequality and the assumption of polynomially bounded growth on the coefficients $a_k$, we have

$$\int_{|x| \geq R} |a_k \psi_m| |\psi_n| \, dx$$

$$\leq A_k A_j \left( \int_{|x| \geq R} (1 + |x|^{2B_k})^2 (1 + |x|^{2B_j})^2 \psi_m(x)^2 \, dx \right)^{1/2} \left( \int_{|x| \geq R} \psi_n(x)^2 \, dx \right)^{1/2}.$$

The first integral on the right hand side can be bounded by

$$16 \int_{\mathbb{R}^d} |x|^{2B} \psi_m(x)^2 \, dx \leq 16 \int_{\mathbb{R}^d} (x_1^{2} + \ldots + x_d^{2})^B \psi_m(x)^2 \, dx,$$

for $B = 4(B_k + B_j)$, since we restrict to $|x_i| \geq R$ with $R > 1$ and $|x| \leq \|x\|_2$. $B$ is even so we can expand out the product $(x_1^{2} + \ldots + x_d^{2})^B \psi_m$ using the recurrence relations for the Hermite functions. In one dimension this gives

$$x \psi(x)_m = \sqrt{\frac{m}{2}} \psi_{m-1}(x) + \sqrt{\frac{m+1}{2}} \psi_{m+1}(x),$$

$$x^2 \psi_m(x) = \sqrt{\frac{m}{2}} \psi_{m-1}(x) + \sqrt{\frac{m+1}{2}} \psi_{m+1}(x),$$

$$= \sqrt{\frac{m}{2}} \left( \frac{m-1}{2} \psi_{m-2}(x) + \frac{m+1}{2} \psi_m(x) \right) + \sqrt{\frac{m+1}{2}} \left( \frac{m+1}{2} \psi_m(x) + \frac{m+2}{2} \psi_{m+2}(x) \right),$$

and so on. We can do the same for tensor products of Hermite functions. In particular, multiplying a tensor product of Hermite functions, $\psi_m$, by $(x_1^{2} + \ldots + x_d^{2})$ induces a linear combination of at most $4d$ such tensor products, each with a coefficient of magnitude at most $(|m| + 2)^2$ and index with $l^\infty$ norm bounded by $|m| + 2$ (allowing repetitions). It follows that $(x_1^{2} + \ldots + x_d^{2})^B \psi_m$ can be written as a linear combination of at most $(4d)^{B/2}$ such tensor products, each with a coefficient of magnitude at most $(|m| + B)^B$. Squaring this and integrating, the orthogonality and normalisation of the tensor product of Hermite functions implies that

$$16 \int_{\mathbb{R}^d} (x_1^{2} + \ldots + x_d^{2})^B \psi_m(x)^2 \, dx \leq 16(4d)^{B/2} (|m| + B)^{2B} =: p_2(|m|).$$

For the other integral, define $p_2(|n|) := 4d(|n| + 2)^4$. We then have

$$\int_{|x| \geq R} |x|^2 \psi_n^2 \, dx \leq \frac{1}{R^4} \int_{\mathbb{R}^d} |x|^4 \psi_n^2 \, dx \leq \frac{p_2(|n|)}{R^4},$$

by using the same argument as above but with $B = 2$.

So given $\delta > 0$ and $n, m, B, A_k, A_j, (and \ d)$ we can choose $r \in \mathbb{N}$ large such that

$$\int_{|x| \geq R} |a_k \psi_m| |\psi_n| \, dx \leq A_k A_j \frac{p_1(|m|)^{1/2} p_2(|n|)^{1/2}}{r^2} \leq \delta.$$

We now have to consider the cases $T \in \Omega^2$ or $T \in \Omega^1$ separately, noting that it is sufficient to approximate the integral $\int_{|x| \leq r} a_k \psi_m |\psi_n| \, dx$ to any given precision. For notational convenience, let

$$L_r(m) = \left[ 1 + \sigma \left( \left( 1 + 2r \sqrt{2(|m| + 1)} \right)^d - 1 \right) \right]$$

so that with $\sigma = 3^d + 1$ as in the definition of $\| \cdot \|_{A_r}$, we have via Lemma $5.6$ that $\|\psi_m\|_{A_r} \leq L_r(m)$.
Case 1: \( T \in \Omega_{MV} \). Given \( k, j, m, n, \delta \) and \( r \in \mathbb{N} \) as above, choose \( M \) large such that
\[
(2r)^d \cdot \frac{C(d) \left( \log(M) + 1 \right)^d}{M} \cdot c_r \cdot L_r(m) \cdot L_r(n) \leq \delta/2,
\]
where \( C(d) \) is as in (5.3) and \( c_r \) controls the total variation as in (2.6). Again, note that such an \( M \) can be chosen in finitely many arithmetic operations and comparisons with the given data and assuming that logarithms and square roots can be computed to arbitrary precision (say by a power series representation and bound on the remainder). Using the fact that \( \mathcal{A}_r \) is a Banach algebra (in particular we can bound the norms of product of functions by the product of their norms) and Theorem 5.5 it follows that
\[
(5.7) \quad \left| \frac{(2r)^d}{M} \sum_{l=1}^{M} a_k(s_l) \overline{\tau_l}(s_l) \psi_m(s_l) \psi_n(s_l) - \int_{|x| \leq r} a_k \overline{\tau_l} \psi_m \psi_n dx \right| \leq \delta/2,
\]
where \( s_l = 2rt_l - (r, r, \ldots, r)^T \) are the rescaled Halton points. Hence it is enough to show that each product \( a_k(s_l) \overline{\tau_l}(s_l) \psi_m(s_l) \psi_n(s_l) \) can be computed to a given accuracy using finitely many arithmetic operations and comparisons. Since each \( s_l \in \mathbb{Q}^d \) we can evaluate \( a_k(s_l) \overline{\tau_l}(s_l) \). Note that we can compute \( \exp(-x^2/2) \) to arbitrary precision with finitely many arithmetic operations and comparisons (again say by a power series representation and bound on the remainder) and that we can compute the coefficients of the polynomials \( Q_m \) with \( \psi_m(x) = Q_m(x) \exp(-x^2/2) \), using the recursion formulae to any given precision, it follows that we can compute \( \psi_m(s_l) \psi_n(s_l) \) to a given accuracy using finitely many arithmetic operations and comparisons. Using the bounds on the \( a_k \) and \( \overline{\tau_l} \) and Cramér’s inequality, we can bound the error in the product and hence the result follows.

Case 2: \( T \in \Omega_{\Lambda} \). On the compact cube \( |x_i| \leq r \) the double series
\[
a_k(x)a_j(x) = \sum_{t \in \mathbb{Z}_{\geq 0}^d} \sum_{s \in \mathbb{Z}_{\geq 0}^d} a_k^t \overline{\tau_j}^s x^{t+s}
\]
converges uniformly (recall that \( \{a_k^t\}_{t \in \mathbb{Z}_{\geq 0}^d} \) are the power series coefficients for \( a_k \)) so we can exchange the series and integration to write
\[
\int_{|x| \leq r} a_k \overline{\tau_j} \psi_m \psi_n dx = \sum_{t \in \mathbb{Z}_{\geq 0}^d} \sum_{s \in \mathbb{Z}_{\geq 0}^d} a_k^t \overline{\tau_j}^s \int_{|x| \leq r} x^{t+s} \psi_m \psi_n(x) dx.
\]
But \( \int_{|x| \leq r} x^{t+s} \psi_m(x) \psi_n(x) dx \) is bounded by \( r^{\ell(t+|s|)} \int_{x \in \mathbb{R}^d} |\psi_m| |\psi_n| dx \leq r^{\ell(t+|s|)} \), by Hölder’s inequality. Let \( \tau = r/(r + 1) \), then using the fact that we know \( d_\ell \) in (2.8), we can bound the tail of the series in (5.8) by
\[
d_\ell^2 \sum_{|t|, |s| > M} r^{\ell(t+|s|)} \leq d_\ell^2 \sum_{|t| > M} r^{\ell(t+1) + \cdots + |s|_d} \left( \sum_{|t| > M} r^{\ell(t+1) + \cdots + |s|_d} \right)^2,
\]
using the fact that \( |x| \leq \langle |x_1| + \cdots + |x_d| \rangle/d \). We can explicitly sum this series (as the difference of geometric series) to gain the bound
\[
d_\ell^2 \left[ \frac{1 - (1 - \tau^{(M+1)/d})^d}{(1 - 1/r^{d})^d} \right]^2.
\]
Given \( r \) and \( d_\ell \) (and \( d \)) we can keep increasing \( M \) and evaluating the bound (strictly speaking an upper bound accurate to \( 1/M \) say), to choose \( M \) large such that the tail is smaller than \( \delta/2 \) for any given \( \delta > 0 \). It follows that it is enough to estimate integrals of the form \( \int_{|x| \leq r} x^{t+s} \psi_m(x) \psi_n(x) dx \). Using the recurrence relations for Hermite functions and writing \( \psi_m(x) = Q_m(x) \exp(-x^2/2) \), it is enough to split the multi-dimensional integral up as products and sums of one-dimensional integrals of the form \( \int_{x^a} x^a \exp(-x^2) dx \), for \( a \in \mathbb{Z}_{\geq 0} \).

Again, we have assumed that we can compute the coefficients of the \( Q_m \) to any given accuracy using finitely many arithmetic operations and comparisons and using this we can bound the total error of the expression by \( \delta/2 \). The above integral vanishes unless \( a \) is even, so integration by parts (again assuming we can evaluate
exp(−x²) to any desired accuracy) reduces this to estimating \( \int_{-r}^{r} \exp(−x²)dx \). Consider the Taylor series for \( \exp(−x²) \). The tail can be bounded by

\[
\sum_{k>N} \frac{r^{2k}}{k!} \leq \frac{r^{2N}}{N!} \exp(−r²).
\]

Integrating this estimate over the interval \([-r, r]\), we can bound this by any given \( \eta > 0 \) by choosing \( N \) large enough. We can then explicitly compute \( \int_{-r}^{r} \sum_{k\leq N} r^{2k}/k! dx \). Keeping track of all the errors is elementary and hence \( \int_{|x|\leq r} a_k \bar{\psi}_m \psi_n dx \) can be computed with finitely many arithmetic operations and comparisons as required. \( \square \)

In some cases, we can also directly compute matrix elements without the cut-off argument used in the above proof. For instance, if each \( a_k(x) \) (and hence \( \bar{a}_k(x) \)) is a polynomial then we can simply integrate the power series to compute \( \langle a_k(x) \psi_m, a_j(x) \psi_n \rangle \) and use the recurrence relations for Hermite functions. If we know a bound on the degree of the polynomials, then clearly we can compute

\[
\langle (T - zI) \psi_m, (T - zI) \psi_n \rangle \quad \text{and} \quad \langle (T - zI)^* \psi_m, (T - zI)^* \psi_n \rangle
\]

to within \( \epsilon \) using finitely many arithmetical operations and comparisons directly. Even if we do not know the degree of the polynomials and are only promised that each \( a_k(x) \) is a polynomial, then we can successively approximate by more terms of the power series and eventually compute \( 5.9 \) to within \( \epsilon \) using finitely many arithmetical operations and comparisons. Though we do not know when the given accuracy has been reached (recall that we only know a finite portion of the coefficients \( c_1, c_2, \ldots \), at any one time for \( T \in \Omega_{\Lambda N}^1 \)).

**Remark 5.8.** Note that in the analytic case when \( T \in \Omega_{\Lambda N}^1 \), integrating the power series term by term will not always converge. For instance, if we consider \( a_k(x) = \exp(−x²) \) and \( a_j(x) = 1 \) in one dimension, then

\[
\langle x^{2k} \psi_0, \psi_0 \rangle = \frac{\Gamma \left( \frac{2k+1}{2} \right)}{\pi},
\]

with \( \Gamma \) denoting the usual gamma function. It follows that the series \( \sum_{k\geq 0} (x^{2k} \psi_0, \psi_0) / k! \) does not converge. However, the technique used in our method always converges.

We can now prove the positive parts of Theorems 2.9 and 2.11.

**Proof of inclusions in Theorems 2.9 and 2.11**

**Step 1:** \( \{ \Xi_1, \Omega_{TV}^1 \}, \{ \Xi_2, \Omega_{AN}^1 \} \in \Sigma_{\Delta}^A \). The proof of this simply strings together the above results. The linear span of \{\( e_1, e_2, \ldots \)\} (the re-ordered Hermite functions) is a core of \( T \) and \( T^* \) by Proposition 5.1. By Proposition 5.7 we can compute the inner products \( \langle (T - zI) e_j, (T - zI) e_i \rangle \) and \( \langle (T - zI)^* e_j, (T - zI)^* e_i \rangle \) up to arbitrary precision with finitely many arithmetic operations and comparisons. Using Lemma 5.2 given \( z \in \mathbb{C} \), we can compute some approximation \( v_n(z, T) \) in finitely many arithmetic operations and comparisons such that

\[
|v_n(z, T)|^2 - \min\{\sigma_1((T - zI)|_{P_n(zT)}), \sigma_1((T^* - zI)|_{P_n(zT)}))\}^2| \leq \frac{1}{n^2}.
\]

We now set

\[
\gamma_n(z, T) = v_n(z, T) + 1/n.
\]

Then \( \gamma_n \) satisfies the hypotheses of Proposition 4.5. The proof of Theorem 2.3 also makes clear that we have error control since \( \gamma_n(z, T) \geq \|R(z, T)\|^{-1} \).

**Step 2:** \( \{ \Xi_2, \Omega_{TV}^2 \}, \{ \Xi_2, \Omega_{AN}^1 \} \in \Sigma_{\Delta}^A \). Consider the sequence of functions \( \gamma_n \) defined by equation (5.10). These converge uniformly to \( \|R(z, T)\|^{-1} \) on compact subsets of \( \mathbb{C} \) and satisfy \( \gamma_n(z, T) \geq \|R(z, T)\|^{-1} \). We can now apply Proposition 4.6.

**Step 3:** \( \{ \Xi_2, \Omega_{TV}^2 \}, \{ \Xi_2, \Omega_{AN}^2 \} \in \Delta_{\Delta}^A \). Let \( T \in \Omega_{TV}^2 \). Our strategy will be to compute the inner products \( \langle (T - zI) e_j, (T - zI) e_i \rangle \) and \( \langle (T - zI)^* e_j, (T - zI)^* e_i \rangle \) to an error which decays rapidly enough as
we let the cut-off parameter $r$ tend to $\infty$. We follow the proof of Proposition 5.7 closely. Recall that given $n, m$, we can choose $r \in \mathbb{N}$ large such that

$$\int_{|x_i| \geq r} |a_k \alpha_j| \psi_m \psi_n \, dx \leq A_k A_j \frac{p_1(|m|)|n|^{1/2}}{r^2},$$

with the crucial difference that now we do not assume we can compute $A_k, A_j, p_1$ or $p_2$. It follows that there exists some polynomial $p_3$, with coefficients not necessarily computable from the given information, such that

$$\int_{|x_i| \geq r} |a_k \alpha_j| \psi_m \psi_n \, dx \leq \frac{p_3(|m|, |n|)}{r^2},$$

for all $|j|, |k| \leq N$. Now we use the sequence $b_r$ to bound the error in the integral over the compact cube asymptotically. We assume without loss of generality that $b_r$ is increasing monotonically to $\infty$ with $r$. Using Halton sequences and the same argument in the proof of Proposition 5.7, we can approximate $\int_{|x_i| \leq r} a_k \alpha_j \psi_m \psi_n \, dx$, with an error that, asymptotically up to some unknown constant, is bounded by

$$r^d \left( \frac{\log(M) + 1}{M} \right)^d \cdot b_r^2 \cdot L_r(m) \cdot L_r(n),$$

where $M$ is the number of Halton points. We can let $M$ depend on $r, n$ and $m$ such that (5.11) is bounded by a constant times $1/r^2$. It follows that we can bound the total error in approximating $\langle a_k \psi_m, a_j \psi_n \rangle$ for any $j, k$ by $p_3(|m|, |n|)/r^2$, by making the coefficients of $p_3$ larger if necessary. We argue similarly for the adjoint and note that $\langle (T - zI) \psi_m, (T - zI) \psi_n \rangle$ and $\langle (T - zI)^* \psi_m, (T - zI)^* \psi_n \rangle$ are both approximated to within

$$(1 + |z|^2) \frac{P(|m|, |n|)}{r^2},$$

for some unknown polynomial $P$. Hence we can apply Lemma 5.2 (the form where we do not know the error in inner product estimates), changing the polynomial $P$ to take into account the basis mapping from $\mathbb{Z}_{\geq 0}^d$ to $\mathbb{N}$ to some polynomial $Q$, to gain some approximation $v_n(z, T)$ in finitely many arithmetic operations and comparisons such that

$$|v_n(z, T)^2 - \min\{\sigma_1((T - zI)|P_n(\mathbb{Z}(N))), \sigma_1((T^* - zI)|P_n(\mathbb{Z}(N)))\}| \leq \frac{n(1 + |z|^2)Q(n)}{r(n, z)^2} + \frac{1}{n^3}.$$

We now choose $r(z, n)$ larger if necessary such that $r(z, n) \geq (1 + |z|^2) \exp(n)$. We now set $\gamma_n(z, T) = v_n(z, T) + 1/n$. Then $\gamma_n$ satisfies the hypotheses of Proposition 4.5 and Proposition 4.6 since the error in (5.12) decays faster than $1/n^2$. We can use these propositions to build the required arithmetical algorithm.

**Step 4:** $\{\Xi_1^n, \Omega_{1N}^n\}, \{\Xi_2^n, \Omega_{2N}^n\} \in \Delta_N^2$. We argue as in step 3. To control the error in the approximation of the integral over a compact hypercube, choose the cut-off $M(r)$ such that

$$\sum_{|t|: |s| > M(r)} \left( \frac{r}{r + 1} \right)^{|t| + |s|} \leq \frac{1}{b_r^2 r^2}.$$

It follows that there exists some (unknown) constant $B$ such that we can bound the error in approximating $\int_{|x_i| \leq r} a_k \alpha_j \psi_m \psi_n \, dx$ by $B/r^2$ where we have absorbed the arbitrarily small error that comes from approximating the integral of the truncated power series using finitely many arithmetic operations and comparisons. The rest of the argument is the same as in step 3. 

**5.2. Proofs of Impossibility Results in Theorems 2.9 and 2.11** We first deal with Theorem 2.9. Recall the maps

$$\Xi_j, \Xi_2 : \Omega_{1TV}^2, \Omega_{2TV}^2 \ni T \mapsto \begin{cases} \text{Sp}(T) \in \mathcal{MAW} & j = 1 \\ \text{Sp}_c(T) \in \mathcal{MAW} & j = 2, \end{cases}$$

We split up the arguments to deal with $\Omega_{1TV}^2$ and then $\Omega_{2TV}^2$. 

Proof that \( \{ \Xi_j, \Omega^1_{TV} \} \notin \Delta^G_1 \). Suppose first for a contradiction that a height one tower, \( \Gamma_n \), exists for the problem \( \{ \Xi_1, \Omega^1_{TV} \} \) such that \( d_{AW}(\Gamma_n(T), \Xi_1(T)) \leq 2^{-n} \). We will deal with the one-dimensional case and higher dimensions are similar. Let \( \rho(x) \) be any smooth bump function with maximum value 1, minimum value 0 and support \([0, 1]\). Let \( \rho_n \) denote the translation of \( \rho \) to have support \([n, n + 1]\). We will consider the two (self-adjoint and bounded) operators

\[
(T_0 u)(x) = 0, \quad (T_m u)(x) = \rho_m(x) u(x),
\]

which have spectra \( \{0\} \) and \([0, 1]\) respectively. For these we can take the polynomial bound (the \( \{ A_k \} \) and \( \{ B_k \} \) to be 1 and the total variation bound to be \( c_r = 1 + \sigma \text{TV}_{[0,1]}(\rho) \). When we compute \( \Gamma_2(T_0) \), we only use finitely many evaluations of the coefficient function \( a_0(x) = 0 \) (as well as the other given information). We can then choose \( m \) large such that the support of \( \rho_m \) does not intersect the points of evaluation. By assumptions (ii) and (iii) in Definition 3.1, \( \Gamma_2(T_m) = \Gamma_2(T_0) \). But this contradicts the triangle inequality since \( d_{AW}(\{0\}, [0,1]) \geq 1 \)

To argue for the pseudospectrum let \( \epsilon > 0 \) and note that \( 2\epsilon \notin \text{Sp}_s(T_0) \) but \( 2\epsilon \in \text{Sp}_s(\epsilon T_m) \). We now alter the given \( c_r \) to \( \epsilon(1 + \sigma \text{TV}_{[0,1]}(\rho)) \) and the polynomial bound to \( \epsilon \). The argument is now exactly as before. Namely, we choose \( n \) large such that

\[
d_{AW}(\Gamma_n(T_0), [-\epsilon, 2\epsilon]) > 2^{-n}
\]

then choose \( m \) large such that \( \Gamma_n(T_0) = \Gamma_n(\epsilon T_m) \).

\( \square \)

Proof that \( \{ \Xi_j, \Omega^2_{TV} \} \notin \Sigma^G_1 \cup \Pi^G_1 \). Suppose first of all that a \( \Sigma^G_1 \) tower, \( \Gamma_n \), exists for \( \{ \Xi_1, \Omega^2_{TV} \} \). We will deal with the one-dimensional case and higher dimensions are similar. Consider the operators

\[
(T_0 u)(x) = 0, \quad (T_1 u)(x) = f(x) u(x),
\]

where we define \( f \) in terms of \( \Gamma_n \) as follows. We will ensure that \( f(x) = 1 \) except for finitely many values of \( x \) where it takes the value 0 and hence \( T_0 \) and \( T_1 \) have spectra \( \{0\} \) and \( \{1\} \) respectively and are both self-adjoint. Note that once the zeros of \( f \) are fixed, this choice ensures that \( f \) has total variation bounded by a constant on any hypercubce and hence we may take \( b_r = 1 \) for all \( r \in \mathbb{N} \). There exists some \( n \) such that \( \Gamma_n(T_0) \) contains \( z_n \in B_{1/n}(0) \) with a guaranteed error estimate of \( \text{dist}(z_n, \text{Sp}(T_0)) \leq 1/4 \). But \( \Gamma_n(T_0) \) can only depend on finitely many evaluations of 0 (as well as \( b_r = 1 \) and the trivial choice of \( g_j(x) = x \)). We choose \( f \) to be zero at precisely these evaluation points. By assumptions (ii) and (iii) in Definition 3.1, \( \Gamma_n(T_1) = \Gamma_n(T_0) \), including the given error estimates, which is the required contradiction.

For \( \{ \Xi_2, \Omega^3_{TV} \} \notin \Sigma^G_1 \), given \( \epsilon > 0 \) we replace \( f \) by \( 3\epsilon f \) in the above argument and keep all other inputs the same. Hence \( T_0 \) and \( T_1 \) have \( \epsilon \)-pseudospectra \( [-\epsilon, \epsilon] \) and \( [2\epsilon, 4\epsilon] \) respectively. We note that again there exists some \( n \) such that \( \Gamma_n(T_0) \) contains \( z_n \in B_{1/8}(0) \) with a guaranteed error estimate of \( \text{dist}(z_n, \text{Sp}(T_0)) \leq \epsilon/4 \). But \( \Gamma_n(T_0) \) can only depend on finitely many evaluations of 0 (as well as \( b_r = 1 \) and the trivial choice of \( g_j(x) = x \)). We choose \( f \) to be zero at precisely these evaluation points. By assumptions (ii) and (iii) in Definition 3.1, \( \Gamma_n(T_1) = \Gamma_n(T_0) \), including the given error estimates, which is the required contradiction.

To argue that neither problem lies in \( \Pi^G_1 \), we can use the same arguments in the proof that \( \{ \Xi_j, \Omega^1_{TV} \} \notin \Delta^G_1 \). The only change now is that the algorithm, \( \Gamma_n \), used to derive the contradiction provides \( \Pi^G_1 \) information rather than \( \Delta^G_1 \). For the spectrum, we consider the operators

\[
(T_0 u)(x) = 0 \quad \text{and} \quad (T_m u)(x) = \rho_m(x) u(x),
\]

and choose \( n \) large such that \( \Gamma_n(T_0) \) produces the guarantee \( \text{Sp}(T_0) \cap B_{1/4}(0)^c = \emptyset \). For \( m \) sufficiently large, we argue as before to get \( \Gamma_n(T_m) = \Gamma_n(T_0) \), including the guarantee, the required contradiction. Again a similar argument works for the pseudospectrum by rescaling \( T_m \) to \( 2\epsilon T_m \). \( \square \)
We now deal with the impossibility results in Theorem 2.11 where

\[ \Xi_j^1, \Xi_j^2 : \Omega_{AN}^1, \Omega_{AN}^2 \to \left\{ \begin{array}{ll} \text{Sp}(T) \in \mathcal{M}_{AW} & j = 1 \\
\text{Sp}_s(T) \in \mathcal{M}_{AW} & j = 2. \end{array} \right. \]

**Proof that** \( \{ \Xi_j^3, \Omega_{AN}^1 \} \not\in \Delta^G_1 \). Suppose for a contradiction that a height one tower, \( \Gamma_n \), exists for \( \{ \Xi_j^3, \Omega_{AN}^1 \} \) such that \( d_{AW}(\Gamma_n(T), \Xi_j^3(A)) \leq 2^{-n} \). Now consider the two (self-adjoint and bounded) operators

\[ (T_1 u)(x) = 0 \quad \text{and} \quad (T_2 u)(x) = x^k \exp(-x^2)u(x)/s_k, \]

where \( k \) is even and will be chosen later. We choose \( s_k \) such that the range of the function is \( x^k \exp(-x^2)/s_k \) is \([0, 1]\) and hence \( T_2 \) has spectrum \([0, 1]\). We can take the polynomial bounding function to be the constant 1 for both operators and must show that we can use the same \( d_r \) for both operators in (2.8), independent of \( k \). Simple calculus yields that \( s_k = (k/(2e))^k/2 \). It follows that such a \( d_r \) must satisfy

\[ (\frac{2e}{k})^{k/2}(r + 1)^{2m + k} / m! \leq d_r, \quad \forall k \in 2\mathbb{N}, m \in \mathbb{Z}_{\geq 0}. \]

Hence it suffices to show that the function on the left hand side of (5.13) is bounded (as a function of \( m, k \) for all \( r \in \mathbb{N} \)). Using Stirling's approximation (explicitly the bounds on \( m! \)) this will follow if we can show

\[ \frac{x^{2m + k}}{k^{2m + 1/2}} \leq \left( \frac{r}{\sqrt{k}} \right)^k \left( \frac{r}{\sqrt{m}} \right)^{2m} \]

is bounded for all \( r \in \mathbb{N} \) (now with \( m > 1 \)). But this is obvious.

We can now choose \( k \) (which depends on the algorithm \( \Gamma_n \)) to gain a contradiction. Since \( \text{Sp}(T_1) = \{0\} \) and \( 1 \in \text{Sp}(T_2) \) for all even \( k \), there exists \( n \) such that \( \text{dist}(1, \Gamma_n(T_i)) > 1/4 \) but \( \text{dist}(1, \Gamma_n(T_2)) < 1/4 \). However, \( \Gamma_n(T) \) can only depend on finitely many of the coefficients \( \{c_j\} \), say \( c_1, \ldots, c_{\tilde{N}(T,n)} \), of \( T \) (as well as the other given information). By assumption (iii) in Definition 3.1 we can choose \( k \) such that the coefficient corresponding to \( x^k \), call it \( c_{\tilde{N}(T,n)} \), has \( l_k > \tilde{N}(T,n) \) and get \( \Gamma_n(T_1) = \Gamma_n(T_2) \), the required contradiction.

To show \( \{ \Xi_j^3, \Omega_{AN}^1 \} \not\in \Delta^G_1 \) uses exactly the same argument as above. In order to gain the necessary separation \( 3\epsilon \not\in \text{Sp}(T_1) \) but \( 3\epsilon \in \text{Sp}(T_2) \). We rescale \( T_2 \) to \( 3\epsilon T_2 \). Then there exists \( n \) such that \( \text{dist}(3\epsilon, \Gamma_n(T_2)) < \epsilon/2 \) but \( \text{dist}(3\epsilon, \Gamma_n(T_1)) > \epsilon/2 \). The rest of the contradiction follows. \( \square \)

**Proof that** \( \{ \Xi_j^4, \Omega_{AN}^2 \}, \{ \Xi_j^4, \Omega_{AN}^1 \} \not\in \Sigma^G_1 \). Since \( \Omega_p \subset \Omega_{AN}^2 \), it is enough to show the results for \( \Omega_p \).

Suppose for a contradiction that there exists a \( \Sigma^G_1 \) algorithm, \( \Gamma_n \), for \( \{ \Xi_j^1, \Omega_p \} \). Consider

\[ (T_1 u)(x) = xu(x) \quad \text{and} \quad (T_2 u)(x) = (x - x^k)u(x), \]

where \( k \) is even and chosen later. (\( T_j \pm iC_0^\infty(\mathbb{R}) \) are dense in \( L^2(\mathbb{R}) \) with \( T_j \) initially defined on \( C_0^\infty(\mathbb{R}) \) symmetric.) It follows that the closure of \( T_j|_{C_0^\infty(\mathbb{R})} \) is self-adjoint and hence that \( T_j \in \Omega_p \). Note that \( \text{Sp}(T_1) = \mathbb{R} \) but \( \text{Sp}(T_2) \subset (-\infty, 1] \). Now choose \( n \) such that \( \Gamma_n(T_1) \) contains a point \( z_n \in B_{1/4}(2) \) with a guaranteed error estimate of \( \text{dist}(z_n, \text{Sp}(T_1)) \leq 1/4 \). However, \( \Gamma_n(T) \) can only depend on the first \( \tilde{N}(T,n) \) coefficients, \( c_1, \ldots, c_{\tilde{N}(T,n)} \) of \( T \) (as well as the trivial choice \( g_k = x \) and the numbers \( b_k = n! \)). By assumption (iii) in Definition 3.1 we can choose \( k \) such that the coefficient corresponding to \( x^k \), call it \( c_{r_k} \), has \( r_k > \tilde{N}(T,n) \) and get \( \Gamma_n(T_1) = \Gamma_n(T_2) \), the required contradiction. Similarly by rescaling as above, we get \( \{ \Xi_j^1, \Omega_p \} \not\in \Sigma^G_1 \).

To show \( \{ \Xi_j^1, \Omega_p \} \not\in \Pi^G_1 \) we argue the same way, but now set \( (T_1 u)(x) = 0 \) and \( (T_2 u)(x) = x^k u(x) \). As before, \( T_j \in \Omega_p \), but now \( \text{Sp}(T_1) = \{0\} \) and \( 1 \in \text{Sp}(T_2) \). Choose \( n \) such that \( \Gamma_n(T_1) \) produces the guarantee \( \text{Sp}(T_1) \cap B_{1/4}(0)^C = \emptyset \). Again, choose \( k \) such that \( c_{r_k} \) has \( r_k > \tilde{N}(T,n) \) and get \( \Gamma_n(T_1) = \Gamma_n(T_2) \), the required contradiction. Rescaling and using the same argument shows \( \{ \Xi_j^1, \Omega_p \} \not\in \Pi^G_1 \). \( \square \)
6. PROOFS OF THEOREMS ON DISCRETE SPECTRA

Here we prove our results related to the discrete spectrum. We need some results on finite section approximations to the discrete spectrum of a Hermitian operator below the essential spectrum. There are two cases to consider; either there are infinitely many eigenvalues below the essential spectrum, or there are only finitely many. The following are well-known and follow from the ‘min-max’ theorem characterising eigenvalues.

**Lemma 6.1.** Let $B \in \mathcal{B}(l^2(\mathbb{N}))$ be self-adjoint with eigenvalues $\lambda_1 \leq \lambda_2 \leq \ldots$ (infinitely many, counted according to multiplicity) below the essential spectrum. Consider the finite section approximates $B_n = P_nBP_n \in \mathbb{C}^n$ and list the eigenvalues of $B_n$ as $\mu_1^\circ \leq \mu_2^\circ \leq \ldots \leq \mu_n^\circ$. Then the following hold:

1. $\lambda_j \leq \mu_j^\circ$ for $j = 1, \ldots, n$,
2. For any $j \in \mathbb{N}$, $\mu_j^\circ \downarrow \lambda_j$ as $n \to \infty$ ($n \geq j$ so that $\mu_j^\circ$ makes sense).

**Lemma 6.2.** Let $B \in \mathcal{B}(l^2(\mathbb{N}))$ be self-adjoint with finitely many eigenvalues $\lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_m$ (counted according to multiplicity) below the essential spectrum and let $a = \inf \{x : x \in \text{Sp}_{\text{ess}}(B)\}$. For $j > m$ we set $\lambda_j = a$. Consider the finite section approximates $B_n = P_nBP_n \in \mathbb{C}^n$ and list the eigenvalues of $B_n$ as $\mu_1^\circ \leq \mu_2^\circ \leq \ldots \leq \mu_n^\circ$. Then the following hold:

1. $\lambda_j \leq \mu_j^\circ$ for $j = 1, \ldots, n$,
2. For any $j \leq m$, $\mu_j^\circ \downarrow \lambda_j$ as $n \to \infty$ ($n \geq j$ so that $\mu_j^\circ$ makes sense),
3. Given $\epsilon > 0$ and $k \in \mathbb{N}$, there exists $N$ such that for all $n \geq N$, $\mu_k^\circ \leq a + \epsilon$.

**Proof of Theorem 2.15.**

**Step 1:** $\{\Xi_1^d, \Omega_1^d\} \notin \Delta_1^d$. Suppose this were false and that there exists some height one tower $\Gamma_n$ solving the problem. Consider the matrix operators $A_m = \text{diag}\{0, 0, \ldots, 0, 2\} \in \mathbb{C}^{m \times m}$ and $C = \text{diag}\{0, 0, \ldots\}$ and set

$$A = \text{diag}\{1, 2\} \oplus \bigoplus_{m=1}^\infty A_{km},$$

where we choose an increasing sequence $k_m$ inductively as follows. Set $k_1 = 1$ and suppose that $k_1, \ldots, k_m$ have been chosen. $\text{Sp}_d(\text{diag}\{1, 2\} \oplus A_{k_1} \oplus A_{k_2} \oplus \ldots \oplus A_{k_m} \oplus C) = \{1, 2\}$ is closed and so there exists some $n_m \geq m$ such that if $n \geq n_m$ then

$$\text{dist}(2, \Gamma_n(\text{diag}\{1, 2\} \oplus A_{k_1} \oplus \ldots \oplus A_{k_m} \oplus C) \leq \frac{1}{4}.$$ (6.1)

Now let $k_{m+1} \geq \max\{N(\text{diag}\{1, 2\} \oplus A_{k_1} \oplus \ldots \oplus A_{k_m} \oplus C, n_m), k_m + 1\}$. Arguing as in the proof of Theorem 2.4 it follows that $\Gamma_{n_m}(A) = \Gamma_{n_m}(\text{diag}\{1, 2\} \oplus A_{k_1} \oplus \ldots \oplus A_{k_m} \oplus C)$. But $\Gamma_{n_m}(A)$ converges to $\text{Sp}_d(A) = \{1\}$, contradicting (6.1).

**Step 2:** $\{\Xi_1^d, \Omega_1^d\} \in \Sigma_1^d$. We now construct an arithmetic height two tower for $\Xi_1^d$ and the class $\Omega_1^d$. To do this, we recall that a height two tower $\Gamma_{n_2,n_1}$ for the essential spectrum of operators in $\Omega_1^d$ was constructed in [8]. For completeness we will write out the algorithm here.

Let $P_n$ be the usual projection onto the first $n$ basis elements and set $Q_n = I - P_n$. Define

$$\mu_{m,n}(A) := \min\{\sigma_1(P_{f(n)}(A - zI)|Q_mP_n(l^2(\mathbb{N}))), \sigma_1(P_{f(n)}(A - zI)^*|Q_mP_n(l^2(\mathbb{N})))\},$$

$$G_n := \min\left\{\frac{s + it}{2^n} : s, t \in \{-2^{2n}, \ldots, 2^{2n}\}\right\},$$

$$\Upsilon_m(z) := z + \{w \in \mathbb{C} : |\text{Re}(w)|, |\text{Im}(w)| \leq 2^{-(m+1)}\}.\]$$

The actual algorithm is slightly more complicated to avoid the empty set, but its listed properties still hold.
We then define the following sets for $n > m$:

(6.5) $S_{m,n}(z) := \{ j = m + 1, \ldots, n : \exists w \in \mathcal{E}_m(z) \cap G_j \text{ with } \mu_{m,i}(w) \leq 1/m \}$,

(6.6) $T_{m,n}(z) := \{ j = m + 1, \ldots, n : \exists w \in \mathcal{E}_m(z) \cap G_j \text{ with } \mu_{m,i}(w) \leq 1/(m + 1) \}$,

(6.7) $E_{m,n}(z) := |S_{m,n}(z)| + |T_{m,n}(z)| - n,$

(6.8) $I_{m,n} := \{ z \in \{ \frac{s + it}{2m} : s, t \in \mathbb{Z} \} : E_{m,n}(z) > 0 \}.$

Finally we define for $n_1 > n_2$

(6.9) $\hat{\Gamma}_{n_2,n_1}(A) = \bigcup_{z \in I_{n_2,n_1}} \mathcal{E}_n(z),$

and set $\hat{\Gamma}_{n_2,n_1}(A) = \{ 1 \}$ if $n_1 \leq n_2.$ Furthermore, the tower has the following desirable properties:

1. For fixed $n_2$, the sequence $\hat{\Gamma}_{n_2,n_1}(A)$ is eventually constant as we increase $n_1$.
2. The sets $\lim_{n_1 \to \infty} \hat{\Gamma}_{n_2,n_1}(A) =: \hat{\Gamma}_n(A)$ are nested, converging down to $\text{Sp}_{\text{disc}}(A)$.

We will also need the height one tower, $\hat{\Gamma}_n$, for the spectrum of operators in $\Omega_N^2$ discussed in §2.1 and §4. Note that $\hat{\Gamma}_n(A)$ is a finite set for all $n$. For $z \in \hat{\Gamma}_n(z)$, this also outputs an error control $E(n, z)$ such that $\text{dist}(z, \text{Sp}(A)) \leq E(n, z)$ and such that $E(n, z)$ converges to the true distance to the spectrum uniformly on compact subsets of $\mathbb{C}$ (with the choice of $g(x) = x$ since the operator is normal - see Remark 4.10). We now fit the pieces together and initially define

$$\zeta_{n_2,n_1}(A) = \{ z \in \hat{\Gamma}_{n_2,n_1}(A) : E(n_1, z) < \text{dist}(z, \hat{\Gamma}_{n_2,n_1}(A) + B_{1/n_2}(0)) \}.$$  

We must show that this defines an arithmetic tower in the sense of Definitions 3.1 and 3.3. Given $z \in \hat{\Gamma}_{n_1}(A)$ and using Pythagoras’ theorem, along with the fact that $\hat{\Gamma}_{n_2,n_1}(A)$ consists of finitely many squares in the complex plane aligned with the real and imaginary axes, we can compute $\text{dist}(z, \hat{\Gamma}_{n_2,n_1}(A))^2$ in finitely many arithmetic operations and comparisons. We can compute $(E(n_1, z) + 1/n_2)^2$ and check if this is less than $\text{dist}(z, \hat{\Gamma}_{n_2,n_1}(A))^2$. Hence $\zeta_{n_2,n_1}(A)$ can be computed with finitely many arithmetic operations and comparisons. There are now two cases to consider:

Case 1: $\text{Sp}_{\text{disc}}(A) \cap (\hat{\Gamma}_{n_2}(A) + B_{1/n_2}(0))^c = \emptyset.$ For large $n_1$, $\hat{\Gamma}_{n_2}(A) = \hat{\Gamma}_{n_2,n_1}(A)$ and this set contains the essential spectrum. It follows, for large $n_1$, since $E(n_1, z) \geq \text{dist}(z, \hat{\Gamma}_{n_2,n_1}(A))$ for all $z \in \hat{\Gamma}_{n_1}(A)$ that $\zeta_{n_2,n_1}(A) = \emptyset$.

Case 2: $\text{Sp}_{\text{disc}}(A) \cap (\hat{\Gamma}_{n_2}(A) + B_{1/n_2}(0))^c \neq \emptyset.$ In this case, this set is a finite subset of $\text{Sp}_{\text{disc}}(A)$, $\{ \hat{z}_1, \ldots, \hat{z}_{m(n_2)} \}$, separated from the closed set $\hat{\Gamma}_{n_2}(A) + B_{1/n_2}(0)$ (we need the $+B_{1/n_2}(0)$ for this to be true to avoid accumulation points of the discrete spectrum). There exists some $\delta_{n_2} > 0$ such that the balls $B_{2\delta_{n_2}}(\hat{z}_j)$ for $j = 1, \ldots, m(n_2)$ are pairwise disjoint and such that their union does not intersect $\hat{\Gamma}_{n_2}(A) + B_{1/n_2}(0).$ Using the convergence of $\hat{\Gamma}_{n_1}(A)$ to $\text{Sp}(A)$ and $E(n, z) \geq \text{dist}(z, \text{Sp}(A))$, it follows that for large $n_1$ that

(6.10) $\zeta_{n_2,n_1}(A) \subset \bigcup_{j=1}^{m(n_2)} B_{2\delta_{n_2}}(\hat{z}_j),$

is non-empty and that $\zeta_{n_2,n_1}(A)$ converges to $\text{Sp}_{\text{disc}}(A) \cap (\hat{\Gamma}_{n_2}(A) + B_{1/n_2}(0))^c \neq \emptyset$ in the Hausdorff metric.

Suppose that $\zeta_{n_2,n_1}(A)$ is non-empty. Recall that we only want one output per eigenvalue in the discrete spectrum. To do this, we partition the finite set $\zeta_{n_2,n_1}(A)$ into equivalence classes as follows. For $z, w \in \zeta_{n_2,n_1}(A)$, we say that $z \sim_{n_1} w$ if there exists a finite sequence $z = z_1, z_2, \ldots, z_n = w \in \zeta_{n_2,n_1}(A)$ such that $B_{E(n_1,z_j)}(z_j)$ and $B_{E(n_1,z_{j+1})}(z_{j+1})$ intersect. The idea is that equivalence classes correspond to clusters of points in $\zeta_{n_2,n_1}(A).$ Given any $z \in \zeta_{n_2,n_1}(A)$ we can compute its equivalence class using finitely many arithmetic operations and comparisons. Let $S_0$ be the set $\{ z \}$ and given $S_n$, let $S_{n+1}$ be the union of any $w \in \zeta_{n_2,n_1}(A)$ such that $B_{E(n_1,w)}(w)$ and $B_{E(n_1,v)}(v)$ intersect for some $v \in S_n$. Given $S_n$, we can
compute $S_{n+1}$ using finitely many arithmetic operations and comparisons. The equivalence class is any $S_n$ where $S_n = S_{n+1}$ which must happen since $\zeta_{n_2,n_1}(A)$ is finite. We let $\Phi_{n_2,n_1}$ consist of one element of each equivalence class that minimises $E(n_1,\cdot)$ over its respective equivalence class. By the above comments it is clear that $\Phi_{n_2,n_1}$ can be computed in finitely many arithmetic operations and comparisons from the given data. Furthermore, due to (6.10) which holds for large $n_1$, the separation of the $B_{2\delta_{n_2}}(\hat{\zeta}_j)$ and the fact that $E(n_1,\cdot)$ converges uniformly on compact subsets to the distance to $\text{Sp}(A)$, it follows that for large $n_1$ there is exactly one point in each intersection $B_{2\delta_{n_2}}(\hat{\zeta}_j) \cap \Phi_{n_2,n_1}(A)$. But we can shrink $\delta_{n_2}$ and apply the same argument to see that $\Phi_{n_2,n_1}(A)$ converges to $\text{Sp}_d(A) \cap (\tilde{\Gamma}_{n_2}(A) + B_{1/n_2}(0))^c \neq \emptyset$ in the Hausdorff metric.

Now suppose that $\zeta_{n_2,n_1}(A)$ is non-empty and $z_1, z_2 \in \Phi_{n_2,n_1}(A)$ and both lie in $B_{\epsilon}(z)$ for some $z \in \text{Sp}_d(A)$ and $\epsilon > 0$ with $\text{Sp}(A) \cap B_{2\epsilon}(z) = \{z\}$. It follows that $z$ minimises the distance to the spectrum from both $z_1$ and $z_2$. Hence, $B_{\epsilon}(z_1,z_2)(z_1)$ and $B_{\epsilon}(z_1,z_2)(z_2)$ both contain the point $z$ so that $z \sim_{n_1} z_2$. But then at most one of $z_1, z_2$ can lie in $\Phi_{n_2,n_1}(A)$ and hence $z_1 = z_2$.

To finish, we must alter $\Phi_{n_2,n_1}(A)$ to take care of the case when $\zeta_{n_2,n_1}(A) = \emptyset$ and to produce a $\Sigma^2$ algorithm. In the case that $\zeta_{n_2,n_1}(A) = \emptyset$, set $\Phi_{n_2,n_1}(A) = \emptyset$. Let $N(A) \in \mathbb{N}$ be minimal such that $\text{Sp}_d(A) \cap (\tilde{\Gamma}_{N}(A) + B_{1/N}(0))^c \neq \emptyset$ (recall the discrete spectrum is non-empty for our class of operators). If $n_2 > N_1$ then set $\Gamma_{n_2,n_1}(A) = \{0\}$, otherwise consider $\Phi_{k,n_1}(A)$ for $n_2 \leq k \leq n_1$. If all of these are empty then set $\Gamma_{n_2,n_1}(A) = \{0\}$, otherwise choose minimal $k$ with $\Phi_{k,n_1}(A) \neq \emptyset$ and let $\Gamma_{n_2,n_1}(A) = \Phi_{k,n_1}(A)$. Note that this defines an arithmetic tower of algorithms, with $\Gamma_{n_2,n_1}(A)$ non-empty. By the above case analysis, for large $n_1$ it holds that

$$\Gamma_{n_2,n_1}(A) = \Phi_{n_2\wedge N(A),n_1}(A)$$

and it follows that

$$\lim_{n_1 \to \infty} \Gamma_{n_2,n_1}(A) =: \Gamma_{n_2}(A) = \text{Sp}_d(A) \cap (\tilde{\Gamma}_{n_2\wedge N(A)}(A) + B_{1/n_2\wedge N(A)}(0))^c.$$ 

Hence $\Gamma_{n_2}(A) \subset \text{Sp}_d(A)$ and $\Gamma_{n_2}(A)$ converges up to $\text{Sp}_d(A)$ in the Hausdorff metric.

**Step 3:** Multiplicities. Suppose that $z_{n_2,n_1} \in \Gamma_{n_2,n_1}(A)$ converges as $n_1 \to \infty$ to some $z_{n_2} = z \in \Gamma_{n_2}(A) \subset \text{Sp}_d(A)$, where $\Gamma_{n_2}$ is the first limit of the height two tower constructed in step 2. Consider the following operator, viewed as a finite matrix acting on $\mathbb{C}^n$, $A_n = P_n(A - z I)^*(A - z I)P_n$. This is a truncation of the operator $(A - z I)^*(A - z I)$. The key observation is that $0$ lies in the discrete spectrum of $(A - z I)^*(A - z I)$ with $h((A - z I)^*(A - z I),0) = h(A,z)$, the multiplicity of the eigenvalue $z$. To see this, note that $\ker((A - z I)^*(A - z I)) = \ker((A - z I)^*(A - z I))$ and that if $\|x\| = 1$ then

$$\|(A - z I)x\| \leq \sqrt{\|(A - z I)^*(A - z I)x\|}.$$ 

Since $(A - z I)$ is bounded below on $\ker((A - z I)^*(A - z I))$, the same must be true for $(A - z I)^*(A - z I)$. Now set

$$h_{n_2,n_1}(A,z_{n_2,n_1}) = \min\{n_2, \{w \in \text{Sp}(P_{n_1}(A - z_{n_2,n_1}I)^*P_{n_1}(A - z_{n_2,n_1}I)P_{n_1}) : \|w\| < 1/n_2 - d_{n_1}\}\},$$ 

where $d_{n_1}$ is some non-negative sequence converging to 0 that we define below. As usual we consider the relevant operator as a matrix acting on $\mathbb{C}^{n_1}$ and we count eigenvalues according to their multiplicity. Via shifting by $(1/n_2 - d_{n_1})I$ and assuming $d_{n_1}$ can be computed with finitely many arithmetic operations and comparisons, Lemma 4.8 shows that this is a general algorithm and can be computed with finitely many arithmetic operations and comparisons. Consider the similar function (that we cannot necessarily compute since we don’t know $z$),

$$q_{n_2,n_1}(A,z) = \min\{n_2, \{|w \in \text{Sp}(A_{n_1}) : |w| < 1/n_2\}\},$$ 

where

$$A_{n_1} = P_{n_1}(A - z I)^*(A - z I)P_{n_1}.$$ 

We set $B = (A - z I)^*(A - z I)$ and list $\lambda_1 \leq \lambda_2 \leq \ldots$ as in Lemmas 6.1 and 6.2 then

$$\lim_{n_1 \to \infty} q_{n_2,n_1}(A,z) = \min\{n_2, |\lambda_j : \lambda_j < 1/n_2\}. $$
It is then clear from the same lemmas that
\[
\lim_{n_2 \to \infty} \lim_{n_1 \to \infty} q_{n_2,n_1}(A, z) = h((A - zI)^* (A - zI), 0) = h(A, z).
\]

We will have completed the proof if we can choose \(d_{n_1}\) such that
\[
\lim_{n_1 \to \infty} |k_{n_2,n_1}(A, z_{n_2,n_1}) - q_{n_2,n_1}(A, z)| = 0.
\]

It is straightforward to show that
\[
|k_{n_2,n_1}(A, z_{n_2,n_1}) - q_{n_2,n_1}(A, z)| = O(1).
\]

Proof of Corollary 2.18. Since \(d\) is the dispersion bound. Choose
\[
d_{n_1} = (E(n_1, z_{n_2,n_1}) + c_{n_1})(E(n_1, z_{n_2,n_1}) + 2|z_{n_2,n_1}| + 2k_{n_1} + c_{n_1}),
\]

where \(k_{n_1}\) overestimates \(2\) by at most \(1\). \(k_{n_1}\) can be computed using a similar positive definiteness test as in DistSpec. Since \(z_{n_2,n_1}\) converges to \(z \in \text{Sp}_d(A)\), it is clear that
\[
\|k_{n_2,n_1}(A, z_{n_2,n_1}) - q_{n_2,n_1}(A, z)| = O(1).
\]

eventually and that \(d_{n_1}\) converges to 0. Weyl’s inequality for eigenvalue perturbations of Hermitian matrices implies the needed convergence. 

Proof of Corollary 2.18. Since \(\Omega_0 \subset \Omega_N^I\), it suffices to show that \(\{\Xi_0^I, \Omega_0^I\} \in \Sigma_2^A\) and \(\{\Xi_1^I, \Omega_0^I\} \notin \Delta_2^G\).

Step 1: \(\{\Xi_0^I, \Omega_0^I\} \notin \Delta_2^G\). The proof is almost identical to step 1 in the proof of Theorem 2.15. Suppose there exists some height one tower \(\Gamma_n\) solving the problem. Consider the matrix operators
\[
A_n = \text{diag}\{0, 0, ..., 0, 2\} \in \mathbb{C}^m \times n \text{ and } C = \text{diag}\{0, 0, ..., 2\}
\]

where we choose an increasing sequence \(k_m\) inductively as follows. Set \(k_1 = 1\) and suppose that \(k_1, ..., k_m\) have been chosen. \(\text{Sp}_d(A_{k_1} \oplus A_{k_2} \oplus ... \oplus A_{k_m} \oplus C) = \{2\}\) so there exists some \(n_m \geq m\) such that if \(n \geq n_m\) then
\[
(6.11) \quad \Gamma_n(A_{k_1} \oplus ... \oplus A_{k_m} \oplus C) = 1.
\]

Now let \(k_{m+1} = \max\{N(\text{diag}\{1, 2\} \oplus A_{k_1} \oplus ... \oplus A_{k_m} \oplus C, n_m), k_m + 1\}\). Arguing as in the proof of Theorem 2.14, it follows that \(\Gamma_{n_m}(A) = \Gamma_{n_m}(A_{k_1} \oplus ... \oplus A_{k_m} \oplus C)\). But \(\Gamma_{n_m}(A)\) converges to 0 as \(A\) has no discrete spectrum and this contradiction finishes this step.

Step 2: \(\{\Xi_0^I, \Omega_0^I\} \in \Sigma_2^A\). Consider the height two tower, \(\zeta_{n_2,n_1}\), defined in step 2 of the proof of Theorem 2.15. Let \(A \in \Omega_N^I\) and if \(\zeta_{n_2,n_1}(A) = \emptyset\), define \(\rho_{n_2,n_1}(A) = 0\), otherwise define \(\rho_{n_2,n_1}(A) = 1\). The discussion in the proof of Theorem 2.15 shows that
\[
(6.12) \quad \lim_{n_2 \to \infty} \rho_{n_2,n_1}(A) =: \rho_n(A) = \begin{cases} 0, & \text{if } \text{Sp}_d(A) \cap (\Gamma_{n_2}(A) + B_{1/2})(0) = \emptyset \\ 1, & \text{otherwise.} \end{cases}
\]

Since \(\text{Sp}_d(A) \cap (\Gamma_{n_2}(A) + B_{1/2})(0)\) increases to \(\text{Sp}_d(A)\), it follows that \(\lim_{n_2 \to \infty} \rho_{n_2}(A) = \Xi_2^A(A)\) and that if \(\rho_{n_2}(A) = 1\), then \(\Xi_2^A(A) = 1\). Hence, \(\rho_{n_2,n_1}\) provides a \(\Sigma_2^A\) tower for \(\{\Xi_0^I, \Omega_0^I\}\). 

Proof of Theorem 2.19. Let \(\epsilon = (E(n_1, z_{n_1}) + \delta)^2\) and consider the matrix
\[
B = P_{n_1}(A - z_{n_1}I)^* P_{f(n_1)}(A - z_{n_1}I)P_{n_1} - \epsilon I_n \in \mathbb{C}^{n \times n},
\]

where $I_n$ is the $n \times n$ identity matrix. $B$ is a Hermitian matrix and is not positive semi-definite. It follows that $B$ can be put into the form
\[ PBPT = LDL^*, \]
where $L$ is lower triangular with $1$’s along its diagonal, $D$ is block diagonal with block sizes $1 \times 1$ or $2 \times 2$ and $P$ is a permutation matrix. This can be computed in finitely many arithmetic operations and comparisons. Without loss of generality we assume that $P = I$. Let $x$ be an eigenvector of $B$ with negative eigenvalue then set $y = L^*x$. Such an $x$ exists by assumption. Note that
\[ \langle y, Dy \rangle = \langle L^*x, DL^*x \rangle = \langle x, Bx \rangle < 0. \]
It follows that there exists a unit vector $y_{n_1}$ with $\langle y_{n_1}, Dy_{n_1} \rangle < 0$. Such a vector is easy to spot if a value in one of the $1 \times 1$ blocks of $D$ is negative. If not then we need to consider $2 \times 2$ blocks. Using the argument in the proof of Lemma 4.8 we can find a $2 \times 2$ block with a negative eigenvalue by computing the trace and determinant. Without loss of generality we assume that this block is the upper $2 \times 2$ portion of $D$. It follows that there exist real numbers $a, b$, not both equal to $0$, such that $y_{n_1} = (a, b, 0, \ldots, 0)^T$ has $\langle y_{n_1}, Dy_{n_1} \rangle < 0$. If $D_{2,2} < 0$ then we can take $a = 0, b = 1$. Otherwise, $a \neq 0$ so set $a = 1$. We then note that there is an open interval $J$ such that if $b \in J$ then $y_{n_1} = (a, b, 0, \ldots, 0)^T$ has $\langle y_{n_1}, Dy_{n_1} \rangle < 0$. We can now perform a search routine on $\mathbb{R}$ with finer and finer spacing to find such a $b$.

$L^*$ is invertible and upper triangular so we can efficiently solve for $\tilde{x}_{n_1} = (L^*)^{-1}y_{n_1}$ using finitely many arithmetic operations and comparisons. We then approximately normalise $\tilde{x}_{n_1}$ by computing $\|\tilde{x}_{n_1}\| = t_{n_1}(\rho) > 0$ to precision $\rho > 0$ using arithmetic operations and comparisons. If we set $x_{n_1} = \tilde{x}_{n_1}/t_{n_1}(\rho)$ then
\[ 1 - \frac{\rho}{t_{n_1}(\rho)} = t_{n_1}(\rho) - \frac{\rho}{t_{n_1}(\rho)} \leq \|x_{n_1}\| \leq \frac{t_{n_1}(\rho) + \rho}{t_{n_1}(\rho)} = 1 + \frac{\rho}{t_{n_1}(\rho)}. \]
So we successively choose $\rho$ smaller until we reach $t_{n_1}(\rho) > \|\tilde{x}_{n_1}\| > 0$. Let $t_{n_1} = t_{n_1}(\rho_{n_1})$, then
\[ \langle x_{n_1}, Bx_{n_1} \rangle = t_{n_1}^{-2}\langle L^*\tilde{x}_{n_1}, DL^*\tilde{x}_{n_1} \rangle = t_{n_1}^{-2}\langle y_{n_1}, Dy_{n_1} \rangle < 0. \]

Note that
\[ \|P_{f_{n_1}}(A - z_{n_1}I)x_{n_1}\|^2 = \langle x_{n_1}, Bx_{n_1} \rangle + \|x_{n_1}\|^2 \epsilon < \|x_{n_1}\|^2 \epsilon. \]
Taking square roots and recalling that $D_{f_{n_1}}(A) \leq c_{n_1}$ and the definition of $D_{f_{n_1}}$ finishes the proof. □

Note that even in the finite-dimensional case this type of error control is the best possible owing to numerical errors due to round-off and finite precision. This method is quick and can easily be efficiently implemented.

**Proof of Theorem 2.20**

**Step 1**: $\{\Xi^I, \Omega^I\} \notin \Delta^G_\mathbb{C}$. Suppose for a contradiction that $\Gamma_{n_2, n_1}$ is a height two tower solving this problem. For this proof we shall use one of the decision problems in [8] that were proven to have $\text{SCI}_G = 3$. Let $(M, d)$ be the discrete space $\{0, 1\}$, let $\Omega'$ denote the collection of all infinite matrices $\{a_{i,j}\}_{i,j \in \mathbb{N}}$ with entries $a_{i,j} \in \{0, 1\}$ and consider the problem function
\[ \Xi(\{a_{i,j}\}) := \text{"Does \{a_{i,j}\} have only finitely many columns containing only finitely many non-zero entries?"} \]

In [8], a Baire category argument was used to prove that $\text{SCI}(\Xi', \Omega')_G = 3$. We will gain a contradiction by using the supposed height two tower for $\{\Xi^I, \Omega^I\}$, $\Gamma_{n_2, n_1}$, to solve $\{\Xi', \Omega'\}$.

Without loss of generality, identify $B^2(L^2(\mathbb{N}))$ with $B(X)$ where $X = C^2 \oplus \bigoplus_{j=1}^\infty X_j$ in the $L^2$-sense with $X_j = L^2(\mathbb{N})$. Now let $\{a_{i,j}\} \in \Omega'$ and for the $j$th column define $B_j \in B(X_j)$ with the following matrix
representation:

\[ B_j = \bigoplus_{r=1}^{M_j} A_{j,r}, \quad A_m := \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{pmatrix} \in \mathbb{C}^{m \times m}, \]

where if \( M_j \) is finite then \( l_j^M = \infty \) with \( A_\infty = \text{diag}(1, 0, 0, \ldots) \). The \( l_j^k \) are defined such that

\[ \sum_{r=1}^{m} a_{i,j} l_j^k = m + \sum_{i=1}^{m} a_{i,j}. \]

Define the self-adjoint operator

\[ A = \text{diag}\{3, 1\} \oplus \bigoplus_{j=1}^{\infty} B_j. \]

Note that no matter what the choices of \( l_j^k \) are, \( 3 \in \text{Sp}_d(A) \) and hence \( A \in \Omega_d^I \). Note also that the spectrum of \( A \) is contained in \( \{0, 1, 2, 3\} \). If \( \Xi(\{a_{i,j}\}) = 1 \) then 1 is an isolated eigenvalue of finite multiplicity and hence in \( \text{Sp}_d(A) \). But if \( \Xi(\{a_{i,j}\}) = 0 \) then 1 is an isolated eigenvalue of infinite multiplicity so does not lie in the discrete spectrum and hence \( \text{Sp}_d(A) \subset \{0, 2, 3\} \).

Consider the intervals \( J_1 = [0, 1/2], \) and \( J_2 = [3/4, \infty) \). Set \( \alpha_{n_2, n_1} = \text{dist}(1, \Gamma_{n_2, n_1}(A)) \). Let \( k(n_2, n_1) \leq n_1 \) be maximal such that \( \alpha_{n_2,k}(A) \in J_1 \cup J_2 \). If no such \( k \) exists or \( \alpha_{n_2,k}(A) \in J_1 \) then set \( \Gamma_{n_2, n_1}(\{a_{i,j}\}) = 1 \). Otherwise set \( \Gamma_{n_2, n_1}(\{a_{i,j}\}) = 0 \). It is clear from (6.13) that this defines a generalised algorithm. In particular, given \( N \) we can evaluate \( \{A_{k,l} : k, l \leq N\} \) using only finitely many evaluations of \( \{a_{i,j}\} \), where we can use a suitable bijection between bases of \( l^2(\mathbb{N}) \) and \( \mathbb{C}^2 \oplus \bigoplus_{j=1}^{\infty} X_j \) to view \( A \) as acting on \( l^2(\mathbb{N}) \). The point of the intervals \( J_1, J_2 \) is that we can show \( \lim_{n_1 \to \infty} \Gamma_{n_2, n_1}(\{a_{i,j}\}) = \Gamma_{n_2}(\{a_{i,j}\}) \) exists. If \( \Xi(\{a_{i,j}\}) = 1 \), then, for large \( n_2 \), \( \lim_{n_1 \to \infty} \alpha_{n_2,k}(A) < 1/2 \) and hence \( \lim_{n_2 \to \infty} \Gamma_{n_2}(\{a_{i,j}\}) = 0 \). Similarly, if \( \Xi(\{a_{i,j}\}) = 0 \), then, for large \( n_2 \), \( \lim_{n_1 \to \infty} \alpha_{n_2,k}(A) > 3/4 \) and hence \( \lim_{n_2 \to \infty} \Gamma_{n_2}(\{a_{i,j}\}) = 1 \). Hence \( \Gamma_{n_1, n_2} \) is a height two tower of general algorithms solving \( \{\Xi', \Omega'\} \), a contradiction.

**Step 2:** \( \{\Xi^d_1, \Omega^d_2\} \notin \Delta^G_3 \). To prove this we can use a slight alteration of the argument in step 1. Replace \( X \) by \( X = l^2(\mathbb{N}) \oplus \bigoplus_{j=1}^{\infty} X_j \) and \( A \) by

\[ A = \text{diag}\{1, 0, 2, 0, 2, \ldots\} \oplus \bigoplus_{j=1}^{\infty} B_j. \]

It is then clear that \( \Xi(A) = 1 \) if and only if \( \Xi(\{a_{i,j}\}) = 1 \).

**Step 3:** \( \{\Xi^d_1, \Omega^d_2\} \in \Sigma^A_3 \). For this we argue similarly to the proof of Theorem 2.15 step 2. It was shown in [8] that there exists a height three arithmetic tower \( \Gamma_{n_3,n_2,n_1} \) for the essential spectrum of operators in \( \Omega^d_1 \) such that

- Each \( \Gamma_{n_3,n_2,n_1}(A) \) consists of a finite collection of points in the complex plane.
- For large \( n_1 \), \( \Gamma_{n_3,n_2,n_1}(A) \) is eventually constant and equal to \( \Gamma_{n_3,n_2}(A) \).
- \( \Gamma_{n_3,n_2}(A) \) is increasing with \( n_2 \) with limit \( \Gamma_{n_3}(A) \) containing the essential spectrum. The limit \( \Gamma_{n_3}(A) \) is also decreasing with \( n_3 \).

Furthermore, it was proven in [8] that for operators in \( \Omega^d_1 \), there exists a height two arithmetic tower \( \Gamma_{n_2,n_1} \) for computing the spectrum such that

- \( \Gamma_{n_2,n_1}(A) \) is constant for large \( n_1 \).
- For any \( z \in \Gamma_{n_2}(A) \), \( \text{dist}(z, \text{Sp}(A)) \leq 2^{-n_2} \).

Using these, we initially define

\[ \zeta_{n_3,n_2,n_1}(A) = \{z \in \Gamma_{n_2,n_1}(A) : 2^{-n_3} - 2^{-n_2} \leq \text{dist}(z, \Gamma_{n_3,n_2,n_1}(A))\}. \]
The arguments in the proof of Theorem 2.15 show that this can be computed in finitely many arithmetic operations and comparisons using the relevant evaluation functions. Note that for large $n_1$

$$\zeta_{n_3,n_2,n_1}(A) = \{ z \in \hat{\Gamma}_{n_2}(A) : 2^{-n_3} - 2^{-n_2} \leq \text{dist}(z, \hat{\Gamma}_{n_3,n_2}(A)) \} =: \zeta_{n_3,n_2}(A).$$

There are now two cases to consider (we use $D_\eta(z)$ to denote the open ball of radius $\eta$ about a point $z$):

**Case 1:** $\text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c = \emptyset$. Suppose, for a contradiction, in this case that there exists $z_{m_j} \in \zeta_{n_3,m_j}(A)$ with $m_j \to \infty$. Then, without loss of generality, $z_{m_j} \to z \in \text{Sp}(A)$. We also have that

$$\text{dist}(z_{m_j}, \hat{\Gamma}_{n_3,m_j}(A)) \geq 2^{-n_3} - 2^{-m_j},$$

which implies that $\text{dist}(z, \hat{\Gamma}_{n_3}(A)) \geq 2^{-n_3}$ and hence $z \in \text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c$, the required contradiction. It follows that $\zeta_{n_3,n_2}(A)$ is empty for large $n_2$.

**Case 2:** $\text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c \neq \emptyset$. In this case, this set is a finite subset of $\text{Sp}_d(A)$, $\{ \hat{z}_1, ..., \hat{z}_{m(n_3)} \}$. Each of these points is an isolated point of the spectrum. It follows that there exists $z_{n_2} \in \hat{\Gamma}_{n_2}(A)$ with $z_{n_2} \to \hat{z}_1$ and $|z_{n_2} - \hat{z}_1| \leq 2^{-n_2}$ for large $n_2$. Since the $\hat{\Gamma}_{n_3,n_2}(A)$ are increasing, this implies that

$$\text{dist}(z_{n_2}, \hat{\Gamma}_{n_3,n_2}(A)) \geq \text{dist}(z_{n_2}, \hat{\Gamma}_{n_3}(A)) \geq \text{dist}(\hat{z}_1, \hat{\Gamma}_{n_3}(A)) - 2^{-n_2} \geq 2^{-n_3} - 2^{-n_2},$$

so that $z_{n_2} \in \zeta_{n_3,n_2}(A)$. The same argument holds for points converging to all of $\{ \hat{z}_1, ..., \hat{z}_{m(n_3)} \}$. On the other hand, the argument used in Case 1 shows that any limit points of $\zeta_{n_3,n_2}(A)$ as $n_2 \to \infty$ are contained in $\text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c$. It follows that in this case $\zeta_{n_3,n_2}(A)$ converges to $\text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + B_{1/n_3}(0))^c \neq \emptyset$ in the Hausdorff metric as $n_2 \to \infty$.

Let $N(A) \in \mathbb{N}$ be minimal such that $\text{Sp}_d(A) \cap (\hat{\Gamma}_{N(A)} + D_{2^{-N(A)}}(0))^c \neq \emptyset$ (recall the discrete spectrum is non-empty for our class of operators). If $n_3 > n_2$ then set $\Gamma_{n_3,n_2,n_1}(A) = \{ 0 \}$, otherwise consider $\zeta_{k,n_2,n_1}(A)$ for $n_3 \leq k \leq n_2$. If all of these are empty then set $\Gamma_{n_3,n_2,n_1}(A) = \{ 0 \}$, otherwise choose minimal $k$ with $\zeta_{k,n_2,n_1}(A) \neq \emptyset$ and let $\Gamma_{n_3,n_2,n_1}(A) = \zeta_{k,n_2,n_1}(A)$. Note that this defines an arithmetic tower of algorithms, with $\Gamma_{n_3,n_2,n_1}(A)$ non-empty. Since we consider finitely many of the sets $\zeta_{k,n_2,n_1}(A)$, and these are constant for large $n_1$, it follows that $\Gamma_{n_3,n_2,n_1}(A)$ is constant for large $n_1$ and constructed in the same manner with replacing $\zeta_{k,n_2,n_1}(A)$ by $\zeta_{k,n_2}(A)$. Call this limit $\Gamma_{n_3,n_2}(A)$.

For large $n_2$,

$$\Gamma_{n_3,n_2}(A) = \zeta_{n_3 \vee N(A),n_2}(A)$$

and it follows that

$$\lim_{n_2 \to \infty} \Gamma_{n_3,n_2}(A) =; \Gamma_{n_3}(A) = \text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3 \vee N(A)}(A) + D_{2^{-n_3 \vee N(A)}}(0))^c.$$

Hence $\Gamma_{n_3}(A) \subset \text{Sp}_d(A)$ and $\Gamma_{n_3}(A)$ converges up to $\overline{\text{Sp}_d(A)}$ in the Hausdorff metric.

**Step 4:** $\{ \Xi_d^\rho, \Omega_d^\rho \} \subset \Sigma_d^\rho$. Consider the height three tower, $\zeta_{n_3,n_2,n_1}$, defined in step 3. Let $A \in \Omega_d^\rho$ and if $\zeta_{n_3,n_2,n_1}(A) = \emptyset$, define $\rho_{n_3,n_2,n_1}(A) = 0$, otherwise define $\rho_{n_3,n_2,n_1}(A) = 1$. The discussion in step 3 shows that

$$\lim_{n_2 \to \infty} \lim_{n_1 \to \infty} \rho_{n_3,n_2,n_1}(A) =: \rho_3(A) = \begin{cases} 0, & \text{if } \text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c = \emptyset \\ 1, & \text{otherwise}. \end{cases}$$

Since $\text{Sp}_d(A) \cap (\hat{\Gamma}_{n_3}(A) + D_{2^{-n_3}}(0))^c$ increases to $\overline{\text{Sp}_d(A)}$, it follows that $\lim_{n_3 \to \infty} \rho_3(A) = \Xi_d^\rho(A)$ and that if $\rho_3(A) = 1$, then $\Xi_d^\rho(A) = 1$. Hence, $\rho_{n_3,n_2,n_1}$ provides a $\Sigma_d^\rho$ tower for $\{ \Xi_d^\rho, \Omega_d^\rho \}$. \qed
7. PROOFS OF THEOREMS ON THE SPECTRAL GAP

Proof of Theorem 2.12. Step 1: \( \{ \Xi_{\text{gap}}, \hat{\Omega}_{\text{SA}} \} \in \Sigma^0. \) Let \( A \in \hat{\Omega}_{\text{SA}}. \) Using Corollary 4.9 we can compute all \( n \) eigenvalues of \( P_nAP_n \) to arbitrary precision in finitely many arithmetic operations and comparisons. Note that it is not completely straightforward to deduce this with the QR algorithm as one has to deal with halting criteria to achieve the correct precision and also one must approximate roots to extract the approximate eigenvalues from a potential \( 2 \times 2 \) matrix block. Thus we use Corollary 4.9 instead. In the notation of Lemmas 6.1 and 6.2 (whose analogous results also hold for the possibly unbounded \( A \in \hat{\Omega}_{\text{SA}} \)), consider an approximation

\[
0 \leq l_n := \mu_2^n - \mu_1^n + \epsilon_n, \quad n \geq 2,
\]

where we have computed \( \mu_2^n - \mu_1^n \) to accuracy \( |\epsilon_n| \leq 1/n \) using Corollary 4.9 with \( B = P_nAP_n. \) Recall that for \( A \in \hat{\Omega}_{\text{SA}} \) we restricted the class so that either the bottom of the spectrum is in the discrete spectrum with multiplicity one, or there is a closed interval in the spectrum of positive measure with the bottom of the spectrum as its left-end point. It follows that \( l_n \) converges to zero if and only if \( \Xi_{\text{gap}}(A) = 0, \) otherwise it converges to some positive number. If \( n_1 = 1 \) then set \( \Gamma_{n_1, n_1}(A) = 1, \) otherwise consider the following.

Let \( J_{n_2}^1 = [0, 1/(2n_2)] \) and \( J_{n_2}^2 = (1/n_2, \infty). \) Given \( n_1 \in \mathbb{N}, \) consider \( l_k \) for \( k \leq n_1. \) If no such \( k \) exists with \( l_k \in J_{n_2}^1 \cup J_{n_2}^2, \) then set \( \Gamma_{n_2, n_1}(A) = 0. \) Otherwise, consider \( k \) maximal with \( l_k \in J_{n_2}^1 \cup J_{n_2}^2 \) and set \( \Gamma_{n_2, n_1}(A) = 0 \) if \( l_k \in J_{n_2}^1 \) and \( \Gamma_{n_2, n_1}(A) = 1 \) if \( l_k \in J_{n_2}^2. \) The sequence \( l_n \to c \geq 0 \) for some number \( c. \) The separation of the intervals \( J_{n_2}^1 \) and \( J_{n_2}^2, \) ensures that \( l_n \) cannot be in both intervals infinitely often as \( n \to \infty \) and hence the first limit \( \Gamma_{n_2}(A) := \lim_{n \to \infty} \Gamma_{n_2, n_1}(A) \) exists. If \( c = 0, \) then \( \Gamma_{n_2}(A) = 0 \) but if \( c > 0 \) then there exists \( n_2 \) with \( 1/n_2 < c \) and hence for large \( n_1, l_{n_1} \in J_{n_2}^2. \) It follows in this case that \( \Gamma_{n_2}(A) = 1 \) and we also see that if \( \Gamma_{n_2}(A) = 1 \) then \( \Xi_{\text{gap}}(A) = 1. \) Hence \( \Gamma_{n_2, n_1} \) provides a \( \Sigma^0 \) tower.

Step 2: \( \{ \Xi_{\text{gap}}, \hat{\Omega}_D \} \notin \Delta^0_2. \) We argue by contradiction and assume the existence of a height one tower, \( \Gamma_n \) converging to \( \Xi_{\text{gap}}. \) The method of proof follows the same lines as before. For every \( A \) and \( n \) there exists a finite number \( N(A, n) \in \mathbb{N} \) such that the evaluations from \( \Lambda_{n}(A) \) only take the matrix entries \( A_{ij} = \langle A e_j, e_i \rangle \) with \( i, j \leq N(A, n) \) into account. List the rationals in \( (0, 1) \) without repetition as \( d_1, d_2, \ldots. \) We will consider the operators \( A_m = \text{diag}\{d_1, d_2, \ldots, d_m\} \in \mathbb{C}^{m \times m}, B_m = \text{diag}\{1, 1, \ldots, 1\} \in \mathbb{C}^{m \times m} \) and \( C = \text{diag}\{1, 1, \ldots\}. \) Let

\[
A = \bigoplus_{m=1}^{\infty} (B_{k_m} \oplus A_{k_m}),
\]

where we choose an increasing sequence \( k_m \) inductively as follows. In what follows, all operators considered are easily seen to be in \( \hat{\Omega}_D. \)

Set \( k_1 = 1 \) and suppose that \( k_1, \ldots, k_m \) have been chosen with the property that upon defining

\[
\zeta_p := \min\{d_r : 1 \leq r \leq k_p\},
\]

we have \( \zeta_p > \zeta_{p+1} \) for \( p = 1, \ldots, m - 1. \) \( \text{Sp}(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \{d_1, d_2, \ldots, d_m, 1\} \) has \( \zeta_m \) the minimum of its spectrum and an isolated eigenvalue of multiplicity 1, hence

\[
\Xi(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{Yes}.
\]

It follows that there exists some \( n_m \geq m \) such that if \( n \geq n_m \) then

\[
\Gamma_n(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{Yes}.
\]

Now let \( k_{m+1} \geq \max\{N(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C, n_m), k_m + 1\} \) with \( \zeta_m > \zeta_{m+1}. \) The same argument used in the proof of Theorem 2.4 shows that \( \Gamma_{n_2}(A) = \Gamma_{n_2}(B_{k_1} \oplus A_{k_1} \oplus \ldots \oplus B_{k_m} \oplus A_{k_m} \oplus C) = \text{Yes}. \) But \( \text{Sp}(A) = \{0, 1\} \) is gapless and so must have \( \lim_{n \to \infty} (\Gamma_n(A)) = \text{No}, \) a contradiction. \( \square \)

Proof of Theorem 2.14. By restricting \( \hat{\Omega}_D \) to \( \hat{\Omega}_D \) and composing with the map

\[
\rho : \{1, 2, 3, 4\} \to \{0, 1\},
\]
\[
\rho(1) = 1, \rho(2) = \rho(3) = \rho(4) = 0, \text{ it is clear that Theorem 2.12 implies } \{\Xi_{\text{class}}, \tilde{\Omega}_D^f\}, \{\Xi_{\text{class}}, \tilde{\Omega}_D\} \notin \Delta_G^G.
\]
Since \(\tilde{\Omega}_D \subset \Omega_{SA}^f\), we need only construct a \(\Pi_2^n\) tower for \(\{\Xi_{\text{class}}, \tilde{\Omega}_D^f\}\).

Let \(A \in \Omega_{SA}^f\). For a given \(n\), set \(B_n = P_n(A)P_n\) and in the notation of Lemmas 6.2 and 6.1 let
\[
0 < \ell_n := \mu^n_j + \mu^n_1 + \epsilon^n_n, \quad \text{for } j < n.
\]
where we again have computed \(\mu^n_j + \mu^n_1\) to accuracy \(|\epsilon^n_n| \leq 1/\nu\) using only finitely many arithmetic operations and comparisons by Corollary 4.9 \(\Xi_{\text{class}}(A) = 1\) if and only if \(\ell^{(n)}_i\) converges to a positive constant as \(n \to \infty\) and \(\Xi_{\text{class}}(A) = 2\) if and only if \(\ell^{(n)}_i\) converges to zero as \(n \to \infty\) but there exists \(j\) with \(\ell^{(n)}_j\) converging to a positive constant.

Note that we can use the algorithm, denoted \(\tilde{\Gamma}_n\), to compute the spectrum presented in \(\Xi\), with error function denoted by \(E(n, \cdot)\) converging uniformly on compact subsets of \(\mathbb{C}\) to the true error from above (again with the choice of \(g(x) = x\) since the operator is normal - see Remark 4.10). Setting
\[
a_n(A) = \min_{x \in \Gamma_n(A)} \{x + E(n, x)\},
\]
we see that \(a_n(A) \geq a(A) := \inf_{x \in \text{Sp}(A)} \{x\}\) and that \(a_n(A) \to a(A)\). Now consider
\[
b_{n_2, n_1}(A) = \min \{E(k, a_k(A) + 1/n_2) + 1/k : 1 \leq k \leq n_1\}
\]
then \(b_{n_2, n_1}(A)\) is positive and decreasing in \(n_1\) so converges to some limit \(b_{n_2}(A)\).

**Lemma 7.1.** Let \(A \in \Omega_{SA}^f\) and \(c_{n_2, n_1}(A) = E(n_1, a_{n_1}(A) + 1/n_2) + 1/n_1\), then
\[
\lim_{n_1 \to \infty} c_{n_2, n_1}(A) = c_2(A) = \text{dist}(a + 1/n_2, \text{Sp}(A)).
\]
Furthermore, if \(\Xi_{\text{class}}(A) \neq 4\) then for large \(n_2\) it follows that \(c_{n_2, n_1}(A) = b_{n_2}(A) = 1/n_2\).

**Proof of Lemma 7.1** We know that \(a_{n_1}(A) + 1/n_2\) converges to \(a(A) + 1/n_2\) as \(n_1 \to \infty\). Furthermore, \(\text{dist}(z, \text{Sp}(A))\) is continuous in \(z\) and \(E(n_1, z)\) converges uniformly to \(\text{dist}(z, \text{Sp}(A))\) on compact subsets of \(\mathbb{C}\). Hence, the limit \(c_{n_2}(A)\) exists and is equal to \(\text{dist}(a(A) + 1/n_2, \text{Sp}(A))\). It is clear that \(b_{n_2}(A) \leq c_{n_2, n_1}(A)\).
Suppose now that \(\Xi_{\text{class}}(A) \neq 4\), then for large \(n_1\), say bigger than some \(N\), and for large enough \(n_2\),
\[
E(n_1, a_{n_1}(A) + 1/n_2) \geq \text{dist}(a_{n_1}(A) + 1/n_2, \text{Sp}(A)) = |a_{n_1}(A) + 1/n_2 - a(A)|
\]
\[
\geq 1/n_2 = \text{dist}(a(A) + 1/n_2, \text{Sp}(A)).
\]
Now choose \(n_2\) large such that the above inequality holds and \(1/n_2 \leq 1/N\). Then \(b_{n_2, n_1}(A) \geq 1/n_2\).
Taking limits finishes the proof. \(\square\)

If \(n_2 \geq n_1\) then set \(\Gamma_{n_2, n_1}(A) = 1\). Otherwise, for \(1 \leq j \leq n_2\), let \(k_{n_2, n_1}^j\) be maximal with \(1 \leq k_{n_2, n_1}^j < n_1\) such that \(l_{k_{n_2, n_1}^j}^1 \in J_{n_2}^1 \cup J_{n_2}^2\) if such \(k_{n_2, n_1}^j\) exist, where \(J_{n_2}^1\) and \(J_{n_2}^2\) are as in the proof of Theorem 2.12.
If \(k_{n_2, n_1}^1 \neq n_1\) exists with \(l_{k_{n_2, n_1}^1}^1 \in J_{n_2}^2\) then set \(\Gamma_{n_2, n_1}(A) = 1\). Otherwise, if any of \(k_{n_2, n_1}^m \in J_{n_2}^2\) for \(2 \leq m \leq n_2\) then set \(\Gamma_{n_2, n_1}(A) = 2\). Suppose that neither of these two cases hold. In this case compute \(b_{n_2, n_1}(A)\). If \(b_{n_2, n_1}(A) \geq 1/n_2\) then set \(\Gamma_{n_2, n_1}(A) = 3\), otherwise set \(\Gamma_{n_2, n_1}(A) = 4\). We now must show this provides a \(\Pi_2^n\) tower solving our problem.

First we show convergence of the first limit. Fix \(n_2\) and consider \(n_1\) large. The separation of the intervals \(J_{n_2}^1\) and \(J_{n_2}^2\) ensures that each sequence \(\{l_{n_1}^1\}_{n_1 \in \mathbb{N}}\) cannot visit each interval infinitely often. Since \(b_{n_2, n_1}(A)\) is non-increasing in \(n_1\), we also see that the question whether \(b_{n_2, n_1}(A) \geq 1/n_2\) eventually has a constant answer. These observations ensure convergence of the first limit \(\Gamma_{n_2, n_1}(A) = \lim_{n_1 \to \infty} \Gamma_{n_2, n_1}(A)\).

If \(\Xi_{\text{class}}(A) = 1\) then for large \(n_2\), \(l_{n_1}^1\) must eventually be in \(J_{n_2}^2\) and hence \(\Gamma_{n_2, n_1}(A) = 1\). It is also clear that if \(\Gamma_{n_2, n_1}(A) = 1\) then \(l_{n_1}^1\) converges to a positive constant, which implies \(\Xi_{\text{class}}(A) = 1\). If \(\Xi_{\text{class}}(A) = 2\) then for large \(n_2\), \(l_{n_1}^1\) eventually lies in \(J_{n_2}^2\) for some \(2 \leq m \leq n_2\), but \(l_{n_1}^1\) eventually in \(J_{n_2}^1\). It follows that
\( \Gamma(q_2(A)) = 2 \). If \( \Gamma(q_2(A)) = 2 \), then we know that there exists some \( l_{n_1} \) convergent to \( l \geq 1/n_2 \) and hence we know \( \Xi_{\text{class}}(A) \) is either 1 or 2.

Now suppose that \( \Xi_{\text{class}}(A) = 3 \), then for fixed \( n_2 \) and any \( 1 \leq m \leq n_2 \), \( l_{n_1} \) eventually lies in \( J_{q_2} \) and hence our lowest level of the tower must eventually depend on whether \( b_{n_2,n_1}(A) \geq 1/n_2 \). From Lemma 7.1 \( b_{q_2,n_2} = c_{n_2}(A) = 1/n_2 \) for large \( n_2 \). It follows that for large \( n_2 \), \( b_{n_2}(A) \geq 1/n_2 \) for all \( n_1 \) and \( \Gamma(q_2(A)) = 3 \). Furthermore, if \( \Gamma(q_2(A)) = 3 \) then we know that \( c_{n_2}(A) \geq b_{n_2}(A) \geq 1/n_2 \), which implies \( \Xi_{\text{class}}(A) \neq 4 \). Finally, note that if \( \Xi_{\text{class}}(A) = 4 \) but there exists \( n_2 \) with \( \Gamma(q_2(A)) \neq 4 \) then the above implies the contradiction \( \Xi_{\text{class}}(A) \neq 4 \). The partial converses proven above imply \( \Gamma(q_2,n_1) \) realises the \( \Pi_A^\ell \) classification.

**Remark 7.2.** Whilst the above proof is fiddly in order to gain convergence of the first limit, the main ideas are clear. We can use the methods in this paper to compute the distance to the spectrum, and we can use Lemmas 6.2 and 6.1 to get a handle on multiplicities.

### 8. Applications and Numerical Examples

In this section, we will demonstrate that the basic algorithms constructed in this paper are usable and can be efficiently implemented for large scale computations. The constructed algorithms have desirable convergence properties, with some converging monotonically or being eventually constant as captured by the \( \Sigma/\Pi \) classification. They are also completely local and hence parallelisable. We can take advantage of this when analysing them numerically. For real-life computations, we may not have access to or be able to store the exact matrix elements of our operator. For instance, it might be the case that the matrix value is irrational or occurs from estimating an inner product. For the algorithms based on \( \text{DistSpec} \) (see below) it is possible, based on the ideas of Lemma 5.2, to carry out an error analysis. If we know the errors and can also bound numerical errors (such as forming matrix products, checking if a matrix is positive definite etc.) then we can incorporate this uncertainty for the estimation of \( \| R(z,A) \|^{-1} \) and still gain the same classification of our problems. We can also restrict all the arithmetic towers of algorithms in this paper to operations over \( \mathbb{Q} \) with only slight modifications - see Appendix A. This is crucial for using the classes \( \Sigma_1/\Pi_1 \) for rigorous numerics and computer-assisted proofs.

**Remark 8.1.** Although we only stated results for the graph case, \( L^2(V(G)) \), in [2.1], the ideas used to prove this show that all the classification results and algorithms in [2.1], [2.3] and [2.4] extend to general separable Hilbert spaces \( \mathcal{H} \). Once a basis is chosen (so that matrix elements make sense) we can introduce concepts like bounded dispersion etc.

#### 8.1. Application: Polynomial PDEs

We will demonstrate how the algorithms to compute the spectrum and pseudospectrum for PDE operators in [2.2] can be applied to a subclass of operators of the form

\[
T = \mathcal{P}(x_1, \ldots, x_d, \partial_1, \ldots, \partial_d)
\]

with domain \( \mathcal{D}(T) \subset L^2(\mathbb{R}^d) \) for polynomials \( \mathcal{P} \). In this case, the algorithms reduce to computing the spectrum/pseudospectrum of infinite matrices \( A \) acting on \( L^2(\mathbb{N}) \). From the comments in Example 4.12 and recurrence relations for Hermite functions, we can choose a basis such that \( f(n) - n \sim Cn^{(d-1)/d} \), where \( f \) is the dispersion function and \( C(d) \) a constant, such that \( f \) also describes the off-diagonal sparsity structure of \( A \) in the sense that \( A_{n,k} = A_{k,n} = 0 \) if \( k > f(n) \). Hence, this section also showcases the algorithms presented in [2.1] and the two different methods become equivalent. To apply the algorithms, we must prove that \( C_{\mathcal{P}}(\mathbb{R}^d) \) forms a core of \( T \) and \( T^* \). Even in the symmetric case, it is a highly non trivial task to decide whether \( T \) is essentially self-adjoint despite the answer being given in terms of Neumann deficiency indices [18]. We point the reader to [84] for many conditions on the potential of a Schrödinger operator that guarantee self-adjointness and the following will also be useful.
Theorem 8.2 (\textit{[45]}). Let $T$ be defined as

$$-\Delta + q(x)$$

with initial domain $C_0^\infty(\mathbb{R}^d)$, where $q$ is a (measurable) complex potential with real part bounded below and $q \in L^2_{\text{loc}}(\mathbb{R}^d)$. Then $T$ is closable and $C_0^\infty(\mathbb{R}^d)$ forms a core of $T^*$. If $q$ is real valued, then $T$ is self-adjoint.

8.1.1. Anharmonic Oscillators. Consider operators of the form

$$H = -\Delta + V(x) = -\Delta + \sum_{j=1}^d (a_j x_j + b_j x_j^2) + \sum_{\alpha \in \mathbb{Z}^d, |\alpha| \leq M} c(\alpha) x^\alpha,$$

where $a_j, b_j, c(\alpha) \in \mathbb{R}$ and the multi-indices $\alpha$ are chosen such that $\sum_{|\alpha| \leq M} c(\alpha) x^\alpha$ is bounded from below. The fact that this is essentially self-adjoint follows from the Faris–Lavine theorem \textit{[84]}. Anharmonic oscillators have attracted interest in quantum research for over three decades \textit{[11, 12, 56, 104]} and amongst their uses are approximations of potentials near stationary points. The problem of developing efficient algorithms to compute their spectra has received renewed interest due to advances in asymptotic analysis and symbolic computing algebra \textit{[6, 59, 102]}. The methods in the cited works are rich and diverse, but lack uniformity. There are two key questions: How can we obtain error control in a computationally efficient manner? How can we deal with higher dimensions? Our algorithms provide answers to both.

The algorithm $\Gamma_n(A)$ for the spectrum can be described by the routine \textit{CompSpecUB}, shown as pseudocode below. Recall that this depends on the routines \textit{Grid} and \textit{CompInvg} described by (4.3) and (4.4) respectively. This relies on the approximation to $\|R(z,A)\|^{-1}$ in Theorem 4.7 given by the routine \textit{DistSpec}.

\begin{verbatim}
Function DistSpec(A,n,z,f(n))
| Input : n \in \mathbb{N}, f(n) \in \mathbb{N}, matrix A, z \in \mathbb{C}
| Output: y \in \mathbb{R}^+\text{, an approximation to the function } z \mapsto \|R(z,A)\|^{-1}

B = (A - zI)(1 : f(n), 1 : n)
C = (A - zI)^*(1 : f(n), 1 : n)
S = B^*B
T = C^*C
\nu = 1, l = 0

while \nu = 1 do
| l = l + 1

end

\end{verbatim}

Throughout we have used the fact that \textit{DistSpec} requires only finitely many arithmetic operations and comparisons. This essentially boils down to using Lemma \textit{[4.8]} in the \textit{IsPosDef} routine. Whilst Lemma \textit{[4.8]} cannot determine whether a finite self-adjoint matrix $M$ is strictly positive definite, it can test for semi-positive definiteness. Furthermore, if we have an estimate on the numerical error when using the $LDL^*$ of Cholesky factorisation (if we allow radicals), we can factor this (as well as the $c_n$) into \textit{DistSpec} to still obtain an estimate which, upon increasing the accuracy of numerical computations, converges to $\|R(z,A)\|^{-1}$ from above on compact subsets of $\mathbb{C}$. All the algorithms in this paper then still carry through. We can also replace the while loop by a much more efficient binary search method.
quantum mechanics \[31\] we can speed up computations using the fact that the algorithm is local. Furthermore, the search routine’s were the main deciding factors in the error bound. Clearly, once we know roughly where the eigenvalues are, the resolution of the search routine and the search accuracy for the smallest singular values, not the matrix size, that the error bounds become the precision of the search routine in \(A\)’s accuracy of \(\alpha\). Suppose that for an \(A\) and an \(n \in \mathbb{N}\), \(f(n) - n \sim C n^\alpha\), where \(f\) is the dispersion function, \(C\) a constant and \(\alpha \in [0, 1)\). Suppose that \(f\) is non-decreasing and also describes the off-diagonal sparsity structure of \(A\) in the sense that \(A_{n,k} = A_{k,n} = 0\) if \(k > f(n)\). If we use a grid spacing \(1/m_1(n)\) and an accuracy of \(1/m_2(n)\) for DistSpec, then the algorithm \(\Gamma_n(A)\) restricted to a finite interval of length \(L(n)\) can be computed in

\[
O(L(n)m_1(n)n^{(\alpha+1)\alpha+1} \log(m_2(n)))
\]

operations.

end

We begin with comparisons to some known results in one dimension, calculated using super-symmetric quantum mechanics \([51]\). \(V_1(x) = x^2 - 4x^4 + x^6\) \(E_0 = -2\)

\(V_2(x) = 4x^2 - 6x^4 + x^6\) \(E_1 = -9\)

\(V_3(x) = (105/64)x^2 - (43/8)x^4 + x^6 - x^8 + x^{10}\) \(E_0 = 3/8\)

\(V_4(x) = (169/64)x^2 - (59/8)x^4 + x^6 - x^8 + x^{10}\) \(E_1 = 9/8\).

The output of the algorithm will be a cluster of points near the eigenvalue. We take the average of these points and their maximum error bound. Note that other methods such as finite section (of the corresponding structure of \(A\)) will converge in this case, but do not provide the sharp \(\Sigma_1\) classification. We found that the grid resolution of the search routine and the search accuracy for the smallest singular values, not the matrix size, were the main deciding factors in the error bound. Clearly, once we know roughly where the eigenvalues are, we can speed up computations using the fact that the algorithm is local. Furthermore, the search routine’s computational time only grows logarithmically in its precision. Hence in this section, we will set the grid spacing and the spacing of the search routine to be 1000\(n\). Table 2 shows the results; all values were computed virtually instantaneously using a local search grid. Note that we quickly gain convergence and that the error bounds become the precision of the search routine in DistSpec. We found that the time taken grew slightly more than linearly with \(n\).

\textbf{Proposition 8.3.\textsuperscript{\[3\]}} Suppose that for an \(A\) and for large \(n\), \(f(n) - n \sim C n^\alpha\), where \(f\) is the dispersion function, \(C\) a constant and \(\alpha \in [0, 1)\). Suppose that \(f\) is non-decreasing and also describes the off-diagonal sparsity structure of \(A\) in the sense that \(A_{n,k} = A_{k,n} = 0\) if \(k > f(n)\). If we use a grid spacing \(1/m_1(n)\) and an accuracy of \(1/m_2(n)\) for DistSpec, then the algorithm \(\Gamma_n(A)\) restricted to a finite interval of length \(L(n)\) can be computed in

\[
O(L(n)m_1(n)n^{(\alpha+1)\alpha+1} \log(m_2(n)))
\]

\textsuperscript{\[3\]Following the physicists’ convention, if the spectrum is discrete and bounded below, we list the energy levels as \(E_0, E_1, \ldots\).}
### Table 2. Test run of algorithm on some potentials with known eigenvalues. Note that we quickly converge to the eigenvalue with error bounds (computed by the algorithm - not the analytic solution) given by the precision of the search routine in DistSpec.

**Proof.** We will show first that testing positive definiteness of $S - \epsilon$ in DistSpec can be achieved in $O(n^{(\alpha+1)\alpha+1})$ operations. Is is then clear that the computations of all the estimates using DistSpec can be achieved in $O(L(n)m_1(n)n^{(\alpha+1)\alpha+1}\log(m_2(n)))$ operations if we use a binary search routine. It is easily seen that the rest of CompSpec can be executed in $O(m_1(n)n)$ operations, yielding the result.

To test positive definiteness (IsPos) we checked whether a Cholesky decomposition of the matrix $S - \epsilon$ was possible. One can see that $S$ also has a dispersion function $\tilde{f}(n) - n \sim \tilde{C}n^\alpha$ and hence without loss of generality we can assume $f = \tilde{f}$. Furthermore, $S - \epsilon$ is sparse with $f$ describing its sparsity structure. We refer the reader to [101] Chapter 23 where Cholesky factorisation is explained. Following the notation there, one computes (assuming $S > \epsilon$)

$$S - \epsilon = R^*_1 \ldots R^*_m R_m \ldots R_1$$

with $R = R_m \ldots R_1$ upper triangular. Using the fact that $f$ is non-decreasing with $f(n) \geq n$ it is straightforward to prove that all $R_i$’s used to compute $R$ have the same sparsity/dispersion function $f$. A simple operation count gives complexity of order

$$\sum_{k=1}^{n} \sum_{j=k+1}^{f(k)} (f(j) - j) \lesssim \sum_{k=1}^{n} \sum_{j=k+1}^{f(k)} j^\alpha \lesssim \sum_{k=1}^{n} (f(k)^{\alpha+1} - k^{\alpha+1}) \lesssim \sum_{k=1}^{n} k^{(\alpha+1)\alpha} \lesssim n^{(\alpha+1)\alpha+1}$$

and we get the result. □

**Remark 8.4.** In general, the estimate is a worst case scenario and assumes that we must compute the whole Cholesky decomposition for each input in the loop that calculates DistSpec. In reality, this does not hold, but for each grid point, we must compute the whole decomposition at least once. Hence the above is up to logarithmic factors optimal for the method we use to compute IsPos. A good strategy to reduce computation time is to use an approximate minimal degree ordering (AMD) for the matrices.

**Remark 8.5.** In the notation of Proposition 8.3 the above example have $L(n)m_1(n)$ constant (we found the local search intervals via previous estimations with $\Gamma_k(A)$ and finite section) and $m_2(n) = n$. Hence we expect the time taken to scale linearly up to log factors. This was found to be the case.

Next, we will demonstrate how the algorithm can be used in higher dimensions. We consider the operator

$$H_1 = -\Delta + x_1^2 x_2^2,$$

which is a classic example of a potential that does not blow up at $\infty$ in every direction, yet still induces an operator with compact resolvent [22]. Figure 1 shows the convergence of the estimate of $\|R(z, H_1)\|^{-1}$ from above as well as finite section estimates. As expected from variational methods, the finite section method produces eigenvalues converging to the true eigenvalues from above (there is no essential spectrum and the operator is positive). Furthermore, the areas where DistSpec has converged correspond to areas where finite section has converged. One expects that the time taken for finite section grows somewhere between
quadratically and cubically whereas the Algorithm grows at most $n^{2.75}$ up to logarithmic factors (if one does not take advantage of previous estimates and compact resolvent to reduce the interval length of searches). This is also shown in Figure [1] where we found that finite section grew roughly cubically and the algorithm grew roughly as $n^{2.25}$ (both shown as reference lines). The speedup for the algorithm, compared with $n^{2.75}$, was due to the AMD ordering used.

8.1.2. Schrödinger Operator with Constant Magnetic Field. In this example, we demonstrate that the algorithm computing the spectrum does not suffer from spectral pollution, often found in other methods used for self-adjoint operators when there is a gap in the essential spectrum. We will demonstrate this on the Schrödinger operator with constant magnetic field ($B \in \mathbb{R}$, $B \neq 0$) in $\mathbb{R}^2$,

$$H_B = \left(-i\partial_{x_1} - \frac{B x_2}{2}\right)^2 + \left(-i\partial_{x_2} + \frac{B x_1}{2}\right)^2,$$

which is essentially self-adjoint [84] and plays an important role in superconductivity theory [58]. It is straightforward via unitary transformations to show that

$$\text{Sp}(H_B) = \{(2k - 1) |B| : k \in \mathbb{N}\},$$

(see [66]) with each element of the spectrum being an eigenvalue of infinite multiplicity (so that the above agrees with the essential spectrum). Figure [2](left) shows the output of finite section over a range of $n$ and $B = 1$. As expected, there is no spectral pollution below the essential spectrum, but there is heavy spectral pollution in the gaps of the essential spectrum. Figure [2](right) shows the output of the algorithm. This avoids spectral pollution whilst converging to the true spectrum.

This is a toy example, given the fact that it is straightforward to provide a basis with respect to which $H_B$ becomes diagonal. However, given an operator, it can be hard to choose an appropriate basis such that finite section avoids spectral pollution and the above example demonstrates that we do not have to worry about this when using the Algorithm. Furthermore, there exist real symmetric tridiagonal matrices that suffer from severe spectral pollution. We refer the reader to [41] for an example in the context of orthogonal polynomials where the spectrum is $[-5, -1] \cup [1, 5]$ and finite section produces limiting eigenvalues for every point in $(-1, 1)$. This can also happen in the unbounded case and is a problem for operators such as the Dirac operator [87].
8.1.3. Pseudospectra and $\mathcal{PT}$ Symmetry. We now turn to demonstrating the algorithm used to compute the pseudospectrum. In this example we will consider non self-adjoint $T$ that still possess a certain symmetry and use Theorem 8.2. The first example is the imaginary cubic oscillator defined formally (in one dimension) by

$$H_2 = -d^2/dx^2 + ix^3.$$  

This operator is the most studied example of a $\mathcal{PT}$ symmetric operator\textsuperscript{4} [9, 10], as well as appearing in statistical physics and quantum field theory [57]. It is known that the resolvent is compact [30] with all eigenvalues simple and residing in $\mathbb{R}_{\geq 0}$ [43, 89]. The eigenvectors are complete but do not form a Riesz basis [91]. Figure 3 shows the computed pseudospectrum computed using $n = 1000$. This demonstrates the instability of the spectrum of the operator.

Next, we consider the imaginary Airy operator

$$H_3 = -d^2/dx^2 + ix,$$

\textsuperscript{4}Meaning $[H_2, \mathcal{PT}] = 0$ with $(\mathcal{P}f)(x) = f(-x)$ and $(\mathcal{T}f)(x) = \overline{f(x)}$. 

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{Left: Finite section for various $n$. Note the extremely heavy spectral pollution, although eigenvalues do appear to cluster around the true spectrum. Right: The estimates provided by DistSpec. The estimate converges quickly to the true value from above. The output of the algorithm can be spotted by eye and corresponds to the local minima of the curves below the cut-off 0.5 in this case.}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure3.png}
\caption{Left: Calculated pseudospectrum for the imaginary cubic oscillator. Note the clear presence of eigenvalues. Right: Calculated pseudospectrum for imaginary Airy operator. Both figures were produced with $n = 1000$.}
\end{figure}
since this is known to have empty spectrum [66], demonstrating the algorithm is effective in this case. Note that any finite section method will overestimate the pseudospectrum due to the presence of false eigenvalues. \( H_3 \) is \( PT \) symmetric and has compact resolvent. The resolvent norm \( \| R(z, H_3) \| \) only depends on the real part of \( z \) and blows up exponentially as \( \text{Re}(z) \to +\infty \). We have shown the computed pseudospectrum for \( n = 1000 \) in Figure 3.

We do not need to discretise anything to apply the above method. Up to numerical errors in the testing of positive definiteness, all computed pseudospectra are guaranteed to be inside the correct pseudospectra. This is in contrast to the numerical experiments conducted in [37] where the operator is discretised. It is also easy to construct examples where discretisations fail dramatically, either not capturing the whole spectrum or suffering from spectral pollution. Algorithms like \texttt{PseudoSpecUB} are a useful tool to test the reliability of such outputs.

The algorithm for computing the pseudospectrum is shown in \texttt{PseudoSpecUB}.

\begin{function}
\textbf{Function} PseudoSpecUB \((A,n,f(n),c_n,\epsilon)\)
\begin{itemize}
  \item [\textbf{Input}]: \( n \in \mathbb{N}, f(n) \in \mathbb{N}, c_n \in \mathbb{R}_+, A \in \hat{\Omega}, \epsilon > 0 \)
  \item [\textbf{Output}]: \( \Gamma \subset \mathbb{C} \), an approximation to \( \text{Sp}_\epsilon(A) \)
  \item \( G = \text{Grid}(n) \)
  \item for \( z \in G \) do
    \begin{itemize}
      \item \( F(z) = \text{DistSpec}(A,n,z,f(n)) + c_n \)
    \end{itemize}
  \item \( \Gamma = \bigcup \{ z \in G \mid |F(z) - \epsilon| \} \)
\end{itemize}
\end{function}

For completion, we also give routines in pseudocode for the problems \( \{\Xi_3, \hat{\Omega} \times K(\mathbb{C})\} \) and \( \{\Xi_4, \hat{\Omega} \times K(\mathbb{C})\} \). The routine \texttt{TestSpec} solves \( \{\Xi_3, \hat{\Omega} \times K(\mathbb{C})\} \) with input \( K_{n_2} \) and access to evaluating the function \( \gamma_{n_1}(z,A) \), which can be computed easily from \( \text{DistSpec} \). Similarly, the routine \texttt{TestPseudoSpec} solves \( \{\Xi_4, \hat{\Omega} \times K(\mathbb{C})\} \) with input \( K_{n_2}, \epsilon > 0 \) and access to evaluating the function \( \gamma_{n_1}(z,A) \).

\begin{function}
\textbf{Function} TestSpec \((n_1, n_2, K_{n_2}, \gamma_{n_1}(z,A))\)
\begin{itemize}
  \item [\textbf{Input}]: \( n_1, n_2 \in \mathbb{N}, K_{n_2} \) an approximation to \( K \), access to evaluation of \( \gamma_{n_1}(z,A) \).
  \item [\textbf{Output}]: \( \Gamma_{n_2,n_1}(A) \), an approximation of \( \Xi_{\delta}(A) \).
  \item \( \Gamma_{n_2,n_1}(A) = \text{"Does there exist some } z \in K_{n_2} \text{ such that } \gamma_{n_1}(z,A) < 1/2^{n_2}?" \)
\end{itemize}
\end{function}

\begin{function}
\textbf{Function} TestPseudoSpec \((n_1, n_2, K_{n_2}, \gamma_{n_1}(z,A), \epsilon)\)
\begin{itemize}
  \item [\textbf{Input}]: \( n_1, n_2 \in \mathbb{N}, K_{n_2} \) an approximation to \( K \), access to evaluation of \( \gamma_{n_1}(z,A), \epsilon > 0 \).
  \item [\textbf{Output}]: \( \Gamma_{n_2,n_1}(A) \), an approximation of \( \Xi_{\delta}(A) \).
  \item \( \Gamma_{n_2,n_1}(A) = \text{"Does there exist some } z \in K_{n_2} \text{ such that } \gamma_{n_1}(z,A) < 1/2^{n_2} + \epsilon?" \)
\end{itemize}
\end{function}

8.2. Numerical Example for Discrete Spectra. Although it is hard to analyse the convergence of a height two tower, we can take advantage of the extra structure in this problem. The routine \texttt{DiscreteSpec} computes \( \Gamma_{n_1,n_1}(A) \) such that \( \lim_{n_1 \to \infty} \Gamma_{n_2,n_1}(A) \) is a finite subset of \( \text{Sp}_d(A) \). Furthermore, for each \( z \in \text{Sp}_d(A) \), there is at most one point in \( z_{n_1} \in \Gamma_{n_2,n_1}(A) \) approximating \( z \). We can use the routine \texttt{DistSpec} to gain an error bound of \( \text{dist}(z_{n_1}, \text{Sp}(A)) \), which, for large \( n_1 \), will be equal to \( |z - z_{n_1}| \) since \( z \) is isolated. As we increase \( n_2 \), more and more of the discrete spectrum (in general portions nearer
the essential spectrum) are approximated. Given $z_{n_1} \to z$, the routine Multiplicity computes the multiplicity, $h(A, z)$, of the eigenvalue $z$.

**Function** `DiscreteSpec(n_1, n_2, \hat{\Gamma}_{n_1}(A), E(n_1, \cdot), \tilde{\Gamma}_{n_1}(A))`

- **Input**: $n_1, n_2 \in \mathbb{N}, \hat{\Gamma}_{n_1}(A)$ an approximation to $\text{Sp}(A)$, error estimate $E(n_1, \cdot)$ over $\hat{\Gamma}_{n_1}(A)$, $\tilde{\Gamma}_{n_1}(A)$ an approximation to $\text{Sp}_{\text{ess}}(A)$
- **Output**: $\Gamma_{n_2, n_1}(A)$, an approximation to $\text{Sp}_{d}(A)$.

```plaintext
if $n_2 \leq n_1$ then
  for $n_2 \leq k \leq n_1$ do
    $\zeta_{k,n_1}(A) = \{ z \in \hat{\Gamma}_{n_1}(A) : E(n_1, z) < \text{dist}(z, \tilde{\Gamma}_{k,n_1}(A)) - 1/k \}$
    for $z, w \in \zeta_{k,n_1}(A)$ do
      $z \sim_{n_1} w$ if and only if $B_{E(n_1, w_j)}(w_j) \cap B_{E(n_1, w_{j+1})}(w_{j+1}) \neq \emptyset$ for some $z = w_1, w_2, \ldots, w_n = w \in \zeta_{k,n_1}(A)$
    end
  end
  This gives equivalence classes $[z_1], \ldots, [z_m]$
  for $j \in \{1, \ldots, m\}$ do
    Choose $z_{k_j} \in [z_j]$ of minimal $E(n_1, \cdot)$
  end
  if $\cup_{j \in \{1, \ldots, m\}} \{ z_{k_j} \} \neq \emptyset$ then
    $\Phi_{k,n_1}(A) = \cup_{j \in \{1, \ldots, m\}} \{ z_{k_j} \}$
  else
    $\Phi_{k,n_1}(A) = \emptyset$
  end
end
if At least one of $\Phi_{k,n_1}(A) \neq \emptyset$ then
  $\Gamma_{n_2, n_1}(A) = \Phi_{k,n_1}(A) = \emptyset$ with $k$ minimal such that $\zeta_{k,n_1}(A) \neq \emptyset$
else
  $\Gamma_{n_2, n_1}(A) = \{0\}$
end
else
  $\Gamma_{n_2, n_1}(A) = \{0\}$
end
```

Our example is the Almost Mathieu Operator on $l^2(\mathbb{Z})$ given by

$$(H_{\alpha}x)_n = x_{n-1} + x_{n+1} + 2\lambda \cos(2\pi n\alpha + \nu)x_n,$$

where we set $\lambda = 1$ (critical coupling). For rational choices of $\alpha$, the operator is periodic and its spectrum is purely absolutely continuous, and depends on $\nu$. For irrational $\alpha$ the spectrum is a Cantor set (Ten Martini Problem) and does not depend on $\nu$. Hence it follows that there is no discrete spectrum. In general, we cannot hope to work with infinite precision and so will have to approximate irrational $\alpha$ by rational approximations. We chose to work with $\nu = 0$ but found similar results for other values. To generate a discrete spectrum, we add a perturbation of the potential of the form

$$V(n) = V_n/|n| + 1,$$
the corresponding \( \sqrt{\epsilon} \) tested the method using higher precision arithmetic and found the error plots to be similar, decreasing to

\[
\delta^{\text{thresh}} \quad \text{case taking} \quad A
\]

eigenvectors of an operator \( A \) in the construction of \( \text{DiscreteSpec} \). Caused sharper inclusion bounds and in general, the value \( \delta \) is conservative for the plot. For comparison, we have also shown the spectrum computed via finite section. It is easy to spot spectral pollution in the gaps of the essential spectrum. This type of problem is well studied in the more general setting of Jacobi operators [68, 100].

Figure 4 shows a typical result. We have shown the essential spectrum for a range of \( \alpha \), computed using Floquet theory, as well as the output of \( \text{DiscreteSpec} \) for \( n_1 \approx 2000 \) and a typical realisation of the random potential. For each \( \alpha \) we took \( n_2 \) large enough for an expected limit inclusion \( \text{Sp}_d(A) \subset \Gamma_{n_2}(A) + B_{0.05}(0) \). We then checked this against using a height one tower to compute the spectrum and subtracting the analytically computable essential spectrum and found our results to agree. Taking \( n_2 \) larger caused sharper inclusion bounds and in general, the value 0.05 is conservative for the plot. For comparison, we have also shown the spectrum computed via finite section. It is easy to spot spectral pollution in the gaps of the essential spectrum that are absent in the output of \( \text{DiscreteSpec} \). For rigorous detection, we have shown eigenvalues at least a distance 0.05 away from the essential spectrum (computed using the height two tower in the construction of \( \text{DiscreteSpec} \)) and output computed by \( \text{DiscreteSpec} \).

The errors in eigenvalue estimates in \( \text{DiscreteSpec} \) are shown in Figure 5 for a representative selection of eigenvalues. We have estimated the true error by taking \( n_1 \) large and have also shown the estimates produced by \( \text{DistSpec} \). As expected, the routine \( \text{DistSpec} \) gives an upper bound on the true error, which converges to zero. It is clear that only a small number of matrix values are required to gain high precision. The method of using Cholesky decompositions to test for positive definiteness means that we cannot expect precision greater than \( \sqrt{\epsilon_{\text{mach}}} \). For these tests this corresponds to approximately \( 10^{-8} \), although we have tested the method using higher precision arithmetic and found the error plots to be similar, decreasing to the corresponding \( \sqrt{\epsilon_{\text{mach}}} \). The error bounds can also be translated into computing approximates of the eigenvectors of an operator \( A \) corresponding to the discrete spectrum with an error bound in the following manner. The routine \( \text{ApproxEigenvector} \) in [8.3] computes a vector \( x_{n_1} \) of norm \( \approx 1 \) such that (in this case taking \( \delta \downarrow 0, c_\delta = 0 \))

\[
\| (A - z_{n_1} I) x_{n_1} \| \leq \text{DistSpec}(A, n_1, f(n_1), z_{n_1}).
\]

We write

\[
x_{n_1} = x_{n_1}^d + y_{n_1}
\]
where $x_{n_1}^d$ is an eigenvector of $A$ with eigenvalue $z$, $y_{n_1}$ is perpendicular to the eigenspace associated with $z$ and $z_{n_1} \to z$. It follows that

$$
\|(A - zI)y_{n_1}\| \leq |z - z_{n_1}| + \text{DistSpec}(A, n_1, f(n_1), z_{n_1}) \leq 2 \times \text{DistSpec}(A, n_1, f(n_1), z_{n_1}),
$$

for large $n_1$. But $A - zI$ is bounded below on the orthogonal complement of the eigenspace, with lower bound $\text{dist}(z, \text{Sp}(A)\{z\})$. Hence,

$$
\|y_{n_1}\| \leq \frac{2 \times \text{DistSpec}(A, n_1, f(n_1), z_{n_1})}{\text{dist}(z, \text{Sp}(A)\{z\})}
$$

for large $n_1$. This also bounds the $l^2$ distance of $x_{n_1}$ to the eigenspace and can be estimated by approximating the spectrum of $A$. We have shown the value of vector components of approximate eigenvalues in Figure 5 for $n_1 = 201$ (corresponding to sites $n = -100, \ldots, 100$). It is also straightforward to adjust this procedure to eigenvalues of multiplicity greater than 1 and approximate the whole eigenspace. We note that for this example, all eigenvalues were found to have multiplicity 1 as expected for a random perturbation. Finally,
we make the remark that the method of computing eigenvectors and error bounds can also be used for the unbounded case when \( z \) lies in the discrete spectrum.

8.3. Other Routines. The routine \( \text{DiscSpecEmpty} \) computes \( \Xi_2^d(A) \) in two limits for \( A \in \Omega^d_n \), the class of bounded normal operators with known dispersion bounding function. The inputs are the algorithm \( \hat{\Gamma}_n \) computing the spectrum (for example, \( \text{CompSpecUB} \)), the error control \( E(n, z) \) (that converges to the true error uniformly on compact subsets of \( \mathbb{C} \)) and the height two tower \( \hat{\Gamma}_{n_2, n_1} \) presented in [8] to compute the essential spectrum.

Function \( \text{DiscSpecEmpty}(n_1, n_2, \hat{\Gamma}_{n_1}(A), E(n_1, \cdot), \hat{\Gamma}_{n_2, n_1}(A)) \)

Input : \( n_1, n_2 \in \mathbb{N}, \hat{\Gamma}_{n_1}(A) \) an approximation to \( \text{Sp}(A) \), error estimate \( E(n_1, \cdot) \) over \( \hat{\Gamma}_{n_1}(A), \hat{\Gamma}_{n_2, n_1}(A) \) an approximation to \( \text{Sp}_{\text{ess}}(A) \).

Output: \( \Gamma_{n_2, n_1}(A) \), an approximation to \( \Xi_2^d(A) \).

\[ \zeta_{n_2, n_1}(A) = \{ z \in \hat{\Gamma}_{n_1}(A) : E(n_1, z) < \text{dist}(z, \hat{\Gamma}_{n_2, n_1}(A)) - 1/n_2 \} \]

if \( \zeta_{n_2, n_1}(A) \neq \emptyset \) then

\[ \Gamma_{n_2, n_1}(A) = 1 \]

else

\[ \Gamma_{n_2, n_1}(A) = 0. \]

end

The routine \( \text{ApproxEigenvector} \) takes as input \( A, n, f(n), z_n \) and the corresponding error bound \( E(n, z_n) \) where

\[ \sigma_1(P_{f(n)}(A - z_n I)|_{P_n(I^2(n))}) \leq E(n, z_n). \]

Given \( \delta > 0 \), it computes an approximate eigenvector \( x_n \) (of finite support) satisfying

\[ \|(A - z_n I)x_n\| \leq \|x_n\| (E(n, z_n) + c_n + \delta) \text{ and } 1 - \delta < \|x_n\| < 1 + \delta. \]

The routine \( \text{SpecGap} \) solves the computational problem (spectral gap) in Theorem 2.12. The only ingredient for this routine is an eigenvalue solver to implement Corollary 4.39 to compute all \( n \) eigenvalues of \( P_n A P_n \) to arbitrary precision in finitely many arithmetic operations and comparisons.
Function \texttt{ApproxEigenvector} \((A, n, f(n), z_n, E(n, z_n), \delta)\)

\textbf{Input} : \(n \in \mathbb{N}, f(n) \in \mathbb{N}, A, z_n \in \mathbb{C},\) error bound \(E(n, z_n)\) and tolerance \(\delta > 0\)

\textbf{Output}: \(x_n \in \mathbb{C}^n,\) a vector satisfying \(\|((A - z_n I)x_n\| \leq \|x_n\|(E(n, z_n) + c_n + \delta)\)

\(\epsilon = (E(n, z_n) + \delta)^2\)

\(B = [(A - z_n I)(1 : f(n), 1 : n)]^*[(A - z_n I)(1 : f(n), 1 : n)] - \epsilon I\)

\([L, D] = \text{ldl}(B)\)

\textbf{if} \(D\) is diagonal \textbf{then}

\quad Find \(i\) with \(D(i, i) < 0\)

\quad \(y = e_i\)

\textbf{else}

\quad Find \(y\) eigenvector of \(D\) with eigenvalue < 0

\textbf{end}

Solve upper triangular system for \(x_n\) with \(y = L^*x_n\) then normalise to precision \(\delta\).

end

Function \texttt{SpecGap}(\(n_1, n_2, P_{n_1}AP_{n_1}\))

\textbf{Input} : \(n_1, n_2 \in \mathbb{N}, P_{n_1}AP_{n_1}\) the square truncation of the matrix \(A\)

\textbf{Output}: \(\Gamma_{n_2, n_1}(A),\) an approximation to \(\Xi_{\text{gap}}(A)\).

\textbf{if} \(n_1 = 1\) \textbf{then}

\quad Set \(\Gamma_{n_2, n_1}(A) = 1\)

\textbf{else}

\quad \textbf{for} \(k \in \{2, \ldots, n_1\}\) \textbf{do}

\quad \quad Compute \(l_k = \mu_k^2 - \mu_1^2 + \epsilon_k, |\epsilon_k| \leq 1/k,\)

\quad \quad using Corollary [4.9] and notation of Lemmas [6.1] and [6.2] applied to \(P_kAP_k.\)

\quad \textbf{end}

\quad Set \(J_{n_2}^1 = [0, 1/(2n_2)]\) and \(J_{n_2}^2 = (1/n_2, \infty)\)

\quad \textbf{if} \(\{l_k : k \in \{1, \ldots, n_1\} \cap (J_{n_2}^1 \cup J_{n_2}^2)\} = \emptyset\) \textbf{then}

\quad \quad Set \(\Gamma_{n_2, n_1}(A) = 0\)

\quad \textbf{else}

\quad \quad Let \(\hat{k} \leq n_1\) be maximal with \(l_{\hat{k}} \in J_{n_2}^1 \cup J_{n_2}^2,\)

\quad \quad \textbf{if} \(l_{\hat{k}} \in J_{n_2}^1\) \textbf{then}

\quad \quad \quad Set \(\Gamma_{n_2, n_1}(A) = 0\)

\quad \quad \textbf{else}

\quad \quad \quad Set \(\Gamma_{n_2, n_1}(A) = 1.\)

\quad \textbf{end}

\textbf{end}

\textbf{end}

The routine \texttt{SpecClass} solves the computational problem (classification) in Theorem 2.14. As well as an eigenvalue solver to implement Corollary [4.9] we need the algorithm \texttt{CompSpecUB} denoted by \(\hat{\Gamma}_n,\) which computes the spectrum together with an error bound \(E(n, \cdot)\) on the output.
**Function SpecClass \((n_1, n_2, A, f)\)**

**Input**: \(n_1, n_2 \in \mathbb{N}, A \in \mathcal{O}_{\text{SA}}^f\), \(f\) the dispersion bounding function

**Output**: \(\Gamma_{n_2,n_1}(A)\), an approximation to \(\Xi_{\text{class}}(A)\).

- **if** \(n_1 \leq n_2\) **then**
  - Set \(\Gamma_{n_2,n_1}(A) = 1\)

- **else**
  - **for** \(n \in \{1, \ldots, n_1\} \text{ and } j \in \{1, \ldots, n-1\} \text{ do}**
    - Compute \(l^n_j = \mu^{n+1}_j - \mu^n_j + \epsilon^n_j, |\epsilon^n_j| \leq 1/n\).
    - using Corollary 4.9 and notation of Lemmas 6.1 and 6.2 applied to \(P_nAP_n\).
  - end
  - Set \(J^1_{n_2} = [0, 1/(2n_2)]\) and \(J^2_{n_2} = (1/n_2, \infty)\)
  - **for** \(j \in \{1, \ldots, n_2\} \text{ do}**
    - Let \(k^n_{n_2,n_1}\) be maximal with \(1 \leq k^n_{n_2,n_1} < n_1\) such that \(l^n_{k^n_{n_2,n_1}} \in J^1_{n_2} \cup J^2_{n_2}\) if such \(k^n_{n_2,n_1}\) exists.
  - end
  - **if** \(k^n_{n_2,n_1}\) exists with \(l^n_{k^n_{n_2,n_1}} \in J^2_{n_2}\) **then**
    - Set \(\Gamma_{n_2,n_1}(A) = 1\)
  - **else**
    - **if** any \(k^m_{n_2,n_1}\) exists with \(l^m_{k^m_{n_2,n_1}} \in J^2_{n_2}\) for \(2 \leq m \leq n_2\) **then**
      - Set \(\Gamma_{n_2,n_1}(A) = 2\)
    - **else**
      - **for** \(k \in \{1, \ldots, n_1\} \text{ do}**
        - Set \(a_k(A) = \min\{x \in f_k(A) | x + E(k,x)\}\).
        - Set \(q_k = E(k,a_k(A) + 1/n_2) + 1/k\).
      - end
      - Set \(b_{n_2,n_1}(A) = \min\{q_k : 1 \leq k \leq n_1\}\).
      - **if** \(b_{n_2,n_1}(A) \geq 1/n_2\) **then**
        - Set \(\Gamma_{n_2,n_1}(A) = 3\)
      - **else**
        - Set \(\Gamma_{n_2,n_1}(A) = 4\).
      - end
    - end
  - end
- end
Appendix A. Turing Towers and Inexact Input

Suppose we are given a computational problem \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \} \), and that the evaluation set \( \Lambda = \{ f_j : \Omega \rightarrow \mathbb{C}^{k_j} \} \in \mathcal{Z} \), where \( \mathcal{I} \) is some countable index set that can be finite or infinite. However, obtaining \( f_j \) may be a computational task on its own. For instance, \( f_j(A) \) could be the number \( e^j \) for example or a matrix value from an inner product integral. Hence, we cannot access \( f_j(A) \), but rather \( f_{j,n}(A) \) where \( f_{j,n}(A) \rightarrow f_j(A) \) as \( n \rightarrow \infty \). Or, just as for problems that are high up in the SCI hierarchy, it could be that we need several limits, in particular one may need mappings \( f_{j,n,m,...,m_n} : \Omega \rightarrow [\mathbb{Q} + i\mathbb{Q}]^{k_j} \) such that

\[
\lim_{n_m \rightarrow \infty} \ldots \lim_{n_1 \rightarrow \infty} f_{j,n_m,...,n_1}(A) = f_j(A) \quad \forall A \in \Omega.
\]

(A.1)

In particular, we may view the problem of obtaining \( f_j(A) \) as a problem in the SCI hierarchy, where \( \Delta_1 \) classification would correspond to the existence of mappings \( f_{j,n} : \Omega \rightarrow [\mathbb{Q} + i\mathbb{Q}]^{k_j} \) such that

\[
\| f_{j,n}(A) - f_j(A) \| \leq 2^{-n} \quad \forall A \in \Omega.
\]

(A.2)

This idea is formalised in the following definition.

**Definition A.1** (\( \Delta_m \)-information). Let \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \} \) be a computational problem. For \( m \in \mathbb{N} \) we say that \( \Lambda \) has \( \Delta_{m+1} \)-information if each \( f_j \in \Lambda \) is not available, however, there are mappings \( f_{j,n_m,...,n_1} : \Omega \rightarrow [\mathbb{Q} + i\mathbb{Q}]^{k_j} \) such that (A.1) holds. Similarly, for \( m = 0 \) there are mappings \( f_{j,n} : \Omega \rightarrow [\mathbb{Q} + i\mathbb{Q}]^{k_j} \) such that (A.2) holds. Finally, if \( k \in \mathbb{N} \) and \( \Lambda \) is a collection of such functions described above such that \( \Lambda \) has \( \Delta_k \)-information, we say that \( \Lambda \) provides \( \Delta_k \) information for \( \Lambda \). Moreover, we denote the family of all such \( \Lambda \) by \( \mathcal{L}^k(\Lambda) \).

With this definition, we can now define what we mean by a computational problem with \( \Delta_m \)-information.

**Definition A.2** (Computational problem with \( \Delta_m \) information). Given \( m \in \mathbb{N} \), a computational problem where \( \Lambda \) has \( \Delta_m \)-information is denoted by \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \}^{\Delta_m} \) and denotes the family of computational problems \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \} \) where \( \Lambda \in \mathcal{L}^m(\Lambda) \).

**Definition A.3** (Tower with \( \Delta_m \)-information). A tower of algorithms of height \( k \) with \( \Delta_m \)-information is a tower of algorithms of height \( k \) for the computational problem \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \} \), where \( \Lambda \) has \( \Delta_m \)-information such that the tower converges (all \( m \)-limits) for any evaluation set \( \hat{\Lambda} \in \mathcal{L}^m(\Lambda) \).

The SCI hierarchy, given \( \Delta_m \)-information, is then defined in the standard obvious way, where the convergence has to happen given any \( \hat{\Lambda} \in \mathcal{L}^m(\Lambda) \). We will use the notation

\[
\{ \Xi, \Omega, \mathcal{M}, \Lambda \}^{\Delta_m} \in \Delta^0_k
\]

to denote that the computational problem is in \( \Delta^0_k \) with respect to towers of algorithms with \( \Delta_m \)-information. Since \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \}^{\Delta_m} \) is the collection of all computational problems with \( \Lambda \) replaced by \( \hat{\Lambda} \in \mathcal{L}^m(\Lambda) \), we note that the use of \( \in \) is a slight abuse of notation. When \( \mathcal{M} \) and \( \Lambda \) are obvious then we will write \( \{ \Xi, \Omega \}^{\Delta_m} \in \Delta^0_k \) for short. In exactly the same way as above, we can define \( \Pi^0_k \) and \( \Sigma^0_k \) for \( \{ \Xi, \Omega, \mathcal{M}, \Lambda \}^{\Delta_m} \) if the metric space that \( \Xi \) maps to is totally ordered or a Hausdorff metric space.

To make a connection with the classical theory of computation, consider the case where \( \Lambda = \{ f_j \} \in \mathcal{Z} \) has some natural (countably infinite) ordering \( \mathcal{I} = \{ \alpha_1, \alpha_2, ... \} \). For example, in the case of spectral operators for general \( A \in B(\ell^2(\mathbb{N})) \) we have the matrix evaluations \( f_{i,j}(A) = (Ae_{j}, e_i) \). Of course given \( \Lambda \in \mathcal{L}^1(\Lambda) \) we must replace \( \mathcal{I} \) by \( \mathcal{I} \times \mathbb{N} \). By a suitable effective enumeration, we can assume each \( f_{j,n} \) maps into \( \mathbb{N} \). We can also view the evaluation functions as an oracle through the mapping defined by

\[
\hat{\Lambda}(A) : \mathbb{N} \times \mathbb{N} \ni (j, n) \mapsto f_{n_1,n}(A) \in \mathbb{N}.
\]

Now suppose that our metric space \( (\mathcal{M}, d) \) is the Hausdorff metric on non-empty compact subsets of \( \mathbb{C}, \mathbb{R} \) or some (at most countable) discrete ordered space. We now have the following definition.
Definition A.4 (Turing Tower). Given a computational problem \( \{\Xi, \Omega, M, \Lambda\} \) where \((M, d)\) is one of the above metric spaces, a Turing Tower of Algorithms of height \(k\) for \( \{\Xi, \Omega, M, \Lambda\} \) is a tower of algorithms of height \(k\) with \(\Delta_1\)-information where the lowest level algorithms

\[
\Gamma = \Gamma_{n_k \ldots n_1} : \Omega \to M
\]
satisfy the following. For each \( A \in \Omega \) and \( \hat{A} \in L^1(\Lambda) \):

1. We can view the output as lying in the space \( \{0, 1\}^* \) by a suitable effective enumeration. For example, if \((M, d) = \mathbb{C} \) (or \( \mathbb{R} \)) with the usual metric, the output \( \Gamma(A) \in \mathbb{Q} + i\mathbb{Q} \) (or \( \mathbb{Q} \)). If \((M, d)\) is the Hausdorff metric on the non-empty compact subsets of \( \mathbb{C} \) or the Attouch-Wets metric on non-empty closed subsets of \( \mathbb{C} \), \( \Gamma(A) \) is a finite collection of points in \( \mathbb{Q} + i\mathbb{Q} \).
2. \( \Gamma \) is an oracle Turing machine such that given the input \((n_1, \ldots, n_k)\) and oracle \( \hat{A}(\Lambda) \), it computes \( \Gamma_{n_k \ldots n_1}(A) \).

Such a tower will be denoted by the superscript \( T \).

Remark A.5. Note that we still require the convergence of our towers in the original metric space \( \{M, d\} \), which of course may not be compatible with the metric induced by the coding of our range space.

Remark A.6. It is sometimes helpful to allow the output not just to be a finite set of points. For instance, in the case of computing the essential spectrum, the algorithms in [8] output a finite collection of squares in the complex plane with complex rational centres and rational side lengths. The above definition can then be easily adapted.

A remarkable consequence of our results is that for the problems considered in this paper, the SCI classification does not change if we consider Turing towers instead of arithmetic towers. This is easy to see through Church’s thesis and a careful but somewhat tedious analysis of the stability of our algorithms (for example, we have been careful to restrict all relevant operations to \( \mathbb{Q} \) rather than \( \mathbb{R} \) and errors incurred from \( \Delta_1 \) information can be removed in the first limit). Explicitly, for the algorithms based on \text{DistSpec} \ (\text{see above}) it is possible to carry out an error analysis. If we know the errors and can also bound numerical errors (or use exact arithmetic on \( \mathbb{Q} \)) then we can incorporate this uncertainty for the estimation of \( \|R(z, A)\|^{-1} \) and still gain the same classification of our problems. Similarly for other algorithms based on similar functions. In other words, it does not matter which model of computation one uses for a definition of ‘algorithm’, from a classification point of view they are equivalent for these spectral problems. This leads to rigorous \( \Sigma_k^\alpha \) or \( \Pi_k^\gamma \) type error control suitable for verifiable numerics. In particular, for \( \Sigma_k^\alpha \) or \( \Pi_k^\gamma \) towers of algorithms, this could be useful for computer-assisted proofs.
