ON RECOVERY OF A BOUNDED ELASTIC BODY BY
ELECTROMAGNETIC FAR-FIELD MEASUREMENTS

TIELEI ZHU∗, JIAQING YANG†, AND BO ZHANG‡

Abstract. This paper is concerned with the problem of scattering of a time-harmonic electromagnetic field by a three-dimensional elastic body. General transmission conditions are considered to model the interaction between the electromagnetic field and the elastic body on the interface by assuming Voigt’s model. The existence of a unique solution of the interaction problem is proved in an appropriate Sobolev space by employing a variational method together with the classical Fredholm alternative. The inverse problem is then considered, which is to recover the elastic body by the scattered wave-field. It is shown that the shape and location of the elastic body can be uniquely determined by the fixed energy magnetic (or electric) far-field measurements corresponding to incident plane waves with all polarizations.

Key words. Interaction, Maxwell’s equations, Navier equation, well-posedness, inverse scattering, uniqueness.

1. Introduction. The interaction of different physical fields has received considerable attention due to the rapidly increasing use of composite materials. Therefore, it is significant to develop the related mathematical model and analysis by physical process. The physical kinematic and dynamic relations are described by the corresponding partial differential equations (PDEs) with certain boundary-transmission conditions. Generally, it is difficult to find an appropriate interaction condition connected with different physical fields on the interface.

For time-harmonic acoustic wave scattering by a solid body, many work has been done on the mathematical analysis of the interaction problem (see, e.g., [6, 9]). Recently, the corresponding inverse problems have also been studied mathematically and numerically of detecting an elastic body via the measurement of the acoustic scattered wave field. We refer the reader to [7,11–13] for detailed discussions. In particular, it is shown in [12] that a uniqueness result was first proved in recovering an elastic body by the acoustic far-field measurements. The proof was then simplified by Monk and Selgas [14] by using the technique of Hähner in [5] for the case of a penetrable, anisotropic obstacle. However, the analysis in [11] relies on the $H^2$-regularity estimate of solutions of the scattering problem, and thus the proposed method remains complicated. Very recently, a much simpler proof was introduced by Qu et al. [13], which is motivated by the previous work of the last two authors [14] for inverse acoustic and electromagnetic scattering by a penetrable obstacle, and can be extended to deal with other more general cases.

In this paper we consider the problem of scattering of a time-harmonic electromagnetic field by a three-dimensional elastic body. Assume by Voigt’s model that the interaction is allowed only through the boundary of the body, which means that the model problem can be described by the Maxwell and Navier equations coupled with a

suitable transmission condition on the interface between the elastic and electromagnetic medium. It was shown [2] that an interaction model was first introduced by Cakoni and Hsiao with possible interface conditions for the coupled electromagnetic and elastic fields, where the uniqueness result and equivalent integral equations and non-local variational formulations have been established for the model. Applying the framework in [2], Gatica et al. [4] proved the existence of a unique solution of the interaction problem by using a variational method. The result was later extended by Bernardo et al. [1] to a different function space for the elastic field, based on a similar idea to [4].

Different from [1] and [4], we study in this paper the interaction problem with general interface transmission conditions which could model more physical situations in applications. An equivalent non-symmetric variational formulation is then obtained by using Green’s formulas so that the existence of a unique solution to the problem can follow from the classical Fredholm alternative with a suitable Helmholtz-type decomposition of the electromagnetic field. Compared with the forward problem, the inverse problem of determining the elastic body is more challenging due to the complication of the interaction model. To the best of our knowledge, no uniqueness result is available for this problem in the literature. Inspired by our previous work [14] where a novel technique was introduced for showing uniqueness in determining an acoustic or electromagnetic penetrable obstacle, we aim to develop a novel and simple technique to prove the unique recovery of the elastic body by the electromagnetic far-field measurement at a fixed frequency. The proposed method is mainly based on constructing a well-posed system of PDEs for the coupled Maxwell and Navier equations in a small domain near the interface in conjunction with a uniform a priori estimate in the $H^1(\text{curl}) \times H^1(\cdot)$ norm of solutions to the interaction problem when the incident electromagnetic fields are induced by a family of electric dipoles with a weak singularity.

The remaining part of the paper is organized as follows. In Section 2 we formulate the interaction scattering problem by collecting some useful functions spaces, trace operators and related properties. In Section 3, we show the existence of a unique solution to the interaction problem by the variational method with aid of a suitable Helmholtz-type decomposition. In Section 4 a global uniqueness theorem is proved for the associated inverse problem of determining the elastic body from the magnetic or electric far-field measurements at a fixed frequency.

2. The model problem. In this section, we first introduce some basic notations and function spaces used throughout this paper and then present the mathematical formulation of the model problem.

2.1. Preliminaries. For a complex number $z \in \mathbb{C}$, its conjugate and modulus are denoted by $\bar{z}$ and $|z|$, respectively. For $x, y \in \mathbb{C}^3$ define $x \cdot y = \sum_{j=1}^{3} x_j y_j$. Let $D \subseteq \mathbb{R}^3$ be a bounded domain with a $C^2$ boundary $\partial D$ and let $\nu$ be the unit outward normal to $\partial D$. For $s \in \mathbb{R}$ denote by $H^s(D)$ and $H^s(\partial D)$ the standard scalar Sobolev spaces defined on $D$ and $\partial D$, respectively, with $L^2(\cdot) := H^0(\cdot)$. We also need the following vector function spaces defined on $D$ and $\partial D$:

$$
H^s(D) := [H^s(D)]^3, \quad s \in \mathbb{R},
$$

$$
H^s(\partial D) := [H^s(\partial D)]^3, \quad s \in \mathbb{R},
$$

$$
H^s_t(\partial D) := \{ \mu \in H^s(\partial D) : \mu \cdot \nu = 0 \}, \quad s \in \mathbb{R},
$$

$$
H(\text{curl}, D) := \{ \mathbf{B} \in L^2(D) : \text{curl} \mathbf{B} \in L^2(D) \}.
$$
For each $s \in \mathbb{R}$, $\langle H^{-s}, H^{s} \rangle$ and $\langle H^{-s}, H^{s} \rangle$ denote the duality product under the extension of the $L^2$-bilinear form

$$\langle u, v \rangle := \int_D u \cdot v \, dx, \quad u, v \in L^2(D).$$

By [10] the tangential trace spaces of $H(\text{curl}, D)$ can be characterized as

$$H_{\text{Div}}^{-1/2}(\partial D) := \{ \mu \in H^{-1/2}_t(\partial D) : \text{Div} \partial_D \mu \in H^{-1/2}(\partial D) \},$$

$$H_{\text{Curl}}^{-1/2}(\partial D) := \{ \mu \in H^{-1/2}_t(\partial D) : \text{Curl} \partial_D \mu \in H^{-1/2}(\partial D) \},$$

where $\text{Div} \partial_D$ and $\text{Curl} \partial_D$ denote the surface divergence and surface curl with respect to the boundary $\partial D$, respectively. For convenience, we also use $\nabla_{\partial D}$ to denote the extension of the $L^2_{\partial D}$, which is a bilinear form.

Further, the duality product between $H_{\text{Div}}^{-1/2}(\partial D)$ and $H_{\text{Curl}}^{-1/2}(\partial D)$ is defined as

$$\langle \varphi, \psi \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} := \int_D [\text{curl} v \cdot w - \text{curl} w \cdot v] \, dx$$

for $v, w \in H(\text{curl}, D)$ satisfying $\gamma_t v = \varphi$ and $\gamma_T w = \psi$. In addition, introduce the tangential trace spaces of $H^1(D)$:

$$H^1_t(\partial D) := \gamma_t(H^1(D)) \quad \text{and} \quad H^{1/2}(\partial D) := \gamma_T(H^1(D)),$$

and denote by $H^{-1/2}_t(\partial D)$ and $H^{-1/2}_t(\partial D)$ the dual space of $H^{1/2}_t(\partial D)$ and $H^{1/2}_t(\partial D)$, respectively. Clearly, $H_{\text{Div}}^{-1/2}(\partial D)$ is a closed subspace of $H_{\text{Div}}^{-1/2}(\partial D)$, which can be understood in the sense that

$$\langle \varphi, \psi \rangle_{H_{\text{Div}}^{-1/2} \times H^{1/2}} := \int_D [\text{curl} w \cdot v - \text{curl} v \cdot w] \, dx$$

for $w \in H(\text{curl}, D)$ and $v \in H^1(D)$ satisfying $\gamma_t w = \varphi \in H_{\text{Div}}^{-1/2}(\partial D)$ and $\gamma_T v = \psi \in H^{1/2}(\partial D)$.

2.2. The mathematical formulation. In this subsection, we formulate the mathematical formulation of the problem of scattering of a time-harmonic electromagnetic wave by an elastic body in $\mathbb{R}^3$. As seen in Figure 2.1, the elastic body is described by a bounded domain $D$ with a smooth boundary of $C^\infty$-class, which is assumed to be inhomogeneous and anisotropic with the stiffness tensor $C := (C_{ijkl}(x))_{i,j,k,l=1}^3$, where $C_{ijkl} \in L^\infty(D)$ ($i,j,k,l = 1, 2, 3$), and the density $\rho(x) \in L^\infty(D)$. The background
medium outside of $D$ is assumed to be homogeneous and isotropic with constant electric permittivity $\varepsilon_0 \in \mathbb{R}_+$ and magnetic permeability $\mu_0 \in \mathbb{R}_+$.

Consider a pair of electromagnetic waves of the form

$$
E^i(x,d,p) = -\frac{1}{i\kappa}\text{curl}^2(\rho e^{i\kappa x \cdot d}), \quad H^i(x,d,p) = \text{curl}(\rho e^{i\kappa x \cdot d}), \quad x \in \mathbb{R}^3
$$

which is incident on $D$ from the unbounded exterior domain $D^e := \mathbb{R}^3 \setminus \overline{D}$, where $\omega \in \mathbb{R}_+$ is the wave frequency, $d \in S^2$ is the direction of wave propagation, $p \in \mathbb{R}^3$ is the polarization vector and $\kappa = \omega \sqrt{\varepsilon_0/\mu_0}$ is the wave number. Then the elastic deformation occurs due to the physical property of the elastic body. Following Voigt’s model, we can assume that the electromagnetic wave does not penetrate the elastic body so that the interaction occurs only on the interface. Under the above physical assumption, the elastic field $u$ satisfies the Navier equation

$$
\nabla \cdot (\mathcal{C} : \nabla u) + \rho \omega^2 u = 0 \quad \text{in} \ D,
$$

where $\mathcal{C} : \nabla u$ is defined as

$$
\mathcal{C} : \nabla u := (\mathcal{C} : \nabla u)_{ij} = \sum_{k,l=1}^3 C_{ijkl} \frac{\partial u_k}{\partial x_l}
$$

and $\nabla \cdot (\mathcal{C} : \nabla u)$ is defined as

$$
\nabla \cdot (\mathcal{C} : \nabla u) = \sum_{j,k,l=1}^3 \frac{\partial}{\partial x_j}(C_{ijkl} \frac{\partial u_k}{\partial x_l}).
$$

Moreover, the stiffness tensor $\mathcal{C}$ in (2.1) satisfies the symmetry condition

$$
C_{ijkl} = C_{klji} = C_{jkil} = C_{ijlk}
$$

and the Legendre elliptic condition

$$
\sum_{i,j,k,l=1}^3 C_{ijkl}(x)a_{ij}a_{kl} \geq c_0 \sum_{i,j=1}^3 |a_{ij}|^2, \quad a_{ij} = a_{ji}
$$

for some positive constant $c_0 > 0$. 

![Fig. 2.1. Interaction between electromagnetic wave and a bounded elastic body](image-url)
In the exterior domain $D^c$, the electromagnetic field $(E, H)$, which is the sum of the incident field $(E^i, H^i)$ and the scattered field $(E^s, H^s)$, satisfies the Maxwell equations

$$\text{curl} \ E - i\kappa H = 0, \quad \text{curl} \ H + i\kappa E = 0 \quad \text{in} \ D^c,$$

(2.3)

with the scattered field $(E^s, H^s)$ satisfying the Silver-M"uller radiation condition

$$\lim_{|x|\to\infty} |x| |(E^s \times \hat{x}) + H^s| = 0,$$

(2.4)

where $\hat{x} = x/|x| \in S^2$.

On the interface, the electromagnetic and elastic fields are assumed to be coupled by the general transmission conditions (cf. [2]):

$$Tu - b_1 \nu \times H^s = b_1 \nu \times H^i \quad \text{on} \ \partial D,$$

(2.5)

$$\nu \times u - b_2 \nu \times E^s = b_2 \nu \times E^i \quad \text{on} \ \partial D,$$

(2.6)

where $b_1, b_2 \in \mathbb{C}$, $b_1 b_2 \neq 0$, $\nu$ is the unit outward normal to $\partial D$ and $T$ is defined as

$$(Tu)_i = \sum_{j,k,l=1}^3 \nu_j C_{ijkl} \frac{\partial u_k}{\partial x_l}, \quad i = 1, 2, 3.$$ We refer the reader to [2,4] for detailed discussions on different choices of $b_1$ and $b_2$.

By the radiation condition (2.4), it is well-known that the scattered field has the asymptotic behavior

$$H^s(x, d, p) = \frac{e^{i|\hat{x}|}}{|\hat{x}|} H^s_\infty(\hat{x}, d, p) + O\left(\frac{1}{|x|^2}\right), \quad \text{as} \ |x| \to \infty$$

and

$$E^s(x, d, p) = \frac{e^{i|\hat{x}|}}{|\hat{x}|} E^s_\infty(\hat{x}, d, p) + O\left(\frac{1}{|x|^2}\right), \quad \text{as} \ |x| \to \infty,$$

where $E^s_\infty(\hat{x}, d, p)$ and $H^s_\infty(\hat{x}, d, p)$ denote the electric and magnetic far-field patterns, respectively, which are analytic in $\hat{x} \in S^2$ and $d \in S^2$, respectively, and satisfy the relations (cf. [3]):

$$H^s_\infty(\hat{x}, d, p) = \hat{x} \times E^s_\infty(\hat{x}, d, p), \quad \hat{x} \cdot E^s_\infty(\hat{x}, d, p) = 0, \quad \hat{x} \cdot H^s_\infty(\hat{x}, d, p) = 0. \quad (2.7)$$

3. The well-posedness of the interaction problem. In this section, we prove the well-posedness of the interaction problem (2.1)-(2.5), employing a variational method. Under the transmission conditions (2.5) and (2.6), the existence of a unique solution can be obtained by showing the variational formulation to be of Fredholm with index 0 in an appropriate Sobolev space.

3.1. Uniqueness of solutions. As known for the fluid-solid interaction problem, non-uniqueness may exist for certain frequencies which are called Jones frequencies. Similarly, there may exist pathological frequencies in the interaction between an electromagnetic wave and an elastic body so that a nontrivial solution exists for the homogeneous problem corresponding to the problem (2.1)-(2.5). Thus, introduce the homogeneous problem

$$\nabla \cdot (C : \nabla u) + \rho \omega^2 u = 0 \quad \text{in} \ D,$$

(3.1)

$$\nu \times u = 0 \quad \text{on} \ \partial D,$$

(3.2)

$$Tu = 0 \quad \text{on} \ \partial D.$$
and let the set \( \mathcal{P}(\omega) \) be consisting of the frequency \( \omega \in \mathbb{R} \) such that (3.1) has a nontrivial solution. Then we have the following result on uniqueness of solutions to the problem (2.1)-(2.5). 

**Theorem 3.1.** Assume that \( \rho, \kappa, \omega \in \mathbb{R} \) and \( \omega \notin \mathcal{P}(\omega) \). If \( \text{Re}(b_1 \bar{b}_2) = 0 \), then the scattering problem (2.1)-(2.5) has at most one solution.

**Proof.** Let \( E^i = H^i = 0 \). Then it is enough to prove that \( E^s = H^s = 0 \). Using Green’s formula and the transmission conditions (2.5) and (2.6), we have

\[
\int_{\partial D} \nu \times E^s \cdot H^s \, ds = -\frac{1}{b_1 b_2} \int_{\partial D} T u \cdot \bar{u} \, ds = -\frac{1}{b_1 b_2} \int_D [E(u, \bar{u}) - \rho \omega^2 |u|^2] \, dx,
\]

where

\[
E(u, v) := \sum_{i,j,k,l=1}^3 C_{ijkl} \frac{\partial u_k}{\partial x_i} \frac{\partial v_l}{\partial x_j}
\]

for \( u, v \in H^1(D) \). Thus

\[
\text{Re} \int_{\partial D} \nu \times E^s \cdot H^s \, ds = -\text{Re} \frac{1}{b_1 b_2} \int_D [E(u, \bar{u}) - \rho \omega^2 |u|^2] \, dx.
\]

By this, Rellich’s lemma (see [3]) and the fact that \( \text{Re}(b_1 \bar{b}_2) = 0 \), we conclude that \( E^s = H^s = 0 \). Then the elastic field \( u \) satisfies (3.1), yielding \( u = 0 \) since \( \omega \notin \mathcal{P}(\omega) \). \( \Box \)

**3.2. Existence of solutions.** We now prove the existence of solutions of the scattering problem (2.1)-(2.5), employing a variational method. To this end, we eliminate the electric field \( E \) and consider the boundary value problem for \( (H, u) \):

\[
\begin{aligned}
\nabla \cdot (C : \nabla u) + \rho \omega^2 u &= 0 & \text{in } D, \\
\text{curl curl } H - \kappa^2 H &= 0 & \text{in } D^c, \\
T u - b_1 \nu \times H &= f_1 & \text{on } \partial D, \\
\nu \times u + \frac{b_2}{i \kappa} \nu \times \text{curl } H &= f_2 & \text{on } \partial D, \\
\lim_{r \to \infty} r \left( \hat{x} \times \text{curl } H + i \kappa \hat{x} \right) &= 0 & r = |x|,
\end{aligned}
\]

where \( f_1 \in H^{-1/2}(\partial D) \) and \( f_2 \in H^{-1/2}(\partial D) \). Note that the scattering problem (2.1)-(2.5) can be viewed as a special case of the problem (3.4) with \( f_1 := b_1 \nu \times H^i \) and \( f_2 := (b_2/i \kappa) \nu \times \text{curl } H^i \).

We now reduce the problem (3.4) into one in the bounded domain \( B_R := \{ x \in \mathbb{R}^3 : |x| \leq R \} \) with \( R \) large enough. To this end, we introduce the Calderón mapping \( G_c : H^{-1/2}_{\text{Div}}(S_R) \to H^{-1/2}_{\text{Div}}(S_R) \) defined by

\[
G_c(\lambda) := \frac{1}{i \kappa} \hat{x} \times \text{curl } \bar{w} \quad \text{on } S_R := \partial B_R
\]

for \( \lambda \in H^{-1/2}_{\text{Div}}(S_R) \), where \( \bar{w} \) satisfies the problem

\[
\begin{aligned}
\text{curl curl } \bar{w} - \kappa^2 \bar{w} &= 0 & \text{in } \mathbb{R}^3 \setminus \overline{B_R}, \\
\hat{x} \times \bar{w} &= \lambda & \text{on } S_R, \\
\lim_{r \to \infty} r (\hat{x} \times \text{curl } \bar{w} + i \kappa \bar{w}) &= 0 & r = |x|.
\end{aligned}
\]
The Calderón mapping $G_e$ has the following properties which were proved in [10].

**Lemma 3.2.** Let $\tilde{G}_e$ be defined as $G_e$ in (3.5) with $\kappa = i$. Then
(a) $G_e + i\kappa \tilde{G}_e$ is compact from $H_{\text{Div}}^{-1/2}(S_R)$ to $H_{\text{Div}}^{-1/2}(S_R)$;
(b) $\langle G_e \lambda, \bar{\lambda} \times \hat{x} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} < 0$ for any $\lambda \in H_{\text{Div}}^{-1/2}(S_R)$ with $\lambda \neq 0$;
(c) $G_e$ can be split as $G_e \lambda := G_1^2 \lambda + G_2^2 \kappa \lambda$ for $\lambda \in H_{\text{Div}}^{-1/2}(S_R)$ such that
   (c.1) The map $H \mapsto G_1^2(\hat{x} \times H)$ is compact from $X_0$ into $H_{\text{Div}}^{-1/2}(S_R)$, where $X_0$ is defined in (3.9) below;
   (c.2) $i\kappa \langle G_2^2(\hat{x} \times H), \gamma T \bar{H} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \geq 0$ for $H \in H(\text{curl}, B_R)$.

With the aid of the Calderón map $G_e$, the problem (3.4) can be equivalently reduced to the boundary value problem

\[
\begin{cases}
\nabla \cdot (C : \nabla u) + \rho \omega^2 u = 0 & \text{in } D, \\
\text{curl curl } H - \kappa^2 H = 0 & \text{in } B_R \setminus \overline{D}, \\
Tu - b_1 \nu \times H = f_1 & \text{on } \partial D, \\
\nu \times u + \frac{b_2}{i\kappa} \nu \times \text{curl } H = f_2 & \text{on } \partial D, \\
\hat{x} \times \text{curl } H = i\kappa G_e(\hat{x} \times H) & \text{on } S_R,
\end{cases}
\]

where $f_1 \in H^{-1/2}(\partial D)$ and $f_2 \in H_{\text{Div}}^{-1/2}(\partial D)$.

Multiplying the first equation of (3.6) with $v \in H^1(D)$ and using integration by parts together with the third equation of (3.6) yield

\[
\int_D (\mathcal{E}(u, \overline{v}) - \rho \omega^2 u \cdot \overline{v}) \, dx - b_1 \langle \gamma H, \gamma T \overline{v} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \frac{1}{2} = \langle f_1, \overline{v} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}}
\]

or equivalently

\[
\frac{-i\kappa}{b_1 b_2} \int_D (\mathcal{E}(u, \overline{v}) - \rho \omega^2 u \cdot \overline{v}) \, dx + \frac{i\kappa}{b_2} \langle \gamma H, \gamma T \overline{v} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \frac{1}{2} = \frac{-i\kappa}{b_1 b_2} \langle f_1, \overline{v} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}}
\]

for all $v \in H^1(D)$. Multiplying the second equation of (3.6) by $-w \in H(\text{curl}, B_R \setminus \overline{D})$ and utilizing the fourth and fifth equations of (3.6) give

\[
- \int_{B_R \setminus \overline{D}} \langle \text{curl } H \cdot \text{curl } w - \kappa^2 H \cdot w \rangle \, dx - i\kappa \langle G_e(\hat{x} \times H), \gamma T \overline{w} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \frac{1}{2} \\
+ \frac{i\kappa}{b_2} \langle \gamma \overline{w}, \gamma T u \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \frac{1}{2} = - \frac{i\kappa}{b_2} \langle f_2, \gamma T \overline{w} \rangle_{H_{\text{Div}}^{-1/2} \times H_{\text{Curl}}^{-1/2}} \frac{1}{2}.
\]

Adding the above two equations together and letting $X = H(\text{curl}, B_R \setminus \overline{D})$ and $Q = H^1(D)$, we obtain the variational formulation of (3.6): find $(u, H) \in Q \times X$ such that

\[
A((u, H), (v, w)) = F(v, w) \quad \forall (v, w) \in Q \times X,
\]
where

$$A((u, H), (v, w)) := \frac{-i\kappa}{b_1 b_2} \int_D (\mathcal{E}(u, v) - \rho \omega^2 u \cdot v) \, dx + \frac{i\kappa}{b_2} (\gamma_t H, \gamma_T v)_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}$$

$$- \int_{B_R \setminus \overline{D}} (\text{curl } H \cdot \text{curl } w - \kappa^2 H \cdot \overline{w}) \, dx$$

$$- \frac{-i\kappa}{b_1 b_2} (f_1, \overline{v})_{H^{-\frac{1}{2}} \times \overline{H}^\frac{1}{2}} - \frac{-i\kappa}{b_2} (f_2, \gamma_T \overline{w})_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}.$$

$$\mathcal{F}((v, w)) := \frac{-i\kappa}{b_1 b_2} (f_1, \overline{v})_{H^{-\frac{1}{2}} \times \overline{H}^\frac{1}{2}} - \frac{-i\kappa}{b_2} (f_2, \gamma_T \overline{w})_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}.$$

We now split the sesquilinear form $A((\cdot, \cdot), (\cdot, \cdot))$ on $(Q \times X) \times (Q \times X)$ into two parts:

$$A((u, H), (v, w)) := A((u, H), (v, w)) + K((u, H), (v, w))$$

(3.8)

with $A((\cdot, \cdot), (\cdot, \cdot))$ and $K((\cdot, \cdot), (\cdot, \cdot))$ defined as follows:

$$A((u, H), (v, w)) := \frac{-i\kappa}{b_1 b_2} \int_D (\mathcal{E}(u, v) + M_1 u \cdot v) \, dx + \frac{i\kappa}{b_2} (\gamma_t H, \gamma_T v)_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}$$

$$- \int_{B_R \setminus \overline{D}} (\text{curl } H \cdot \text{curl } w - \kappa^2 H \cdot \overline{w}) \, dx$$

$$- \frac{-i\kappa}{b_1 b_2} (f_1, \overline{v})_{H^{-\frac{1}{2}} \times \overline{H}^\frac{1}{2}} - \frac{-i\kappa}{b_2} (f_2, \gamma_T \overline{w})_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}.$$

$$K((u, H), (v, w)) := \frac{i\kappa}{b_1 b_2} \int_D (\rho \omega^2 + M_1) u \cdot v \, dx$$

for all $(u, H), (v, w) \in Q \times X$, where $M_1 > 0$ is a constant chosen such that $M_1 > \omega^2 \|\rho\|_{L^\infty}$. Further, the sesquilinear form $A((\cdot, \cdot), (\cdot, \cdot))$ can be written as

$$A((u, H), (v, w)) = A_2(u, v) - A_1(H, w) + \frac{i\kappa}{b_2} (\gamma_t H, \gamma_T v)_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}}$$

$$+ \frac{i\kappa}{b_2} (\gamma_t \overline{w}, \gamma_T u)_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}},$$

for all $(u, H), (v, w) \in Q \times X$, where

$$A_1(H, w) := \int_{B_R \setminus \overline{D}} (\text{curl } H \cdot \text{curl } w - \kappa^2 H \cdot \overline{w}) \, dx + \frac{i\kappa}{b_2} (G_{\kappa} (\nu \times H), \gamma_T \overline{w})_{H_{\text{Div}}^\frac{1}{2} 	imes H_{\text{Curl}}^\frac{1}{2}},$$

$$A_2(u, v) := \frac{-i\kappa}{b_1 b_2} \int_D (\mathcal{E}(u, v) + M_1 u \cdot v) \, dx.$$

Note that $A_1(\cdot, \cdot)$ corresponds to the magnetic field $H$ and $A_2(\cdot, \cdot)$ corresponds to the elastic field $u$. It is easy to see that $A_2(\cdot, \cdot)$ is coercive in $H^1(D) \times H^1(D)$. However, it is difficult to directly analyze $A_1(\cdot, \cdot)$ in $H(\text{curl, } B_R \setminus \overline{D}) \times H(\text{curl, } B_R \setminus \overline{D})$ since the imbedding map of $H(\text{curl, } B_R \setminus \overline{D}) \hookrightarrow L^2(B_R \setminus \overline{D})$ is not compact. To overcome
From Lemma 3.3 it follows that such φ where a > 0 for some constant c.
Then the sesquilinear form A_1(·, ·) can be rewritten on S as
\[ A_1(\nabla \phi, \nabla \psi) := a(\phi, \psi) + b(\phi, \psi) \quad \text{for all } \phi, \psi \in S, \]
where a(·, ·) and b(·, ·) are defined as
\[ a(\phi, \psi) := -\kappa^2 \langle \nabla \phi, \nabla \psi \rangle + \kappa^2 \langle \hat{G}_e(\hat{x} \times \nabla \phi), \nabla S_R \psi \rangle_{H^1_{\text{int}} \times H^1_{\text{cut}}} - \frac{\kappa}{\epsilon} \],
\[ b(\phi, \psi) := \kappa \langle (G_e + \kappa \hat{G}_e)(\hat{x} \times \nabla \phi), \nabla S_R \psi \rangle_{H^1_{\text{int}} \times H^1_{\text{cut}}}. \]

We have the following result which was proved in [10].

Lemma 3.3. \( a(·, ·) \) is bounded and elliptic on \( S \times S \), and there exists a compact operator \( K_1 \) on \( S \) such that \( b(\phi, \psi) = a(K_1 \phi, \psi) \) for all \( \phi, \psi \in S \). Further, \( I + K_1 \) is an isomorphism on \( S \).

In order to analyze \( A_1(·, ·) \) on \( X \times X \), we introduce the following subspace of \( X \):
\[ X_0 := \{ H \in X : -\kappa^2 \langle H, \nabla \psi \rangle + \kappa^2 \langle \hat{G}_e(\hat{x} \times H), \nabla S_R \psi \rangle_{H^1_{\text{int}} \times H^1_{\text{cut}}} = 0 \ \forall \psi \in S \} \]
\[ = \{ H \in X : \nabla \cdot H = 0 \ \text{in } B_R \setminus D, \ -\kappa^2 \hat{x} \cdot H = \kappa \nabla S_R \cdot G_e(\hat{x} \times H) \ \text{on } S_R, \]
\[ \text{and } \nu \cdot H = 0 \ \text{on } \partial D \}. \] (3.9)

We then have the following Helmholtz-type decomposition for \( X \).

Lemma 3.4. \( \nabla S \) and \( X_0 \) are closed linear subspaces of \( X \), and \( X = X_0 \oplus \nabla S \) is the direct sum of \( \nabla S \) and \( X_0 \). Further, there exist constants \( c_1, c_2 > 0 \) such that
\[ c_1 \| w + \nabla \phi \|_X^2 \leq \| w \|_X^2 + \| \nabla \phi \|_X^2 \leq c_2 \| w + \nabla \phi \|_X^2 \] (3.10)
for all \( w \in X_0 \) and \( \phi \in S \).

Proof. The closeness of \( \nabla S \) follows from the property that \( \text{curl} \nabla \psi = 0 \) for \( \psi \in X \) and the boundedness of the differential operator \( \nabla \) from \( H^1(·) \) into \( L^2(·) \). For a fixed \( \psi \in S \), the linear functionals \( H_0 \rightarrow \langle H_0, \nabla \psi \rangle \) and \( H_0 \rightarrow \langle G_e(\hat{x} \times H_0), \nabla S_R \psi \rangle_{H^1_{\text{int}} \times H^1_{\text{cut}}} - \frac{\kappa}{\epsilon} \) are bounded on \( X \), yielding that \( X_0 \) is closed.

Given \( H \in X \), we now construct a function \( \phi \in S \) such that
\[ A_1(\nabla \phi, \nabla \psi) = A_1(H, \nabla \psi) \quad \text{for all } \psi \in S. \] (3.11)

From Lemma 3.3 it follows that such \( \phi \) is well defined and satisfies that
\[ \| \nabla \phi \|_{L^2(B_R \setminus D)} \leq c \| H \|_{H(\text{curl, } B_R \setminus D)} \]
for some constant \( c > 0 \). Let \( w = H - \nabla \phi \). Then, and by (3.11) and the definition of \( A_1(·, ·) \) we deduce that \( w \in X_0 \). It remains to show that the intersection \( \nabla S \cap X_0 \) contains only a trivial element. In fact, if there exists \( \phi \in S \) such that \( \nabla \phi \in X_0 \), then
\[ A_1(\nabla \phi, \nabla \psi) = 0 \quad \text{for all } \psi \in S, \]
implying that $\phi = 0$.

Finally, the inequality (3.10) follows from the boundedness of the projection operators $X \rightarrow \nabla S$ and $X \leftrightarrow X_0$. \(\Box\)

**Lemma 3.5.** $X_0$ is compactly imbedded in $L^2(B_R \setminus \overline{D})$.

**Proof.** Since $X_0$ is a Hilbert space, it is enough to show that $u_j \rightarrow 0$ in $L^2(B_R \setminus \overline{D})$ as $j \rightarrow \infty$ if $\{u_j\}_{j \in \mathbb{N}} \subset X_0$ and $\mathbf{u}_j \rightarrow 0$ in the weak sense as $j \rightarrow \infty$.

For each $j \in \mathbb{N}$, define $v_j \in H_{loc}(\text{curl}, \mathbb{R}^3 \setminus \overline{B_R})$ which satisfies that

\[
\begin{cases}
\nabla \cdot v_j = \nabla \cdot u_j & \text{in } \mathbb{R}^3 \setminus \overline{B_R}, \\
\hat{x} \times v_j = \hat{x} \times u_j & \text{on } S_R, \\
\lim_{r \to \infty} r(\hat{x} \times \nabla v_j + i\kappa v_j) = 0 & \text{for } r = |x|.
\end{cases}
\]

For each $j \in \mathbb{N}$, define

\[
\mathbf{u}_j = \begin{cases} u_j & \text{in } B_R \setminus \overline{D}, \\
v_j & \text{in } \mathbb{R}^3 \setminus B_R.
\end{cases}
\]

Then it is clear that $\mathbf{u}_j$ is the extension of $u_j$ in the sense of $H(\text{curl}, \cdot)$.

Recalling the definition of the space $X_0$, one has $-\kappa^2 \hat{x} \cdot u_j = i\kappa \nabla S_R \cdot G_e(\hat{x} \times u_j)$ on $S_R$, which, combined with the definition of $G_e$ and the Maxwell equation for $v_j$, gives

\[
\hat{x} \cdot u_j = -\frac{i}{\kappa} \nabla S_R \cdot G_e(\hat{x} \times u_j) = -\frac{i}{\kappa} \nabla S_R \cdot \left( \frac{1}{i\kappa} \hat{x} \times \nabla v_j \right) \\
= -\frac{1}{\kappa^2} \nabla S_R \cdot (\hat{x} \times \nabla v_j) = \frac{1}{\kappa^2} \hat{x} \cdot \nabla v_j = \hat{x} \cdot v_j \quad \text{on } S_R. \tag{3.12}
\]

Noting that $\nabla \cdot u_j = 0$ in $B_R \setminus \overline{D}$ and $\nabla \cdot v_j = 0$ in $\mathbb{R}^3 \setminus \overline{B_R}$, we conclude from (3.12) that the extended function $\mathbf{u}_j$ satisfies

\[
\nabla \cdot \mathbf{u}_j = 0 \quad \text{in } \mathbb{R}^3 \setminus \overline{D} \quad \text{and} \quad \nu \cdot \mathbf{u}_j = 0 \quad \text{on } \partial D.
\]

Then it follows from Theorem 3.50 of [10] that $\mathbf{u}_j \in H^{1/2+s}_{loc}(\mathbb{R}^3 \setminus \overline{D})$ for some $s \geq 0$. By the compactness of the imbedding $H^{1/2}(B_R \setminus \overline{D}) \hookrightarrow L^2(B_R \setminus \overline{D})$, there is a subsequence of $\{u_j\}$ converging to 0 in $L^2(B_R \setminus \overline{D})$. This completes the proof. \(\Box\)

We are now ready to analyze the sesquilinear form $A_1(\cdot, \cdot)$ on $X_0$. First, for $H$, $w \in X$, by Lemma 3.4 there exist $H_0, w_0 \in X_0$ and $\phi, \psi \in S$ such that $H = H_0 + \nabla \phi$ and $w = w_0 + \nabla \psi$. Thus, by the definition of $X_0$ one has

\[
A_1(H, w) = A_1(H_0, w_0) + A_1(\nabla \phi, w_0) + A_1(\nabla \phi, \nabla \psi). \tag{3.13}
\]

We split $A_1(\cdot, \cdot)$ into two parts:

\[
A_1(H_0, w_0) := a_0(H_0, w_0) + b_0(H_0, w_0) \quad \forall H_0, w_0 \in X_0,
\]

where

\[
a_0(H_0, w_0) := (\text{curl } H_0, \text{curl } w_0) + (H_0, \overline{w_0}) + i\kappa (G_e^2(\hat{x} \times H_0), \gamma_r \overline{w_0})_{H^{\frac{1}{2}}_{D_0} \times H^{-\frac{1}{2}}_{\text{curl}}},
\]

\[
b_0(H_0, w_0) := -(\kappa^2 + 1)(H_0, \overline{w_0}) + i\kappa (G_e^3(\hat{x} \times H_0), \gamma_r \overline{w_0})_{H^{\frac{1}{2}}_{D_0} \times H^{-\frac{1}{2}}_{\text{curl}}},
\]
Similar to Lemma 3.3, we have the following result for $a_0(\cdot, \cdot)$ and $b_0(\cdot, \cdot)$ on $X_0$.

**Lemma 3.6.** $a_0(\cdot, \cdot)$ is coercive on $X_0 \times X_0$, and there exists a compact operator $K_2$ on $X_0$ such that $b_0(H_0, w_0) = a_0(K_2H_0, w_0)$ for all $H_0, w_0 \in X_0$. Further, $I + K_2$ is an isomorphism on $X_0$.

**Proof.** The coerciveness of $a_0(\cdot, \cdot)$ follows easily from the property of $G^2_\epsilon$ (see (c.2) in Lemma 3.2). By the Cauchy-Schwartz inequality, it is easy to see that, for each fixed $H_0 \in X_0$, $b_0(H_0, \cdot)$ defines a bounded linear functional on $X_0$. Thus, and by the Lax-Milgram theorem and the coerciveness of $a_0(\cdot, \cdot)$ on $X_0 \times X_0$, there is an operator $K_2$ on $X_0$ such that $b_0(H_0, w_0) = a_0(K_2H_0, w_0)$. The compactness of $K_2$ follows easily from the property of $G^2_\epsilon$ (see Lemma 3.2) and the compact imbedding $X_0 \hookrightarrow L^2(B_R \setminus \bar{D})$ (see Lemma 3.5).

We now prove that $I + K_2$ is an isomorphism on $X_0$. By the Riesz-Fredholm theory, it is enough to show that $I + K_2$ is injective. Let $(I + K_2)w = 0$ with $w \in X_0$. Then $w$ satisfies

$$A_1(w, \psi) = a_0(w + K_2w, \psi) = 0 \quad \text{for all } \psi \in X_0.$$  

By the definition of $X_0$, we know that $A_1(w, \nabla \phi) = 0$ for all $\phi \in S$. This, combined with the Helmholtz-type decomposition for $\Psi \in X$, yields

$$A_1(w, \Psi) = 0 \quad \text{for all } \Psi \in X.$$  

Therefore, $w$ satisfies the boundary value problem

$$\begin{cases}
\text{curl curl } w - \kappa^2 w = 0 & \text{in } B_R \setminus \bar{D}, \\
\nu \times \text{curl } w = 0 & \text{on } \partial D, \\
\frac{1}{i\kappa} \hat{x} \times \text{curl } w = G_\epsilon(\hat{x} \times w) & \text{on } S_R
\end{cases}$$  

in the distribution sense. By the third equation in the above problem it is seen that $w$ can be extended into $\mathbb{R}^3 \setminus B_R$ by considering the exterior problem

$$\begin{cases}
\text{curl curl } v - \kappa^2 v = 0 & \text{in } \mathbb{R}^3 \setminus \bar{B}_R, \\
\hat{x} \times v = \hat{x} \times w & \text{on } S_R, \\
\lim_{r \to \infty} r(\hat{x} \times \text{curl } v + i\kappa v) = 0, & r = |x|.
\end{cases}$$  

By the definition of $G_\epsilon$, it follows that $\hat{x} \times \text{curl } w = \hat{x} \times \text{curl } v$ on $S_R$. Hence, the function $w^e$, which is defined by $w$ in $B_R \setminus \bar{D}$ and by $v$ in $\mathbb{R}^3 \setminus \bar{B}_R$, satisfies the exterior problem

$$\begin{cases}
\text{curl curl } w^e - \kappa^2 w^e = 0 & \text{in } \mathbb{R}^3 \setminus \bar{D}, \\
\nu \times \text{curl } w^e = 0 & \text{on } \partial D, \\
\lim_{r \to \infty} r(\hat{x} \times \text{curl } w^e + i\kappa w^e) = 0, & r = |x|.
\end{cases}$$  

Using Green’s formula for $w^e$, one has

$$\int_{S_R} \nu \times \overline{w^e} \cdot \frac{1}{i\kappa} \text{curl } w^e \, ds = 0.$$  

This, together with the Rellich lemma and the unique continuation principle, implies $w^e \equiv 0$ in $\mathbb{R}^3 \setminus \bar{D}$, and thus $w = 0$. Therefore, $I + K_2$ is injective on $X_0$, which ends the proof. □
Based on the above analysis and Lemmas 3.3, 3.4, 3.5 and 3.6, we can split \( A((u, H), (v, w)) \) as follows:

\[
A((u, H), (v, w)) := \tilde{A}((u, H), (v, w)) + K_3((u, H), (v, w))
\]

for all \( u, v \in Q \) and \( H, w \in X \) with \( H = H_0 + \nabla \phi \) and \( w = w_0 + \nabla \psi \), \( H_0, w_0 \in X_0 \) and \( \phi, \psi \in S \), where \( \tilde{A}(\cdot, \cdot) \) and \( K_3(\cdot, \cdot) \) are defined as

\[
\tilde{A}((u, H), (v, w)) := A_2(u, v) - a(\phi, \psi) - a_0(H_0, w_0) - A_1(\nabla \phi, w_0)
\]

\[
+ \frac{ik}{b_2} \left[ \gamma_l \nabla \phi, \gamma_H \nabla \psi \right]_{H^{1/2} \times H^{1/2}} + \frac{ik}{b_2} \left[ \gamma_l \nabla \psi, \gamma_T u \right]_{H^{1/2} \times H^{1/2}}
\]

\[
K_3((u, H), (v, w)) := -b(\phi, \psi) - b_0(H_0, w_0) + \frac{ik}{b_2} \left[ \gamma_l H_0, \gamma_T v \right]_{H^{1/2} \times H^{1/2}}
\]

\[
+ \frac{ik}{b_2} \left[ \gamma_l w_0, \gamma_T u \right]_{H^{1/2} \times H^{1/2}}.
\]

Further, define the sesquilinear form

\[
\tilde{K}((u, H), (v, w)) := K((u, H), (v, w)) + K_3((u, H), (v, w)).
\]

Then (3.7) can be reduced to the problem: find \((u, H) \in Q \times X\) such that

\[
\tilde{A}((u, H), (v, w)) + \tilde{K}((u, H), (v, w)) = F((v, w))
\]

(3.14)

for all \((v, w) \in Q \times X\).

Let \( \tilde{A}, \tilde{K} : Q \times X \rightarrow (Q \times X)' \) be the linear, bounded operators induced by the corresponding sesquilinear forms \( \tilde{A}(\cdot, \cdot), \tilde{K}(\cdot, \cdot) \), respectively, with using the Riesz representation lemma in Hilbert spaces. Then we have the following result.

**Theorem 3.7.** If \( \text{Im}(b_1b_2) < 0 \), then \( \tilde{A} + \tilde{K} \) is of Fredholm type with index 0.

**Proof.** By the compact imbedding \( H^1(D) \hookrightarrow L^2(D) \) we deduce that \( K(\cdot, \cdot) \) is a compact form on \( H^1(D) \times H^1(D) \). By Lemma 3.2 it is known that \( b(\cdot, \cdot) \) is a compact form on \( S \times S \), and by Lemmas 3.5 and 3.2 it is also known that \( b_0(\cdot, \cdot) \) is a compact form on \( X_0 \times X_0 \). Further, by a similar argument as in deriving (3.12) (see also [10]) it follows that, if \( w_0 \in X_0 \) then \( w_0|_{\partial D} \in H^{1/2}(\partial D) \). This, combined with the compact imbedding \( H^{1/2}(\partial D) \hookrightarrow L^2(\partial D) \), gives that \( K_3(\cdot, \cdot) \) is a compact form on \((Q \times X) \times (Q \times X)\). Thus, the operator \( \tilde{K} \) is compact from \( Q \times X \) into \((Q \times X)'\). It remains to show that \( \tilde{A} \) is an isomorphism from \( Q \times X \) into \((Q \times X)'\).

Since \( \text{Im}(b_1b_2) < 0 \), we obtain by using Korn’s inequality that

\[
\text{Re}[A_2(u, u)] \geq C\|u\|_D^2
\]

(3.15)

for some constant \( C > 0 \). Further, by Lemmas 3.2 and 3.3 it can be concluded that

\[
-\text{Re}[a(\phi, \phi)] \geq C\|\nabla \phi\|_X^2
\]

for all \( \phi \in S \),

\[
\text{Re}[a_0(H_0, H_0)] \geq C\|H_0\|_X^2
\]

(3.17)

for some constant \( C > 0 \). Recalling that

\[
\frac{ik}{b_2} + \frac{ikc}{b_2} = 2ik\text{Re}(b_2)\left|\frac{1}{b_2}\right|^2,
\]
we immediately have
\[
\Re \left[ \frac{ik}{\tilde{b}_2} \langle \gamma_I \nabla \phi, \gamma_I \nabla_T \tilde{u} \rangle_{H_{\Div}^{-\frac{1}{2}} \times H_{\Curl}^{-\frac{1}{2}}} + \frac{ik}{\tilde{b}_2} \langle \gamma_I \nabla \tilde{\phi}, \gamma_I \nabla_T \tilde{u} \rangle_{H_{\Div}^{-\frac{1}{2}} \times H_{\Curl}^{-\frac{1}{2}}} \right] = 0. \tag{3.18}
\]
Therefore, by (3.15)-(3.16) and (3.18) we obtain that the real part of
\[
\tilde{A}_1((\tilde{\mathbf{u}}, \tilde{\phi}), (\mathbf{v}, \psi)) := A_2(\mathbf{u}, \mathbf{v}) - a(\phi, \psi) + \frac{i k}{\tilde{b}_2} \langle \gamma_I \nabla \phi, \gamma_I \nabla_T \mathbf{v} \rangle_{H_{\Div}^{-\frac{1}{2}} \times H_{\Curl}^{-\frac{1}{2}}} + \frac{i k}{\tilde{b}_2} \langle \gamma_I \nabla \tilde{\phi}, \gamma_I \nabla_T \mathbf{v} \rangle_{H_{\Div}^{-\frac{1}{2}} \times H_{\Curl}^{-\frac{1}{2}}}
\]
is coercive on $(Q \times S) \times (Q \times S)$. Thus, and by the Lax-Milgram lemma, for each bounded functional $(f_1, f_2) \in Q' \times (\nabla S)'$ there exists a unique element $(\tilde{\mathbf{u}}, \tilde{\phi}) \in (Q \times S)$ satisfying that
\[
\tilde{A}_1((\tilde{\mathbf{u}}, \tilde{\phi}), (\mathbf{v}, \psi)) = f_1(\mathbf{v}) + f_2(\nabla \psi) \quad \text{for all } (\mathbf{v}, \psi) \in Q \times S \tag{3.19}
\]
and the estimate
\[
\|\tilde{\mathbf{u}}\|_Q + \|\nabla \tilde{\phi}\|_X \leq C(\|f_1\|_{Q'} + \|f_2\|_{(\nabla S)'}) \tag{3.20}
\]
for some constant $C > 0$.

Moreover, by (3.17), the boundedness of $A_1(\cdot, \cdot)$ and the Lax-Milgram lemma, for each $f_3 \in (X_0)'$ there exists a unique element $\tilde{\mathbf{H}}_0 \in X_0$ satisfying that
\[
-a_0(\tilde{\mathbf{H}}_0, \mathbf{w}_0) = A_1(\nabla \phi, \mathbf{w}_0) + f_3(\mathbf{w}_0) \quad \text{for all } \mathbf{w}_0 \in X_0 \tag{3.21}
\]
and the estimate
\[
\|\tilde{\mathbf{H}}_0\|_X \leq C(\|\nabla \tilde{\phi}\|_X + \|f_3\|_{(X_0)'}) \leq C(\|f_1\|_{Q'} + \|f_2\|_{(\nabla S)'}) + \|f_3\|_{(X_0)'}) \tag{3.22}
\]
where $C > 0$ is a constant. Combining (3.19)-(3.22) implies that $\tilde{A}$ is an isomorphism from $Q \times X$ to $(Q \times X)'$. The proof is thus complete. \( \Box \)

Using Theorem 3.8, we can easily obtain the following well-posedness result for the problem (3.6).

**Theorem 3.8.** Let $\omega \notin \mathcal{P}(\omega)$. If $\Re(b_1 \tilde{b}_2) = 0$ and $\Im(b_1 \tilde{b}_2) < 0$, then the problem (3.6) has a unique solution $(\mathbf{u}, \mathbf{H}) \in Q \times X$ satisfying the estimate
\[
\|\mathbf{u}\|_Q + \|\mathbf{H}\|_X \leq C(\|f_1\|_{H^{-\frac{1}{2}}(\partial D)} + \|f_2\|_{H^{-\frac{1}{2}}_{\Div}(\partial D)}),
\]
where $C > 0$ is a constant independent of the choice of $f_1$ and $f_2$.

**4. Uniqueness of the inverse problem.** In this section, based on the analysis for the forward scattering problem (2.1)-(2.5), we investigate the inverse problem of determining the elastic body $D$ by the electromagnetic far-field measurements. We shall show that the shape and location of the elastic body can be uniquely recovered by the magnetic or electric far-field pattern corresponding to incident plane waves with all incident directions and polarizations. Motivated by our previous work in [14] for the reduced wave equation and the Maxwell equations, our method is based on a coupled system of PDEs constructed in a sufficiently small domain as well as the uniform a priori estimate in $H^1(\cdot)$ for the elastic field.
4.1. A coupled system of PDEs. In order to study the inverse problem, we introduce the following boundary value problem in a bounded, simply connected domain $\Omega$ with a Lipschitz continuous boundary $\partial \Omega$:

\[
\begin{cases}
\text{curl curl } H + H = \xi_1 & \text{in } \Omega, \\
\nabla \cdot (\hat{\mathcal{C}} : \nabla u) - u = \xi_2 & \text{in } \Omega, \\
Tu - \hat{b}_1 \nu \times H = h_1 & \text{on } \partial \Omega, \\
\nu \times \text{curl } H + \frac{\imath \kappa}{\hat{b}_2} \nu \times u = h_2 & \text{on } \partial \Omega,
\end{cases}
\tag{4.1}
\]

where $\hat{\mathcal{C}} := (\hat{C}_{ijkl}(x))_{i,j,k,l=1}^3$ with $\hat{C}_{ijkl} \in L_\infty(\Omega)$ ($i, j, k, l = 1, 2, 3$), $\hat{b}_1, \hat{b}_2 \in \mathbb{C}$ with $\hat{b}_1 \hat{b}_2 \neq 0$, $\xi_1, \xi_2 \in L^2(\Omega)$, $h_1 \in H^{-1/2}(\partial \Omega)$, $h_2 \in H_{\text{Div}}^{-1/2}(\partial \Omega)$ and $\hat{\mathcal{C}}$ satisfies the symmetry condition and the Legendre elliptic condition (see Subsection 2.2).

**Lemma 4.1.** If $\text{Im}(\hat{b}_1 \hat{b}_2) < 0$, then the problem (4.1) has a unique solution $(H, u) \in H(\text{curl}, \Omega) \times H^1(\Omega)$ such that

\[
\|H\|_{H(\text{curl}, \Omega)} + \|u\|_{H^1(\Omega)} 
\leq C \left[ \|\xi_1\|_{L^2(\Omega)} + \|\xi_2\|_{L^2(\Omega)} + \|h_1\|_{H^{-1/2}(\partial \Omega)} + \|h_2\|_{H_{\text{Div}}^{-1/2}(\partial \Omega)} \right],
\]

where $C > 0$ is a constant independent of $\xi_1, \xi_2, h_1$ and $h_2$.

**Proof.** By using Green’s formula, the problem (4.1) can be reformulated as the variational problem: find $(H, u) \in H(\text{curl}, \Omega) \times H^1(\Omega)$ such that

\[
\hat{A}((H, u), (w, v)) = \hat{\mathcal{F}}((w, v)) \quad \text{for } (w, v) \in H(\text{curl}, \Omega) \times H^1(\Omega),
\tag{4.2}
\]

where

\[
\hat{A}((H, u), (w, v)) := \int_{\Omega} \left( \text{curl } H \cdot \text{curl } \overline{w} + H \cdot \overline{w} \right) \text{d}x + \frac{-\imath \kappa}{\hat{b}_1 \hat{b}_2} \int_{\Omega} \left( \mathcal{E}(u, \overline{v}) + u \cdot \overline{v} \right) \text{d}x \\
+ \frac{\imath \kappa}{\hat{b}_2} \left( \gamma_1(\overline{w}, \gamma_T u)_{H_{\text{Div}}^{-\frac{1}{2}} \times H_{\text{Curl}}^{-\frac{1}{2}}} - \frac{-\imath \kappa}{\hat{b}_2} \langle \gamma_1 H, \gamma_T \overline{v} \rangle_{H_{\text{Div}}^{-\frac{1}{2}} \times H_{\text{Curl}}^{-\frac{1}{2}}} \right),
\]

\[
\hat{\mathcal{F}}((w, v)) := \frac{-\imath \kappa}{\hat{b}_1 \hat{b}_2} \langle h_1, \overline{v} \rangle_{H_{\text{Div}}^{-\frac{1}{2}} \times H_{\text{Curl}}^{-\frac{1}{2}}} - \langle h_2, \gamma_T \overline{w} \rangle_{H_{\text{Div}}^{-\frac{1}{2}} \times H_{\text{Curl}}^{-\frac{1}{2}}} \\
+ \int_{\Omega} \left( \xi_1 \cdot \overline{w} + \frac{\imath \kappa}{\hat{b}_1 \hat{b}_2} \xi_2 \cdot \overline{v} \right) \text{d}x.
\]

By the Cauchy-Schwarz inequality and the trace theorem, there exists a constant $C > 0$ such that

\[
|\hat{A}((H, u), (w, v))| \leq C \|H\|_{H(\text{curl}, \Omega) \times H^1(\Omega)} \|(w, v)\|_{H(\text{curl}, \Omega) \times H^1(\Omega)},
\]

\[
|\hat{\mathcal{F}}((w, v))| \leq C \left[ \|\xi_1\|_{L^2(\Omega)} + \|\xi_2\|_{L^2(\Omega)} + \|h_1\|_{H^{-\frac{1}{2}}(\partial \Omega)} + \|h_2\|_{H_{\text{Div}}^{-\frac{1}{2}}(\partial \Omega)} \right] \|(w, v)\|_{H(\text{curl}, \Omega) \times H^1(\Omega)},
\]

which implies that both $\hat{A}(\cdot, \cdot)$ and $\hat{\mathcal{F}}(\cdot)$ are bounded in $H(\text{curl}, \Omega) \times H^1(\Omega)$.
Now, let \((w, v) := (H, u)\) in (4.2). Then it follows that
\[
\hat{A}((H, u), (H, u)) = \int_{\Omega} \left( \text{curl} H \cdot \text{curl} \overline{H} + |H|^2 + \frac{-ik}{b_1b_2}(E(u, \overline{u}) + |u|^2) \right) dx
+ \frac{ik}{b_2} \langle \gamma_1 \overline{H}, \gamma_T u \rangle_{H^{\frac{1}{2}}_\text{Div} \times H^{-\frac{1}{2}}_\text{Curl}} - \frac{-ik}{b_2} \langle \gamma_1 H, \gamma_T \overline{u} \rangle_{H^{-\frac{1}{2}}_\text{Div} \times H^{\frac{1}{2}}_\text{Curl}}.
\]
Thus,
\[
\text{Re} \left[ \hat{A}((H, u), (H, u)) \right] \geq c \left[ \|H\|_{L^2(H^{\text{curl}}, \Omega)}^2 + \|u\|_{H^1(\Omega)}^2 \right]
\]
for some constant \(c > 0\). The required result then follows from the Lax-Milgram lemma.

4.2. Uniqueness in recovering the elastic body. Assume that \(D\) and \(\tilde{D}\) are two elastic bodies corresponding to with the electromagnetic far-field patterns \((E_s^\infty, \hat{H}_s^\infty)\) and \((\tilde{E}_s^\infty, \tilde{H}_s^\infty)\), generated by the incident plane waves given in (2.1) with the incident direction \(d \in S^2\) and the polarization vector \(p \in \mathbb{R}^3\).

**Theorem 4.2.** If \(H_s^\infty = \tilde{H}_s^\infty\) for all \(\hat{x}, d \in S^2\) and \(p \in \mathbb{R}^3\), then \(D = \tilde{D}\).

**Proof.** Suppose \(D \neq \tilde{D}\). Then there would exist \(z_* \in \partial D \setminus \partial \tilde{D}\) and a small ball \(B\) centered at \(z_*\) such that
\[
z_j := z_* + \frac{\delta}{j} \nu(z_*) \in B, \quad \text{for} \quad j = 1, 2, \ldots
\]
for small enough \(\delta > 0\) and \(B \cap \tilde{D} = \emptyset\); see Figure 4.1 for the geometric description.

![Fig. 4.1. Two different elastic bodies](image)

Consider the scattering problem (3.4) with the boundary data \(f_1\) and \(f_2\) induced by the electric dipoles
\[
H^i(x, z_j, q) = \text{curl} \left( q \Phi(x, z_j) \right) / \|\text{curl} (q \Phi(x, z_j))\|_{L^2(\partial D)},
\]
\[
E^i(x, z_j, q) = -\frac{1}{ik} \text{curl} H^i(x, z_j, q)
\]
for \(q \in \mathbb{R}^3\), where \(\Phi(\cdot, \cdot)\) is the fundamental solution to the three-dimensional Helmholtz equation given by
\[
\Phi(x, z) := \frac{1}{4\pi} e^{ik|x-z|}, \quad x \neq z.
\]
By Theorem 3.3 we know that, for each \( j \in \mathbb{N} \) the problem (3.4) has a unique solution \((E^i(\cdot, z, q), H^s(\cdot, z, q), u(\cdot, z, q)) \in H_{loc}(\text{curl}, \mathbb{R}^3 \setminus \overline{D}) \times H_{loc}(\text{curl}, \mathbb{R}^3 \setminus \overline{D}) \times H^1(D)\) with respect to the elastic body \( D \) and a unique solution \((E^s(\cdot, z, q), H^i(\cdot, z, q), \tilde{u}(\cdot, z, q)) \in H_{loc}(\text{curl}, \mathbb{R}^3 \setminus \overline{D}) \times H_{loc}(\text{curl}, \mathbb{R}^3 \setminus \overline{D}) \times H^1(D)\) with respect to the elastic body \( \tilde{D} \). Define the total electromagnetic fields as follows:

\[
\begin{align*}
E(\cdot, z, q) &:= E^i(\cdot, z, q) + E^s(\cdot, z, q) \quad \text{in} \ \mathbb{R}^3 \setminus \overline{D}, \\
H(\cdot, z, q) &:= H^i(\cdot, z, q) + H^s(\cdot, z, q) \quad \text{in} \ \mathbb{R}^3 \setminus \overline{D}, \\
\tilde{E}(\cdot, z, q) &:= \tilde{E}^i(\cdot, z, q) + \tilde{E}^s(\cdot, z, q) \quad \text{in} \ \mathbb{R}^3 \setminus \overline{D}, \\
\tilde{H}(\cdot, z, q) &:= \tilde{H}^i(\cdot, z, q) + \tilde{H}^s(\cdot, z, q) \quad \text{in} \ \mathbb{R}^3 \setminus \overline{D}.
\end{align*}
\]

We now prove that the following mixed reciprocity relation holds for the scattering solutions of the problem (3.4) associated with the incident plane wave given in (2.1) and the electric dipoles given in (4.3) and (4.4):

\[
\begin{align*}
\frac{1}{c_j} 4\pi p \cdot E^s(\cdot, z, q) &= q \cdot E^i(\cdot, d, p), \\
\frac{1}{c_j} 4\pi p \cdot \tilde{E}^s(\cdot, z, q) &= q \cdot \tilde{E}^i(\cdot, d, p),
\end{align*}
\]

where \( c_j := 1/\|\text{curl}(q\Phi(x, z))\|_{L^2(\partial D)} \), \( E^s(\cdot, z, q) \) and \( \tilde{E}^s(\cdot, z, q) \) are the electric far-field patterns corresponding to \( D \) and \( \tilde{D} \), respectively. We only prove (4.5) since (4.6) can be shown similarly. First, use the vector Gauss divergence theorem and the radiation condition (2.4) to obtain that for each \( p, q \in \mathbb{R}^3 \),

\[
\begin{align*}
\int_{\partial D} (\nu \times E(\cdot, z, q) \cdot H(\cdot, d, p) + \nu \times H(\cdot, z, q) \cdot E(\cdot, d, p)) \, ds &= 0, \\
\int_{\partial D} (\nu \times E^s(\cdot, z, q) \cdot H^i(\cdot, d, p) + \nu \times H^i(\cdot, z, q) \cdot E^s(\cdot, d, p)) \, ds &= 0.
\end{align*}
\]

Next, by the Stratton-Chu formula (cf. [3]) we get

\[
\begin{align*}
4\pi p \cdot E^s(\cdot, z, q) &= \int_{\partial D} (\nu \times E^s(\cdot, z, q) \cdot H^i(\cdot, d, p) + \nu \times H^i(\cdot, z, q) \cdot E^s(\cdot, d, p)) \, ds, \\
q \cdot E^i(\cdot, z, q) &= \frac{1}{c_j} \int_{\partial D} (\nu \times E^i(\cdot, d, p) \cdot H^i(\cdot, z, q) + \nu \times H^i(\cdot, d, p) \cdot E^i(\cdot, z, q)) \, ds.
\end{align*}
\]

Combining the above four equations with the transmission conditions yields

\[
\begin{align*}
4\pi p \cdot E^s(\cdot, z, q) - c_j q \cdot E^i(\cdot, d, p)
&= \int_{\partial D} [\nu \times E(\cdot, z, q) \cdot H(\cdot, d, p) + \nu \times H(\cdot, z, q) \cdot E(\cdot, d, p)] \, ds \\
&= -\frac{1}{b_1b_2} \int_{\partial D} [u(\cdot, z, j) \cdot Tu(\cdot, d, p) - u(\cdot, d, p) \cdot Tu(\cdot, z, j)] \, ds \\
&= -\frac{1}{b_1b_2} \int_D [u(\cdot, z, j) \cdot (\nabla \cdot (C \cdot \nabla u(\cdot, d, p))) - u(\cdot, d, p) \cdot (\nabla \cdot (C \cdot \nabla u(\cdot, z, j)))] \, dx \\
&= 0,
\end{align*}
\]
that is, (4.5) holds.

Since \( \mathbf{H}_0^j(\hat{x}, d, p) = \mathbf{H}_\infty^j(\hat{x}, d, p) \) for all \( \hat{x}, d \in S^2 \) and \( p \in \mathbb{R}^3 \), we obtain by (2.7) and Rellich’s lemma that for each \( p \in \mathbb{R}^3 \),

\[
E^\ast(x, d, p) = \tilde{E}^\ast(x, d, p), \quad \mathbf{H}^\ast(x, d, p) = \tilde{H}^\ast(x, d, p) \quad x \in G_0,
\]

where \( G_0 \) denotes the unbounded component of \( \mathbb{R}^3 \setminus (D \cup \bar{D}) \). This, together with the mixed reciprocity relations (4.5) and (4.6) and Rellich’s lemma again, implies that for each \( q \in \mathbb{R}^3 \),

\[
E^\ast(x, z_j, q) = \tilde{E}^\ast(x, z_j, q), \quad \mathbf{H}^\ast(x, z_j, q) = \tilde{H}^\ast(x, z_j, q) \quad x \in G_0. \quad (4.7)
\]

We now prove the uniform boundedness in an appropriate Sobolev space of both \( \mathbf{H}^\ast(\cdot, z_j, q) \) and \( u(\cdot, z_j, q) \) as \( j \to \infty \). To this end, define the function

\[
\mathbf{H}_j(x) := \mathbf{H}^\ast(x, z_j, q) - \text{curl} \left[ \Phi(x, y_j) \right] / \| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)}, \quad x \in \mathbb{R}^3 \setminus \bar{D},
\]

where \( y_j := z_j - (\delta/j)\nu(z_j) \in D \) for \( j \in \mathbb{N} \). It is easy to verify that \( (u(\cdot, z_j, q), \mathbf{H}_j(\cdot)) \) satisfies the scattering problem

\[
\begin{aligned}
\text{curl curl } \mathbf{H}_j - \kappa^2 \mathbf{H}_j &= 0 \quad \text{in } D^c, \\
\nabla \cdot (\mathbf{C} : \nabla u(\cdot, z_j, q) + \rho \omega^2 u(\cdot, z_j, q) &= 0 \quad \text{in } D, \\
Tu(\cdot, z_j, q) - b_1 \nu \times \mathbf{H}_j &= f_{1j} \quad \text{on } \partial D, \\
\nu \times \text{curl } \mathbf{H}_j + \frac{ik}{b_2} \nu \times u(\cdot, z_j, q) &= in f_{2j} \quad \text{on } \partial D, \\
\lim_{r \to \infty} r(\hat{x} \times \text{curl } \mathbf{H}_j + in \mathbf{H}_j) &= 0, \quad r = |x|,
\end{aligned}
\]

where the data \( f_{1j} \) and \( f_{2j} \) are given by

\[
f_{1j}(x) := \nu \times \mathbf{H}_j(x, z_j, q) + \frac{\nu \times \text{curl } \left[ \Phi(x, y_j) \right]}{\| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)}}
\]

\[
= \nu \times \text{curl } \left[ \Phi(x, z_j) \right] / \| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)} + \nu \times \text{curl } \left[ \Phi(x, y_j) \right] / \| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)},
\]

\[
f_{2j}(x) := \nu \times \mathbf{E}_j(x, z_j, q) - \frac{1}{ik} \nu \times \text{curl } \left[ \Phi(x, y_j) \right]/\| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)}
\]

\[
= \frac{1}{ik} \left( \nu \times \text{curl } \Phi(x, z_j) / \| \Phi(x, z_j) \|_{L^2(\partial D)} + \nu \times \text{curl } \left[ \Phi(x, y_j) \right] / \| \text{curl} \left[ \Phi(x, z_j) \right] \|_{L^2(\partial D)} \right).
\]

Noting that \( \text{Div} (\nu \times f) = -\nu \cdot \text{curl } f \) and \( \text{curl} \text{curl } f = (-\Delta + \nabla \text{Div}) f \) for a smooth function \( f \), one immediately has

\[
\| f_{1j} \|_{L^2(\partial D)} + \| \text{Div } f_{2j} \|_{L^2(\partial D)} \leq C_1
\]

uniformly for all \( j \in \mathbb{N} \), where \( C_1 > 0 \) is a fixed positive constant. Moreover, by the definition of \( z_j \) and \( y_j \), and on taking \( q := \nu(z_j) \), we can further prove that \( f_{2j} \) is uniformly bounded in \( L^2(\partial D) \) for all \( j \in \mathbb{N} \), that is,

\[
\| f_{2j} \|_{L^2(\partial D)} \leq C_2
\]
for some fixed constant $C_2 > 0$. In fact, a direct calculation shows that

\[
\frac{1}{\|\text{curl} [q\Phi(x, z)]\|_{L^2(\partial D)}} \{\nu \times \text{curl}^2[q\Phi(x, z)] + \nu \times \text{curl}^2[q\Phi(x, y)]\}
\]

\[
= \nu \times \text{grad div} [q\Phi(x, z)] + q\Phi(x, y)] + \kappa^2 \nu \times [q\Phi(x, z)] + q\Phi(x, y)]
\]

\[
= \nu \times \text{grad grad} [q\Phi(x, z)] + q\Phi(x, y)]q + \kappa^2 \nu \times [q\Phi(x, z)] + q\Phi(x, y)]
\]

\[
= I_j + II_j.
\]

(4.12)

It is easy to see that $II_j \in L^2(\partial D)$ is uniformly bounded for $j \in \mathbb{N}$ since the fundamental solution $\Phi(\cdot, \cdot)$ is weakly singular. To estimate $I_j$, without loss of generality, we may take $z^* = (0, 0, 0)^T$ and $\nu(z^*) = (0, 0, 1)^T$. Since $q = \nu(z^*)$, we have

\[
I_j = \frac{1}{\|\text{curl} [q\Phi(x, z)]\|_{L^2(\partial D)}} \nu(x) \times \left( \frac{\partial \Phi(x, z)}{\partial x_1, \Phi(x, z)} + \frac{\partial \Phi(x, z)}{\partial x_2, \Phi(x, z)} \right).
\]

\[
= \frac{1}{\|\text{curl} [q\Phi(x, z)]\|_{L^2(\partial D)}} \nu(z_3) \times \left( \frac{\partial \Phi(x, z)}{\partial x_1, \Phi(x, z)} + \frac{\partial \Phi(x, z)}{\partial x_2, \Phi(x, z)} \right)
\]

\[
+ \frac{1}{\|\text{curl} [q\Phi(x, z)]\|_{L^2(\partial D)}} (\nu(x) - \nu(z_3)) \times \left( \frac{\partial \Phi(x, z)}{\partial x_1, \Phi(x, z)} + \frac{\partial \Phi(x, z)}{\partial x_2, \Phi(x, z)} \right)
\]

\[
= I_j^{(1)} + I_j^{(2)}.
\]

Let $x = (x_1, x_2, x_3)^T$ and $z = (z^{(1)}, z^{(2)}, z^{(3)})^T$. Then a direct calculation gives

\[
4\pi^2 \partial \Phi(x, z) = -\kappa^2 \frac{(x_3 - z^{(3)})(x_\ell - z^{(\ell)})e^{i\kappa|x - z|}}{|x - z|^3} - 3i\kappa \frac{(x_3 - z^{(3)})(x_\ell - z^{(\ell)})e^{i\kappa|x - z|}}{|x - z|^4}
\]

\[
+ 3 \frac{(x_3 - z^{(3)})(x_\ell - z^{(\ell)})e^{i\kappa|x - z|}}{|x - z|^5}
\]

for $\ell = 1, 2$, (4.13)

and

\[
4\pi^2 \partial \Phi(x, z) = -\kappa^2 \frac{(x_3 - z^{(3)})^2e^{i\kappa|x - z|}}{|x - z|^3} + \kappa \frac{e^{i\kappa|x - z|}}{|x - z|^2} - 3i\kappa \frac{(x_3 - z^{(3)})^2e^{i\kappa|x - z|}}{|x - z|^4}
\]

\[
- \frac{e^{i\kappa|x - z|}}{|x - z|^2} + 3 \frac{(x_3 - z^{(3)})^2e^{i\kappa|x - z|}}{|x - z|^5}
\]

for $\ell = 3$. (4.14)

Since $\partial D$ is $C^2$ smooth, we have the unit normal vector function $\nu(x) \in C^1(\partial D)$, and thus $|\nu(x) - \nu(z_3)| = O(|x - z_3|)$ for all $x \in \partial D$. This, combined with (4.13), (4.14)
and the fact that
\[
\|\text{curl}(q\Phi(\cdot, z_j))\|_{L^2(\partial D)}^2 = \int_{\partial D} |\nabla \Phi(x, z_j) \times \nu(z_j)|^2 \, ds
\]
implies that \( I_j^{(2)} \in L^2(\partial D) \) is uniformly bounded for all \( j \in \mathbb{N} \). It remains to show that \( I_j^{(1)} \in L^2(\partial D) \) is uniformly bounded for all \( j \in \mathbb{N} \). From the definition of \( I_j^{(1)} \) and the equality (4.13), it is sufficient to prove this fact for the first component of \( I_j^{(1)} \). In view of (4.13) and (4.15), we only need to show that the sequence
\[
\frac{1}{\|\text{curl} [q\Phi(x, z_j)]\|_{L^2(\partial D)}} \left( \frac{(x_3 - z_j^{(3)})x_2 e^{i|z-x|} - (x_3 - y_j^{(3)})x_2 e^{i|z-y|}}{|x-z|^5} + \frac{(x_3 - y_j^{(3)})x_2 e^{i|z-y|}}{|x-y|^5} \right)
\]
is uniformly bounded in \( L^2(\partial D) \) for all \( j \in \mathbb{N} \).

For \( x = (x_1, x_2, x_3)^T, y = (y_1^{(1)}, y_2^{(2)}, y_3^{(3)})^T \) and \( z = (z_1^{(1)}, z_2^{(2)}, z_3^{(3)})^T \), by a direct calculation we have
\[
\frac{(x_3 - z_j^{(3)})x_2 e^{i|x-z|} - (x_3 - y_j^{(3)})x_2 e^{i|x-y|}}{|x-z|^5} + \frac{(x_3 - y_j^{(3)})x_2 e^{i|x-y|}}{|x-y|^5} = (x_3 - z_j^{(3)})x_2 e^{i|x-z|} - (x_3 - y_j^{(3)})x_2 e^{i|x-y|} + \left( \frac{(x_3 - z_j^{(3)})x_2 e^{i|x-z|}}{|x-z|^4} + \frac{(x_3 - y_j^{(3)})x_2 e^{i|x-y|}}{|x-y|^4} \right) \left( \frac{1}{|x-z|} - \frac{1}{|x-y|} \right)
\]
\[
+ \left( \frac{(x_3 - z_j^{(3)})x_2 e^{i|x-y|}}{|x-z|^3} + \frac{(x_3 - y_j^{(3)})x_2 e^{i|x-y|}}{|x-y|^3} \right) \left( \frac{1}{|x-z|} - \frac{1}{|x-y|} \right)
\]
(4.17)
It follows from (4.12) that there exists a constant \( C_3 > 0 \) such that
\[
\left| \frac{1}{|x-z_j|} - \frac{1}{|x-y_j|} \right| \leq C_3, \quad |\Phi(x, z_j) - \Phi(x, y_j)| \leq C_3, \quad x \in \partial D. \quad (4.18)
\]
Recalling \( z_\ast = (0, 0, 0)^T \) and \( \nu(z_\ast) = (0, 0, 1)^T \), we deduce by Taylor’s expansion that there exists a constant \( C_4 > 0 \) such that
\[
|x_3| \leq C_4(x_1^2 + x_2^2) \quad \text{for all } x \in \partial D. \quad (4.19)
\]
Inserting (4.18) and (4.19) into (4.17) and using (4.15), we obtain that the sequence in (4.16) is uniformly bounded in \( L^2(\partial D) \) for all \( j \in \mathbb{N} \), which means that \( I_j^{(1)} \) is uniformly bounded in \( L^2(\partial D) \) for all \( j \in \mathbb{N} \). Thus, and by (4.12), the inequality (4.11) holds. By (4.10), (4.11) and Theorem 3.8 for the problem (4.9), we obtain the uniform estimate
\[
\|H_j(\cdot)\|_{H^{1}(\partial D)} + \|u(\cdot, z_j, q)\|_{H^1(\partial D)} \leq C_4(\|f_{1j}\|_{H^{-1/2}(\partial D)} + \|f_{2j}\|_{H^{-1/2}(\partial D)}) \leq C_5, \quad (4.20)
\]
where \( C_4, C_5 > 0 \) are two positive constants independent of \( j \in \mathbb{N} \).
Since $\partial D \in C^2$ and $D_1 \neq D_2$, we can choose a small subdomain of $D$, denoted by $D_0$ with a $C^2$-smooth boundary $\partial D_0$, satisfying that $D_0 \subset D \setminus \overline{D}$ and the intersection $B \cap \partial D_0$ contains an open segment of $\partial D$. In $D_0$, we can construct the following boundary value problem

$$
\begin{cases}
\text{curl } \text{curl } F_{0,j} + F_{0,j} = \xi_{1,j} & \text{in } D_0, \\
\nabla \cdot (C : \nabla E_{0,j}) - E_{0,j} = \xi_{2,j} & \text{in } D_0, \\
TE_{0,j} - b_1 \nu \times F_{0,j} = h_{1,j} & \text{on } \partial D_0, \\
\nu \times \text{curl } F_{0,j} + \frac{i\kappa}{b_2} \nu \times E_{0,j} = h_{2,j} & \text{on } \partial D_0,
\end{cases}
$$

(4.21)

with $\xi_{1,j}, \xi_{2,j}, h_{1,j}$ and $h_{2,j}$ defined as follows:

$$
\begin{align*}
\xi_{1,j} &= (\kappa^2 + 1) \tilde{H}(\cdot, z_j, q), \\
\xi_{2,j} &= (\rho \omega^2 + 1) u(\cdot, z_j, q), \\
h_{1,j} &= T u(\cdot, z_j, q) - b_1 \nu \times \tilde{H}(\cdot, z_j, q), \\
h_{2,j} &= \nu \times \text{curl } \tilde{H}(\cdot, z_j, q) + \frac{i\kappa}{b_2} \nu \times u(\cdot, z_j, q).
\end{align*}
$$

By Theorem 5.8 it can be verified that all data are well-defined in the related Sobolev spaces for each fixed $j \in \mathbb{N}$. By Lemma 4.1 the problem (4.21) is uniquely solvable with the estimate

$$
\|F_{0,j}\|_{H^1(D_0)} + \|E_{0,j}\|_{H^1(D_0)} \leq C_0 \left[ \left\|\xi_{1,j}\right\|_{L^2(D_0)} + \left\|\xi_{2,j}\right\|_{L^2(D_0)} + \|h_{1,j}\|_{H^{-\frac{1}{2}}(\partial D_0)} + \|h_{2,j}\|_{H^{-\frac{1}{2}}(\partial D_0)} \right],
$$

(4.22)

where $C_0 > 0$ is a fixed constant.

We now claim that the right-hand side of the inequality (4.22) is uniformly bounded for all $j \in \mathbb{N}$. In fact, it first follows from (4.20) that $\xi_{2,j}$ is uniformly bounded in $L^2(D_0)$ for all $j \in \mathbb{N}$. Due to the positive distance between $D_0$ and $\overline{D}$, it can be concluded by the well-posedness of the problem (4.4) associated with the elastic body $\overline{D}$ and the uniform boundedness of $H^1(\cdot, z_j, q)$ in $L^2(D_0)$ that $\xi_{1,j}$ is uniformly bounded in $L^2(D_0)$ for all $j \in \mathbb{N}$. By recalling the equality (4.7) and the transmission conditions (2.5) and (2.6), it is deduced that

$$
h_{1,j} = 0, \quad h_{2,j} = 0 \quad \text{on } \partial D_0 \cap \partial D
$$

for all $j \in \mathbb{N}$. Thus we only need to show that $h_{1,j}$ and $h_{2,j}$ are uniformly bounded in $H^{-1/2}(\Gamma)$ and $H^{-1/2}(\partial D_0 \cap \partial D_0)$, respectively, where $\Gamma := \partial D_0 \setminus \overline{B_\varepsilon(z_*)}$ and $B_\varepsilon(z_*)$ is a ball with sufficiently small radius $\varepsilon > 0$ such that $B_\varepsilon(z_*) \subset D_0$. Since $\tilde{H}(\cdot, z_j, q) = H^1(\cdot, z_j, q) + \tilde{H}^v(\cdot, z_j, q)$, and by (4.20), we deduce that

$$
\|u(\cdot, z_j, q)\|_{H^1(D_0 \setminus \overline{B_\varepsilon(z_*)})} + \|\tilde{H}(\cdot, z_j, q)\|_{H^1(D_0 \setminus \overline{B_\varepsilon(z_*)})} \leq C_7
$$

for some constant $C_7 > 0$, whence the uniform boundedness of $\|h_{1,j}\|_{H^{-1/2}(\partial D_0)}$ and $\|h_{2,j}\|_{H^{-1/2}(\partial D_0)}$ follows from the trace theorems.

It is easy to verify that $(F_{0,j}, E_{0,j}) := (\tilde{H}(\cdot, z_j, q), u(\cdot, z_j, q))$ is the unique solution to the problem (4.21). Then, by (4.22) we have

$$
\|\tilde{H}(\cdot, z_j, q)\|_{H^1(D_0)} \leq C_8 \quad \forall j \in \mathbb{N}
$$

(4.23)
for some constant $C_8 > 0$ independent of $j \in \mathbb{N}$. On the other hand, due to the positive distance between $z_*$ and $\tilde{D}$, we have

$$\| \tilde{H}^e(\cdot, z_j, q) \|_{H(\text{curl}, D_0)} \leq C_9 \quad \forall j \in \mathbb{N} \quad (4.24)$$

for some constant $C_9 > 0$ independent of $j \in \mathbb{N}$. From (4.24) it follows that

$$\| \tilde{H}(\cdot, z_j, q) \|_{H(\text{curl}, D_0)} = \| H^i(\cdot, z_j, q) + \tilde{H}^e(\cdot, z_j, q) \|_{H(\text{curl}, D_0)}$$

$$\geq \| H^i(\cdot, z_j, q) \|_{H(\text{curl}, D_0)} - \| \tilde{H}^e(\cdot, z_j, q) \|_{H(\text{curl}, D_0)}$$

$$\geq \| H^i(\cdot, z_j, q) \|_{H(\text{curl}, D_0)} - C_9.$$  

By [14, Theorem 3.8] it is seen that the right-hand side of the above inequality goes to infinity as $j \to \infty$, which contradicts to the inequality (4.23), meaning that $D = \tilde{D}$. The proof is thus complete. □
