Algebraic genericity of frequently universal harmonic functions on trees

N. Biehler, V. Nestoridis, A. Stavrianidi

Abstract

We show that the set of frequently universal harmonic functions on a tree $T$ contains a vector space except 0 which is dense in the space of harmonic functions on $T$ seen as subset of $\mathbb{C}^T$. In order to prove this we replace the complex plane $\mathbb{C}$ by any separable Fréchet space $E$ and we repeat all the theory.

AMS classification numbers: 05C05, 31A20, 60J49, 30K99, 46M99

Keywords and phrases: Infinite trees, harmonic functions, boundary of a tree, universal functions, frequently universal functions, Baire’s theorem.

1 Introduction

For the theory of universality and the use of Baire’s Category theorem we refer to [9], [8], [13], [6], [12], [4], [7].

A tree $T$ is a connected, simply connected countable graph without non-trivial loops. With abuse of notation we shall also write $T$ for the set of vertices of the tree. We do not assume that $T$ is homogeneous: The number of edges joining at every vertex may be different, but shall always be finite. For $x, y \in T$ we write $x \sim y$ if $x$ and $y$ are neighbors, and also for any $x, y \in T$ there exists a unique natural number $n \in \mathbb{N}$ and a unique minimal finite sequence $\{z_0, z_1, \ldots, z_n\}$ such that $z_0 = x$, $z_n = y$ and $z_k \sim z_{k+1}$ for every $k < n$; this sequence is called the geodesic path from $x$ to $y$ and will be denoted by $[x, y]$.

The natural number $n$ as above is called the length of $[x, y]$ and will be denoted by $\ell(x, y)$; $\ell$ is a metric on $T$. By fixing a reference vertex $x_0 \in T$ we obtain a partial ordering $\leq$ as such: $x \leq y$ if $x$ belongs to the geodesic path from $x_0$ to $y$. We denote by $y^-$ the unique neighbor of $y \neq x_0$ that belongs to $[x_0, y]$ that is $y^- \leq y$. We call $y^-$ the parent of $y$. We shall denote with $T_n$ the set of all vertices at distance $n$ from $x_0$, and with $T_0 = \{x_0\}$. For every $x \in T$ we also denote with $S(x)$ the set of all $y \in T$ such that $y \sim x$ and $y \neq y^-$; we will assume that for every vertex $x$, the set $S(x)$ contains at least two elements. For every $x \in T$ and every $y \in S(x) \cup \{x^-\}$ we associate a number...
\(q(x, y) \geq 0\) such that \(q(x, x^-) = 0\) and \(q(x, y) > 0\) for all \(y \in S(x)\). These numbers satisfy:

\[
\sum_{y \in S(x)} q(x, y) = 1.
\]

The set \(T\) is infinite denumerable. The space \(\mathbb{C}^T\) of all complex valued functions defined on \(T\) is a complete metric space with respect to the metric:

\[
\rho(f, g) = \sum_{j=0}^{\infty} \frac{1}{2^j} \frac{|f(x_j) - g(x_j)|}{1 + |f(x_j) - g(x_j)|} \tag{*}
\]

where \(\{x_j : j \in \mathbb{N}\}\) is any enumeration of \(T\). The induced topology is the topology of pointwise convergence.

**Definition 1.1.** A function \(f : T \to \mathbb{C}\) is said to be \(Q\)-harmonic (or simply harmonic) if for all vertices \(x \in T\) the following holds:

\[
f(x) = \sum_{y \sim x} q(x, y)f(y).
\]

The set \(H_Q(T)\) of all \(Q\)-harmonic functions on \(T\) is a closed subset of \(\mathbb{C}^T\) and thus, a complete metric space. (Therefore Baire’s Category Theorem applies, \([9], [8]\)).

We define the boundary \(\partial T\) of the tree \(T\) to be the set of all the infinite geodesics starting at \(x_0\); that is, all \(e = \{z_n : n \in \mathbb{N}\}\) such that \(z_0 = x_0\) and \(z_{n+1} \in S(z_n)\) for every \(n \in \mathbb{N}\). A vertex \(x \in T\) defines a boundary sector \(B_x\) of \(\partial(T)\) which is the set of all \(e \in \partial T\) such that \(x \in e\). We assign a probability \(p(B_x)\), where \(x \in T_n\), as the product \(\prod_{j=0}^{n-1} q(y_j, y_{j+1})\), where \(y_j \in T_j\), \(y_n = x\), \(y_0 = x_0\) and of course \(y_j \sim y_{j+1}\), for every \(j\): \(0 \leq j \leq n - 1\). The family \(\{B_x\}_{x \in T_n}\) generates a \(\sigma\)-algebra \(\mathcal{M}_n\) on \(\partial T\) and the above probabilities \(p(B_x)\) extend to a probability measure \(P_n\) on \(\mathcal{M}_n\). One can check that \(\mathcal{M}_n \subseteq \mathcal{M}_{n+1}\) and \(P_{n+1}|_{\mathcal{M}_n} = P_n\) for every \(n \in \mathbb{N}\). The Kolmogorov Consistency Theorem ([10]) implies that there exists a unique probability measure \(P\) on the \(\sigma\)-algebra \(\mathcal{M}\) of subsets of \(\partial T\) generated by the union \(\bigcup_{n=0}^{\infty} \mathcal{M}_n\), such that \(P|_{\mathcal{M}_n} = P_n\) for every \(n \in \mathbb{N}\).

Let \(f \in H_Q(T)\) be a harmonic function. Then a sequence \(\{\omega_n(f)\}_{n=0}^{\infty}\) of functions \(\omega_n(f) : \partial T \to \mathbb{C}\) is defined by setting \(\omega_n(f)(e) = f(y_n)\), where \(y_n \in e \cap T_n\), for every \(e \in \partial T\) and every \(n \in \mathbb{N}\). It is obvious that the restriction of \(\omega_n(f)\) on \(B_x(x \in T_n)\) is constant and therefore, \(\omega_n(f)\) is \(\mathcal{M}_n\)-measurable and hence \(\mathcal{M}\)-measurable. Since \(f(x) = \sum_{y \sim x} q(x, y)f(y)\) it follows that the sequence \(\{(\omega_n(f), \mathcal{M}_n, P)\}_{n=0}^{\infty}\) defines a martingale and thus

\[
\mathbb{E}[\omega_m(f) | \mathcal{M}_n] = \omega_n(f) \quad \text{for every} \quad m > n \quad [11].
\]
Definition 1.2. Let $\tau \subseteq \mathbb{N}$ be an infinite set. A $Q$-harmonic function $f \in H_Q(T)$ belongs to the class $\tilde{U}_\tau(T)$ if for every $\mathcal{M}$-measurable function $\Psi : \partial T \to \mathbb{C}$ there exists a sequence $\{\lambda_n\}_{n=0}^\infty \subseteq \tau$ such that $\omega_{\lambda_n}(f)$ converges to $\Psi$ in probability.

Remark 1.3. In Definition 1.2 it is equivalent to require that a subsequence $\omega_{\lambda_{kn}}(f)$ of $\omega_{\lambda_n}(f)$ converge to $\Psi$ $\mathbb{P}$-almost surely. The space of $\mathcal{M}$-measurable functions on $\partial T$ shall be denoted by $L^0(\partial T, \mathbb{C}) = L^0(\partial T)$ and considered with the topology induced by convergence in probability is a complete metric space with respect to the metric $d(\Psi, \Phi) = \int_{\partial T} |\Psi - \Phi| d\mathbb{P}$. Definition 1.2 is analogue to the definition of universal trigonometric series in the sense of Menchoff ([12]).

In [3] the following theorems are proven:

Theorem 1.4. The class $\tilde{U}_\tau(T)$ is dense and $G_\delta$ in $H_Q(T)$.

Theorem 1.5. The class $\tilde{U}_\tau(T) \cup \{0\}$ contains a dense linear subspace of $H_Q(T)$.

Definition 1.6. For a subset $A$ of $\{0, 1, 2, \ldots\}$ the lower density $d(A)$ of $A$ is defined as:

$$d(A) = \liminf_{n \to \infty} \frac{1}{n+1} \cdot \text{card}\{m \in A : m \leq n\}.$$

In [3] the following definition has been given:

Definition 1.7. A harmonic function $f \in H_Q(T)$ is frequently universal, if for every non-void open subset $V$ of $L^0(\partial T, \mathbb{C})$, the set $\{n \in \{0, 1, 2, \ldots\} : \omega_n(f) \in V\}$ has positive lower density. The set of frequently universal harmonic functions will be denoted as $U_{FM}(T)$.

The following theorem is stated in [3] without proof.

Theorem 1.8. The class $U_{FM}(T)$ is dense in $H_Q(T)$ and meager, that is, it is contained in a countable union of closed subsets with empty interior.

The motivation of the present paper was to strengthen Theorem 1.5 by proving that $U_{FM} \cup \{0\}$ contains a vector space which is dense in $H_Q(T)$. Initially we proved it by considering functions $f = (f_1, f_2, \ldots)$, $f_k \in H_Q(T)$ harmonic on the tree $T$, $f : T \to \mathbb{C}^N$. The space of those $f$ is denoted by $(H_Q)^N$ or $H_Q(T, \mathbb{C}^N) = (H_Q)^N$ endowed with the Cartesian topology. We use the notation: $\omega_n(f) = (\omega_n(f_1), \omega_n(f_2), \ldots)$. Then $f$ is universal, if the sequence $\omega_n(f)$, $n = 0, 1, \ldots$ is dense in the space $L^0(\partial T, \mathbb{C}^N)$ of measurable functions $h : \partial T \to \mathbb{C}^N$, $h = (h_1, h_2, \ldots)$,

$$h_k \in L^0(\partial T, \mathbb{C}), \quad L^0(\partial T, \mathbb{C}^N) = [L^0(\partial T, \mathbb{C})]^N.$$
endowed with the Cartesian topology. Also \( f \) is called frequently universal, if, for every non-empty open set \( V \subset L^0(\partial T, \mathbb{C}^N) \) the set: \( \{n \in \mathbb{N} : \omega_m(f) \in V \} \) has strictly positive lower density. If \( f = (f_1, f_2, \ldots) \) is frequently universal then it can be easily seen that the linear span of \( f_1, f_2, \ldots \) except zero, i.e. \( \text{span}\{f_1, f_2, \ldots\}\backslash\{0\} \) is contained in the set of frequently universal functions \( U_{FM} \). Furthermore, the sequence \( f_1, f_2, \ldots \) can be chosen to be dense in \( H_Q(T) \) and simultaneously \( f = (f_1, f_2, \ldots) \) to be frequently universal. It follows that \( \text{span}\{f_1, f_2, \ldots\} \) is a dense vector subspace of \( H_Q(T) \) contained in \( U_{FM} \cup \{0\} \). Thus, we have algebraic genericity for \( U_{FM} \) which strengthens Theorem 1.

It is also possible to repeat all the theory for the new harmonic universal functions \( f : T \to \mathbb{C}^N, f = (f_1, f_2, \ldots) \in (H_Q)_{N_0} = H_Q(T, \mathbb{C}^{N_0}) \).

In order to prove algebraic genericity of the frequently universal functions \( f = (f_1, f_2, \ldots) \in (H_Q)_{N_0} = H_Q(T, \mathbb{C}^{N_0}) \) we are led to consider the space \((H_Q)_{N_0}^{N_0} = H_Q(T, (\mathbb{C}^{N_0})^{N_0}) = (f_{n,k})_{n,k=1,2,\ldots}\) and to repeat the theory for this new space and so on.

The spaces \(((H_Q^{N_0})^{N_0})^{N_0} \ldots\) are separable Fréchet spaces and everything will be simplified if we fix \( E \) a separable Fréchet space (on the field of real numbers \( \mathbb{R} \) or complex numbers \( \mathbb{C} \)), if we consider the space \( H_Q(T, E) = \{f : T \to E \text{ harmonic} \} \subset E^T \) endowed with the cartesian topology and if we define what it means that \( f \in H_Q(T, E) \) is universal or frequently universal and repeat all the theory. This is done in the following sections and as a corollary we obtain the algebraic genericity of \( U_{FM} \).

2 Universal harmonic functions

Let \( T \) be a tree as in §1 and let \( E \) be a separable Fréchet space. We denote by \( d \) the metric in \( E \).

**Definition 2.1.** A function \( f : T \to E \) is called harmonic if

\[
f(x) = \sum_{y \in S(x)} q(x, y)f(y) \quad \text{for each} \quad x \in T.
\]

The set of such functions is denoted by \( H_Q(T, E) \). It is a subset of \( E^T \) endowed with the cartesian topology.

Since \( E \) is complete and \( T \) denumerable, those spaces are complete.

Since \( E \) is a separable metric space, the same is true for \( E^T \) and \( H_Q(T, E) \).

If \( f \in H_Q(T, E) \), the function \( \omega_n(f) : \partial T \to E \) is defined in a similar way as in §1 and the sequence \( \omega_n(f), n = 0, 1, 2, \ldots \) is a martingale with values in \( E \).

A function \( h : \partial T \to E \) is \( \mathcal{M} \)-measurable (\( \mathcal{M}_n \)-measurable) if, for every open set \( W \subset E \) we have \( h^{-1}(W) \in \mathcal{M} \) (\( h^{-1}(W) \in \mathcal{M}_n \) respectively).
Identifying two $M$-measurable functions if they are $P$-almost everywhere equal, we obtain the space $L^0(\partial T, E)$.

We endow $L^0(\partial T, E)$ with the topology of convergence in probability, that is, for any $h_1, h_2 \in L^0(\partial T, E)$ their distance is

$$\tilde{\rho}(h_1, h_2) = \int_{\partial T} \frac{d(h_1(x), h_2(x))}{1 + d(h_1(x), h_2(x))} dP(x).$$

Since $E$ is separable, for every $n$ the space of $M_n$-measurable functions defined on $\partial T$ with values in $E$ is separable. It follows that $L^0(\partial T, E)$ is also separable and it has a dense sequence $h_n \in L^0(\partial T, E)$, $n = 1, 2, \ldots$ where each $h_n$ is $M_{\tau(n)}$-measurable for some $\tau(n) \in \{0, 1, 2, \ldots\}$.

**Definition 2.2.** A harmonic function $f \in H_Q(T, E)$ is universal if the sequence $\omega_n(f)$, $n = 0, 1, 2, \ldots$ is dense in $L^0(\partial T, E)$. The set of universal harmonic functions $f \in H_Q(T, E)$ is denoted by $U(T, E)$.

**Theorem 2.3.** Under the above assumptions and notation the set $U(T, E)$ is a dense and $G_\delta$ subset of $H_Q(T, E)$; hence $U(T, E)$ is non-void.

**Proof.** The proof is similar to the proof of Theorem 2.2 in [3] and is omitted. It suffices to replace $C$ by $E$.

**Remark 2.4.** Let $f \in U(T, E)$; then, the sequence $h_n = \omega_n(f)$, $n = 0, 1, 2, \ldots$ is dense in $L^0(\partial T, E)$ and $h_n$ is $M_n$-measurable.

**Remark 2.5.** Let $E, F$ be two isomorphic separable Fréchet spaces and $\varphi : E \to F$ an isomorphism. Let $f : T \to E$ be a function. Then, $f \in H_Q(T, E)$ iff $\varphi \circ f \in H_Q(T, F)$ and $f \in U(T, E)$ iff $\varphi \circ f \in U(T, F)$.

### 3 Frequently universal harmonic functions

In analogy with Definition 1.7 we give the following definition.

**Definition 3.1.** A function $f \in H_Q(T, E)$ is frequently universal, if, for every non-empty open set $V \subset L^0(\partial T, E)$ the set $\{n \in \mathbb{N} : \omega_n(f) \in V\}$ has strictly positive lower density. We denote the set of such functions by $U_{FM}(T, E)$. Obviously $U_{FM}(T, E) \subseteq U(T, E)$.

**Remark 3.2.** If $E$ and $F$ are two isomorphic separable Fréchet spaces and $\varphi : E \to F$ is an isomorphism, then $f \in U_{FM}(T, E)$ iff $\varphi \circ f \in U_{FM}(T, F)$.

**Theorem 3.3.** Under the above assumptions and notation $U_{FM}(T, E)$ is dense and meager in $H_Q(T, E)$. In particular $U_{FM}(T, E) \neq \emptyset$. 
The proof of Theorem 3.3 is a modification of the proof in [1], [2]. Since these papers are not yet published we give all the details of the proof.

**Proof of Theorem 3.3** We consider a dense sequence \( \{h_k, k \in \mathbb{N}\} \) in \( H_Q(T, E) \) where each \( h_k \) is \( \mathcal{M}_k \)-measurable. It can be easily seen that such a sequence exists according to Remark 2.4.

To construct a frequently universal function \( f \) it suffices that, for every \( k \in \mathbb{N} \) the set:

\[
\{ n \in \mathbb{N} : \omega_n(f) \in B\left(h_k, \frac{1}{2^k}\right) \}
\]

has positive lower density. For this purpose we will use the following sequence of integers.

**Lemma 3.4.** Let \( \ell(k) = s + 1 \), where \( k = 2^s \cdot d \) and \( d \) is an odd number. We also set \( r_1 = 0 + \ell(1) \) and for \( k \geq 2 \), \( r_k = r_{k-1} + \ell(k) \).

This sequence has the following properties:

(i) \( r_n = \sum_{k=1}^{n} \ell(k) \)

(ii) \( r_{2N} = 2^{N+1} - 1 \) for \( N \in \mathbb{N} \)

(iii) For \( m \leq N \) it holds that \( \text{card}\{k : 1 \leq k \leq 2^N \text{ such that } \ell(k) = m\} = 2^{N-m} \)

(iv) For \( m \geq 1 \) the set \( \{r_n : n \in \mathbb{N}, \ell(n) = m\} \) has strictly positive lower density.

**Proof of Lemma 3.4** ([1], [2]).

i) This is obvious.

ii) To see this we proceed by induction on \( N \): For \( N = 0, 1 \) it is obviously true. Suppose that \( r_{2N} = 2^{N+1} - 1 \), we will prove that \( r_{2N+1} = 2^{N+2} - 1 \).

We have that

\[
r_{2N+1} = \sum_{k=1}^{2^{N+1}} \ell(k) = \sum_{k=1}^{2^N-1} \ell(k) + \ell(2^N) + \sum_{k=2^N+1}^{2^{N+1}-1} \ell(k) + \ell(2^{N+1}).
\]

But \( \ell(2^N) = N + 1 \), \( \ell(2^{N+1}) = N + 2 \). We set

\[
S_1 = \sum_{k=1}^{2^N-1} \ell(k) \quad \text{and} \quad S_2 = \sum_{k=2^N+1}^{2^{N+1}-1} \ell(k).
\]

We have that \( S_1 = S_2 \) because for \( k = 1, 2, \ldots, 2^N - 1 \) we have \( \ell(k) = \ell(k+2^N) \). Indeed let \( k = 2^s \cdot d \) with \( s < N \) and \( d \) odd. Then \( \ell(k) = s + 1 \) and \( k + 2^N = 2^s \cdot d + 2^N = 2^s(d + 2^{N-s}) \) with \( d + 2^{N-s} \) an odd number since \( N > s \). Thus \( \ell(k+2^N) = s + 1 = \ell(k) \).

It follows that:

\[
r_{2N+1} = 2 \left( \sum_{k=1}^{2^N-1} \ell(k) \right) + 2(N + 1) + 1 = 2 \left( \sum_{k=1}^{2^N} \ell(k) \right) + 1
\]
because \( N + 1 = \ell(2^N) \).

We also have \( \sum_{k=1}^{2^N} \ell(k) = r_{2^N} \) and therefore: \( r_{2^{N+1}} = 2(r_{2^N}) + 1 \) and using the induction hypothesis we find \( r_{2^{N+1}} = 2(2^{N+1} - 1) + 1 = 2^{N+2} - 1 \).

This proves property (ii)

iii) For \( m = 1 \) half of the \( k \in [1, 2^N], k \in \mathbb{N} \) satisfy \( \ell(k) = 1 \) (the odd \( k \)), so

\[
\text{card}(\{ k : 1 \leq k \leq 2^N : \ell(k) = 1 \}) = \frac{2^N}{2} = 2^{N-1}.
\]

For \( m = 2 \) we have half of the half (that is \( \frac{1}{4} \)) which give \( \frac{2^N}{4} = 2^{N-2} \).

Continuing this way we see that:

\[
\text{card}(\{ k : 1 \leq k \leq 2^N : \ell(k) = m \}) = 2^{N-m} \text{ where } m \leq N.
\]

iv) We want to show that the set:

\[\{ r_n : n \in \mathbb{N}; \ell(n) = m\} \text{ has strictly positive lower density in } \mathbb{N}.\]

The sequence \( r_n \) is increasing so we have to show that

\[
\liminf_{M \in \mathbb{N}} \frac{\text{card}\{ n \in \mathbb{N} : r_n \leq M, \ell(n) = m \}}{M + 1} > 0
\]

Because \( r_{2^N} = 2^{N+1} - 1 \) it suffices to show the following:

\[
\inf_{N: N \geq m} \frac{\text{card}\{ n : r_n \leq r_{2^N}, \ell(n) = m \}}{r_{2^N} + 1} > 0.
\]

Since the sequence \( r_n \) is strictly increasing this reduces to the following

\[
\inf_{N: N \geq m} \frac{\text{card}\{ n : 1 \leq n \leq 2^N : \ell(n) = m \}}{r_{2^N} + 1} > 0.
\]

Indeed, we have that the numerator is equal to \( 2^{N-m} \) as we have already seen. The denominator equals \( 2^{N+1} \). Thus, we find \( \frac{2^{N-m}}{2^{N+1}} = 2^{-m-1} > 0 \).

Thus, the set \( \{ r_n : n \in \mathbb{N} \text{ with } \ell(n) = m\} \) has strictly positive lower density.

The proof of Lemma 3.4 is completed.

To construct a function \( f \in U_{F,M}(T, E) \) it suffices to construct \( f \in H_Q(T, E) \) such that:

\[
\omega_{r_k}(f) \in B(h_{\ell(k)}, \frac{1}{2^{\ell(k)}}) \text{ for all } k \geq 1,
\]

where the sequence \( h_n, n = 0, 1, \ldots \) is dense in \( H_Q(T, E) \) and each \( h_n \) is \( M_n \)-measurable, as previously mentioned. For this purpose, we will need the following lemma.
Lemma 3.5. Let $n > 0$, $s > 0$ be natural numbers and let $\varphi$ be harmonic on $T_0 \cup T_1 \cup \cdots \cup T_s$. Then it is possible to extend $\varphi$ to a harmonic function $\Psi$ on $T_0 \cup T_1 \cup \cdots \cup T_{s+n-1}$ defined on $T_0 \cup T_1 \cup \cdots \cup T_{s+n}$ (i.e. $\Psi|_{T_0 \cup T_1 \cup \cdots \cup T_s} \equiv \varphi$) in such a way that:

$$\omega_{s+n}(\Psi) \in B\left(h_n, \frac{1}{2^n}\right).$$

Proof of Lemma 3.5. Consider a vertex $v \in T_s$. Let $V \subseteq T_{s+n}$ be the set of all vertices of $T_{s+n}$ which are at distance $n$ from $v$. Clearly $V$ contains a vertex $w$ such that the probability to go from $v$ to $w$ is less than or equal to $\frac{1}{2^n}$.

We set

$$\Psi(u) = h_n(e) \quad \text{where} \quad e \cap T_{s+n} = \{u\}$$

for every $u \in V \setminus \{w\}$. $\Psi$ is well-defined this way because $h_n$ is $M_{n+s}$-measurable and hence the value of $h_n(e)$, where $e \cap T_{s+n} = \{u\}$ does not depend on the choice of $e$.

Clearly we can extend $\Psi$ to all vertices $x \in T_{s+1} \cup \cdots \cup T_{s+n}$ such that $v \in [0,x]$ in such a way that $\Psi$ is harmonic.

We do the same procedure with all vertices of $T_s$ and we define $\Psi$ on $T_0 \cup \cdots \cup T_{s+n}$ and extends $\varphi$. We also have: $\omega_{s+n}(\Psi) \in B\left(h_n, \frac{1}{2^n}\right)$ because the set $\{w = w(v) \in T_{n+s} : v \in T_s\}$ has probability at most $\frac{1}{2^n}$ and outside this set we have $\Psi \equiv h_n$ on $T_{n+s}$. This proves Lemma 3.5.

By Lemma 3.5 it is possible to construct $f \in H_Q(T, E)$ by induction such that

$$\omega_{r_k}(f) \in B\left(h_{\ell(k)}, \frac{1}{2^\ell(k)}\right) \quad \text{for every} \quad k \in \mathbb{N}.$$ 

Indeed, it suffices to apply Lemma 3.5 for $s = r_{k-1}$, $n = \ell(k)$, $s + n = r_k$ because $r_k = r_{k-1} + \ell(k)$.

We have that $\omega_{r_k}(f) \in B\left(h_{\ell(k)}, \frac{1}{2^\ell(k)}\right)$ for each $k \in \mathbb{N}$. Since, according to Lemma 3.4 the set $\{r_k, k \in \mathbb{N} : \ell(k) = n\}$ has positive lower density, $f$ is frequently universal.

Hence $U_{FM}(T, E) \neq \emptyset$. We will now prove that $U_{FM}(T, E)$ is dense.

We consider $f_0 \in U_{FM}(T, E)$. We also consider $\varphi \in H_Q(T, E)$ such that $\omega_n(\varphi) = \omega_{n_0}(\varphi)$ for every $n \geq n_0$ for some $n_0 \in \mathbb{N}$. We can easily see that $f_0 + \varphi \in U_{FM}(T, E)$ by considering the open set $V - \omega_{n_0}(\varphi)$ and using the fact that the set $\{n \in \mathbb{N} : \omega_n(f_0) \in V - \omega_{n_0}(\varphi)\}$ has positive lower density. Since the set $L = \{\varphi \in H_Q(T, E) : \omega_n(\varphi) = \omega_{n_0}(\varphi) \quad \text{for all} \quad n \geq n_0 \quad \text{for some} \quad n_0 \in \mathbb{N}\}$ is dense in $H_Q(T, E)$ the same holds for the set of translations $f_0 + \varphi, \varphi \in L$. This set is dense and contained in $U_{FM}(T, E)$. This proves the density of $U_{FM}(T, E)$.

We will now prove that $U_{FM}(T, E)$ is meager in $H_Q(T, E)$. We need the following preliminaries:
Definition 3.6. For a subset $A$ of the natural numbers $\mathbb{N}$ the upper density $\overline{d}(A)$ of $A$ is defined as:

$$\overline{d}(A) = \limsup_{n \in \mathbb{N}} \frac{1}{n + 1} \cdot \text{card} \{ m \in A : m \leq n \}.$$ 

Definition 3.7. A harmonic function $f \in H_{Q}(T, E)$ belongs to the class $X(T, E)$ if the following holds:

For every non-void open subset $V$ of $L^{0}(\partial T, E)$ the set $\{ n \in \mathbb{N} : \omega_{n}(f) \in V \}$ has upper density in $\mathbb{N}$ exactly equal to 1.

Proposition 3.8. The class $X(T, E)$ is $G_{\delta}$ and dense in $H_{Q}(T, E)$.

Proof of Proposition 3.8 ([1], [2]).

Let $V_{j}, j \in \mathbb{N}$ be a denumarable base of open sets in $L^{0}(\partial T, E)$ and $n, m \in \mathbb{N}$. We consider the set: $E(j, m, n) = \{ f \in H_{Q}(T, E) : \text{there exists } q \in \mathbb{N} : n > q > (1 - \frac{1}{m}) \cdot n \text{ and natural numbers } n_{1}, n_{2}, \ldots, n_{q} \text{ such that } 1 \leq n_{1} < n_{2} < \cdots < n_{q} < n: \omega_{n}(f) \in V_{j} \text{ for all } \ell = 1, 2, \ldots, q \}.$

Then it can be seen that:

$$X(T, E) = \bigcap_{j,m,N} \bigcup_{n \geq N} E(j, m, n).$$

We can easily see that $E(j, m, n)$ is open for every $j, m, n \in \mathbb{N}$.

Therefore $X(T, E)$ is $G_{\delta}$ in $H_{Q}(T, E)$. In order to use Baire’s Category Theorem in the complete metric space $H_{Q}(T, E)$ it suffices to prove that $\bigcup_{n \geq N} E(j, m, n)$ is dense in $H_{Q}(T, E)$. We imitate the proof of the density in Theorem 2.3.

We construct a harmonic function $f$ up to a certain level $n_{1}$ such that $\omega_{n_{1}}(f) \in V_{j}$. We extend harmonically $f$ so that $\omega_{k}(f) = \omega_{n_{1}}(f)$ for all $k = n_{1}, n_{1} + 1, \ldots, n_{1} + \sigma$ where $\sigma > \left(1 - \frac{1}{m}\right)(n_{1} + \sigma)$. To do this extension we set $f(x) = f(x^{-})$ for all $x \in \bigcup_{\ell \geq n_{1} + 1} T_{\ell}$.

This extension is harmonic because $q(x, x^{-}) = 0$.

This proves Proposition 3.8.

Proposition 3.9.

$$X(T, E) \cap U_{FM}(T, E) = \emptyset.$$ 

Proof of Proposition 3.9 ([1], [2]). We suppose that $X(T, E) \cap U_{FM}(T, E) \neq \emptyset$ to arrive at a contradiction.

Let $f$ be an element of $X(T, E) \cap U_{FM}(T, E)$. We consider $V_{1}, V_{2}$ two disjoint open balls in $L^{0}(\partial T, E)$.

Then $\{ n \in \mathbb{N} : \omega_{n}(f) \in V_{1} \} \cap \{ n \in \mathbb{N} : \omega_{n}(f) \in V_{2} \} = \emptyset$.

Since $f \in U_{FM}(T, E)$, there exists $\delta > 0$ and $m \in \mathbb{N}$, such that $\text{card} \{ n \in \mathbb{N} : n \leq N : \omega_{n}(f) \in V_{1} \} > \frac{\delta}{2}(N + 1)$ for all $N \geq m$. 

Since $f \in X(T, E)$ there exists $N_0 \geq m$ such that

$$\text{card}(\{n \leq N_0 : \omega_n(f) \in V_2\}) > \left(1 - \frac{\delta}{2}\right) (N_0 + 1).$$

Combining those two we find:

$$1 + N_0 = \text{card}(\{n \leq N_0\}) \geq \text{card}(\{n \leq N_0 : \omega_n(f) \in V_1 \cup V_2\})$$

$$= \text{card}(\{n \leq N_0 : \omega_n(f) \in V_1\}) + \text{card}(\{n \leq N_0 : \omega_n(f) \in V_2\})$$

$$> \frac{\delta}{2} (N_0 + 1) + \left(1 - \frac{\delta}{2}\right) (N_0 + 1) = N_0 + 1.$$}

Thus: $1 + N_0 > 1 + N_0$ which is absurd.

This proves Proposition 3.9.

Since $U_{FM}(T, E)$ is disjoined from $X(T, E)$, which is $G_\delta$ and dense, we conclude that $U_{FM}(T, E)$ is meager in $H_Q(T, E)$. This completes the proof of Theorem 3.3.

4 Algebraic genericity

Let $E$ be a separable Fréchet space, then the infinite denumerable product $E^\mathbb{N}$ is also a separable Fréchet space. According to Theorem 3.3 there exists $f = (f_1, f_2, \ldots) \in U_{FM}(T, E^\mathbb{N})$ where $f_k : T \to E$ are harmonic functions.

Claim 4.1. The linear space $(f_1, f_2, \ldots)$ of $f_1, f_2, \ldots$ where $f = (f_1, f_2, \ldots) \in U_{FM}(T, E^\mathbb{N})$ is contained in $U_{FM}(T, E) \cup \{0\}$.

Proof. We consider a linear combination of those $f_n, n \in \mathbb{N}, a_1f_1 + \cdots + a_sf_s$ where $a_s \neq 0$.

Let $V$ be a non-void, open subset of $L^0(\partial T, E)$. There exists some function $h$ such that $B\left(h, \frac{1}{2^M}\right) \subseteq V$ for some $M \in \mathbb{N}$.

Let $\varepsilon = \frac{1}{s \cdot 2^M}$ and we consider the set:

$$\tilde{V} = B\left(0, \varepsilon \cdot \min \left\{ \frac{1}{|a_1|}, 1 \right\} \right) \times B\left(0, \varepsilon \cdot \min \left\{ \frac{1}{|a_2|}, 1 \right\} \right) \times \cdots \times B\left(\frac{h}{|a_s|}, \varepsilon \cdot \min \left\{ \frac{1}{|a_s|}, 1 \right\} \right) \times L^0(\partial T, E) \times \cdots.$$

Since the metric $(\tilde{\rho})$ in $L^0(\partial T, E^\mathbb{N})$ is equivalent to the cartesian metric considering that $L^0(\partial T, E^\mathbb{N})$ is the infinite denumerable product of spaces $L^0(\partial T, E)$, we have that $\tilde{V}$ is open in $L^0(\partial T, E^\mathbb{N})$. 

(We assume $1/0 = \infty$ and hence $\min\{\infty, 1\} = 1$).

Since $f \in U_{FM}(T, E^\mathbb{N})$ we have that the set $\{n \in \mathbb{N} : \omega_n(f) \in \tilde{V}\}$ has positive lower density. Therefore, for all $n$ in this set we have
\[
\omega_n(f) \in \tilde{V} \iff \omega_n(f_i) \in B\left(0, \varepsilon \cdot \min\left\{\frac{1}{|a_i|}, 1\right\}\right)
\]
for $1 \leq i \leq s - 1$ and
\[
\omega_n(f_s) \in B\left(h \cdot \frac{1}{|a_s|}, \varepsilon \cdot \min\left\{\frac{1}{|a_s|}, 1\right\}\right).
\]
It follows that: $\omega_n(f_i) \in B(0, \varepsilon)$ for $1 \leq i \leq s - 1$ and $\omega_n(f_s) \in B(h, \varepsilon)$.

As a result
\[
\tilde{\rho}(\omega_n(a_1f_1), 0) < \varepsilon \quad \text{for} \quad 1 \leq i \leq s - 1 \quad \text{and} \quad \tilde{\rho}(\omega_n(a_sf_s), h) < \varepsilon.
\]
We now have:
\[
\tilde{\rho}(\omega_n(a_1f_1 + \cdots + a_sf_s), h) \leq \tilde{\rho}(\omega_n(a_1f_1), 0) + \cdots + \tilde{\rho}(\omega_n(a_{s-1}f_{s-1}), 0) + \tilde{\rho}(\omega_n(a_sf_s), h) \leq s \cdot \varepsilon = \frac{1}{2M}
\]
where we used the fact that the metric $d$ in the Fréchet space $E$ is invariant under translations.

This implies $\omega_n(a_1f_1 + \cdots + a_sf_s) \in B\left(h, \frac{1}{2M}\right) \subseteq V$ and this is true for every $n \in \mathbb{N}$ such that $\omega_n(f) \in \tilde{V}$. The set of such $n \in \mathbb{N}$ has positive lower density. As a result the set $\{n \in \mathbb{N} : \omega_n(a_1f_1 + \cdots + a_sf_s) \in V\}$ has positive lower density. This implies that $a_1f_1 + \cdots + a_sf_s \in U_{FM}(T, E)$ and thus
\[
\text{span}\{f_n : n \in \mathbb{N}\} \subseteq U_{FM}(T, E) \cup \{0\}.
\]

The proof of the claim is completed.

Next we will show the following.

**Claim 4.2.** There exists a sequence $f_1, f_2, \ldots$ dense in $H_Q(T, E)$ such that $f = (f_1, f_2, \ldots) \in U_{FM}(T, E^\mathbb{N})$.

**Proof of the claim.** We consider a sequence $\{\varphi_n : n \in \mathbb{N}\}$ which is dense in $H_Q(T, E)$ and a function $f \in U_{FM}(T, E^\mathbb{N})$, $f = (f_1, f_2, \ldots)$.

For every $n \in \mathbb{N}$ there exists some $j_0(n) \in \mathbb{N}$ such that:
\[
\sum_{j=j_0(n)}^{\infty} \frac{1}{2^j} < \frac{1}{n}.
\]
Theorem 4.3. Under the above assumptions and notation $U_{FM}(T, E^N) \cup \{0\}$ contains a vector space which is dense in $H_Q(T, E)$.
Proof. Let $f = (f_1, f_2, \ldots) \in U_{FM}(T, E^N)$ as in Claim 4.2. Since the sequence $f_1, f_2, \ldots$ is dense in $H_Q(T, E)$ it follows that their linear span $\langle f_1, f_2, \ldots \rangle$ is also dense in $H_Q(T, E)$. Since $f = (f_1, f_2, \ldots) \in U_{FM}(T, E^N)$, it follows that $\langle f_1, f_2, \ldots \rangle \subset U_{FM}(T, E) \cup \{0\}$ according to Claim 4.1. This completes the proof of Theorem 4.3.

Corollary 4.4. Under the above assumptions and notation $U(T, E) \cup \{0\}$ contains a vector space which is dense in $H_Q(T, E)$.

Proof. This follows immediately from Theorem 4.3 because $U_{FM}(T, E) \subset U(T, E)$ Corollary 4.4 for $E = \mathbb{C}$ coincides with Theorem 1.5. Theorem 4.3 for $E = \mathbb{C}$ gives a strengthened version of Theorem 1.5 which is the algebraic genericity of $U_{FM}$ and was the motivation of this paper.
