**KP GOVERSNS RANDOM GROWTH OFF A ONE DIMENSIONAL SUBSTRATE**

JEREMY QUASTEL AND DANIEL REMENIK

**Abstract.** The logarithmic derivative of the marginal distributions of randomly fluctuating interfaces in one dimension on a large scale evolve according to the Kadomtsev–Petviashvili (KP) equation. This is derived algebraically from a Fredholm determinant obtained in [MQR17] for the KPZ fixed point as the limit of the transition probabilities of TASEP, a special solvable model in the KPZ universality class. In addition, it is noted that known exact solutions of the KPZ equation also solve KP.

1. **Matrix KP equation for multidimensional distributions**

The one dimensional KPZ universality class consists of random growth models, last passage percolation and directed polymers, and random stirred fluids. All models in the class have an analogue of the height function \( h(t, x) \) (free energy, integrated velocity) whose long time large scale evolution is the principal object of study. The name of the class comes from the Kardar-Parisi-Zhang equation,

\[
\partial_t h = \lambda (\partial_x h)^2 + \nu \partial_x^2 h + \sigma \xi \tag{1.1}
\]

with \( \xi \) a space-time white noise, a canonical continuum equation for random growth introduced in [KPZ86]. However, the key interest is on the universal features which are only found in large space-time scales, under the 1:2:3 scaling corresponding to \( \epsilon \to 0 \) in

\[
\epsilon^{1/2} h(\epsilon^{-3/2} t, \epsilon^{-1} x) - C_\epsilon t. \tag{1.2}
\]

The KPZ equation is not invariant under this scaling, which sends \( (\lambda, \nu, \sigma) \) to \( (\lambda, \epsilon^{1/2} \nu, \epsilon^{1/4} \sigma) \). A key problem is to find the true, scaling invariant equation for random interface growth.

*Date: September 23, 2019.*
Since the early 2000’s [Joh03; Sas05; BFPS07] it was known, for a number of models in the class, and special scaling invariant initial data narrow wedge and flat, that the distributional limits of (1.2) were the Tracy-Widom distributions of random matrix theory. In an earlier article [MQR17] it was shown that, at least for one model in the class, TASEP, (1.2) converges to a 1:2:3 invariant Markov process $h(t,x)$ with completely integrable transition probabilities given in terms of Fredholm determinants of kernels $K$ depending on the initial data (in [NQR19; MQR+] this is extended to other models related to TASEP). It is widely believed that this KPZ fixed point governs the limiting fluctuation for all models in the class.

The KPZ fixed point does not satisfy a stochastic differential equation. In place of that, it inherits a variational formulation from TASEP; a Hopf-Lax type formula involving a non-trivial input noise called the Airy sheet $A(x,y)$,

$$h(t,x) \overset{\text{dist}}{=} \sup_{y\in\mathbb{R}} \{ t^{1/3} A(t^{-2/3}x, t^{-2/3}y) - \frac{1}{\tau} (x-y)^2 + h_0(y) \}. \quad (1.3)$$

The Airy sheet $A(x,y)$ can be thought of as the height function at $x$ at time 1, starting from a narrow wedge at $y$ at time 0, and therefore involves coupling different initial conditions. As far as we know at the present time, the coupled initial condition problem is not integrable, and therefore the distribution of the Airy sheet is unknown. This led to a problem in that it was unclear that (1.3) even involved a unique object on the right hand side. An important advance is in [DOV19], who show that the Airy sheet is a functional of the Airy line ensemble. This puts the variational formula (1.3) on a solid footing, as it obviates the need for uniqueness of the Airy sheet. However, the functional is completely non-explicit. In this sense, (1.3) is not satisfying as a universal scaling invariant equation.

Instead of a universal stochastic equation, one can study the $n$-space point distribution functions,

$$F(t,x_1,\ldots,x_n, r_1, \ldots, r_n) = \mathbb{P}_{h_0}(h(t,x_1) \leq r_1, \ldots, h(t,x_n) \leq r_n) \quad (1.4)$$

where $h(t,x)$ is the KPZ fixed point starting from a non-random $h_0$. In the cases of narrow wedge and flat initial data, it was known [Joh00; Sas05; BFPS07] that the one-dimensional distributions $F(1,x,r)$ were, respectively, the Tracy-Widom GUE and GOE random matrix distributions (but, except in the particular case of narrow wedge initial data, the connection between random growth and random matrices has remained tangential and murky). The multidimensional distributions in these cases are given by Fredholm determinants, and define the Airy$_2$ and Airy$_1$ processes. The one-dimensional distributions can be written in terms of the Hastings-McLeod solution of Painlevé II; a longstanding open question was whether the distributions satisfy an equation in the more general setting.

In (3.8) we will define a tau function $Q = ((I - K)^{-1}K)(0,0)$ which is an $n \times n$ matrix valued function of $t, x_1, \ldots, x_n, r_1, \ldots, r_n,$ and the initial height profile $h_0$; at this point its exact definition is not important. Define

$$D_r = \sum_{i=1}^n \partial_{r_i}, \quad D_x = \sum_{i=1}^n \partial_{x_i}. \quad (1.5)$$

Our main result is:

**Theorem 1.1.** $Q$ and its derivative $q = D_r Q$ solve the matrix Kadomtsev–Petviashvili (KP) equation

$$\partial_t q + \frac{1}{2} (q D_r q + D_r q q) + \frac{1}{12} D_r^3 q + \frac{1}{4} D^2_x Q + \frac{1}{2} (q D_x Q - D_x Q q) = 0, \quad (1.6)$$

and the logarithmic derivative of the $n$ point distribution (1.4) is given by

$$D_r \log F = \text{tr} Q.$$

In particular, the one point marginals (i.e. in the case $n=1$), $\phi = \partial_r^2 \log F$ satisfy the scalar KP-II equation

$$\partial_t \phi + \phi \partial_r \phi + \frac{1}{12} \partial_r^3 \phi + \frac{1}{4} \partial_r^{-1} \partial^2_x \phi = 0. \quad (1.7)$$
Remark 1.2.

1. The result is completely unexpected. We do not have physical intuition why it is true; it follows by, essentially, algebra from the form of the kernel in the Fredholm determinant for (1.4), and we believe it is the first example of a physical law having been obtained in such a fashion. In retrospect, there are not so many natural partial differential equations with the necessary invariance under
\[ \phi(t, x, r) \mapsto \alpha^{-2}\phi(\alpha^{-3}t, \alpha^{-2}x, \alpha^{-1}r), \quad \mathfrak{h}_0(x) \mapsto \alpha^{-1}\mathfrak{h}_0(\alpha^2x). \]

The question is why they should satisfy a closed equation at all.

2. The KP equation (1.7) was originally derived from studies of long waves in shallow water [AS79]. It has come to be accepted as the natural two dimensional extension of the Korteweg-de Vries equation (KdV); when \( \phi \) is independent of \( x \), corresponding to our case to flat initial data, it reduces to KdV,
\[ \partial_t \phi + \phi \partial_x \phi + \frac{1}{12} \partial^3_x \phi = 0. \] (1.8)

KP is completely integrable and plays an important role in the Sato theory as the first equation in the KP hierarchy [MJD00]. The matrix KP equation (1.6) exists in the literature, see e.g. [Kon82; Sak03]. None of the previous physical derivations of KP seem to be related to the problem at hand, and it could well be that our evolution is through a class of functions where the equation is formally the same, because of similarities in the weakly nonlinear asymptotics, but the physics is completely different.

3. The one dimensional distribution functions themselves therefore satisfy the equivalent Hirota bilinear equation,
\[ F\partial_t^2 F - \partial_t F \partial_r F + \frac{1}{12} F \partial^4_x F - \frac{1}{3} \partial_r F \partial^3_x F + \frac{1}{4} (\partial^2_r F)^2 + \frac{1}{4} F \partial^2_x F - \frac{1}{4}(\partial_x F)^2 = 0, \]

which again has the necessary 1:2:3 invariance, now under
\[ F(t, x, r) \mapsto F(\alpha^{-2}t, \alpha^{-2}x, \alpha^{-1}r), \quad \mathfrak{h}_0(x) \mapsto \alpha^{-1}\mathfrak{h}_0(\alpha^2x). \]

4. Unlike other limit points for fluctuation universality classes in probability, the Tracy-Widom distributions themselves lack any invariance. Thm. 1.1 recovers the invariance of the scaling limit (see Sec. 1.2).

1.1. Initial data. The natural class of initial data for our problem (the “one dimensional substrate”) are upper semicontinuous functions \( \mathfrak{h} : \mathbb{R} \to [-\infty, \infty) \) with a growth condition \( \mathfrak{h}(x) \leq A|x| + B. \) A function is upper semicontinuous if and only if its hypograph \( \text{hypo}(\mathfrak{h}) = \{(x, y) : y \leq \mathfrak{h}(x)\} \) is closed in \([ -\infty, \infty ) \times \mathbb{R} \). We endow \([ -\infty, \infty ) \) with the distance \( d_{[-\infty,\infty)}(y_1, y_2) = |e^{y_1} - e^{y_2}| \), and use the topology of local Hausdorff convergence, which means Hausdorff convergence of the restrictions to \(-L \leq x \leq L\) of hypo(\(\mathfrak{h}_n\)) to hypo(\(\mathfrak{h}\)) for each \( L > 0 \). This space is called UC.

Example 1.3. (Finite collection of narrow wedges) Let \( a_1 < a_2 < \cdots < a_k, b_1, b_2, \ldots, b_k \in \mathbb{R} \) and take \( \mathfrak{h} = \mathfrak{h}_a^b \), defined by
\[ \mathfrak{h}_a^b(x) = b_i \text{ if } x = a_i \text{ for some } i, \quad \mathfrak{h}_a^b(x) = -\infty \text{ otherwise}. \]

The initial data for (1.7) is the “escarpment”
\[ \phi(0, x, r) = 0 \text{ for } r \geq \mathfrak{h}_0(x), \quad \phi(0, x, r) = -\infty \text{ for } r < \mathfrak{h}_0(x). \] (1.9)

These are unusual and do not fit into any well-posedness schemes known for the KP equation. Although the \( \infty \) looks formal, we believe the solutions to the equations with such initial data are well posed, but we leave the proofs for future work. They also appear not to develop solitons. Since \( F \) is given by a

---

1. However, see the preprint [Pro19] from two days before this article was first posted, where it is shown that particular finite volume solutions [BL19] can be written as superpositions of solitons.

2. With some work this can be relaxed to \( \mathfrak{h}(x) \leq Ax^2 + B \) up to a finite time \( t = t(A) \).

3. [KPV97] consider as initial data for KdV an odd polynomial with positive leading coefficient, which is somewhat in the same spirit.
Fredholm determinant, these initial conditions represent an entirely new class of integrable initial data for KP.

The initial data for the matrix KP equation (1.6) is formally

\[ Q_{i,j} = \begin{cases} \mathbb{P}^{\mathbb{R} \ni \mathbb{R}^2} (r_i, r_j) & \text{if } i < j, \\ \infty & \text{if } i = j \text{ and } r_i < h_0(x_i), \\ 0 & \text{otherwise.} \end{cases} \]  

where

\[ \mathbb{P}^{\mathbb{R} \ni \mathbb{R}^2} (r_i, r_j) = \mathbb{P}_{\mathbb{B}(x_i) = r_i, (\mathbb{B}(y) \geq h_0(y) \forall y \in [x_i, x_j]), \mathbb{B}(x_n) \leq r_n \text{ for each } x_n \in (x_i, x_j), \mathbb{B}(x_j) \in dr_j}. \]  

The probability is with respect to a Brownian motion \( \mathbb{B}(\cdot) \) with diffusivity \( 2 \) starting at \( r_i \) at time \( x_i \). This is derived in Appdx. A for finite collections of narrow wedges. Unlike the scalar case, one can see immediately that the initial data as written is insufficient because in the matrix product the 0 and \( \infty \) interact. Wrongly interpreted it appears to produce anomalous solutions, so the initial data written would have to be augmented by at least some description of the rate of convergence to 0 and \( \infty \) in the \( t \downarrow 0 \) limit. We leave this also for future work.

1.2. Tracy-Widom distributions. A key observation is that the GUE and GOE Tracy-Widom distributions are now seen to simply arise as special similarity solutions of the KP equation (1.7):

Example 1.4. (Tracy-Widom GUE distribution) If \( h_0 = 0_0 \), the narrow wedge initial condition defined as \( d_0(0) = 0 \) and \( d_0(x) = -\infty \), \( x \neq 0 \), we look for a self-similar solution of (1.7) the form

\[ \phi(t, x, r) = t^{-2/3} \psi(t^{-1/3} r + t^{-4/3} x^2). \]

This turns (1.7) into

\[ \psi'' + 12\psi' - 4r\psi' - 2\psi = 0. \]

The transformation \( \psi = -q^2 \) takes (1.7) into Painlevé II

\[ q'' = rq + 2q^3. \quad (1.11) \]

As \( r \to -\infty \) the solution is approximately \( \phi(t, x, r) \sim -\left( \frac{r}{t} + \frac{q^2}{2t^2} \right) \), picking out the Hastings-McLeod solution \( q(r) \sim -\text{Ai}(r) \) as \( r \to \infty \). Thus we recover

\[ F(t, x, r) = F_{\text{GUE}}(t^{-1/3} r + t^{-4/3} x^2) \]

where \( F_{\text{GUE}} \) is the GUE Tracy-Widom distribution [TW94], usually written in the equivalent form

\[ F_{\text{GUE}}(s) = \exp \left\{ - \int_s^\infty du (u - s) q^2(u) \right\}. \]

Example 1.5. (Tracy-Widom GOE distribution) If \( h_0(x) \equiv 0 \) (flat initial condition) there is no \( x \) dependence and (1.7) reduces to KdV. We look for a self-similar solution of (1.7) the form

\[ \phi(t, r) = (t/4)^{-2/3} \psi((t/4)^{-1/3} r), \]

obtaining the ordinary differential equation

\[ \psi'' + 12\psi' - r\psi' - 2\psi = 0. \]

Miura’s transform

\[ \psi = \frac{1}{2} (q' - q^2) \]

brings this to Painlevé II (1.11). So we recover

\[ F(t, x, r) = F_{\text{GOE}}(4^{1/3} t^{-1/3} r) \]

where \( F_{\text{GOE}} \) is the GOE Tracy-Widom distribution [TW96], usually written in the equivalent form

\[ F_{\text{GOE}}(r) = \exp \left\{ - \frac{1}{2} \int_r^\infty q(u) du \right\} F_{\text{GUE}}(r^{1/2}). \]
These two examples also have the following interpretation. Let \( \lambda_{Nt}^{\text{max,GOE}} \) and \( \lambda_{Nt}^{\text{max,GUE}} \) be the largest eigenvalues of \( N \times N \) matrices chosen from the Gaussian Unitary and Gaussian Orthogonal Ensembles multiplied by \( \sqrt{N} \), so that \( \lambda_{Nt}^{\text{max,GOE}} \sim 2N + N^{1/3} \zeta_{\text{GOE}} \) and \( \lambda_{Nt}^{\text{max,GUE}} \sim 2N + N^{1/3} \zeta_{\text{GUE}} \) with \( \zeta_{\text{GOE}} \) and \( \zeta_{\text{GUE}} \) the standard Tracy-Widom GOE and GUE random variables. Let

\[
F_1(t, r) = \lim_{N \to \infty} P(N^{-1/3}(\lambda_{Nt}^{\text{max,GOE}} - 2Nt) \leq 4^{1/3}r) = F_{\text{GOE}}(4^{1/3}t^{-1/3}r),
\]

\[
F_2(t, x, r) = \lim_{N \to \infty} P(N^{-1/3}(\lambda_{Nt}^{\text{max,GUE}} - 2Nt) \leq r + x^2/t) = F_{\text{GUE}}(t^{-1/3}r + t^{-4/3}x^2)
\]

(3.5) in the GOE case is just to coordinate conventions with random growth). As we have seen, \( \partial_r^2 \log F_1 \) and \( \partial_r^2 \log F_{\text{GUE}} \) satisfy the KP equation (1.7). In the former case, there is no dependence on \( x \) and KP reduces to KdV (1.8).

1.3. PDEs for other initial data. Another question is whether there are analogues of Painlevé II for other self-similar solutions. It is natural to observe \( \phi \) in the frame of the inviscid solution \( \frac{1}{4}(\partial_x \bar{h})^2 - \partial_t \bar{h} = 0 \) of Burgers’ equation,

\[
\phi(t, x, r) := \phi(t, x, r - \bar{h}(t, x));
\]

one obtains

\[
\partial_t \phi + \bar{\phi} \partial_r \bar{\phi} + \frac{1}{12} \partial_r^3 \bar{\phi} + \frac{1}{4} \partial_r^{-1} \partial^2_x \bar{\phi} + V \bar{\phi} = 0
\]

with \( V = -\frac{1}{4} \partial_r^2 \bar{h} \) and with initial data \( \psi(0, x, r) = 0 \) for \( r \geq 0 \) and \(-\infty \) for \( r < 0 \). In order to get a solution for the rescaled spatial process, let

\[
\phi(t, x, r) := t^{-2/3} \psi(t, t^{-2/3}x, t^{-1/3}(r - \bar{h}(t, x)))
\]

Then

\[
0 = -\frac{1}{3} r \partial_r \psi + \frac{1}{12} \partial^2_r \psi - \frac{2}{3} \psi + \psi \partial_r \psi + \frac{1}{4} \partial_r^{-1} \partial^2_x \psi - \frac{t}{4} \partial^2_x \bar{h} \psi - \left( \frac{2}{3} t^{-2/3} x + \frac{t^{1/3}}{2} \partial_x \bar{h} \right) \partial_x \psi + t \partial_t \psi
\]

Example 1.6. (Half-flat initial data) Consider \( \bar{h}_0(x) = 0, x \leq 0 \) and \( \bar{h}_0(x) = -\infty, x > 0 \). Now \( \bar{h}(t, x) = -x^2/t1_{x \geq 0} \). There is dependence on \( x \), though not on \( t \). This gives rise to a partial differential equation for \( \psi(x, r) \):

\[
0 = -\frac{1}{3} r \partial_r \psi + \frac{1}{12} \partial^2_r \psi - \left( \frac{1}{6} 1_{x \geq 0} + \frac{3}{4} 1_{x < 0} \right) \psi + \psi \partial_r \psi + \frac{1}{4} \partial_r^{-1} \partial^2_x \psi - \left( \frac{3}{4} 1_{x < 0} - \frac{1}{3} 1_{x \geq 0} \right) x \partial_x \psi.
\]

Remark 1.7. (Lower tail heuristics) Typically the equation is controlled on large scales by the equation with the third derivative dropped, and the Burgers’ equation makes sense for such wedge type initial data. Let

\[
\tilde{\psi} = \psi - \eta
\]

where \( \eta = \frac{c}{t} r 1_{t < 0} \). Then \( \tilde{\psi}(0, x, r) = 0 \) and

\[
\partial_t \tilde{\psi} + \tilde{\psi} \partial_r \tilde{\psi} + \frac{1}{12} \partial^2_r \tilde{\psi} + \frac{1}{4} \partial_r^{-1} \partial^2_x \tilde{\psi} + \partial_r(\eta \tilde{\psi}) + \mu \tilde{\psi} + \gamma \partial_r \tilde{\psi} + \nu \partial_x \tilde{\psi} + V = 0,
\]

where \( V = \frac{1}{4} \left( \mu + 1 + \epsilon \right) \eta + \delta \mu \frac{c}{t} 1_{r < 0} - \frac{c}{12} \partial^2_x \eta \). One hopes to set things up so that \( \tilde{\psi} \) has good decay at \( \pm \infty \). Consider our two basic examples. In the flat case \( \delta = 0, \mu = 0 \) and we take \( c = 1 \) to make the last term drop out, which will lead to the conclusion that \( \phi(t, r) \sim r/t, \) or \( F(t, r) \sim \exp\left\{-\frac{c}{12} r^{1/3} t\right\} \) as \( r \to -\infty \), recovering the Tracy-Widom GOE lower tail. In the narrow wedge case \( \mu = 1/2 \) and we take \( c = 1/2 \) leading to \( F(t, r) \sim \exp\left\{-\frac{1}{12} (r + \frac{c}{3} t)^{3/2}\right\} \), recovering the Tracy-Widom GUE lower tail.

The conclusion is that the lower tail of the distributions can be seen directly from the “Burgers” part of the KP equation, which dominates in that region.
1.4. Airy process. The Airy process $A(x)$ is defined as

$$A(x) := h(1, x; d_0) + x^2$$

where $h(t, x; d_0)$ is the KPZ fixed point starting from a narrow wedge $d_0$ at the origin. The Airy process is stationary and the one point distribution is the Tracy-Widom GUE distribution.

K. Johansson famously asked whether there is an equation for the multipoint distribution. Equations were given by [AM05; TW03]; starting with narrow wedge initial data the matrix KP equation (1.6) gives us an equation which is similar to that in [TW03] (and possibly equivalent). The relation with the equation derived in [AM05] is completely unclear. But by skew time reversal invariance we get something better.

Let $d_{nw}^m$ denote a multiple narrow wedge (see Ex. 1.3). For $y \in \mathbb{R}$ write $\vec{x} + y = (x_1 + y, \ldots, x_m + y)$ and write similarly $\vec{r} + a$. By skew time reversibility and translation and affine invariance of the KPZ fixed point [MQR17, Thm. 4.5],

$$F(t, \vec{x} + y, \vec{r} + a) = \mathbb{P}(h(t, x_i + y; d_0) \leq r_i + a \text{ for all } i) = \mathbb{P}(h(t, \cdot; d_0) \leq -d_{x+y}^{-\vec{r}-a})$$

$$= \mathbb{P}(h(t, \cdot; d_{x+y}^{-\vec{r}}) \leq -d_0) = \mathbb{P}(h(t, 0; d_{x+y}^{-\vec{r}}) \leq a)$$

$$= \mathbb{P}(h(t, -y; d_{x+y}^{-\vec{r}}) \leq a).$$

Now the right hand side is just the one point distribution at $-y$ with a given, fixed initial condition. So if we let $G(t, y, a) = F(t, \vec{x} + y, \vec{r} + a)$ we see that $\partial_y^2 \log G$ satisfies (1.7) in $(t, y, a)$ (in terms of (1.9), the initial data is $G(0, y, a) = -\infty$ if $y = -x_i$ for some $i$ and $a < -r_i$ and $G(0, y, a) = 0$ otherwise). But $\partial_y G = \partial_y F = \mathcal{D}_y F$ and similarly $\partial_a G = \partial_a F = \mathcal{D}_a F$. So setting now $a = y = 0$ we deduce that $\phi = \mathcal{D}_y^2 \log F$ satisfies

$$\partial_t \phi + \phi \mathcal{D}_y \phi + \frac{1}{12} \mathcal{D}_r^3 \phi + \frac{1}{3} \mathcal{D}_r^{-1} \mathcal{D}_y^2 \phi = 0$$

(1.12)

(the initial data is now similarly $\phi(0, \vec{x}, \vec{r}) = -\infty$ if $x_i = 0$ for some $i$ and $r_i < 0$ and $\phi(0, \vec{x}, \vec{r}) = 0$ otherwise).

Note that from Thm. 1.1, we know that $\mathcal{D}_y^2 \log F = \text{tr} q$ and $\partial_t \text{tr} q + \text{tr}(q \mathcal{D}_r q) + \frac{1}{12} \mathcal{D}_r^3 \text{tr} q + \frac{1}{3} \mathcal{D}_r^2 \text{tr} Q = 0$ (using $\text{tr}(AB) = \text{tr}(BA)$). But the above argument implies then that $\text{tr} q$ itself solves KP (1.12). As a consequence, we deduce in the narrow wedge case that $\text{tr}(q \mathcal{D}_r q) = \text{tr}(q) \text{tr}(\mathcal{D}_r q)$. This can also be proved directly using the fact that in this case $(\partial_u + \partial_v)\mathbf{K}_t^{\text{hypo}(h_0)}(u, v)$ is a rank one kernel, which implies that $q$ is a rank one matrix.

An alternative derivation of (1.12) using the path integral formula for the KPZ fixed point can be found in Appendix B.

2. KP-II in special solutions of the KPZ equation

The proof of Thm. 1.1 in Sec. 3 shows also that some special explicit solutions for one dimensional distributions of the Kardar-Parisi-Zhang equation (1.1) also satisfy the KP-II equation (1.7). At this point we do not know if this is part of a more general fact, or if KP-II only holds in these special cases because of some symmetry. All we have is examples.

Example 2.1. (Narrow wedge solution of KPZ) Let $h_{nw}$ be the narrow wedge solution of (1.1) with $\lambda = \nu = \frac{1}{4}$ and $\sigma = 1$. In other words, $h_{nw} = \log Z$ where $Z$ is the fundamental solution of the stochastic heat equation (SHE) with multiplicative noise

$$\partial_t Z = \frac{1}{4} \partial_x^2 Z + \xi Z, \quad Z(0, x) = \delta_0(x).$$

(2.1)

The KPZ generating function is

$$G_{nw}(t, x, r) = \mathbb{E} \left[ \exp \left\{ -e^{h_{nw}(t, x) + \frac{4}{12} - r} \right\} \right].$$

(2.2)
The distribution of $h_{nw}(t, x)$ was computed in 2010 in [ACQ11; SS10; Dot10; CDR10], with the result that
\[ G_{nw}(t, x, r) = \det(I - K)_{L^2[0, \infty]} \]
with
\[ K(u, v) = \int_{-\infty}^{\infty} dy t^{-2/3} \frac{1}{1 + e^{y}} \text{Ai}(t^{-1/3}(u + r - y) + t^{-4/3}x^2) \text{Ai}(t^{-1/3}(v + r - y) + t^{-4/3}x^2). \]

If we conjugate the operator by multiplying the kernel by $e^{(u-v)x/t}$ we get
\[ K(u, v) = U_{t} e^{-x^2 \partial^2} M e^{x^2 \partial^2} U_{t}^{-1}(u + r, v + r) \]
with $M$ the multiplication operator $M f(u) = (1 + e^{a})^{-1} f(u)$ and $U_{t}$ the Airy unitary operator defined in (3.2) (see Sec. 3.1 also for the meaning of $e^{x^2 \partial^2} U_{t}$ for general $x$). In particular, $K$ satisfies the (one-point version of the) same differential relations (3.7)/(3.9) as the KPZ fixed point kernel, whence it follows that $\phi_{nw} := \partial^2_r \log G_{nw}$ also satisfies KP-II. The initial condition is $t_{\eta > 0} \phi_{nw}(t, x, r - x^2/t - \log \sqrt{\pi t}) = -e^{-r}$. This suggests defining the $x$ independent, shifted variable $\hat{\phi}_{nw}(t, r) = \phi_{nw}(t, x, r - x^2/t - \log \sqrt{\pi t})$ which now satisfies the cylindrical KdV equation,
\[ \partial_t \hat{\phi}_{nw} + \frac{1}{27} \partial_r \hat{\phi}_{nw} + \hat{\phi}_{nw} \partial_r \hat{\phi}_{nw} + \frac{1}{12} \partial_r^2 \hat{\phi}_{nw} + \frac{1}{27} \hat{\phi}_{nw} = 0, \quad \hat{\phi}_{nw}(0, r) = -e^{-r}. \]

**Example 2.2. (Spiked/half-Brownian initial data)** Consider now the solution $h_{b}$ of (1.1) with $\lambda = \nu = \frac{1}{3}$, $\sigma = 1$, and $m$-spiked initial data, where $b = (b_{1}, \ldots, b_{m}) \in \mathbb{R}^m$ are the spike parameters. When $m = 1$, this corresponds to half-Brownian initial data (more precisely, at the level of the SHE one sets $Z(0, x) = e^{B(x) + b_{1} x} \mathbb{1}_{x \geq 0}$ where $B(x)$ is a Brownian motion with diffusivity 2); for the definition in the general case $m \geq 1$ we refer to [BCF14, Defn. 1.9]. Define $G_{b}$ as in (2.2) (with $h_{b}$ in place of $h_{nw}$). Then from [BCF14, Thm. 1.10] we get now that $G_{b}(t, 0, r) = \det(I - K_{0})_{L^2[0, \infty]}$ with (see footnote 4 again)
\[ K_{0}(u, v) = \int_{C_{t}} d\eta \int_{C_{t}'} d\xi \frac{t^{-1/3}}{\sin(t^{-1/3}(\eta - \xi))} e^{t^{3/3} - (u + t^{-1/3})\eta / \xi} \prod_{k=1}^{m} \frac{\Gamma(t^{-1/3}(\xi - b_{k}) - x/t)}{\Gamma(t^{-1/3}(\eta - b_{k}) - x/t)}, \]
where $C_{t}$ goes from $\frac{1}{2} + i \infty$ to $\frac{1}{2} + i \infty$ crossing the real axis to the right of $t^{1/3}b_{1}, \ldots, t^{1/3}b_{m}$ and $C_{t}' = C_{t} + \frac{1}{2} + i \infty$. We scale $(\eta, \xi) \mapsto (t^{1/3}\eta, t^{1/3}\xi)$ and $(u, v) \mapsto (t^{-1/3}u, t^{-1/3}v)$ (in the Fredholm determinant) so that $K_{0}(u, v)$ is now given as $\int_{C_{t}} d\eta \int_{C_{t}'} d\xi \frac{\pi}{\sin(\pi(\eta - \xi))} e^{t^{3/3} - (u + t^{-1/3})\eta / \xi} \prod_{k=1}^{m} \frac{\Gamma(\xi - b_{k} - x/t)}{\Gamma(\eta - b_{k} - x/t)} \prod_{k=1}^{m} \frac{\Gamma(\xi - b_{k} - x/t)}{\Gamma(\eta - b_{k} - x/t)}$.

Since $h_{b}(t, x) + x^2/t$ is stationary in $x$ (see [BCF14, Rem. 1.14]), we may write $G_{b}(t, x, r) = \det(I - K)_{L^2[0, \infty]}$ with
\[ \tilde{K}(u, v) = \int_{\tilde{C}_{t}} d\eta \int_{\tilde{C}_{t}'} d\xi \frac{\pi}{\sin(\pi(\eta - \xi))} e^{t^{3/3} - (u + t^{-1/3})\eta / \xi} \prod_{k=1}^{m} \frac{\Gamma(\xi - b_{k} - x/t)}{\Gamma(\eta - b_{k} - x/t)} \prod_{k=1}^{m} \frac{\Gamma(\xi - b_{k} - x/t)}{\Gamma(\eta - b_{k} - x/t)} \]
(here the contour $\tilde{C}_{t}$ has to cross the real axis to the right of $b_{i} + x/t$ for all $i$). Conjugating the kernel by $e^{ux/t}$ (i.e. replacing $\tilde{K}(u, v)$ by $K(u, v) = e^{(u-v)x/t} \tilde{K}(u, v)$, which does not change the value of the determinant) and changing variables $\eta \mapsto \eta + x/t, \xi \mapsto \xi + x/t$, we get
\[ G_{b}(t, x, r) = \det(I - K)_{L^2[0, \infty]} \]
with
\[ K(u, v) = \int_{C_{t}} d\eta \int_{C_{t}'} d\xi \frac{\pi}{\sin(\pi(\eta - \xi))} e^{t^{3/3} + x\eta^2 - (u + r)\eta} \prod_{k=1}^{m} \frac{\Gamma(\xi - b_{k})}{\Gamma(\eta - b_{k})} \]
As in Ex. 2.1, $K$ satisfies the necessary differential relations, so it follows again that $\phi_{b} := \partial^2_r \log G_{b}$ satisfies KP-II.

---

4See [BCF14, Thm. 1.10], which computes the generating function directly. In comparing with that formula, we are changing variables $(t, x) \mapsto (2t, 2x)$ to match the two different scaling conventions for (2.1), and using the fact that $h(t, x) + x^2/t$ is stationary.
Remark 2.3. A similar claim was made for the solution of the KPZ equation with flat initial data in the first version of this paper posted to the arXiv, but it was based on an argument which seems to be flawed. We thank Pierre Le Doussal for pointing out an inconsistency with known moment formulas [LDC12].

Our next two examples are related with the last one. Here we abandon the setting of the KPZ equation and go back to random matrix distributions and the KPZ fixed point.

Example 2.4. (The BBP distribution for spiked random matrices) Consider $G_{\theta}$ as in the previous example. It is known (see [BCF14, Cor.1.15] for the case $t = 1, x = 0$, the general case follows in the same way or by scaling and shift invariance) that

$$
\lim_{\varepsilon \to 0} G_{\varepsilon} \left( e^{-3/2} t, e^{-1} x, e^{-1/2} r \right) = F_{BBP, t^{1/3} \theta - \varepsilon, 3 x} \left( t^{1/3} r + t^{4/3} x^2 \right)
$$

where $F_{BBP, \theta}$ is the Baik-Benzécri-Péché (BBP) distribution arising from spiked (unitarily invariant) random matrices [BBP05]. On the other hand, by scaling invariance of KP-II (see Rem. 1.2), for each fixed $\varepsilon > 0$, $\phi_{\varepsilon} = \partial^2 \log G_{\varepsilon} \left( e^{-3/2} t, e^{-1} x, e^{-1/2} r \right)$ satisfies KP-II as well. As a consequence, one expects that if

$$
\tilde{F}_{BBP, \theta}(t, x, r) = F_{BBP, t^{1/3} \theta - 2 - 3 x} \left( t^{1/3} r + t^{4/3} x^2 \right)
$$

then $\phi_{BBP, \theta} = \partial^2 \log \tilde{F}_{BBP, \theta}$ will also satisfy KP-II. This is indeed the case, as can be checked in a similar way as above using the explicit Fredholm determinant formula for $F_{BBP, \theta}$ (see for instance [BCF14, Eqn. (1.4)]).

Example 2.5. (The KPZ fixed point with half-Brownian initial data) Consider the KPZ fixed point $h$ with half-Brownian initial data $h_0(x) = B(-x)$ for $x \leq 0$ and $h_0(x) = -\infty$ for $x > 0$, where $B$ is a Brownian motion started at 0 with diffusivity 2. In the setting of [MQR17], this corresponds to starting TASEP with a product measure with density

$$\phi_{BBP} = I - \frac{1}{2} \partial^2.$$

Comparing with Ex. 2.4 we deduce that $\phi_{half-BM} = \partial^2 \log F_{half-BM}$ also satisfies KP-II.

3. The determinantal formula and derivation of KP

3.1. KPZ fixed point formula. In [MQR17] a determinantal formula is given for (1.4). The first thing to do is to rewrite the kernel in a natural way to obtain logarithmic derivatives in $r, t$ and $x$. We recall how the kernel is defined. For $h \in UC$ let

$$
P^\text{hit/No hit} \left( \ell_1, \ell_2 \right) du_2 u_2 = P(B(\ell_1) = u_1) B(y) > h(y) \text{ on } \ell_1, B(\ell_2) \in du_2), \quad P^\text{Hit/No hit} \left( \ell_1, \ell_2 \right) = I - P^\text{No hit} \left( \ell_1, \ell_2 \right),
$$

where $B$ is a Brownian motion with diffusion coefficient 2. The Brownian scattering transform of $h$ is the formal object

$$
K^\text{hyp}(h) = \lim_{\ell_2 \to -\infty} e^{\ell_1 \partial} P^\text{Hit/No hit} \left( \ell_1, \ell_2 \right) e^{-\ell_2 \partial^2} = I - \lim_{\ell_2 \to -\infty} e^{\ell_1 \partial} P^\text{Hit/No hit} \left( \ell_1, \ell_2 \right) e^{-\ell_2 \partial^2}, \quad (3.1)
$$

where $P^\text{Hit/No hit} \left( \ell_1, \ell_2 \right)$ are thought of as operators with the given integral kernels. This doesn’t make sense since the backward heat operator is asked to act on non-analytic functions. In fact, $K^\text{hyp}(h)$ will never actually be used by itself, but only after conjugation by the Airy unitary group,

$$
U_t = e^{-\frac{1}{3} t \partial^3},
$$

with $t \neq 0$ and $\partial^3$ the third derivative operator. For a fixed vector $a \in \mathbb{R}^m$ and indices $n_1 < \ldots < n_m$ we introduce the functions

$$
\chi_a(n_j, x) = 1_{x > a_j}, \quad \bar{\chi}_a(n_j, x) = 1_{x \leq a_j},
$$

which we also regard as multiplication operators acting on $L^2(\{x_1, \ldots, x_m\} \times \mathbb{R})$. For simplicity we will write $\chi_a(x)$ when $m = 1$.  

We take $t > 0$ in which case the Airy semigroup acts by convolution with Airy functions. These are not themselves in $L^2(\mathbb{R})$; however, for $t > 0$ and $r < -\infty$, $U_t^{-1}X_r$ maps $L^2(\mathbb{R})$ into the domain of $e^{x\partial^2}$ for any $x \in \mathbb{R}$. So for $t > 0$ and $r < -\infty$, we define on $L^2([r, \infty))$

$$K_t^{\text{hypo}(h)} = \lim_{\ell_1 \to -\infty} \lim_{\ell_2 \to +\infty} U_t e^{\ell_1 \partial^2} P^{\text{Hit}} h e^{-\ell_2 \partial^2} U_t^{-1}. \quad (3.3)$$

For any $t > 0$ and $r < -\infty$ the limit on the right hand side of (3.3) exists in trace class on $L^2([r, \infty))$ [QR19; MQR17], and defines the left hand side as a trace class operator in this space. It satisfies the semigroup property

$$U_s K_t^{\text{hypo}(h)} U_s^{-1} = K_{t+s}^{\text{hypo}(h)}$$

Because it satisfies the semigroup property, we can write (at least informally)

$$K_t^{\text{hypo}(h)} = U_t K^{\text{hypo}(h)} U_t^{-1}. \quad (3.4)$$

Note that we avoid the problem of domains by not defining the left hand side of (3.3) as a product of three operators, but just as one operator with the semigroup property. In this sense the Brownian scattering operator is the germ of the semigroup. Alternatively one can think of the Brownian scattering operator as the entire semigroup (3.4). The fact that (3.1) is formal is important. We will see in (A.2) that the limit of (3.4) as $t \searrow 0$ is not $K^{\text{hypo}(h)}$.

From $K^{\text{hypo}(h)}$ we build an extended Brownian scattering operator acting on $L^2(\{x_1, \ldots, x_m\} \times \mathbb{R})$,

$$K_{\text{ext}}^{\text{hypo}(h)}(x_i, \cdot; x_j, \cdot) = -e^{(x_j-x_i)\partial^2} 1_{x_j < x_i} + e^{-x_i\partial^2} K^{\text{hypo}(h)} e^{x_j\partial^2}, \quad (3.5)$$

with the analogous caveat that in order to make sense each of the above $(x_i, x_j)$ entries should be conjugated by $U_t$ and the whole operator should be surrounded by $\chi_r$ which acts independently in each coordinate by $\chi_r$. In this language the KPZ fixed point formula reads

$$F(t, x_1, \ldots, x_n, r_1, \ldots, r_n) = \det \left( I - \chi_r U_t K_{\text{ext}}^{\text{hypo}(h)} U_t^{-1} \chi_r \right)_{L^2(\{x_1, \ldots, x_m\} \times \mathbb{R})} \quad (3.6)$$

Sometimes we write $K_t^{\text{hypo}(h)_{\text{ext}}} = U_t K_{\text{ext}}^{\text{hypo}(h)} U_t^{-1}$.

3.2. The logarithmic derivative. The next two sections contain the proof that the Fredholm determinant (3.6) satisfies the matrix KPZ equation. After we performed the very complicated computation, we discovered that a very similar argument was actually known [Po89] in the one dimensional case. It is shown there that the Fredholm determinant of a kernel satisfying suitable differential relations solves the Hirota equations. The differential relations turn out to be equivalent to the way the kernel depends on $t$, $x$ and $r$ above. It seems to actually go back to [ZS74; ZS79] though it is not explicit there, and rediscovered in the literature multiple times.

Call $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ with $x_1 < x_2 < \cdots < x_n$, and $r = (r_1, \ldots, r_n) \in \mathbb{R}^n$. Let

$$\Phi(t, r, x) = D_r \log \det(I - \chi_r U_t K_{\text{ext}}^{\text{hypo}(h)} U_t^{-1} \chi_r)_{L^2(\{x_1, \ldots, x_m\} \times \mathbb{R})}$$

where $D_r$ is defined in (1.5). Shifting variables in the kernel we get

$$\Phi(t, r, x) = D_r \log \det(I - K)_{L^2(\mathbb{R}^n) \oplus \cdots \oplus L^2(\mathbb{R}^n)}$$

where $K(x_a, u_a; x_b, u_b) = K_{\text{ext}}^{\text{hypo}(h)}(x_a, u_0 + r_a; x_b, u_0 + r_b)$. From now on we omit the subscript on the Fredholm determinant and traces. We think of $K$ as an operator-valued matrix; to ease notation we will write $K_{ab} = K(x_a, \cdot; x_b, \cdot)$.

Given an operator $A$ acting on $L^2(\mathbb{R})$ with kernel $A(u, v)$ we will write $d_1 A$ and $d_2 A$ for the operators with kernels given by

$$(d_1 A)(u, v) = \partial_u A(u, v) \quad \text{and} \quad (d_2 A)(u, v) = \partial_v A(u, v),$$

while in the matrix case we let

$$D_i K = (d_i K_{ab})_{a,b=1,\ldots,n}, \quad i = 1, 2.$$
We will use this in the formula
\[ D_r K = (D_1 + D_2) K. \] (3.7)
Then
\[ \Phi(t, r, x) = \sum_a \partial_r a \log(\det(I - K)) = -\sum_a \text{tr}((I - K)^{-1} \partial_r a K) = -\text{tr}((I - K)^{-1} D_r K) \]
\[ = -\text{tr}((I - K)^{-1}(D_1 + D_2) K) = -\text{tr}((I - K)^{-1} D_1 K + D_2((I - K)^{-1} K)) \]
\[ = -\text{tr}(D_1 K(I - K)^{-1} + D_2((I - K)^{-1} K)) = -\text{tr}((D_1 + D_2)((I - K)^{-1} K)) \]
\[ = -\sum_a \int_0^\infty d\xi \partial_\xi ((I - K)^{-1} K)_{aa}(\xi, \xi) = \sum_a ((I - K)^{-1} K)_{aa}(0, 0), \]
where we used the cyclicity of the trace. Introducing the notation \([A] = (A_{a, b}(0, 0))_{a, b=1,...,n}\), this tells us that \(\Phi\) can be expressed as an \(n\)-dimensional trace,
\[ \Phi(t, r, x) = \text{tr}[RK] \quad \text{with} \quad R = (I - K)^{-1}. \]
Note here that \(I - K\) is invertible because the determinant is non-zero.

3.3. Formulas for the partial derivatives. Let now \(Q\) denote the matrix
\[ Q = [RK] \] (3.8)
and write \(K' = D_r K\). The above argument shows that \(D_r \log F = \text{tr} Q\). The goal is now to prove that \(Q\) satisfies the matrix KP equation (1.6).

Using the general formula \(\partial_a (I - A(a))^{-1} = (I - A(a))^{-1} \partial_a A(a) (I - A(a))^{-1}\) for an operator \(A(a)\) depending smoothly on a parameter \(a\) we have
\[ D_r Q = [D_r (RK)] = [\sum_a (R \partial_r a KRK + R \partial_r a K)] = [RK'RK + RK'] = [RK'R], \]
and similarly
\[ D_r^2 Q = 2[RK'RK' + [RK'R]], \]
\[ D_r^3 Q = 6[RK'RK'RK'] + 3[RK''RK'R] + 3[RK'RK''R] + [RK'''R], \]
\[ \partial_t Q = [R \partial_t KR]. \]
On the other hand, from the definition of the Brownian scattering transform we have
\[ \partial_t K = -\frac{1}{4} (D_1^2 + D_2^2) K \quad \text{and} \quad D_r K = (D_2^2 - D_1^2) K \] (3.9)
(we are using here also the fact that \((d_1^2 + d_2^2)e^{\ell \sigma^2} = 0\) for any \(\ell > 0\).

Next we want to compute \((D_r Q)^2\). Note that, in general,
\[ ([A][B])_{a, b} = -\sum_c \int_0^\infty d\eta \partial_\eta (A_{ac}(0, \eta) B_{cb}(\eta, 0)) \]
\[ = -\sum_c \int_0^\infty d\eta \left( d_2 A_{ac}(0, \eta) B_{cb}(\eta, 0) + A_{ac}(0, \eta) d_1 B_{cb}(\eta, 0) \right) \]
\[ = -(D_2 AB)_{ab}(0, 0) - (AD_1 B)_{ab}(0, 0) \]
so that the following integration by parts formula holds:
\[ [A][B] = -(AD_1 B + D_2 AB]. \] (3.10)
We will use this in the formula
\[ (D_r Q)^2 = ([RK'RK] + [RK'])^2 = [RK'RK]^2 + [RK'RK][RK'] + [RK'][RK'RK] + [RK']^2. \]
The first term equals (using \(D_2(K_a K_b) = K_a D_2 K_b\))
\[-[RK'(D_2KR + KD_1R)K'RK] = -[RK'RK'RK'R] + [RK'R(D_1KR - KD_1R)K'RK]. \]
Similarly, the fourth term equals
\[-[RK''RK'] + [R(d_1K'R - K'd_1R)K']\]
and the two middle ones equal
\[-[RK'RK'RK'] - [RK''RK'RK] + [RK'R(d_1KR - Kd_1R)K'] + [R(d_1K'R - K'd_1R)K'RK].\]
Using this together with our formulas for \(\partial_t Q\) and \(D_r^2 Q\) yields
\[
12\partial_t Q(t, r, x) + D_r^3 Q(t, r, x) + 6(D_r Q(t, r, x))^2 \nonumber
\]
\[
= -4[R(D_1^3 + D_2^2)KR] + [RK'RK'RK'] + 3[RK''RK'] \nonumber
\]
\[
- 2[R(D_1K'R - K'D_1R)K'] \nonumber
\]
\[
- 6[RK''RK'] + 6(R(D_1K'R - K'D_1R)K'] \nonumber
\]
\[
+ 2[RD_1KR - KD_1R)K'] \nonumber
\]
\[
+ 6(R(D_1K'R - K'D_1R)K'RK] \nonumber
\]
\[
= -[RK'RK'RK'] + [RK''RK'RK] + 6(R(D_1K'R - K'D_1R)K'RK] \nonumber
\]
\[
+ 6(R(D_1K'R - K'D_1R)K'RK] \nonumber
\]
\[
= [RK'RK'RK'] + 6(R(D_1K'R - K'D_1R)K'RK] \nonumber
\]
\[
+ 6(R(D_1K'R - K'D_1R)K'RK]. \nonumber
\]

We will use the identity \(KR = RK = R - I\) repeatedly. (12) equals \(6[RK'RK'RK'] - 6[RK'RK'RK']\), so
\[
S_I := -(1) + (2) + (5) - (8) - (12) = -3[R(D_1^3 + D_2^2)KR] \nonumber
\]
\[
= -3[R(D_1 - D_2)^2(D_1 + D_2)KR] = -3[R(D_1 - D_2)^2K'R]. \nonumber
\]
Similarly
\[
S_{II} := +3 + (4) - (6) - (9) = -3[RK''RK'] + 3[RK'RK''R] \nonumber
\]
and
\[
S_{III} := +(7) + (10) + (11) + (13) = +6[R(D_1K'R - K'D_1R)K'] + 6[RK'R(D_1KR - KD_1R)K']. \nonumber
\]

So
\[
4\partial_t Q(t, r, x) + \frac{1}{3}D_r^3 Q(t, r, x) + 2(D_r Q(t, r, x))^2 = \frac{1}{3}(S_I + S_{II} + S_{III}) \nonumber
\]
\[
= -[RK''RK'] + [RK'RK''R] - [R(D_1^3 + D_2^2 - D_1D_2^2)KR] \nonumber
\]
\[
+ 2[R(D_1K'R - K'D_1R)K'] + 2[RK'R(D_1KR - KD_1R)K'] \nonumber
\]
\[
- 2[RK'D_1KR'] + 2[RK'RD_1KR']. \nonumber
\]

Using now \(-[RK'RD_1KR'] + [RK'RD_1KR'] = -[RK'RD_1(I - K)KR'],\) which equals \(-[RK'RD_1K']\), yields
\[
4\partial_t Q(t, r, x) + \frac{1}{3}D_r^3 Q(t, r, x) + 2(D_r Q(t, r, x))^2 \nonumber
\]
\[
= -[R(D_2 - D_1)K'RK'] - [RK'R(D_1 - D_2)KR'] - [R(D_1 - D_2)^2K'R]. \quad (3.11) \nonumber
\]

**Remark 3.1.** At this stage we can already see that the one point distribution in the flat case \(h_0 = 0\) satisfies the (integrated) KdV equation. In fact, the arguments in [MQR17, Sec. 4.4] lead in this case to \(K_h^{hypos(b)} = I - U_t(I - q)\hat{\chi}_0(I - \hat{q})U_t^{-1} = U_t\hat{q}U_t^{-1}\) with \(qf(x) = f(-x)\), which means that \(K\) is a Hankel kernel, so that the right hand side in (3.11) vanishes.

Next we add the derivatives in the \(x_1\) variables. As for \(D_r^2 Q\), we have
\[
D_r^2 Q = 2[RD_xKR/DR_xKR] + [RDR_xKR]. \quad (3.12) \nonumber
\]
On the other hand, if we apply $\mathcal{D}_r$ to (3.11) and use (3.9) to write $(D_2 - D_1)K' = D_2 K$ we get

$$- [RK'R D_x KR R'] - [R D_x K'R R'] - 2[R D_x K'R KR'] - [R D_2 K R' R']$$

$$+ 2[RK'R KR D_x K R] + [RK''R D_x K R] + [RK'R D_x K R]$$

$$+ [RK'R(D_1 - D_2) D_x K R] + [R(D_1 - D_2) D_2 K R] + [R(D_1 - D_2) D_2 K R] R.$$ Note that the first and eighth terms cancel. We want to add $D_2^2 Q(t, r, x)$. Since $(D_1 - D_2) D_2 K' = D_x (D_1^2 - D_2^2) K = -D_x^2 K$, the next-to-last term in the last expression cancels the second bracket on the right hand side of (3.12). Using additionally $D_2 K' + (D_1 - D_2) D_2 K = 2D_1 D_2 K$ and $-D_2 K' + (D_1 - D_2) D_2 K = -2D_2 D_2 K$ and writing

$$q = \mathcal{D}_r Q,$$

we deduce that

$$4\partial_t q + \frac{1}{6} \partial_x^3 q + (q \mathcal{D}_r q + \mathcal{D}_r q q) + D_2^2 Q(t, r, x)$$

$$= 2 \left( - [RD_2 D_x KR R'] - [RD_2 K R R'] - \frac{1}{2}[R D_x K R R']ight.$$

$$+ [RK'R KR D_x K R] + \frac{1}{2}[RK''R D_x K R] + [RK'R D_1 D_x K R]$$

$$+ [R D_x K R D_x K R] \right).$$

We claim that the right hand side equals two times

$$- ( [R D_x K R D_1 K R'] + [R D_2 D_2 K R R']) + ( [RK'R D_2 K R D_2 K R] + [RK'R D_1 D_x K R])$$

$$- ( [R D_x K R D_2 K R'] + [R D_x K R D_1 K R']) + ( [RK'R D_1 K R D_2 K R] + [R D_2 K' R D_x K R]).$$

To see this, express the right hand side of (3.13) as $2(r_1 + r_2 + \ldots + r_7)$, express (3.14) as $q_1 + q_2 + \ldots + q_8$, and note first that $r_1 = q_2$, $r_6 = q_4$, $r_2 = q_1 + q_5$ and $r_4 = q_3 + q_7$. On the other hand we have

$$r_3 = -\frac{1}{2}[R D_x K R (D_1 + D_2) K R]$$

$$= q_6 + \frac{1}{2}[R D_x K R (D_1 - D_2) K R] = q_6 - \frac{1}{2} r_7$$

and similarly

$$r_5 = \frac{1}{2}[R (D_1 + D_2) K' R D_x K R]$$

$$= q_8 + \frac{1}{2}[R (D_1 - D_2) K' R D_x K R] = q_8 - \frac{1}{2} r_7.$$ This gives

$$r_3 + r_5 + r_7 = q_6 + q_8,$$ and finishes proving the claim.

Integrating by parts (i.e. using (3.10)) within each parenthesis in (3.14) we get

$$2\partial_t q + \frac{1}{6} \partial_x^3 q + (q \mathcal{D}_r q + \mathcal{D}_r q q) + \frac{1}{2} D_2^2 Q(t, r, x)$$

$$= - [RD_2 K (R D_1 K R - D_1 R) K R'] + [RD_2 K] [RK'R]$$

$$+ [RK' (R D_2 K R - D_2 R) D_x K R] - [RK' R D_x K R]$$

$$- [R D_2 K (R D_2 K R - D_2 R) K'R'] + [R D_2 K] [K'R]$$

$$+ [RK' (R D_1 K R - D_1 R) D_x K R] - [RK'] [R D_x K R].$$

Write this as $s_1 + \ldots + s_8$. Notice that $s_1 + s_5$ yields a term involving

$$(RD_1 K R - D_1 R) + (RD_2 K R - D_2 R) = R (KD_1 K + D_2 K K) R - (D_1 + D_2) I,$$

where we have used $RK = KR = R - I$ again, and thus integrating by parts one more time we get

$$s_1 + s_5 = - [RD_2 K (R (KD_1 K + D_2 K K) R - (D_1 + D_2) I) K'R]$$

$$= [RD_2 K RK R] [RK'R'] + [RD_2 K ((D_1 + D_2) I) K'R]$$

$$= [RD_2 K] [RK'R'] - s_2 - s_6 + [RD_2 K] [K'R] + [RD_2 K ((D_1 + D_2) I) K'R].$$

In a similar fashion we get

$$s_3 + s_7 = - [RK'R] [RD_2 K R] - s_4 - s_8 - [RK'] [K R] - [RK' ((D_1 + D_2) I) D_x K R].$$
Therefore
\[ 2\partial_t q + \frac{1}{2} \partial_{t,x}^2 q + (q \partial_x q + \partial_t q q) + \frac{1}{2} \partial_{t,x}^2 Q(t, r, x) = [\mathcal{R} \mathcal{D}_x \mathbf{K}][\mathbf{K}' \mathbf{R}] + [\mathcal{R} \mathcal{D}_x \mathbf{K}((D_1 + D_2) \mathbf{I}) \mathbf{K}' \mathbf{R}] \]
\[ - [\mathbf{R} \mathbf{K}'][\mathcal{D}_x \mathbf{K} \mathbf{R}] - [\mathbf{R} \mathbf{K}']((D_1 + D_2) \mathcal{I})[\mathcal{D}_x \mathbf{K} \mathbf{R}] + [\mathcal{R} \mathcal{D}_x \mathbf{K}][\mathbf{R} \mathbf{K}' \mathbf{R}] - [\mathbf{R} \mathbf{K}'][\mathcal{R} \mathcal{D}_x \mathbf{K} \mathbf{R}]. \]
In order to complete the proof we note that if \( A \) and \( B \) are nice kernels then integrating by parts we get
\[ [\mathbf{A}((D_1 + D_2) \mathbf{I}) \mathbf{B}] = [\mathbf{A} \mathbf{D}_1 \mathbf{B}] + [\mathbf{A} \mathbf{D}_2 \mathbf{I} \mathbf{B}] = -[\mathbf{A}][\mathbf{B}], \]
which immediately yields
\[ 2\partial_t q + \frac{1}{2} \partial_{t,x}^2 q + (q \partial_x q + \partial_t q q) + \frac{1}{2} \partial_{t,x}^2 Q(t, r, x) = [\mathcal{R} \mathcal{D}_x \mathbf{K}][\mathbf{R} \mathbf{K}' \mathbf{R}] - [\mathbf{R} \mathbf{K}'][\mathcal{R} \mathcal{D}_x \mathbf{K} \mathbf{R}]. \]
The right hand side equals \( \mathcal{D}_x Q q - q \mathcal{D}_x Q \), so the result follows.

**APPENDIX A. MULTIPRODUCT INITIAL DATA**

A.1. \( t \to 0 \) limit of the Brownian scattering operator. Let the initial data for the KPZ fixed point be a finite collection of narrow wedges \( \mathcal{D}_a^b \) as in Eq. 1.3. Fix \( x_1 < \ldots < x_m \). We want to compute
\[ \lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hypos}(\mathcal{D}_a^b)} e^{x_j \partial^2}. \]
Throughout this section we will use the notation
\[ S_{t,x} = e^{-\frac{1}{2} \partial^2 + x \partial^2} = e^{-\partial^2} U_t. \]
The \( S_{t,x} \) act by convolution \( S_{t,x} f(z) = \int_{-\infty}^{\infty} dy S_{t,x}(z - y) f(y) \) where, for \( t > 0 \),
\[ S_{t,x}(u) = t^{-1/3} e^{x u - u^3 / 3t} \chi(t-u) \]
while for \( t < 0 \), \( S_{t,x}(u) = S_{-t,-x}(-u) \) (see [MQR17, Eqn. (3.10)]).

We consider first the single narrow wedge case, \( k = 1 \), writing \( a = a_1, b = b_1 \). In this case, by definition of \( \mathcal{K}_t^{\text{hypos}(\mathcal{D})} \) we have
\[ \mathcal{K}_t^{\text{hypos}(\mathcal{D})} = \lim_{\ell \to \infty} S_{-t-\ell} P^r_{\ell,-t} S_{t,-\ell} = \lim_{\ell \to \infty} S_{-t-\ell} e^{(a+\ell) \partial^2} \chi(t) e^{(t-a) \partial^2} S_{t,-\ell} = S_{-t,0} \chi_b S_{t,0}. \]
In particular,
\[ \lim_{t \to 0} e^{-a \partial^2} \mathcal{K}_t^{\text{hypos}(\mathcal{D})} e^{a \partial^2} = \lim_{t \to 0} S_{-t,0} \chi_b S_{t,0} = \chi_b, \]
so in the case \( x_i \leq a \leq x_j \) we get
\[ \lim_{t \to 0} e^{-x_i \partial^2} \mathcal{K}_t^{\text{hypos}(\mathcal{D})} e^{x_j \partial^2} = \lim_{t \to 0} e^{(a-x_i) \partial^2} (e^{-a \partial^2} \mathcal{K}_t^{\text{hypos}(\mathcal{D})} e^{a \partial^2}) e^{(x_j-a) \partial^2} = e^{(a-x_i) \partial^2} \chi_b e^{(x_j-a) \partial^2} = P^r_{x_i,x_j}. \]
Next consider the case when the inequality \( x_i \leq a \leq x_j \) does not hold. We have
\[ |e^{-x_i \partial^2} \mathcal{K}_t^{\text{hypos}(\mathcal{D})} e^{x_j \partial^2} (u, v)| \leq \int_{-\infty}^{b} d\eta |S_{t,a-x_i} (u-\eta)||S_{t,x_j-a} (v-\eta)| \]
\[ = t^{-1/3} \int_{-\infty}^{b} d\eta e^{2(a-x_i)^3/3t^2 + 2(x_j-a)^3/3t^2 - (u-\eta)(a-x_i)/t - (v-\eta)(x_j-a)/t} \]
\[ \times |\text{Ai}(t^{-1/3}(u-\eta) + t^{-4/3}(a-x_i)^2) Ai(t^{-1/3}(v-\eta) + t^{-4/3}(x_j-a)^2)|. \]
Let \( \kappa \in (0, 1) \) and note that both \( t^{-1/3}(u-\eta) + (1 - \kappa^2/3)t^{-4/3}(a-x_i)^2 > 0 \) and \( t^{-1/3}(v-\eta) + (1 - \kappa^2/3)t^{-4/3}(x_j-a)^2 > 0 \) for all \( \eta \leq b \) if \( t \) is small enough. Therefore, using the classical bound on the Airy function \( |\text{Ai}(u)| \leq Ce^{-\frac{2}{3}(u^3)^{1/3}} \), the last integral is bounded by
\[ Ct^{-2/3} e^{2(a-x_i)^3 - \kappa(a-x_i)^3 + (x_j-a)^3 - \kappa(x_j-a)^3} e^{|x_j-a|^3/3t^2} \int_{-\infty}^{b} d\eta e^{-(u-\eta)(a-x_i)/t - (v-\eta)(x_j-a)/t}. \]
It is easy to check that whenever \( x_i \leq a \leq x_j \), does not hold, the prefactor can be bounded by \( e^{-c/t^2} \) for some \( c > 0 \) by choosing \( \kappa \) close enough to 1, and hence computing the \( \eta \) integral shows that the whole expression goes to 0 as \( t \to 0 \).

The conclusion of all this is that, in the case of narrow wedge initial data \( \mathfrak{h}_a^b \),

\[
\lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hyp}(\mathfrak{h}_a^b)} e^{x_j \partial^2} = \lim_{t \to 0} S_{t,a-x_i} \tilde{\chi}_t S_{t,x_j-a} = e^{(a-x_i) \partial^2} \tilde{\chi}^a B_t \chi_j \partial^2 1_{x_i \leq a \leq x_j} = \mathbf{P}^{\text{Hit}} \mathfrak{h}_a^b 1_{x_i \leq x_j} . \tag{A.1}
\]

Now we turn to the general case \( h = \mathfrak{h}_a^b \). For \( \ell > |a_1| \lor |a_k| \) we have, by inclusion-exclusion,

\[
P^{\text{Hit}} \mathfrak{h}_a^b = \sum_{n=1}^k (-1)^{n+1} \sum_{1 \leq p_1 < \cdots < p_n \leq k} e^{(a_{p_1}-\ell) \partial^2} \tilde{\chi}^a_{p_1} e^{(a_{p_2}-a_{p_1}) \partial^2} \tilde{\chi}^a_{p_2} \cdots e^{(a_{p_n}-a_{p_{n-1}}) \partial^2} \tilde{\chi}^a_{p_n} e^{(\ell-a_{p_n}) \partial^2},
\]

so \( e^{-x_i \partial^2} K_t^{\text{hyp}(\mathfrak{h}_a^b)} e^{x_j \partial^2} \) equals

\[
\sum_{n=1}^k (-1)^{n+1} \sum_{1 \leq p_1 < \cdots < p_n \leq k} S_{t,a_{p_1}-x_i} \tilde{\chi}^a_{p_1} e^{(a_{p_2}-a_{p_1}) \partial^2} \tilde{\chi}^a_{p_2} \cdots e^{(a_{p_n}-a_{p_{n-1}}) \partial^2} \tilde{\chi}^a_{p_n} S_{t,x_j-a_{p_n}} .
\]

Each summand can be factored as

\[
(S_{t,a_{p_1}-x_i} \tilde{\chi}^a_{p_1} S_{t,0})(S_{t,a_{p_2}-a_{p_1}} S_{t,0}) \cdots (S_{t,a_{p_n}-a_{p_{n-1}}} \tilde{\chi}^a_{p_n} S_{t,x_j-a_{p_n}}) .
\]

By (A.1), as \( t \to 0 \) the first factor goes to \( P_{x_i,a_{p_1}} 1_{x_i \leq a_{p_1}} \), the last factor goes to \( P_{a_{p_n-1},a_{p_n}} 1_{a_{p_n} \leq x_j} \), and each of the inner factors goes to \( P_{a_{p_{s-1}},a_{p_s}} 2 \leq s \leq n-1 \). Therefore

\[
\lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hyp}(\mathfrak{h}_a^b)} e^{x_j \partial^2} = \sum_{n=1}^k (-1)^{n+1} \sum_{1 \leq p_1 < \cdots < p_n \leq k} P_{x_i,a_{p_1}} P_{a_{p_1},a_{p_2}} \cdots P_{a_{p_{n-1}},a_{p_n}} 1_{x_i \leq a_{p_1}, x_j \leq a_{p_n}}
\]

and then, using inclusion-exclusion again, we deduce finally that

\[
\lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hyp}(\mathfrak{h}_a^b)} e^{x_j \partial^2} = P_{x_i,x_j} 1_{x_i \leq x_j} .
\]

### A.2. Matrix KP initial data.

Consider now compactly supported initial data \( h \in \text{UC} \), meaning that \( h(y) = -\infty \) for \( y \) outside some compact interval. Approximating \( h \) by initial data of the form \( \mathfrak{h}_a^b \) we obtain

\[
\lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hyp}(h)} e^{x_j \partial^2} = P_{x_i,x_j} 1_{x_i \leq x_j} .
\]

In terms of the extended Brownian scattering operator (3.5), this gives

\[
K_{0,\text{ext}}^{\text{hyp}(h)} (x_i, \cdot; x_j, \cdot) := \lim_{t \to 0} e^{-x_i \partial^2} K_t^{\text{hyp}(h)} (x_i, \cdot; x_j, \cdot) e^{x_j \partial^2} = \begin{cases} -P_{x_i,x_j}^\text{No hit} h & \text{if } i < j, \\ \tilde{\chi} h(x_i) & \text{if } i = j, \\ 0 & \text{if } i > j. \end{cases} \tag{A.2}
\]

**Remark A.1.** This formula recovers correctly the KPZ fixed point initial data: since \( K_{0,\text{ext}}^{\text{hyp}(h)} (x_i, \cdot; x_j, \cdot) \) is upper triangular, we have

\[
\det (I - \chi_{x_i} K_{0,\text{ext}}^{\text{hyp}(h)} \chi_{x_j}) = \prod_{i=1}^m \det (I - \chi_{r_i} \tilde{\chi} h(r_i) \chi_{r_i}) = \prod_{i=1}^m 1_{r_i \geq h(r_i)}
\]

as desired.
Now we compute $[\mathbf{RK}]$ with $\mathbf{K}$ as in Section 3.3. Recalling that in that section we shifted the entries of the kernel by $r_i$ (which we are not doing here), this corresponds in the current setting to evaluating the $\{i, j\}$ entry of $(\mathbf{I} - \mathbf{K}^{-1})\mathbf{K}$ at $(r_i, r_j)$. Since $\mathbf{K}^{\text{hypot}}$ is upper triangular we can expand (formally) the entries of $(\mathbf{I} - \mathbf{K}^{-1})\mathbf{K}$ as

$$
(\mathbf{I} - \mathbf{K}^{-1})_{i,j} = 1_{i < j} \sum_{\pi: i \rightarrow j} |\pi|^{-1} \prod_{n=1}^{\pi_{i,j}} \chi_{r_{\pi(n)}} \mathbf{K}_{\pi(n), \pi(n+1)} \chi_{r_{\pi(n+1)}},
$$

(A.3)

where the sum is over non-decreasing paths $\pi$ going from $i$ to $j$ along integers and $|\pi|$ denotes the length of the path. Fix $i \leq j$ and assume first that $r_i \geq h(x_i')$ for each $i \leq \ell \leq j$. Consider a fixed path $\pi$ from $i$ to $j$. If $\pi(n) = \pi(n+1)$ for some $n$ then the corresponding factor in the product inside the sum will be $\chi_{r_{\pi(n)}} \bar{\chi}_{h(x_{\pi(n)})} \chi_{r_{\pi(n)}} = 0$, so only strictly increasing paths contribute to the sum and we get (note that this sum is now finite)

$$
(\mathbf{I} - \mathbf{K}^{-1})_{i,j} = 1_{i < j} \sum_{\pi: i \rightarrow j} (-1)^{\ell} |\pi|^{-1} \prod_{n=1}^{\pi_{i,j}} \chi_{r_{\pi(n)}} \mathbf{P}_{\text{No hit } h}^{\text{st. incr.} \pi_{x(x),x_{n+1}}} \chi_{r_{\pi(n+1)}},
$$

Evaluating at $(r_i, r_j)$ and applying inclusion-exclusion again, we deduce that as desired (compare with (1.10)) that

$$
[\mathbf{RK}]_{i,j} = -1_{i < j} \mathbf{P}_{x_i',x_j'} \mathbf{B}(r_i - r_i(y) \geq h(y)) \forall y \in [x_i, x_j],
$$

$$
\mathbf{B}(x_n) \leq r_n \text{ for each } x_n \in (x_i, x_j), \mathbf{B}(x_j) \in dr_j / dr_j \tag{A.4}
$$

Suppose next that $r_\ell < h(x_\ell)$ for some $i \leq \ell \leq j$, and for simplicity assume that this is the only such index satisfying the condition (the argument can be generalized easily). Assume also that $i < j$. From the argument in the previous case we know that if $\pi: i \rightarrow j$ has a constant piece which stays at any index other than $\ell$, then $\pi$ does not contribute to the sum in (A.3). Hence any path $\pi$ from $i$ to $j$ which does contribute to the sum can be decomposed as $\pi_1 \circ v \circ \pi_2$ with $\pi_1: i \rightarrow \ell$ and $\pi_2: \ell \rightarrow j$ strictly increasing (we allow for $\pi_1$ or $\pi_2$ to be empty if $\ell = i$ or $\ell = j$), and $v$ staying at $\ell$ for a given number of steps (which could be 0). The product inside the sum in (A.3) splits between factors coming from the three pieces of the path, and in the middle part we get a factor

$$
\left( \chi_{r_\ell} \bar{\chi}_{h(x_\ell)} \chi_{r_j} \right)^{|\nu|} = 1 \cdot 1_{|\nu|=0} + \chi_{r_\ell} \bar{\chi}_{h(x_\ell)} 1_{|\nu|>0}.
$$

In other words, and repeating the previous argument,

$$
(\mathbf{I} - \mathbf{K})_{i,j} = -\sum_{\pi_1: i \rightarrow \ell} \sum_{\pi_2: \ell \rightarrow j} \sum_{\nu \geq 0} (-1)^{|\pi_1| - 1} \prod_{n=1}^{\pi_{1,\ell}} \chi_{r_{\pi_1(n)}} \mathbf{P}_{x_{\pi_1(n)},x_{\pi_2(n)+1}}^{\text{No hit } h} \chi_{r_{\pi_1(n)+1)}
$$

$$
\times \left( \mathbf{I} \cdot 1_{|\nu|=0} + \chi_{r_\ell} \bar{\chi}_{h(x_\ell)} 1_{|\nu|>0} \right) (-1)^{|\pi_2| - 1} \prod_{n=1}^{\pi_{2,j}} \chi_{r_{\pi_2(n)}} \mathbf{P}_{x_{\pi_2(n)},x_{\pi_2(n)+1}}^{\text{No hit } h}
$$

$$
= -\sum_{\nu \geq 0} \chi_{r_\ell} \mathbf{P}_{x_\ell,x_j}^{\geq h \leq \nu} \left( \mathbf{I} \cdot 1_{|\nu|=0} + \chi_{r_\ell} \bar{\chi}_{h(x_\ell)} 1_{|\nu|>0} \right) \mathbf{P}_{x_\ell,x_j}^{\geq h \leq \nu},
$$

But $\mathbf{P}_{x_\ell,x_j}^{\geq h \leq \nu} = 0$, because at the endpoint $v$ it requires $h(x_\ell) \leq v \leq r_\ell$ (the analogous statement holds for the other factor). Hence we conclude that, in this case, $[\mathbf{RK}]_{i,j} = 0$, which for the same reason means that (A.4) still holds.

Suppose finally that $i = j$ and $r_i < h(x_i)$. Now the only possible paths in (A.3) are constant paths $\pi$ of arbitrary length $|\pi| \geq 1$. Each such $|\pi|$ contributes a term of the form $\chi_{r_i} \bar{\chi}_{h(x_i)}$, which evaluated at $(r_i, r_i)$ is taken to be 1, and hence $[\mathbf{RK}]_{i,i}$ diverges to $\infty$ in this case (which coincides with the physical meaning of this quantity, namely $\partial_i \log F(t, x_1, \ldots, x_n, r_1, \ldots, r_n)$).
The conclusion is then that

$$[\text{RK}]_{i,j} = \begin{cases} -\mathbb{P}_{x_i,x_j}^{h_1 \leq h_2}(r_i, r_j) & \text{if } i < j, \\ \infty & \text{if } i = j \text{ and } r_i < h(x_i), \\ 0 & \text{otherwise}. \end{cases}$$

APPENDIX B. ALTERNATIVE DERIVATION OF KP-II FOR NARROW WEDGE MULTIPONT DISTRIBUTIONS

In this section we will derive the KP-II equation (1.12) for the Airy$_2$ process directly using the path-integral formula for the KPZ fixed point [MQR17, Prop. 4.3]. Define \( F(t, \vec{x} + y, \vec{r} + a) \) as in Sec. 1.4. Then letting \( K_{t,x} = K_t^\text{hypo}(h_0)(x, \cdot ; x, \cdot) \) we have

$$F(t, \vec{x} + y, \vec{r} + a) = \det(I - K_{t,x_1+y} + \chi_{r_1+a}e^{(x_2-x_1)\partial^2} \chi_{r_2+a} \cdots \chi_{r_m+a}e^{(x_{2-m} - x_m)\partial^2} K_{t,x_1+y})$$

$$= \det(I - K + \chi_{r_1}e^{(x_2-x_1)\partial^2} \chi_{r_2} \cdots \chi_{r_m}e^{(x_{2-m} - x_m)\partial^2} K)$$

with \( K = K_{t,x_1+y}(a + \cdot, a + \cdot) = e^{a\partial}K_{t,x_1+y}e^{-a\partial}. \) Note that the product of operators preceding \( K \) in the last term does not depend on \( t, y \) or \( a \); call it \( I - P \) so that \( F = \det(I - PK) \). Up to here this is general, but now we specialize to the narrow wedge case, for which \( K = e^{a\partial}(S_{t,-x_1-y})^\dagger \chi_0 S_{t,x_1+y}e^{-a\partial}. \) Using the cyclic property of the determinant we get

$$F = \det(I - \chi_0 S_{t,x_1+y}e^{-a\partial} P e^{a\partial}(S_{t,-x_1-y})^\dagger \chi_0) = \det(I - \chi_0 e^{a\partial} S_{t,x_1+y} P (S_{t,-x_1-y})^\dagger e^{a\partial} \chi_0)$$

with \( \phi \) the reflection operator \( g f(x) = f(-x) \). So letting

$$L = \partial_x e^{-a\partial} S_{t,x_1+y} P (S_{t,-x_1-y})^\dagger e^{a\partial} \phi = e^{a\partial}(S_{t,x_1+y})^\dagger (\partial_x P) S_{t,-x_1-y} e^{-a\partial}$$

(the second equality is a simple computation) we get \( F = \det(I - L) \). Now \( \partial_a L = (d_1 + d_2) L, \partial_x L = -\frac{1}{2}(d_1^3 + d_2^3), \) and \( \partial_y L = (d_1^2 - d_2^2) L, \) which is just (3.7)/(3.9) in this case (except for the change \( y \to -y \), which as in Sec. 1.4 is irrelevant), so the same computations yield that \( \phi = \partial_y^2 \log(F) \) solves KP-II in \((t, y, a)\), and translating back to the \( \mathcal{D}_r, \mathcal{D}_x \) derivatives yields (1.12).
