THE LOGARITHMIC SOBOLEV INEQUALITY FOR A
SUBMANIFOLD IN EUCLIDEAN SPACE

SIMON BRENDLE

ABSTRACT. We prove a logarithmic Sobolev inequality which holds for
submanifolds of arbitrary dimension and codimension. Like the Michael-
Simon Sobolev inequality, this inequality includes a term involving the
mean curvature (in this case, the shrinker mean curvature).

1. INTRODUCTION

In 1973, Michael and Simon [11] proved a Sobolev inequality which holds
on any submanifold of Euclidean space (see also [1], Section 7, and [5]).
This inequality contains a term involving the mean curvature; it is partic-
ularly useful on minimal submanifolds. In a recent paper [3], we proved
a sharp version of the Michael-Simon Sobolev inequality for submanifolds
of codimension at most 2. In particular, this implies a sharp isoperimetric
inequality for minimal submanifolds of Euclidean space.

In 2000, Ecker [7] proved a logarithmic Sobolev inequality which holds on
any submanifold of Euclidean space. In this paper, we improve the inequality
in [7], and obtain a sharp constant:

Theorem 1. Let \( \Sigma \) be a compact \( n \)-dimensional submanifold of \( \mathbb{R}^{n+m} \) without boundary, and let
\[
\mu = (4\pi)^{-\frac{n}{2}} e^{-\frac{|x|^2}{4}} \, dvol
\]
denote the Gaussian measure on \( \Sigma \). Let \( f \) be a positive smooth function on
\( \Sigma \). Then
\[
\int_{\Sigma} f \log f \, d\mu - \int_{\Sigma} \frac{\left| \nabla \Sigma f \right|^2}{f} \, d\mu - \int_{\Sigma} f \left| H + \frac{x}{2} \right|^2 d\mu
\]
\[
\leq \left( \int_{\Sigma} f \, d\mu \right) \log \left( \int_{\Sigma} f \, d\mu \right).
\]
where \( H \) denotes the mean curvature vector of \( \Sigma \).

The logarithmic Sobolev inequality in Euclidean space has been studied by
numerous authors, see e.g. [2], [8], [10]. The logarithmic Sobolev inequality
also plays a central role in Perelman’s monotonicity formula for the entropy
under Ricci flow (see [12]).

This project was supported by the National Science Foundation under grant DMS-1806190 and by the Simons Foundation.
The Gaussian measure $\mu$ is very natural from a geometric point of view. In particular, $\mu(\Sigma)$ is the Gaussian density which appears in Huisken’s monotonicity formula for mean curvature flow (cf. [9]). The term $\int_\Sigma |H + \frac{x^2}{2}|^2 \, d\mu$ appears on the right hand side in Huisken’s monotonicity formula. Note that the quantity $H + \frac{x^2}{2}$ vanishes if and only if $\Sigma$ is a self-similar shrinking solution to mean curvature flow. We note that the Gaussian density and Huisken’s monotonicity formula are of fundamental importance in the study of mean curvature; see e.g. the work of Colding and Minicozzi [6].

The proof of Theorem 1 follows a similar strategy as in [3] and is inspired by the Alexandrov-Bakelman-Pucci maximum principle (cf. [4]). Alternatively, we could employ ideas from optimal transport; in that case, we would consider the transport map from $\mathbb{R}^{n+m}$ equipped with the Gaussian measure to $(\Sigma, f \, d\mu)$.

2. PROOF OF THEOREM 1

We first assume that $\Sigma$ is connected. Without loss of generality, we may assume that $\int_\Sigma f \, d\mu = 1$. Let us define a real number $\alpha$ by

$$\int_\Sigma f \log f \, d\mu - \int_\Sigma \frac{\nabla^2 f}{f} \, d\mu - \int_\Sigma f \left|H + \frac{x^2}{2}\right|^2 \, d\mu = -\alpha.$$ 

Since $\Sigma$ is connected, the operator $v \mapsto \text{div}_\Sigma(e^{-\frac{|x|^2}{4}} f \nabla^2 v)$ has one-dimensional kernel and cokernel. Hence, we can find a smooth function $v$ such that

$$\text{div}_\Sigma(e^{-\frac{|x|^2}{4}} f \nabla^2 v) = e^{-\frac{|x|^2}{4}} f \log f - e^{-\frac{|x|^2}{4}} \frac{\nabla^2 f}{f} - e^{-\frac{|x|^2}{4}} f \left|H + \frac{x^2}{2}\right|^2 + \alpha e^{-\frac{|x|^2}{4}} f$$

for some constant $\alpha$.

**Lemma 2.** The function $u(x) := v(x) + \frac{|x|^2}{2}$ satisfies $\Delta_\Sigma u - \frac{\nabla^2 u}{4} + \frac{|x|^2}{4} + |H|^2 - n \leq \log f + \alpha$.

**Proof.** We compute

$$\Delta_\Sigma u - \frac{\nabla^2 u}{4} + \frac{|x|^2}{4} + |H|^2 - n$$

$$= \Delta_\Sigma v - \frac{1}{2} \langle x, \nabla^2 v \rangle - \frac{\nabla^2 v}{4} + \left|H + \frac{x^2}{2}\right|^2$$

$$= \frac{1}{f} e^{-\frac{|x|^2}{4}} \text{div}_\Sigma(e^{-\frac{|x|^2}{4}} f \nabla^2 v) + \left|H + \frac{x^2}{2}\right|^2$$

$$+ \frac{\nabla^2 f}{f^2} - \frac{2 \nabla^2 f + f \nabla^2 v}{4f^2}$$

$$= \log f + \alpha - \frac{2 \nabla^2 f + f \nabla^2 v}{4f^2}$$

$$\leq \log f + \alpha.$$
This proves the assertion.

We define
\[ \Omega := \{(x, y) : x \in \Sigma, y \in T_x^\perp \}, \]
\[ A := \{(x, y) \in \Omega : D^2_\Sigma u(x) - \langle II(x), y \rangle \geq 0 \}. \]

Moreover, we define a map \( \Phi : \Omega \to \mathbb{R}^{n+m} \) by
\[ \Phi(x, y) = \nabla \Sigma u(x) + y. \]

Note that \( |\Phi(x, y)|^2 = |\nabla \Sigma u(x)|^2 + |y|^2 \) since \( \nabla \Sigma u(x) \in T_x \Sigma \) is orthogonal to \( y \in T_x^\perp \Sigma \).

**Lemma 3.** We have \( \Phi(A) = \mathbb{R}^{n+m} \).

**Proof.** Given \( \xi \in \mathbb{R}^{n+m} \), there is a point \( \bar{x} \in \Sigma \) where the function \( u(x) - \langle x, \xi \rangle \) attains its minimum. Then \( \xi = \nabla \Sigma u(x) + \bar{y} \) for some vector \( \bar{y} \in T_x^\perp \Sigma \). Moreover, \( D^2_\Sigma u(x) - \langle II(x), \xi \rangle \geq 0 \), and consequently \( D^2_\Sigma u(x) - \langle II(x), \bar{y} \rangle \geq 0 \). Thus, \((\bar{x}, \bar{y}) \in A \) and \( \Phi(\bar{x}, \bar{y}) = \xi \).

**Lemma 4.** The Jacobian determinant of \( \Phi \) satisfies
\[ 0 \leq e^{-\frac{|\Phi(x, y)|^2}{4}} \det D\Phi(x, y) \leq e^{-\frac{|x|^2}{4} - \frac{|y+2H(x)|^2}{4} + \alpha f(x)} \]
for each point \( (x, y) \in A \).

**Proof.** Consider a point \((x, y) \in A\). Then \( D^2_\Sigma u(x) - \langle II(x), y \rangle \geq 0 \). Moreover, Lemma 2 implies
\[ \Delta \Sigma u(x) - \langle H(x), y \rangle - n \]
\[ \leq \frac{|\nabla \Sigma u(x)|^2}{4} + \frac{|y|^2}{4} - \frac{|x|^2}{4} - \frac{|y + 2H(x)|^2}{4} + \log f + \alpha \]
\[ = \frac{|\Phi(x, y)|^2}{4} - \frac{|x|^2}{4} - \frac{|y + 2H(x)|^2}{4} + \log f + \alpha. \]

Using the elementary inequality \( \lambda \leq e^{\lambda - 1} \), we obtain
\[ 0 \leq \det(D^2_\Sigma u(x) - \langle II(x), y \rangle) \]
\[ \leq e^{\Delta \Sigma u(x) - \langle H(x), y \rangle - n} \]
\[ \leq e^{-\frac{|\Phi(x, y)|^2}{4} - \frac{|x|^2}{4} - \frac{|y + 2H(x)|^2}{4} + \alpha f(x)}. \]

Using the identity
\[ \det D\Phi(x, y) = \det(D^2_\Sigma u(x) - \langle II(x), y \rangle) \]
(cf. [3]), we conclude that
\[ 0 \leq \det D\Phi(x, y) \leq e^{-\frac{|\Phi(x, y)|^2}{4} - \frac{|x|^2}{4} - \frac{|y + 2H(x)|^2}{4} + \alpha f(x)}. \]

This proves the assertion.
After these preparations, we now complete the proof of Theorem 1. We compute

\[1 = (4\pi)^{-\frac{m+n}{2}} \int_{\mathbb{R}^{n+m}} e^{-\frac{|\xi|^2}{4}} d\xi \]
\[\leq (4\pi)^{-\frac{m+n}{2}} \int_{\Sigma} \left( \int_{T_{y}^\perp \Sigma} e^{-\frac{|x|^2}{4} - \frac{|y|^2}{4} + \alpha f(x)} dy \right) d\text{vol}(x) \]
\[\leq (4\pi)^{-\frac{m+n}{2}} \int_{\Sigma} \left( \int_{T_{y}^\perp \Sigma} e^{-\frac{|x|^2}{4} - \frac{|y|^2}{4} + \alpha f(x)} dy \right) d\text{vol}(x) \]
\[= (4\pi)^{-\frac{n}{2}} \int_{\Sigma} e^{-\frac{|x|^2}{4} + \alpha} f(x) d\text{vol}(x) = e^{\alpha}, \]

where in the last step we have used the normalization \( \int_{\Sigma} f d\mu = 1 \). Thus, we conclude that \( \alpha \geq 0 \). This proves Theorem 1 in the special case when \( \Sigma \) is connected.

It remains to consider the case when \( \Sigma \) is disconnected. In that case, we apply the inequality to each individual connected component of \( \Sigma \), and sum over all connected components. Since \( a \log a + b \log b < (a + b) \log(a + b) \) for \( a, b > 0 \), we conclude that

\[\int_{\Sigma} f \log f d\mu - \int_{\Sigma} \frac{\nabla^\Sigma f}{f} d\mu - \int_{\Sigma} f \left| H + \frac{x^\perp}{2} \right|^2 d\mu \leq \left( \int_{\Sigma} f d\mu \right) \log \left( \int_{\Sigma} f d\mu \right). \]

if \( \Sigma \) is disconnected. This completes the proof of Theorem 1.
