BOUND FOR THE REGULARITY OF PRODUCT OF EDGE IDEALS

ARINDAM BANERJEE, PRIYA DAS, AND S SELVARAJA

Abstract. Let $I$ and $J$ be edge ideals in a polynomial ring $R = K[x_1, \ldots, x_n]$ with $I \subseteq J$. In this paper, we obtain a general upper and lower bound for the Castelnuovo-Mumford regularity of $IJ$ in terms of certain invariants associated with $I$ and $J$. Using these results, we explicitly compute the regularity of $IJ$ for several classes of edge ideals. Let $J_1, \ldots, J_d$ be edge ideals in a polynomial ring $R$ with $J_1 \subseteq \cdots \subseteq J_d$. Finally, we compute the precise expression for the regularity of $J_1 J_2 \cdots J_d$ when $d \in \{3, 4\}$ and $J_d$ is the edge ideal of complete graph.

1. Introduction

Let $M$ be a finitely generated graded module over $R = K[x_1, \ldots, x_n]$, where $K$ is a field. The Castelnuovo-Mumford regularity (or simply, regularity) of $M$, denoted by $\text{reg}(M)$, is defined to be the least integer $i$ so that, for every $j$, the $j$th syzygy of $M$ is generated in degrees $\leq i + j$. Regularity is an important invariant in commutative algebra and algebraic geometry that measures the computational complexity of ideals, modules, and sheaves. In this paper, we study bounds on the regularity of product of ideals in a polynomial ring.

The regularity of products of ideals was studied first by Conca and Herzog [8]. They studied whether for homogeneous ideal $I$ and finitely generated graded module $M$ over $R$, one has $\text{reg}(IM) \leq \text{reg}(I) + \text{reg}(M)$. This question is essentially a generalization of the simple fact that the highest degree of a generator of the product $IM$ is bounded above by the sum of the highest degree of a generator of $M$ and the highest degree of a generator of $I$ and the answer to this question is negative in general. There are several counterexamples already with $M = I$ such that $\text{reg}(I^2) > 2 \cdot \text{reg}(I)$, see Sturmfels [22]. They found some special classes of ideal $I$ and module $M$ for which the above inequality holds. In particular, they showed that if $I$ is a homogeneous ideal in a polynomial ring $R$ with $\dim(R/I) \leq 1$, then $\text{reg}(IM) \leq \text{reg}(I) + \text{reg}(M)$, for any finitely generated module $M$ over $R$.

In case $M$ is also a homogeneous ideal, the situation becomes particularly interesting. For example, Sidman proved that if $\dim(R/I) \leq 1$, then the regularity of $IJ$ is bounded above by $\text{reg}(I) + \text{reg}(J)$, [21]. Also, she proved that if two ideals of $R$, say $I$ and $J$, define schemes whose intersection is a finite set of points, then $\text{reg}(IJ) \leq \text{reg}(I) + \text{reg}(J)$. In [6], Chardin, Minh and Trung proved that if $I$ and $J$ are monomial complete intersections, then $\text{reg}(IJ) \leq \text{reg}(I) + \text{reg}(J)$. Cimpoeaş proved that for two monomial ideals of Borel type $I, J$, $\text{reg}(IJ) \leq \text{reg}(I) + \text{reg}(J)$, [4]. Caviglia in [3] and Eisenbud, Huneke and Ulrich in [9] studied the more general problem of regularity of tensor products and various Tor modules of $R/I$ and $R/J$.

In this paper, we study the same problem for the case of edge ideals and seek for better bounds by exploiting the combinatorics of the underlying graph. Let $G$ be a finite simple graph on the vertex set $\{x_1, \ldots, x_n\}$ and $I(G) := (\{x_i x_j \mid \{x_i, x_j\} \in E(G)\}) \subseteq K[x_1, \ldots, x_n]$ be the edge ideal corresponding to the graph $G$. In general, computing the regularity of $I(G)$ is NP-hard ([23, Corollary 23]). A primary inspiration for this paper is Katzman’s and Woodroofe’s theorems from [19] and [23]. They showed that if $G$ is a graph, then

$$\nu(G) + 1 \leq \text{reg}(I(G)) \leq \text{co-chord}(G) + 1,$$

where $\nu(G)$ denotes the induced matching number of $G$ (see Section 2 for definition) and co-chord$(G)$ denotes the co-chordal cover number of $G$ (see Section 2 for definition). Several recent papers have related the $\text{reg}(I(G))$ with various invariants of the graph $G$ (see 2 for a survey in this direction). In
this context, the natural question arises if $I$ and $J$ are edge ideals in $R$, then what is the regularity of $IJ$? More precisely, if $I$ and $J$ are the edge ideal of a graph $H$ and $G$ respectively, then

1. what is the lower and upper bounds for the regularity of $IJ$ using combinatorial invariants associated to the graphs $H$ and $G$?

2. what is the precise expression for the regularity of $IJ$ for particular classes of graphs $H$ and $G$?

This paper evolves around these two questions.

The first main result of the paper answers question (1). We prove:

**Theorem 1.1** (Theorem 3.3 and Theorem 3.4). Let $I$ and $J$ be the edge ideal of a graph $H$ and $G$ respectively with $I \subseteq J$. Then

$$\nu_{GH} + 3 \leq \text{reg}(IJ) \leq \max\{\text{co-chord}(G) + 3, \text{co-chord}(H) + 1\},$$

where $\nu_{GH}$ denotes the induced matching number of $G$ as well as $H$.

Theorem 1.1 has a number of interesting consequences. For example, Corollary 3.6 says that if $H$ is any subgraph of $G$, then $\text{reg}(IJ) \leq m(G) + 3$, where $m(G)$ denotes the matching number of $G$. On the other hand, Corollary 3.7 says that if $H$ is an induced subgraph of $G$, then

$$\nu(H) + 3 \leq \text{reg}(IJ) \leq \text{co-chord}(G) + 3,$$

where $\nu(H)$ denotes the induced matching number of $H$.

Another way of bounding the regularity of $IJ$, than using combinatorial invariants, is to relate it to the regularity of $I$ and regularity of $J$. We prove:

**Theorem 3.9.** Let $I$ and $J$ be edge ideals with $I \subseteq J$. Then

$$\text{reg}(IJ) \leq \max\{\text{reg}(J) + 3, \text{reg}(I)\}.$$ 

We then move on to compute the precise expressions for the regularity of product of edge ideals. First, we observe that for certain classes of graphs, the induced matching number coincides with the co-chordal cover number, for example, cycle with $3n$ vertices, weakly chordal, unmixed bipartite, bipartite graph with regularity 3 and graph having induced matching. Then we use (1.2) to prove that $\text{reg}(IJ) = \nu(G) + 3$ when $H$ is an induced subgraph of $G$ and $\nu(H) = \nu(G)$ (Corollary 4.1, Remark 4.2).

As a consequence of the techniques that we have developed, we compute the regularity of $IJ$ when $J$ has linear resolution. More precisely:

**Theorem 4.3.** Suppose $J$ has linear resolution and $I \subseteq J$.

1. If $\text{reg}(I) \leq 4$, then $IJ$ has linear resolution.
2. If $5 \leq \text{reg}(I)$, then $\text{reg}(IJ) = \text{reg}(I)$.

Next, we study the regularity of product of more than two edge ideals. We prove:

**Theorem 4.6.** Let $J_1, \ldots, J_d$ be edge ideals and $J_1 \subseteq J_2 \subseteq \cdots \subseteq J_d$, $d \in \{3, 4\}$. Suppose $J_d$ is the edge ideal of complete graph.

1. If $\text{reg}(J_1 \cdots J_{d-1}) \leq 2d$, then $J_1 \cdots J_d$ has linear resolution.
2. If $\text{reg}(J_1 \cdots J_{d-1}) \geq 2d + 1$, then $\text{reg}(J_1 \cdots J_d) = \text{reg}(J_1 \cdots J_{d-1})$.

Our paper is organized as follows. In Section 2 we collect the necessary notion, terminology and some results that are used in the rest of the paper. Bounds for the regularity of product of two edge ideals is studied in Section 3. The precise expressions for the regularity of product of edge ideals have been discussed in Section 4.

2. Preliminaries

In this section, we set up the basic definitions and notation needed for the main results. Let $G$ be a finite simple graph with vertex set $V(G)$ and edge set $E(G)$. A subgraph $H \subseteq G$ is called induced if $\{u, v\}$ is an edge of $H$ if and only if $u$ and $v$ are vertices of $H$ and $\{u, v\}$ is an edge of $G$. For $\{u_1, \ldots, u_r\} \subseteq V(G)$, let $N_G(u_1, \ldots, u_r) = \{v \in V(G) \mid \{u_i, v\} \in E(G) \text{ for some } 1 \leq i \leq r\}$. For $\{u_1, \ldots, u_r\} \subseteq V(G)$, let $N_G[u_1, \ldots, u_r] = N_G(u_1, \ldots, u_r) \cup$
\{u_1, \ldots, u_r\}. For \(U \subseteq V(G)\), denote by \(G \setminus U\) the induced subgraph of \(G\) on the vertex set \(V(G) \setminus U\). Let \(C_k\) denote the cycle on \(k\) vertices.

Let \(G\) be a graph. We say 2 non-adjacent edges \(\{f_1, f_2\}\) form an \(2K_2\) in \(G\) if \(G\) does not have an edge with one endpoint in \(f_1\) and the other in \(f_2\). A graph without \(2K_2\) is called \(2K_2\)-free also called \(gap-free\) graph. It is easy to see that, \(G\) is gap-free if and only if \(G^c\) contains no induced \(C_4\). Thus, \(G\) is gap-free if and only if it does not contain two vertex-disjoint edges as an induced subgraph.

A matching in a graph \(G\) is a subgraph consisting of pairwise disjoint edges. The largest size of a matching in \(G\) is called its \textit{matching number} and denoted by \(m(G)\) and the \textit{minimum matching number} of \(G\), denoted by \(\text{min-match}(G)\), is the minimum cardinality of the maximal matchings of \(G\). If the subgraph is an induced subgraph, the matching is an \textit{induced matching}. The largest size of an induced matching in \(G\) is called its \textit{induced matching number} and denoted by \(\nu(G)\). The largest size of induced matching of \(H\) as well as \(G\) denoted by \(\nu_{GH}\). The \textit{complement} of a graph \(G\), denoted by \(G^c\), is the graph on the same vertex set in which \(\{u, v\}\) is an edge of \(G^c\) if and only if it is not an edge of \(G\). A graph \(G\) is \textit{chordal} if every induced cycle in \(G\) has length 3, and is co-chordal if \(G^c\) is chordal. The \textit{co-chordal cover number}, denoted \(\text{co-chord}(G)\), is the minimum number \(n\) such that there exist co-chordal subgraphs \(H_1, \ldots, H_n\) of \(G\) with \(E(G) = \bigcup_{i=1}^n E(H_i)\). Observe that for any graph \(G\), we have

\[
\nu(G) \leq \text{co-chord}(G) \leq \text{min-match}(G) \leq m(G).
\]  

\textbf{Example 2.1.} Let \(G\) be the graph as shown in figure. Then

\[
\{\{x_1, x_2\}, \{x_3, x_4\}, \{x_5, x_6\}, \{x_7, x_8\}\}
\]

forms a matching of \(G\), but not an induced matching. The set \(\{\{x_1, x_2\}, \{x_4, x_5\}\}\) forms an induced matching.

Let \(H\) be a subgraph of \(G\) with \(E(H) = \{\{x_1, x_2\}, \{x_3, x_4\}\}\). It is not hard to verify that \(\nu(G) = 2\), \(\nu(H) = 2\) and \(\nu_{GH} = 1\). Let \(H_1, H_2\) and \(H_3\) be the subgraphs of \(G\) with \(E(H_1) = \{\{x_1, x_2\}, \{x_2, x_3\}, \{x_3, x_4\}\}\), \(E(H_2) = \{\{x_4, x_5\}, \{x_5, x_6\}, \{x_6, x_7\}\}\) and \(E(H_3) = \{\{x_7, x_8\}, \{x_8, x_1\}\}\) respectively. We can see that \(H_1, H_2\) and \(H_3\) are co-chordal subgraphs of \(G\) and \(E(G) = \bigcup_{i=1}^3 E(H_i)\). Therefore, \(\text{co-chord}(G) = 3\).

A subset \(C \subseteq V(G)\) is a vertex cover of \(G\) if for each \(e \in E(G), e \cap C \neq \emptyset\). If \(C\) is minimal with respect to inclusion, then \(C\) is called \textit{minimal vertex cover} of \(G\). A graph \(G\) is called \textit{unmixed} if all minimal vertex covers of \(G\) have the same number of elements. A graph \(G\) is \textit{weakly chordal} if every induced cycle in both \(G\) and \(G^c\) has length at most 4.

Polarization is a process that creates a squarefree monomial ideal (in a possibly different polynomial ring) from a given monomial ideal, [14, Section 1.6]. In this paper, we repeatedly use one of the important properties of the polarization, namely:

\textbf{Corollary 2.2.} [14 Corollary 1.6.3(a)] Let \(I\) be a monomial ideal in \(K[x_1, \ldots, x_n]\). Then \(\text{reg}(I) = \text{reg}(\overline{I})\).

\section{Upper and Lower Bound for the Regularity of Product of Two Edge Ideals}

In this section, we obtain a general upper and lower bound for the regularity of product of two edge ideals. The main idea is to analyze the ideal \((IJ : ab)\), where \(I\) and \(J\) are edge ideals and \(ab \in I\).

We first fix certain set-up that we consider throughout this paper.

\textbf{Set-up 3.1.} Let \(I\) and \(J\) be the edge ideal of a graph \(H\) and \(G\) respectively with \(I \subseteq J\). For a monomial ideal \(K\), let \(G(K)\) denotes the minimal generating set of \(K\). For a monomial \(m \in R = K[x_1, \ldots, x_n]\), support of \(m\) is the set of variables appearing in \(m\) and is denoted by \(\text{supp}(m)\), i.e., \(\text{supp}(m) = \{x_i \mid x_i \text{ divides } m\}\).

The following result is being used repeatedly in this paper:
Theorem 3.2. Then the colon ideal \((IJ : ab)\) is generated by quadratic monomial ideal for any \(ab \in I\). More precisely

\[(IJ : ab) = J + K_1 + K_2,
\]

where \(K_1 = \langle pq \mid p \in N_G(a) \text{ and } q \in N_H(b) \rangle\) and \(K_2 = \langle rs \mid r \in N_H(a) \text{ and } s \in N_G(b) \rangle\).

Proof. Let \(m \in \mathcal{G}((IJ : ab))\). By degree consideration \(m\) can not have degree \(1\). Suppose \(\deg(m) \geq 3\). Then for \(e \in \mathcal{G}(I)\) and \(f \in \mathcal{G}(J), e \mid mab\). Since \(m\) is minimal, then there does not exist \(m' \neq m\) and \(m' \mid m\) such that \(e \mid m'a\). Now if there exist \(g \in \mathcal{G}(J)\) such that \(g \mid m\), then for minimality of \(m\) and \(g \in (IJ : ab)\) both implies \(g = m\). This is a contradiction to \(\deg(m) \geq 3\). Therefore, \(\deg(m) = 2\). We assume that \(g \nmid m\) for any \(g \in \mathcal{G}(J)\). Then \(e \nmid ab\). Let \(e = ax\), where \(x \mid m\). Therefore, \(xf \mid mb\). If \(f = by\) where \(y \mid \left(\frac{m}{x}\right)\), then \(xy \mid m\). Hence, by minimality of \(m\), \(m\) is a quadratic monomial. Similarly, for \(e = bx\) we can prove in a similar manner.

Clearly, \(J + K_1 + K_2 \subseteq (IJ : ab)\). We need to prove reverse inclusion. Let \(uv \in \mathcal{G}(IJ : ab)\). If \(uv \in J\), then we are done. Suppose \(uv \notin J\). Since \(uvab \in IJ\), we have the following cases: \(ua \in I\) and \(vb \in J\) or \(ua \in J\) and \(vb \in I\) or \(uv \in J\) and \(va \in J\) or \(ab \in J\) and \(va \in I\). In all cases, one can show that either \(uv \in K_1\) or \(uv \in K_2\). Therefore, \((IJ : ab) = J + K_1 + K_2\).

Let \(I\) and \(J\) be the edge ideal of \(H\) and \(G\) respectively with \(I \subseteq J\). Then for any \(\{a, b\} \in E(H)\), \((IJ : ab)\) is a quadratic squarefree monomial ideal, by Theorem 3.2. There exists a graph \(P\) associated to \((IJ : ab)\). Observe that \(G\) is a subgraph of \(P\). For example, let \(I = (x_1x_2, x_2x_3, x_3x_4, x_4x_5, x_5x_6, x_1x_6, x_4x_6)\) and \(J = (x_1x_2, x_2x_3, x_3x_4, x_4x_5, x_5x_6, x_1x_6, x_4x_6)\). Then \((IJ : x_4x_5) = J + (x_2^2, x_3x_6) \subseteq \mathbb{K}[x_1, \ldots, x_6]\) and \((IJ : ab) = J + (x_6y_1, x_3x_6) \subseteq \mathbb{K}[x_1, \ldots, x_6, y_1]\). Then \(P\) is given by the graph \(G\) with the edges \(\{x_6, y_1\}\) and \((x_4, x_6)\) attached to \(G\).

We are now ready to establish the general lower bound for the regularity of \(IJ\).

Theorem 3.3. Then \(\nu_{GH} + 3 \leq \reg(IJ)\).

Proof. Let \(f_1, f_2, \ldots, f_{\nu_GH}\) be the induced matching of \(H\) as well as \(G\). Let \(Q\) be the graph with \(E(Q) = \{f_1, \ldots, f_{\nu_GH}\}\) and \(P = I(Q)\). Then \(Q\) is an induced subgraph of \(H\) as well as \(G\). In [1] Lemma 4.2, Beyarslan et al., proved that if \(K'\) is any induced subgraph of \(K\), then for any \(s \geq 1, i, j \geq 0\), we have \(\beta_{i,j}(K(K')^s) \leq \beta_{i,j}(I(K)^s)\).

In our case, the assumption that \(Q\) is an induced subgraph of \(H\) as well as \(G\). Using this property, one can see that their proof goes through in our case as well i.e., \(\beta_{i,j}(P^2) \leq \beta_{i,j}(IJ)\). By [1] Lemma 4.4, \(\reg(P^2) = \nu_{GH} + 3\). Hence \(\nu_{GH} + 3 \leq \reg(IJ)\).

The following lemma helps to obtain upper bound for the regularity of \(IJ\).

Lemma 3.4. Let \(P\) be the graph associated to \((IJ : ab)\) for any \(\{a, b\} \in E(H)\). Then

\[
\cochord(P) \leq \cochord(G).
\]

Proof. Let \(\cochord(G) = n\) and \(e = \{a, b\}\). Then there exist co-chordal subgraphs \(H_1, \ldots, H_n\) of \(G\) such that \(E(G) = \bigcup_{i=1}^{n} E(H_i)\). If \(E(G) = E(P)\), then we are done. Suppose \(E(G) \neq E(P)\). Let \(N_G(a) \setminus \{b\} = \{a_1, \ldots, a_\alpha\}, N_H(a) \setminus \{b\} = \{a_1, \ldots, a_\alpha'\}, N_G(b) \setminus \{a\} = \{b_1, \ldots, b_\beta\}, N_H(b) \setminus \{a\} = \{b_1, \ldots, b_\beta'\}\), where \(\alpha' \leq \alpha\) and \(\beta' \leq \beta\). Set for any \(x, y \in V(G)\),

\[
[x, y] = \begin{cases} 
\{x, y\} & \text{if } x \neq y; \\
\{x, z_x\} & \text{if } x = y, \text{ where } z_x \text{ is a new vertex.}
\end{cases}
\]

By Theorem 3.2

\[
E(P) = E(G) \bigcup \left\{ \{[a_i, b_j] \mid 1 \leq i \leq \alpha, 1 \leq j \leq \beta \} \right\} \bigcup \left\{ \{[a_i, b_j] \mid 1 \leq i \leq \alpha', 1 \leq j \leq \beta' \} \right\}
\]

\[
\bigcup \left\{ \{[a_i, b_j] \mid 1 \leq i \leq \alpha', 1 \leq j \leq \beta' \} \right\}.
\]
Since $H_m$ is co-chordal for all $1 \leq m \leq n$, by \cite{3} Lemma 1 and Theorem 2, there is an ordering of edges of $H_m$, $f_1 < \cdots < f_{m'}$, such that for $1 \leq r \leq t_m$, $(V(H_m), \{f_1, \ldots, f_r\})$ has no induced subgraph isomorphic to $2K_2$. We add certain edges to $H_m$ with a rule as described below, to get a new graph $H'_m$.

**Rule 1:** If for $1 \leq \mu \leq \alpha$, $f_k = \{a, a_\mu\}$ for some $1 \leq k \leq t_m$, then set
\[ \cdots < f_k < D < f_{k+1} < \cdots, \]
where $D = \{[a_\mu, b_1] \}< \cdots < \{[a_\mu, b_{\beta'}]\}$. 

**Rule 2:** If for $1 \leq \mu \leq \beta$, $f_k = \{b, b_\mu\}$ for some $1 \leq k \leq t_m$, then set
\[ \cdots < f_k < E < f_{k+1} < \cdots, \]
where $E = \{[b_\mu, a_1]\}< \cdots < \{[b_\mu, a_\alpha]\}$. 

**Rule 3:** If $f_k = \{a, b\}$ for some $1 \leq k \leq t_m$, then set
\[ \cdots < f_k < F_1 < F_2 < F_3 < f_{k+1} < \cdots, \]
where
\[ F_1 = \{a, a_1\}< \cdots < \{a, a_\alpha\}, \quad F_2 = \{b, b_1\}< \cdots < \{b, b_{\beta'}\} \]
and
\[ F_3 = \{[a_1, b_1]\}< \cdots < \{[a_1, b_{\beta'}]\}< \{[a_2, b_1]\}< \cdots < \{[a_2, b_{\beta'}]\}< \cdots < \{[a_\alpha, b_1]\}< \cdots < \{[a_\alpha, b_{\beta'}]\}. \]

Then we have $E(\mathcal{P}) = \bigcup_{m=1}^{n} E(H'_m)$. We claim that $H'_m$ is co-chordal for all $1 \leq m \leq n$. Let $E(H'_m) = \{g_1, \ldots, g_{m'}\}$ be edge set of $H'_m$ and linearly ordered as given above. By Lemma 1 and Theorem 2 of \cite{3}, it is enough to prove that for $1 \leq r' \leq t_m$, $(V(H'_m), \{g_1, \ldots, g_{r'}\})$ has no induced subgraph isomorphic to $2K_2$. Suppose $H'_m$ is not co-chordal. Then there exists a least $j$ such that $(V(H'_m), \{g_1, \ldots, g_{j}\})$ has an induced $2K_2$-subgraph, say $\{g_i, g_j\}$ for some $i < j$. By the above construction, one can see that, $g_i$ and $g_j$ both can not be in $E(H_m)$ (or $D$ or $E$ or $F_1 \cup F_2 \cup F_3$). Therefore, we have the following cases:

1. $g_i \in E(H_m)$, $g_j \in D \cup E \cup F_1 \cup F_2 \cup F_3$, or $g_i \in D \cup E \cup F_1 \cup F_2 \cup F_3, g_j \in E(H_m)$;
2. $g_i, g_j \in D \cup E \cup F_1 \cup F_2 \cup F_3$;

**Case 1:** Suppose $g_i = \{u, v\} \in E(H_m)$ and $g_j = \{[a_\mu, b_p]\} \in D$, for some $1 \leq \mu \leq \alpha, 1 \leq p \leq \beta'$. By Rule 1, we have
\[ g_i < g_j = \{a_\mu, a_\mu\} < g_j. \]
Since $g_i, g_{j'} \in E(H_m)$, they can not form an induced $2K_2$ subgraph of $H_m$. Therefore, either $g_{j'}$ and $g_j$ have a vertex in common or there exist an edge $g_{j'} \in E(H_m)$ such that $g_i < g_{j'}$ connecting $g_i$ and $g_{j'}$. If $g_i$ and $g_{j'}$ have a vertex in common, then this contradicts the assumption that $\{g_i, g_j\}$ forms an induced $2K_2$-subgraph. Suppose $g_i$ is an edge connecting $g_i$ and $g_{j'}$. Let $g_i = \{u, a\}$ and $u \neq b$. Then $u \in N_G(a)$. By Rule 1, we have $g_i < \{[u, b_p]\} < g_{j'} < g_j$. This is a contradiction to $\{g_i, g_j\}$ is an induced $2K_2$-subgraph. Suppose $g_i = \{a, u\}$ and $u = b$. By Rule 3, we have $g_i < \{b, b_p\} < g_{j'} < g_j$. This also contradicts the assumption that $\{g_i, g_j\}$ is an induced $2K_2$-subgraph. Similarly, if $g_i = \{u, a_\mu\}$ or $g_i = \{v, a\}$ or $g_i = \{v, a_\mu\}$, then one arrives at a contradiction.

If $g_i \in D$ and $g_j \in E(H_m)$, then we get a contradiction in a similar manner.

**Case 2:** Suppose either $g_i = \{u, v\} \in E(H_m)$, $g_j = \{[b_\mu, a_p]\} \in E$ or $g_i = \{u, v\} \in E(H_m), g_j = \{[b_\mu, a_p]\} \in E$ for some $1 \leq \mu \leq \beta, 1 \leq p \leq \alpha'$. Proceeding as in the Case 1, one can show that $g_i$ and $g_j$ can not form an induced $2K_2$-subgraph.

**Case 3:** Suppose $g_i = \{u, v\} \in E(H_m), g_j = \{a_\alpha, a_\alpha\} \in F_1$ for some $1 \leq \mu \leq \alpha'$, then by Rule 3, we have
\[ g_i < g_j = \{a_\mu, b_\mu\} < g_j. \]
Since $g_i, g_{j'} \in E(H_m)$, they can not form an induced $2K_2$ subgraph of $H_m$. Therefore, either $g_{j'}$ and $g_i$ have a vertex in common or there exist an edge $g_i \in E(H_m)$ such that $g_i < g_{j'}$ connecting $g_i$ and $g_{j'}$. If
$g_i$ and $g_j'$ have a vertex in common, then this contradicts the assumption that $\{g_i, g_j\}$ forms an induced 2-$K_2$-subgraph. Suppose $g_i$ is an edge connecting $g_i$ and $g_j'$. If $g_i = \{b, u\}$, then by Rule 2, we have

$$g_i < \{\{u, a_p\}\} < g_{j'} < g_j.$$  

This also contradicts the assumption that $\{g_i, g_j\}$ is an induced 2-$K_2$-subgraph. Similarly, if $g_i = \{v, b\}$ or $g_i = \{u, a\}$ or $g_i = \{u, a\}$, then one arrives at a contradiction.

If $g_j = \{b, b_p\} \in \mathcal{F}_2$ for some $1 \leq \mu \leq \beta'$, then we get a contradiction in a similar manner.

Suppose $g_j = \{\{a_p, b_p\}\} \in \mathcal{F}_3$ for some $1 \leq p \leq \alpha'$, $1 \leq q \leq \beta'$. By Rule 3, we have

$$g_i < g_{j'} = \{a, b\} < g_j.$$  

Since $g_i, g_{j'} \in E(H_m)$, they cannot form an induced 2-$K_2$-subgraph of $H_m$. Therefore, either $g_{j'}$ and $g_j$ have a vertex in common or there exist an edge $g_i \in E(H_m)$ such that $g_i < g_{j'}$ connecting $g_i$ and $g_{j'}$. Suppose $g_i$ and $g_{j'}$ have a vertex in common. If $u = a$, then by Rule 1 we have $g_i < \{\{v, b_p\}\} < g_{j'} < g_j$. This is a contradiction to $\{g_i, g_j\}$ forms an induced 2-$K_2$-subgraph. Similarly, if $u = b$ or $v = a$ or $v = b$, then one arrives at a contradiction. Suppose $g_i$ is an edge connecting $g_i$ and $g_{j'}$. If $g_i = \{u, a\}$, then by Rule 1, we have $g_i < \{\{u, b_p\}\} < g_{j'} < g_j$. This also contradicts the assumption that $\{g_i, g_j\}$ is an induced 2-$K_2$-subgraph. Similarly, if $g_i = \{v, b\}$ or $g_i = \{v, a\}$ or $g_i = \{u, b\}$, then one arrives at a contradiction.

If $g_i \in \mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3$ and $g_j \in E(H_m)$, then we get a contradiction in a similar manner.

**Case 4:** Suppose $g_i = \{\{a_p, b_p\}\} \in \mathcal{D}$ and $g_j = \{\{a_p, b_p'\}\} \in \mathcal{E}$, for some $1 \leq p \leq \alpha'$, $1 \leq q \leq \beta'$, $1 \leq p' \leq \alpha'$ and $1 \leq q' \leq \beta$. Then by Rule 1 and Rule 2, we have

$$g_{j'} = \{a, a_p\} < g_i < g_{j'} = \{b, b_p'\} < g_j.$$  

Since $g_{j'}, g_{j'} \in E(H_m)$, they can not form an induced 2-$K_2$-subgraph of $H_m$. Therefore, either $g_{j'}$ and $g_j$ have a vertex in common or there exist an edge $g_i \in E(H_m)$ such that $g_i < g_{j'}$ connecting $g_i$ and $g_{j'}$. If $g_i$ and $g_{j'}$ have a vertex in common, then this contradicts the assumption that $\{g_i, g_j\}$ forms an induced 2-$K_2$-subgraph. Suppose $g_i$ is an edge connecting $g_i$ and $g_{j'}$. If $g_i = \{a_p, b_p\}$, then this contradicts the assumption that $\{g_i, g_j\}$ forms an induced 2-$K_2$-subgraph. If $g_i = \{a_p, b\}$, then by Rule 2, we have $g_i < \{\{a_p, a_p\}\} < g_{j'} < g_j$. This also contradicts the assumption that $\{g_i, g_j\}$ is an induced 2-$K_2$-subgraph. Similarly, if $g_i = \{a, b_p\}$, then one arrives at a contradiction. If $g_i = \{a, b\}$, then by Rule 3, we have $g_i < \{\{a_p, b_p'\}\} < g_{j'} < g_j$. This also contradicts the assumption that $\{g_i, g_j\}$ is an induced 2-$K_2$-subgraph.

If $g_i = \{\{a_p, b_p\}\} \in \mathcal{E}$ and $g_j = \{\{a_p, b_p\}\} \in \mathcal{D}$ for some $1 \leq p' \leq \alpha'$, $1 \leq q' \leq \beta$, $1 \leq p \leq \alpha$ and $1 \leq q \leq \beta'$, then we get a contradiction in a similar manner.

**Case 5:** Suppose $g_i = \{\{a_p, b_p\}\} \in \mathcal{D}$, for some $1 \leq p \leq \alpha$ and $1 \leq q \leq \beta'$.

If $g_j = \{a, a_p\} \in \mathcal{F}_1$ for some $1 \leq p' \leq \alpha'$, then by Rule 1, we have $g_{j'} = \{a, a_p\} < g_i < g_j$. If $g_j = \{b, b_p'\} \in \mathcal{F}_2$ for some $1 \leq p' \leq \beta'$, then by Rule 1, we have $g_{j'} = \{a, a_p\} < \{\{a_p, b_p'\}\} < g_j$. Suppose $g_j = \{\{a_p, b_p\}\} \in \mathcal{F}_3$, for some $1 \leq p' \leq \alpha'$ and $1 \leq q' \leq \beta'$. By Rule 1, we have $g_{j'} = \{a, a_p\} < \{\{a_p, b_p'\}\} < g_j$. Therefore, we get a contradiction to $\{g_i, g_j\}$ forms an induced 2-$K_2$-subgraph for all cases.

If $g_i \in \mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3$ and $g_j = \{\{a_p, b_p\}\} \in \mathcal{D}$ for some $1 \leq p \leq \alpha$ and $1 \leq q \leq \beta'$, then we get a contradiction in a similar manner.

Similarly, if $g_i = \{\{a_p, b_p\}\} \in \mathcal{E}$ and $g_j = \{\{a_p, b_p\}\} \in \mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3$, for some $1 \leq p \leq \alpha'$ and $1 \leq q \leq \beta$, then one arrives at a contradiction. Also one can prove that, if $g_i = \{\{a, a_p\}\} \in \mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3$ and $g_j = \{\{a_p, b_p\}\}$, for some $1 \leq q \leq \beta$ and $1 \leq p \leq \alpha'$, then $\{g_i, g_j\}$ can not form an induced 2-$K_2$-subgraph.

Therefore, $H'_m$ is a co-chordal graph for all $1 \leq m \leq n$ and $E(P) = \bigcup_{i=1}^n E(H'_i)$. Hence co-chord$(P) \leq n$.  \[ \square \]

We now prove an upper bound for the regularity of $IJ$.

**Theorem 3.5.** Then

$$\text{reg}(IJ) \leq \max\{\text{co-chord}(G) + 3, \text{reg}(I)\}. \quad (3.1)$$
In particular,
\[ \text{reg}(IJ) \leq \max\{\text{co-chord}(G) + 3, \text{co-chord}(H) + 1\}. \]

**Proof.** Set \( I = (f_1, \ldots, f_t) \). It follows from set of short exact sequences:
\[
\begin{align*}
0 & \quad \rightarrow \quad \frac{R}{(IJ : f_i)} (-2) \quad \rightarrow \quad \frac{R}{IJ} \quad \rightarrow \quad 0; \\
\vdots & \quad \quad \quad \quad \quad \vdots \\
0 & \quad \rightarrow \quad \frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_i)} (-2) \quad \rightarrow \quad \frac{R}{(IJ, f_1, \ldots, f_{t-1})} \quad \rightarrow \quad R_{IJ} \quad \rightarrow \quad 0,
\end{align*}
\]
that
\[
\text{reg}\left(\frac{R}{IJ}\right) \leq \max\left\{ \text{reg}\left(\frac{R}{(IJ : f_i)}\right) + 2, \ldots, \text{reg}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_i)}\right) + 2, \text{reg}\left(\frac{R}{IJ}\right) \right\}.
\]

Note that ((\(IJ, f_1, \ldots, f_{t-1}) : f_i)) = (IJ : f_i) + (\text{variables}) for any \( 1 \leq i \leq t \).
\[
\text{reg}((IJ, f_1, \ldots, f_{t-1}) : f_i) \leq \text{reg}((IJ : f_i)) \quad \text{(by [18, Theorem 1.2])}
\]
\[
= \text{reg}((IJ : f_i)) \quad \text{(by Corollary 3.3)}
\]

Let \( P_i \) be the graph associated to \((\widetilde{IJ} : f_i)\). Therefore, by [23, Theorem 1] and Lemma 3.4,
\[
\text{reg}(\widetilde{IJ} : f_i) \leq \text{co-chord}(P_i) + 1 \leq \text{co-chord}(G) + 1.
\]
Hence \( \text{reg}(IJ) \leq \max\{\text{co-chord}(G) + 3, \text{reg}(I)\} \). Now the second assertion follows from [23, Theorem 1]. \( \square \)

As an immediate consequence, we have the following statements.

**Corollary 3.6.** Then \( \text{reg}(IJ) \leq m(G) + 3 \).

**Proof.** Since \( H \) is a subgraph of \( G \), \( m(H) \leq m(G) \). Hence the assertion follows from Theorem 3.5. \( \square \)

**Corollary 3.7.** If \( H \) is an induced subgraph of \( G \), then
\[
\nu(H) + 3 \leq \text{reg}(IJ) \leq \text{co-chord}(G) + 3.
\]

**Proof.** If \( H \) is an induced subgraph of \( G \), then \( \text{co-chord}(H) \leq \text{co-chord}(G) \) and \( \nu_{GH} = \nu(H) \). Therefore, by Theorem 3.2 and Theorem 3.5, \( \nu(H) + 3 \leq \text{reg}(IJ) \leq \text{co-chord}(G) + 3 \). \( \square \)

The following example shows that the inequality given in Corollary 3.6 is sharp.

**Example 3.8.** Let \( I = (x_2 x_3, x_4 x_5) \) and \( J = (x_1 x_2, x_1 x_3, x_1 x_4, x_1 x_5, x_2 x_3, x_2 x_4 x_5) \). It is not hard to verify that \( m(G) = 2 \) and \( \nu_{GH} = 2 \). Therefore, by Theorem 3.3 and Corollary 3.6, \( \text{reg}(IJ) = 5 \).

We now prove an upper bound for the regularity of product of edge ideals in terms of the regularity of the original graphs.

**Theorem 3.9.** Then \( \text{reg}(IJ) \leq \max\{\text{reg}(J) + 3, \text{reg}(I)\} \).

**Proof.** Setting \( I = (f_1, \ldots, f_t) \) and it follows from set of short exact sequences, similar to (3.2), that
\[
\text{reg}\left(\frac{R}{IJ}\right) \leq \max\left\{ \text{reg}\left(\frac{R}{IJ : f_i}\right) + 2, \ldots, \text{reg}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_i)}\right) + 2, \text{reg}\left(\frac{R}{IJ}\right) \right\}.
\]

Since ((\(IJ, f_1, \ldots, f_{t-1}) : f_i)) = (IJ : f_i) + (\text{variables}) for all \( 1 \leq i \leq t \), by [18, Theorem 1.2] and Corollary 3.2, \( \text{reg}((IJ, f_1, \ldots, f_{t-1}) : f_i) \leq \text{reg}((IJ : f_i)) \).

Let \( P_i \) be the graph associated to \((\widetilde{IJ} : f_i)\) which is contained in an appropriate polynomial ring \( R_1 \) for some \( 1 \leq i \leq t \). Set \( f_i = \{x_i, y_i\} \) and \( N_G(x_i) = \{\alpha_i, \ldots, \alpha_p, \beta_i, \ldots, \beta_q\} \), where \( \{x_i, \alpha_i\} \in E(H) \)
and \( \{x_i, \beta_{i'}\} \in E(G) \setminus E(H) \) for all \( 1 \leq j \leq p, 1 \leq j' \leq q \). It follows from set of short exact sequences, similar to \( \ref{3.12} \), that
\[
\text{reg}(R_1/P_i) \leq \max \left\{ \text{reg} \left( \frac{R_1}{P_i \alpha_{i1}} \right) + 1, \ldots, \text{reg} \left( \frac{R_1}{(P_i \alpha_{i1}, \ldots, \alpha_{ip}, \beta_{i1})} \right) + 1, \ldots, \right. \\
\left. \text{reg} \left( \frac{R_1}{(P_i \alpha_{i1}, \ldots, \alpha_{ip}, \beta_{i1}, \ldots, \beta_{i,q-1})} \right) + 1, \right. \\
\left. \text{reg} \left( \frac{R_1}{(P_i \alpha_{i1}, \ldots, \alpha_{ip}, \beta_{i1}, \ldots, \beta_{i,q})} \right) \right\}.
\]

By Theorem 3.2, \( P_i \setminus NP_i \) is an induced subgraph of \( G \). Therefore by \( \ref{10} \) Proposition 4.1.1, \( \text{reg}(P_i, \alpha_{i1}, \ldots, \alpha_{ip}, \beta_{i1}, \ldots, \beta_{i,q}) \leq \text{reg}(J) \).

It follows from Theorem 3.2 that every new edge in \( G \) is an edge from a neighbor of \( x_i \) in \( G \) to a neighbor of \( y_i \) in \( H \) and a neighbor of \( x_i \) in \( H \) to a neighbor of \( y_i \) in \( G \). Therefore \( P_i \setminus NP_i \) and \( P_i \setminus \{\alpha_{i1}, \ldots, \alpha_{ip}, \beta_{i1}, \ldots, \beta_{i,q}\} \) are induced subgraphs of \( G \) for any \( 1 \leq j \leq p, 1 \leq j' \leq q \). Hence by \( \ref{10} \) Proposition 4.1.1,
\[
\text{reg}(P_i : \alpha_{ij}) \leq \text{reg}(J) \text{ and } \text{reg}(P_i : \alpha_{i1}, \ldots, \alpha_{i,p}) : \beta_{ij} \leq \text{reg}(J).
\]
Since \( (P_i, \alpha_{i1}, \ldots, \alpha_{i,q-1}) : \alpha_{ij} \) and \( (P_i, \alpha_{i1}, \ldots, \alpha_{i,p}, \beta_{i1}, \ldots, \beta_{i,q-1}) : \beta_{ij} \) corresponds to an induced subgraph of \( (P_i : \alpha_{ij}) \) and \( (P_i : \alpha_{i1}, \ldots, \alpha_{i,p}) : \beta_{ij} \) respectively. Therefore \( \text{reg}(P_i) \leq \text{reg}(J) + 1 \).

Therefore,
\[
\text{reg}(IJ) \leq \max\{\text{reg}(J) + 3, \text{reg}(I)\}.
\]

We would like to note here that upper bounds given in Theorems 3.3 and 3.9 are incomparable in general, as we can see in the \( \ref{1.1} \).

The following example shows that the inequality given in Theorem 3.9 is sharp.

**Example 3.10.** Let \( G = C_{16} : x_1 \cdots x_{16} \) and \( H \) be a subgraph of \( G \) with
\[
E(H) = \left\{ \{x_1, x_2\}, \{x_3, x_4\}, \{x_5, x_6\}, \{x_7, x_8\}, \{x_9, x_{10}\}, \{x_{11}, x_{12}\}, \{x_{13}, x_{14}\}, \{x_{15}, x_{16}\} \right\}.
\]

Since \( H \) is the disjoint union of edges, \( \text{reg}(I) = 9 \). By \( \ref{10} \) Theorem 7.6.28, \( \text{reg}(J) = \nu(G) + 1 = 6 \). Therefore, by Theorem 3.9, \( \text{reg}(IJ) \leq 9 \). A computation in Macaulay2 \( \ref{13} \) shows that the \( \text{reg}(IJ) = 9 \).

A graph which is isomorphic to the graph with vertices \( a, b, c, d \) and edges \( \{a, b\}, \{b, c\}, \{a, c\}, \{a, d\}, \{b, d\} \) is called a diamond. A graph which is isomorphic to the graph with vertices \( w_1, w_2, w_3, w_4, w_5 \) and edges \( \{w_1, w_3\}, \{w_2, w_3\}, \{w_3, w_4\}, \{w_3, w_5\}, \{w_4, w_5\} \) is called a cricket.

As a consequence of Theorem 3.9 we obtain the following corollary.

**Corollary 3.11.** Let \( H \) be a subgraph of \( G \).

1. If \( G, H \in \{(\text{gap, cricket)}\)-free, \( (\text{gap, diamond})\)-free, \( (\text{gap, C}_4)\)-free\}, \text{ then } \text{reg}(IJ) \leq 6.
2. If \( G \) and \( H \) are \( (\text{gap, n-claw})\)-free, then \( \text{reg}(IJ) \leq n + 3 \).
3. Suppose \( G \) is a graph and \( H = C_k, k \geq 3 \) is a subgraph of \( G \). If \( V(H) \) is a vertex cover of \( G \), then \( \text{reg}(IJ) \leq \left\lceil \frac{k}{3} \right\rceil + 3 \).

**Proof.** The assertions (1) and (2) follows from \( \ref{11} \) Theorem 3.4 and Theorem 3.5, \( \ref{10} \) Theorem 3.5, \( \ref{11} \) Proposition 2.11 and Theorem 3.9.

(3) Let \( V(H) = \{x_1, \ldots, x_k\} \). If \( k \) is even, then \( \{x_1, x_2\}, \{x_3, x_4\}, \ldots, \{x_{k-1}, x_k\} \) are minimum size of maximal matching of \( G \). Therefore, by \( \ref{2.1} \), \( \text{co-chord}(G) \leq \left\lceil \frac{k}{2} \right\rceil \). If \( k \) is odd, then \( \{x_2, x_3\}, \{x_4, x_5\}, \ldots, \{x_{k-1}, x_k\} \) are matching of \( G \). Therefore, by \( \ref{2.1} \), \( \text{co-chord}(G) \leq \left\lceil \frac{k}{2} \right\rceil \). Note that for all \( 3 \leq k \leq 4 \), \( \text{co-chord}(C_k) + 1 = 2 \leq \left\lceil \frac{k}{2} \right\rceil + 3 \) and for all \( k \geq 5 \), \( \text{co-chord}(C_k) + 1 = \left\lceil \frac{k}{2} \right\rceil + 1 \leq \left\lceil \frac{k}{2} \right\rceil + 3 \). Therefore, by Theorem 3.3, \( \text{reg}(IJ) \leq \left\lceil \frac{k}{2} \right\rceil + 3 \). \( \square \)
4. Precise expression for the regularity of product of edge ideals

In this section, we apply Corollary 3.7 to obtain precise expressions for the regularity of product of two edge ideals of various classes of graphs.

**Corollary 4.1.** Let $H$ be an induced subgraph of $G$ with $\nu(H) = \nu(G)$. If $G$ is a

1. cycle with $3n$ vertices for all $n \geq 1$;
2. weakly chordal graph;
3. unmixed bipartite graph, or
4. bipartite graph with regularity $3$,

then $$\text{reg}(IJ) = \nu(G) + 3.$$ 

**Proof.** If $G$ is a cycle with $3n$ vertices, then $\nu(G) = \text{co-chord}(G)$. If $G$ is weakly chordal or unmixed bipartite or bipartite with regularity 3, then by [17, Remark 4.11 and Observation 5.3], $\nu(G) = \text{co-chord}(G)$. Therefore, by Corollary 3.7, $\text{reg}(IJ) = \nu(G) + 3$. \hfill $\square$

**Remark 4.2.** Let $G$ and $H$ be graphs with $I = I(H)$ and $J = I(G)$. If $H$ is an induced subgraph of $G$ with $\nu(G) = \nu(H)$, then by Corollary 3.7 and (2.1) we have

$$\nu(G) + 3 \leq \text{reg}(IJ) \leq \min\text{-match}(G) + 3.$$ 

A dominating induced matching of $L$ is an induced matching which also forms a maximal matching of $L$. If $L$ has a dominating induced matching, then $\nu(L) = \min\text{-match}(L)$. Hence for any graph $G$ with dominating induced matching and $H$ is any induced subgraph of $G$ with $\nu(G) = \nu(H)$, we have

$$\text{reg}(IJ) = \nu(G) + 3.$$ 

In [15] Proposition 2.1 and Theorem 2.3, Hibi et al. characterized graphs $G$ with dominating induced matchings and also satisfying $\nu(G) = \min\text{-match}(G)$.

As an application of our result Lemma 3.4, we compute the regularity of $IJ$ when $H$ has linear resolution.

**Theorem 4.3.** Suppose $J$ has linear resolution.

1. If $\text{reg}(I) \leq 4$, then $IJ$ has linear resolution.
2. If $5 \leq \text{reg}(I)$, then $\text{reg}(IJ) = \text{reg}(I)$.

**Proof.** Suppose $\text{reg}(I) \leq 4$. Since $G$ is a co-chordal graph, by [3.1], $4 \leq \text{reg}(IJ) \leq \max\{4, \text{reg}(I)\}$. Hence $\text{reg}(IJ) = 4$.

Suppose $\text{reg}(I) \geq 5$. By [3.1], we have $\text{reg}(IJ) \leq \max\{4, \text{reg}(I)\} \leq \text{reg}(I)$. Since $4 \leq \text{reg}(R/I)$, there exist $i, j$ such that $j - i \geq 4$ and $\beta_{i,j}(R/I) \neq 0$, where $\beta_{i,j}(-)$ denotes the $(i,j)$-th graded Betti number of $-$. From Equation (3.2), either $\beta_{i,j}\left(\frac{R}{(IJ, f_1, \ldots, f_{t-1})}\right) \neq 0$ or $\beta_{i-1,j}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_t)}(-2)\right) \neq 0$.

Note that $((IJ, f_1, \ldots, f_{t-1}) : f_t) = (IJ : f_t) + (\text{variables})$. Let $P$ be the graph associated to $(IJ : f_t)$. Since $G$ is a co-chordal graph, by Lemma 4.3 $\text{reg}(I(P)) = 2$. If $\beta_{i-1,j-2}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_t)}\right) \neq 0$, then $\text{reg}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_t)}\right) \geq j - 1 - i \geq 4 - 1 = 3$. This is a contradiction to $\text{reg}\left(\frac{R}{((IJ, f_1, \ldots, f_{t-1}) : f_t)}\right) \leq 1$.

Therefore, $\beta_{i,j}\left(\frac{R}{(IJ, f_1, \ldots, f_{t-1})}\right) \neq 0$. Then again either

$$\beta_{i,j}\left(\frac{R}{(IJ, f_1, \ldots, f_{t-2})}\right) \neq 0 \text{ or } \beta_{i-1,j}\left(\frac{R}{((IJ, f_1, \ldots, f_t) : f_t)}(-2)\right) \neq 0.$$
As in the previous case, we get \( \beta_{i,j} \left( \frac{R}{(IJ, f_1, \ldots, f_{i-2})} \right) \neq 0 \). Then one proceeds in the same manner.

At each stage, we get either
\[
\beta_{i,j} \left( \frac{R}{(IJ, f_1, \ldots, f_{i-1})} \right) \neq 0 \quad \text{or} \quad \beta_{i-1,j} \left( \frac{R}{((IJ, f_1, \ldots, f_{i-1}) : f_j)} (-2) \right) \neq 0 \quad \text{for all } l.
\]

Therefore, \( \beta_{i,j} \left( \frac{R}{IJ} \right) \neq 0 \). Hence \( \text{reg}(R/I) \leq \text{reg}(R/IJ) \). \( \Box \)

**Remark 4.4.** Suppose \( H \) is any graph and \( V(H) = \{ x_1, \ldots, x_n \} \). If \( G \) is a complete graph and \( V(H) \subseteq V(G) \), then \( H \) is a subgraph of \( G \). By [12, Theorem 1], \( J \) has linear resolution. Therefore, by Theorem 4.3, \( IJ \) has linear resolution when \( \text{reg}(I) \leq 4 \).

**Corollary 4.5.** Suppose \( J \) has linear resolution. Then \( IJ \) has linear resolution if

1. \( \text{co-chord}(H) \leq 3 \);
2. \( H \) is (gap, cricket)-free or (gap, diamond)-free or (gap, \( C_4 \))-free or
3. \( H \) is a graph such that \( H^c \) has no triangle;

**Proof.** By [23, Theorem 1], [1, Theorem 3.4], [10, Theorem 3.5], [11, Proposition 2.11] and [20, Theorem 2.10], \( \text{reg}(I) \leq 4 \). Therefore, by Theorem 4.3, \( IJ \) has linear resolution. \( \Box \)

So far, we have been discussing about the regularity of product of two edge ideals. Now we study the regularity of product of more than two edge ideals.

**Theorem 4.6.** Let \( J_1, \ldots, J_d \) be edge ideals and \( J_1 \subseteq J_2 \subseteq \cdots \subseteq J_d, d \in \{3,4\} \). Suppose \( J_d \) is the edge ideal of complete graph.

1. If \( \text{reg}(J_1 \cdots J_{d-1}) \leq 2d \), then \( J_1 \cdots J_d \) has linear resolution.
2. If \( \text{reg}(J_1 \cdots J_{d-1}) \geq 2d + 1 \), then \( \text{reg}(J_1 \cdots J_d) = \text{reg}(J_1 \cdots J_{d-1}) \).

**Proof.** Set \( \mathcal{J} := J_1 \cdot \cdots \cdot J_d \) and \( J_1 \cdots J_{d-1} = (\mathcal{F}_1, \ldots, \mathcal{F}_i) \). Now we claim that, if \( (\mathcal{F}_j : \mathcal{F}_i) = (u^s) \) for some \( s \geq 3 \) and \( j \neq i \), then \( u^s \in (\mathcal{J} : \mathcal{F}_i) \). Clearly \( d > 3 \). Set \( \mathcal{F}_j = g_1g_2g_3 \) and \( \mathcal{F}_i = f_1f_2f_3 \), where \( g_k, f_k \in J_i \) for all \( 1 \leq i \leq 3 \). Since \( s \geq 3 \), we have \( u \mid g_i \) and \( u \nmid f_i \) for all \( 1 \leq i \leq 3 \). Let \( g_1 = ua, g_2 = ub, g_3 = uc, f_1 = x_1x_2, f_2 = x_3x_4 \) and \( f_3 = x_5x_6 \) (\( x_i \) may be equal to \( x_j \), for some \( 1 \leq i, j \leq 5 \)). Note that \( abc \mid f_1f_2f_3 \). If \( ab \mid f_i \) and \( c \mid f_j \), for some \( 1 \leq i, j \leq 3 \), then \( uabf_jf_k \in \mathcal{J} \), where \( k \neq i, j \). If \( a \mid f_i, b \mid f_j, c \mid f_k \) for some \( 1 \leq i, j, k \leq 3 \), then \( uabf_k(f_i/f_j) \in \mathcal{J} \). Therefore \( u^s \in (\mathcal{J} : \mathcal{F}_i) \). Hence the claim.

Let \( m \in \mathcal{G}(\mathcal{J} : \mathcal{F}_i) \). By degree consideration \( m \) can not have degree \( 1 \). We now claim that \( \text{deg}(m) = 2 \).

Suppose \( |\text{supp}(m)| \geq 2 \). Since \( J_d \) is a edge ideal of complete graph, \( \text{deg}(m) = 2 \). Suppose \( |\text{supp}(m)| = 1 \).
Assume that \( \text{deg}(m) \geq 3 \). Set \( m = u^s \) for some \( s \geq 3 \). Clearly \( n_1 \cdots n_d = u^s \mathcal{F}_i \), where \( n_i \in \mathcal{G}(J_i) \) for all \( 1 \leq i \leq d \). Then \( n_1 \cdots n_{d-1} \mid u^s \mathcal{F}_i \). Also, \( u^s \in (n_1 \cdots n_{d-1} : \mathcal{F}_i) \).

By above claim, \( u^s \in (\mathcal{J} : \mathcal{F}_i) \). This is contradiction to \( \text{deg}(m) \geq 3 \). Therefore \( \text{deg}(m) = 2 \).

By the above arguments, one can see that the ideal \( (\mathcal{J}, \mathcal{F}_1, \ldots, \mathcal{F}_{i-1}) : \mathcal{F}_i \) is generated by quadratic monomial ideals. Note that \( J_d \subseteq (\mathcal{J}, \mathcal{F}_1, \ldots, \mathcal{F}_{i-1}) : \mathcal{F}_i \). Since \( J_d \) is the edge ideal of complete graph, \( K_i \) is the graph obtained from complete graph by attaching pendant to some vertices. Hence \( K_i \) is a co-chordal graph. By [12, Theorem 1], \( \text{reg}((\mathcal{J}, \mathcal{F}_1, \ldots, \mathcal{F}_{i-1}) : \mathcal{F}_i)) = 2 \) for all \( 1 \leq i \leq t \).

Consider the similar exact sequences as in [3,2], we get
\[
\text{reg} \left( \frac{R}{IJ} \right) \leq \max \left\{ \text{reg} \left( \frac{R}{(IJ, f_1, \ldots, f_i)} \right) + 2(d - 1), \ldots, \text{reg} \left( \frac{R}{(IJ, f_1, \ldots, f_{i-1}) : f_i} \right) + 2(d - 1), \text{reg} \left( \frac{R}{(IJ, f_1, \ldots, f_{i-1})} \right) \right\}.
\]

Proceeding as in the proof of Theorem 4.3 we will get the desired conclusion. \( \Box \)
