Abstract. We describe certain moduli spaces of Bridgeland-stable objects on the Kuznetsov component of Fano threefolds of index 2 and Picard rank 1, via the stability conditions constructed in [BLMS17]. Furthermore, we study the behavior of the Abel–Jacobi map on these moduli. As an application in the case of degree $d = 2$, we prove a strengthening of the categorical Torelli Theorem from [BT16].

1. Introduction

It is a well-established principle that the bounded derived category $D(Y)$ of a smooth projective variety contains rich information about the geometry of $Y$. One technique to extract this information is the study of semi-orthogonal decompositions of $D(Y)$

$$D(Y) = \langle A_1, ..., A_n \rangle$$

where $A_i$ are full triangulated subcategories satisfying semi-orthogonality conditions. It is often the case that all but one $A_i$ are equivalent to the derived category of a point, while the remaining one is non-trivial and carries information about $Y$. This strategy is particularly fruitful if $Y$ is a smooth Fano threefold of Picard rank 1 and index 2. These have been classified by Mori and Iskovskih (see [IP99]) and belong to one of the following 5 families, indexed by the degree $d := H_3 \in \{1, ..., 5\}$ (here $H$ denotes the ample generator of $\text{Pic}(Y) \simeq \mathbb{Z}$):

- $Y_5 = \text{Gr}(2, 5) \cap \mathbb{P}^6 \subset \mathbb{P}^9$ is a linear section of codimension 3 of the Grassmannian $\text{Gr}(2, 5)$ in the Plücker embedding;
- $Y_4 = Q_1 \cap Q_2 \subset \mathbb{P}^5$ is the intersection of two quadric hypersurfaces;
- $Y_3 \subset \mathbb{P}^4$ is a cubic hypersurface;
- $Y_2 \xrightarrow{\pi} \mathbb{P}^3$ is a double cover ramified over a quartic surface, or equivalently a hypersurface of degree 4 in the weighted projective space $\mathbb{P}(1, 1, 1, 1, 2)$;
- $Y_1$ is a hypersurface of degree 6 in the weighted projective space $\mathbb{P}(1, 1, 1, 2, 3)$.

If $Y$ is one of the above, Kuznetsov shows in a series of papers that the derived category of $Y$ admits a semi-orthogonal decomposition

$$D(Y) = \langle \mathcal{K}u(Y), \mathcal{O}_Y, \mathcal{O}_Y(1) \rangle$$

whose non-trivial part $\mathcal{K}u(Y)$ captures a great deal of the geometry of $Y$ [Kuz08, Kuz14]. The Grothendieck group $K(\mathcal{K}u(Y))$ is a rank 2 lattice spanned by the classes

$$v := 1 - \frac{1}{d} H^2 \quad \text{and} \quad w := H - \frac{1}{2} H^2 + \left( \frac{1}{6} - \frac{1}{d} \right) H^3$$

with intersection form given by

$$\begin{bmatrix} -1 & -1 \\ 1 - d & -d \end{bmatrix}.$$
Remark 1.1. In some cases, the nontrivial component $K_u(Y)$ can be explicitly described:

\( (d = 5) \) The restriction $U_2$ and $U_3$ of tautological bundles on $Gr(2, 5)$ of rank 2 and 3 to $Y$ are exceptional, and they generate $K_u(Y)$. Since $\text{hom}(U_2, U_3) = 3$, then $K_u(Y)$ is equivalent to a category of representations of a Kronecker quiver with two vertices and 3 arrows [Orl91].

\( (d = 4) \) The moduli space of spinor bundles on $Y$ is a genus 2 hyperelliptic curve $C$, and $K_u(Y)$ is equivalent to the bounded derived category $D(C)$ [BO95].

\( (d = 3) \) The category $K_u(Y)$ is orthogonal to an exceptional object in the derived category of certain twisted sheaves on $\mathbb{P}^2$ [BMMS12].

\( (d = 2) \) The category $K_u(Y)$ is an Enriques category [KP17].

\( (d = 1) \) In this case, we are unaware of any nice description of $K_u(Y)$.

In [BLMS17] the authors construct a Bridgeland stability condition on $K_u(Y)$. This allows the formulation of moduli problems in $K_u(Y)$: the purpose of this work is to investigate certain moduli spaces of Bridgeland-stable objects of $K_u(Y)$; in particular, we focus on objects of class $w$.

Summary of the results. Let $Y$ be a smooth Fano threefold of Picard rank 1 and index 2 of fixed degree $d$. As in [BLMS17], there is a weak stability condition $\sigma_{u, \beta}^0 = (\text{Coh}(X), Z_{u, \beta})$ on $D(Y)$, which induces a stability condition $\sigma$ on $K_u(Y)$. Let $M_{\sigma}(w)$ denote the moduli spaces of $\sigma$-semistable objects in $K_u(Y)$ of class $w$.

Our first result is a description of $M_{\sigma}(w)$:

Theorem 1.2. The moduli space $M_{\sigma}(w)$ is projective for all $d$. There is a subvariety $Y \subset M_{\sigma}(w)$ isomorphic to $Y$ parametrizing objects $E_p$ fitting in a distinguished triangle

\[ (1) \quad \mathcal{O}(-1)[1] \to E_p \to \mathcal{I}_p, \]

for $p$ a point in $Y$. The complement $M_{\sigma}(w) \setminus Y$ has dimension $d + 1$ and its general object is a sheaf $\mathcal{I}_s(\mathcal{O}_S(\ell_1 - \ell_2))$, where $\iota : S \hookrightarrow Y$ is a hyperplane section containing distinct lines $\ell_1, \ell_2$.

This theorem is proven in Section 2 by comparing $M_{\sigma}(w)$ with $M_{G}(w)$, the moduli space of Gieseker-semistable sheaves on $Y$ with respect to the polarization $H$. In fact, the general Gieseker-semistable sheaf on $Y$ is either the ideal sheaf $\mathcal{I}_{p/S}$ of a point of $Y$ restricted to a hyperplane section $S$, or one of the $\mathcal{I}_s(\mathcal{O}_S(\ell_1 - \ell_2))$ (Proposition 2.3). Then, we show that $M_{\sigma}(w)$ is isomorphic to the space $M^{tilt}(w)$ of tilt-semistable objects in $D(Y)$ of class $w$ (Proposition 2.10), which is related to $M_{G}(w)$ via wall-crossing. The proof shows how wall-crossing replaces objects $\mathcal{I}_{p/S}$, fitting in a triangle

\[ \mathcal{I}_p \to \mathcal{I}_{p/S} \to \mathcal{O}_Y(-1)[1], \]

with extensions of the form (1) (Proposition 2.9).

For a more detailed study of $M_{\sigma}(w)$, we then consider the Abel–Jacobi map

\[ \Phi : \mathbb{Z}_\hom^2(Y) \to J(Y) \]

from the space of codimension-2 cycles to the intermediate Jacobian $J(Y)$ of $Y$, and extend it to a map

\[ \Psi : M_{\sigma}(w) \to J(Y) \quad F \quad \Phi(c_2(F)). \]

In Section 3 we assume that $Y$ has degree 2, i.e. $Y$ is a double solid ramified over a quartic surface $R$. Then, we have:
Theorem 1.3. Suppose $d = 2$. The space $\mathcal{M}_\sigma(w)$ on $\mathcal{K}u(Y)$ is projective of pure dimension 3, and it has two irreducible components $\mathcal{Y}$ and $C$. The component $\mathcal{Y}$ is isomorphic to $Y$, and intersects $C$ exactly at the ramification locus $R$; moreover, $C$ is smooth outside of $R$.

The map $\Psi: \mathcal{M} \to J(Y)$ contracts the component $\mathcal{Y}$ to a singular point $y$ of the Theta divisor and is a generic embedding on $C$.

As an application, we prove a (refined) categorical Torelli theorem:

Theorem 1.4. Let $Y$ and $Y'$ be two Fano threefolds of index 2 with Picard rank 1 and degree 2 such that there exists an equivalence $u: \mathcal{K}u(Y') \cong \mathcal{K}u(Y)$. Then $Y' \simeq Y$.

This theorem improves a result of Bernardara and Tabuada [BT16, Cor. 3.1 (iii)] who show that the same holds under the additional assumption that $u$ be of Fourier–Mukai type. Our technique of proof is inspired by that of [BMMS12]; we use the equivalence to construct an isomorphism between moduli spaces and argue that this is sufficient to conclude.

In Section 4, we consider $Y = Y_1$. The analogue of Theorem 1.3 is proven in a similar way:

Theorem 1.5. Suppose $d = 1$. The space $\mathcal{M}_\sigma(w)$ is projective and it has two irreducible components $\mathcal{Y}$ and $\mathcal{F}$, respectively of dimension 3 and 2. The component $\mathcal{Y}$ is isomorphic to $Y$, and intersects $\mathcal{F}$ exactly at the special curve $C \subset Y$. Moreover, there is an isomorphism between $\mathcal{F}$ and $F(Y)$, the Fano scheme of lines on $Y$, so that in particular $\mathcal{F}$ is smooth outside of $C$.

The Abel–Jacobi map $\Psi: \mathcal{M}_\sigma(w) \to J(Y)$ contracts $Y$ to a singular point $y$ in the Theta divisor and it is an embedding elsewhere. Moreover, the image $\Psi(\mathcal{M})$ determines $Y$ uniquely.

Further problems. There are some natural questions which remain unanswered by this work.

(i) (Torelli theorem for $d = 1$) It is expected that an analogue of Theorem 1.4 holds in degree 1 as well, but some technical issues prevent us from applying the same proof technique;

(ii) (Equivalences of Fourier–Mukai type) A conjecture of Kuznetsov [Kuz07, Conj. 3.7] implies, in the case of quartic double solids, that every equivalence $u: \mathcal{K}u(Y') \cong \mathcal{K}u(Y)$ is of Fourier–Mukai type (i.e. that the composition $D(Y') \to \mathcal{K}u(Y') \to \mathcal{K}u(Y) \to D(Y)$ is a Fourier–Mukai functor). Combining Theorem 1.4 with [BT16, Prop. 3.5] shows that $\mathcal{K}u(Y')$ and $\mathcal{K}u(Y)$ are equivalent if and only if they are Fourier–Mukai equivalent, but at the moment we are unable to prove the statement of [Kuz07, Conj. 3.7] for degree 2.

Acknowledgements. We are grateful to our doctoral advisor, Aaron Bertram, for his guidance and his enthusiasm. We wish to thank Arend Bayer for encouraging us in pursuing this problem. We also thank Paolo Stellari and Huachen Chen, for discussing this problem with us on various occasions. This project benefited from the participation of the second and third author to the workshop "Semiorthogonal decompositions, stability conditions and sheaves of categories" held in Toulouse in 2018 and of the first and third author to the workshop on "Derived Categories, Moduli Spaces and Deformation Theory" held in Cetraro in 2019. We thank the organizers and the participants of these events.

2. Construction of the moduli spaces

2.1. Stability and wall-crossing. Consider the set of stability conditions on $\mathcal{K}u(Y)$ induced by the weak stability conditions $\sigma_{\alpha, \beta} = (\text{Coh}_{\alpha, \beta}^0(Y), Z_{\alpha, \beta}^0)$ on $D(Y)$ for $\beta = -\frac{1}{2}$ and $0 < \alpha \ll 1$ (see Appendix A and [BLMS17]); here $\text{Coh}_{\alpha, \beta}^0(Y)$ is the usual double tilt, and

$$Z_{\alpha, \beta}^0(E) = \text{ch}_1^\beta(E) + i \left( \text{ch}_2^\beta(E) - \frac{\alpha^2}{2} \text{ch}_0(E) \right).$$

Remark 2.1. Notice that with this choice of stability condition, if an object has class $w$ and an appropriate shift of it belongs to the heart, then the object will automatically be stable. Indeed, such an object will have maximal phase so it will be semistable by definition; moreover, the class $w$ is primitive in $\mathcal{K}u(Y)$, so that there are no strictly semistable object of that class.
We are now interested in studying the moduli space $\mathcal{M}_\sigma(w)$ of objects of class $w$ in $Ku(Y)$ which are semistable with respect to one of the stability conditions $\sigma$ constructed above. To do that, we relate stability in $Ku(Y)$ with tilt-stability in $D(Y)$.

**Lemma 2.2.** Let $E \in Ku(Y)$ of class $w$: then $E$ is stable with respect to $\sigma = \sigma_0^{\alpha,-\frac{1}{2}}$ on $Ku(Y)$ if and only if $E$ is semistable with respect to the weak stability condition $\sigma_0^{\alpha,-\frac{1}{2}}$ on $D(Y)$.

**Proof.** Up to a shift, $E \in Ku(Y)$ stable implies that $E \in A = \text{Coh}^{0}_{\alpha,-\frac{1}{2}}(Y) \cap Ku(Y)$, so in particular $E \in \text{Coh}^{0}_{\alpha,-\frac{1}{2}}(Y)$; since $E$ is in the heart of a (weak) stability condition and it has maximal phase, by definition $E$ must be semistable.

Conversely, if $E \in Ku(Y)$ is semistable in $\text{Coh}^{0}_{\alpha,-\frac{1}{2}}(Y)$ then in particular $E$ belongs to the heart $A$, hence it is stable by the above Remark 2.1. \hfill $\square$

Now notice that $\sigma_0^{\alpha,-\frac{1}{2}}$ is just a rotation of the usual tilt stability $\sigma_{\alpha,-\frac{1}{2}}$, so stability of objects of a fixed class is not affected (cfr Definition A.5).

Therefore, the above Lemma 2.2 tells us that the moduli space $\mathcal{M}_\sigma(w)$ is contained in the moduli space $\mathcal{M}^{\text{tilt}}(w)$ of tilt-semistable objects of class $w$ with respect to $\sigma_{\alpha,-\frac{1}{2}}$ with $0 < \alpha < 1$ on $D(Y)$.

To understand $\mathcal{M}^{\text{tilt}}(w)$ and how $\mathcal{M}_\sigma(w)$ sits inside it, we start from a description of the Gieseker moduli (Proposition 2.3), then we perform wall-crossing and describe $\mathcal{M}^{\text{tilt}}(w)$ (Proposition 2.9) and we compare it to $\mathcal{M}_\sigma(w)$ in Proposition 2.10.

**Proposition 2.3.** The moduli $\mathcal{M}_G(w)$ of Gieseker semistable objects of class $w$ on $Y$ contains a distinguished component $\mathcal{P}_d$ of dimension $d + 3$, given by ideal sheaves $\mathcal{I}_{p/S}$ of a point in a (possibly singular) hyperplane section $S$; this component intersects the rest of the moduli exactly in those points for which $S$ is singular at $p$.

Moreover, $\mathcal{M}_G(w) \setminus \mathcal{P}_d$ has dimension $d + 1$, and the general element in $\mathcal{M}_G(w) \setminus \mathcal{P}_d$ is an object of the form $\iota_*(\mathcal{O}_S(\ell_1 - \ell_2))$ for $S$ a smooth hyperplane section.

**Proof.** Since the class $w$ is torsion, a Gieseker stable sheaf $E$ of class $w$ must be pure; this implies that $E = \iota_*(F)$ for some sheaf $F$ supported on a hyperplane section $\iota: S \to Y$, otherwise the kernel of the map $E \to \iota_*\iota^*E$ would give a destabilizing subsheaf of smaller dimension.

Stability of $E$ implies that $F$ is a torsion-free rank-one stable sheaf on $S$. Then, $F$ must have the form $F = \mathcal{I}_Z \otimes L$, with $Z$ a zero-dimensional subscheme and $L = \mathcal{O}_S(D)$ a reflexive sheaf of rank 1 associated to a Weil divisor $D$ (see for example [HL10]).

Additionally, by applying the Grothendieck-Riemann-Roch theorem, one sees that if $E = \iota_*(F)$ has class $w$, then $[F] = (1, D, -1)$, with $D.H = 0$.

If $D = 0$, one must have $F = \mathcal{I}_{p/S}$ with $S$ a possibly singular hyperplane section; the moduli space of such objects is a projective bundle over $Y$ with fiber $\mathbb{P}^d \simeq \mathbb{P}(H^0(\mathcal{O}_p(1) \otimes \mathcal{I}_p))$; here $\mathbb{P}$ denotes the ambient space, which is a $d+1$-dimensional straight projective space for $d = 3, 4, 5$ and a weighted projective space for $d = 1, 2$.

By Lemma 2.4 below, $\text{Ext}^1(\mathcal{I}_{p/S}; \mathcal{I}_{p/S}) = \mathbb{C}^{d+3}$ if $S$ is not singular at $p$, meaning that the $\mathbb{P}^d$-bundle over $Y$ that we just constructed is an entire irreducible component, which we denote $\mathcal{P}_d$. Lemma 2.5 shows that the dimension of the tangent space jumps exactly when $S$ is singular at $p$, meaning that $\mathcal{P}_d$ intersects other components of the moduli in that locus. For the case $D \neq 0$, instead, we can give a precise description of our objects only when $S$ is general (hence smooth). First of all, when $S$ is smooth $L$ is actually a line bundle, so that $[F] = \left(1, D, \frac{D^2}{2} - z\right)$ where $z \in \mathbb{N}$ is the length of $Z$; moreover, since $S$ is a del Pezzo surface of degree $d$ there are no numerically trivial divisors in $\text{NS}(S)$, hence by Hodge Index Theorem we must have $D^2 < 0$, which implies $D^2 = -2$ and $z = 0$. We then get $E = \iota_*(\mathcal{O}_S(D))$ with $D$ having the above properties, and the dimension of $\mathcal{M}_G(w) \setminus \mathcal{P}_d$ is $d + 1$ by Lemma
The map in the top row is an isomorphism. The last statement can be checked using the correspondence of divisors of that form with the roots of certain lattices \( (A_4, D_5, E_6, E_7, \text{ and } E_8, \text{ for } d = 5, 4, 3, 2, 1 \text{ respectively}) \) and the description of lines in del Pezzo surfaces (see for example [Dol12]).

Lemma 2.4. Let \( S \subset Y_d \) be a hyperplane section, and let \( p \) a smooth point of \( S \). Then we have \( \text{Ext}^1(I_{p/S}, I_{p/S}) = \mathbb{C}^{d+3} \).

Proof. Since \( I_{p/S} = [\mathcal{O}_S \to \mathbb{C}_p] \), then \( R \text{Hom}(I_{p/S}, I_{p/S}) \) is the totalization of a double complex \( K^{•,•} \) isomorphic to 

\[
R \text{Hom}(\mathbb{C}_p, \mathcal{O}_S) \to R \text{Hom}(\mathcal{O}_S, \mathcal{O}_S) \oplus R \text{Hom}(\mathbb{C}_p, \mathbb{C}_p) \to R \text{Hom}(\mathcal{O}_S, \mathbb{C}_p),
\]

so we may compute \( \text{Ext}^1(I_{p/S}, I_{p/S}) \) using a spectral sequence 

\[
E_1^{p,q} = H^q(K^{•,p}) \Rightarrow H^{p+q}(K^{•,•}).
\]

Then page \( E_1 \) is

\[
\begin{array}{c|cc}
 & 1 & 0 \\
1 & 3 & 0 \\
0 & d+4 & 1 \\
0 & 2 & 1 \\
\end{array}
\]

The map in the top row is an isomorphism \( \text{Ext}^2(\mathbb{C}_p, \mathcal{O}_S) \to \text{Ext}^3(\mathbb{C}_p, \mathbb{C}_p) \). The map in the second row is \( \text{Ext}^2(\mathbb{C}_p, \mathcal{O}_S) \to \text{Ext}^2(\mathbb{C}_p, \mathbb{C}_p) \), and the map in the third row is \( \text{Ext}^1(\mathbb{C}_p, \mathbb{C}_p) \to \text{Ext}^1(\mathcal{O}_S, \mathbb{C}_p) \). If \( p \) is smooth in \( S \) these are both non-zero, and if \( p \) is singular, they are both 0. The map in the bottom row is surjective because \( \text{Hom}(\mathcal{O}_S, \mathcal{O}_S) \to \text{Hom}(\mathcal{O}_S, \mathbb{C}_p) \) is.

Lemma 2.5. If \( p \in S \) is singular, then \( \text{Ext}^1(I_{p/S}, I_{p/S}) = \mathbb{C}^{d+4} \).

Proof. From the above proof we can conclude that this group is either \( \mathbb{C}^{d+4} \) or \( \mathbb{C}^{d+5} \). Using the same spectral sequence as before, only this time starting with the short exact sequence 

\[
\mathcal{O}_Y(-1) \to I_p \to I_{p/S}
\]

it is not hard to see that it cannot be \( \mathbb{C}^{d+5} \).

Lemma 2.6. Suppose that \( E = \iota_∗F \), where \( F = \mathcal{O}_S(D) \) is a line bundle on a smooth hyperplane section \( \iota : S \to Y \). Then

\[
R^i \text{Hom}(E, E) = \begin{cases} 
\iota_∗\mathcal{O}_S, \text{ if } i = 0 \\
\iota_∗\mathcal{O}_S(1) \text{ if } i = 1 \\
0 \text{ otherwise.}
\end{cases}
\]

Therefore \( \text{Ext}^1(E, E) = \mathbb{C}^{d+1} \), and \( \text{Ext}^2(E, E) = \text{Ext}^3(E, E) = 0 \).

Proof. By Grothendieck-Verdier duality, we have

\[
\iota_∗R\text{Hom}_S(F, L\iota^∗(E) \otimes \mathcal{O}_S(1)[-1]) \simeq R\text{Hom}_Y(E, E).
\]

We first compute \( L\iota^∗E \). Since \( \iota^∗ = \iota^{-1}(\_ \otimes^L \mathcal{O}_S) \), we can compute \( E \otimes^L \mathcal{O}_S \) by tensoring the short exact sequence 

\[
\mathcal{O}_Y(-1) \to \mathcal{O}_Y \to \mathcal{O}_S
\]

with \( E \). This gives that \( L^0\iota^∗E = F \) and \( L^1\iota^∗E = F(-1) \). Since \( F \) is a line bundle, we have \( \text{Hom}(F, F) = \mathcal{O}_S \), so the statement follows from the spectral sequence for the left hand side in (2).

We have seen that the Gieseker moduli space has at least two components that intersect. Here is a constructive proof of this for a generic point in the intersection; we’ll use a refinement of this argument later.
and since \( O \) zero-dimensional subscheme \( Z \) duality with \( F \) one has that \( F \) fibers are \( S \) Here the vertical map is induced by the dual of the relative dualizing sheaf of \( M. \) ALTAVILLA, M. PETKOVIC, AND F. ROTA

Proof. By the Large Volume Limit, the moduli of tilt-(semi)stable objects of class \( w \) given by objects as in 1, while the general object in the complement is of the form \( I_{\ell} \) for a general smooth \( S \).

Proposition 2.9. The moduli space \( \mathcal{M}^{\text{tilt}}(w) \) of tilt-semistable objects of class \( w \) with respect to \( \sigma_{\alpha, -1} \) for \( 0 < \alpha \ll 1 \) is obtained from \( \mathcal{M}_G(w) \) by contracting the \( \mathbb{P}^d \)-bundle in \( \mathcal{P}_d \) to its base, while the rest of the moduli is unaffected. The wall crossing then produces a locus \( Y \subset \mathcal{M}^{\text{tilt}}(w) \) isomorphic to \( Y \) given by objects as in 1, while the general object in the complement is of the form \( I_{\ell}(O_S(\ell_1 - \ell_2)) \) for a general smooth \( S \).

Proof. By the Large Volume Limit, the moduli of tilt-(semi)stable objects of class \( w \) for \( \alpha \gg 0 \) coincides with \( \mathcal{M}_G(w) \), described in Proposition 2.3. Since \( w \) is a torsion class, the walls in

Example 2.7 (\( \mathcal{T}_{p/S} \) as a limit of \( \iota_*(\mathcal{O}_S(D)) \)'s). Let \( f : Y = Y_d \to \mathbb{P}^d \) be the map induced by \( -K_Y/2 \) (assume \( d \geq 2 \)). Denote with \( S \) the universal hyperplane section. Let \( h_0 \in \mathbb{P}^{d+1} \) cut out a hyperplane section \( S_0 \subset Y \) that is singular at \( p \). Assume that \( p \) is an isolated \( A1 \) singularity, and \( S_0 \) has no other singularities. Let \( \Delta \subset \mathbb{P}^{d+1} \) \( F \) be a 1-dimensional open disk containing \( h_0 \). For \( h_t \in \Delta \), let \( S_t \subset Y \) be the corresponding hyperplane section, and \( f_t : S_t \to \mathbb{P}^d \) the restriction of \( f \) to \( S_t \).

Del Pezzo surfaces with isolated singularities all arise by specializing the \( 9 - d \) points in \( \mathbb{P}^2 \). Therefore the family of surfaces \( S_t \) can be reconstructed by blowing up \( 9 - d \) sections \( s_i \) of the projection \( p : \Delta \times \mathbb{P}^2 \to \Delta \). The sections \( s_i \) are in general position for \( t \neq 0 \), and \( s_1, s_2, s_3 \) become collinear over \( t = 0 \). Denote the blowup with \( g : S' \to \Delta \times \mathbb{P}^2 \). The map induced by the dual of the relative dualizing sheaf \( \omega_{\text{pog}} \) factors through the universal hyperplane section restricted to \( \Delta \):

\[
\begin{array}{ccc}
S' & \xrightarrow{-\omega_{\text{pog}}} & \Delta \times \mathbb{P}^d \\
\downarrow & & \downarrow \\
S_\Delta & \xrightarrow{\cdot} & \Delta \\
\end{array}
\]

Here the vertical map is induced by the dual of the relative dualizing sheaf of \( S_\Delta \to \Delta \). Its fibers are \( f_t : S_t \to \mathbb{P}^d \).

Let \( E_i \) be the exceptional divisors of \( g \). Define \( D = -g^*(\mathcal{O}_{\mathbb{P}^2}(1)) + E_1 + E_2 + E_3 \). Then the fiber of \( D \) over \( t \neq 0 \) is a Cartier divisor \( D_t \) of degree 0 and \( D_t^2 = -2 \), and when \( t = 0 \), \( D \) restricts to \( -E \), where \( E \) is the \((-2)\) curve in the central fiber of the blowup \( g \). If we pushforward to \( \Delta \times Y \), we get a flat family of divisors \( \iota_*(\mathcal{O}_S(D_t)) \) over a general fiber, and \( \mathcal{T}_{p/S_0} \) in the central fiber.

Now we turn to the study of the wall crossing; we need a preparatory Lemma:

Lemma 2.8. The only tilt-semistable sheaves \( F' \) \( \in \text{Coh}_{\alpha, -\frac{1}{2}}(Y) \) having truncated Chern class \( ch_{\leq 2}(F') = \left(1, \frac{1}{2}, \frac{1}{8}\right) \) are \( \mathcal{O}_Y \) and \( \mathcal{I}_Z \), with \( Z \) a zero-dimensional subscheme.

Proof. Since for any object \( E \) one has that \( ch_{\frac{1}{2}}(E) \in \frac{1}{2} \mathbb{Z}H \), it then follows that \( H^2 \cdot \frac{1}{2}H = \inf\{H^2 \cdot ch_{\frac{1}{2}}(E) > 0 \mid E \in \text{Coh}_{\alpha, -\frac{1}{2}}\} \); hence by Lemma 7.2.1 and Lemma 7.2.2 in [BMT14] one has that \( F' \) must be a slope-stable sheaf, so in particular torsion-free. Since the untwisted Chern character of \( F' \) is \( ch_{\leq 2}(F') = (1, 0, 0) \), we must have \( F' \cong \mathcal{O}_Y \) or \( F' \cong \mathcal{I}_Z \) for some zero-dimensional subscheme \( Z \).
tilt stability are concentric semicircles centered at $\alpha = 0$ and $\beta = -\frac{1}{2}$. In particular, the line $\beta = -\frac{1}{2}$ intersects all the possible walls for the class $w$.

As $\alpha$ gets smaller, we want to control the possible walls we may encounter; first of all, we have

$$\text{ch}_{\leq 2}^{-1}(F) = (0, 1, 0),$$

hence if $F'$ gives a numerical wall for $F$ and $\text{ch}_{\leq 2}^{-1}(F') = (x, y, z)$, the equation of the wall at the point with coordinate $\beta = -\frac{1}{2}$ yields

$$z - \frac{\alpha^2}{2} x = 0$$

meaning that $z$ and $x$ must have the same sign and cannot be equal to 0 (otherwise they would not give a wall).

An actual wall in tilt-stability intersecting the vertical line $\beta = -1/2$ must be given by a short exact sequence $0 \rightarrow F' \rightarrow F \rightarrow Q \rightarrow 0$ with $0 < \text{ch}_{1}^{-1/2}(F') < \text{ch}_{1}^{-1/2}(F) = 1$; since $\text{ch}_{1}^{-1/2}(F') \in \frac{1}{2}\mathbb{Z}$, we get $\text{ch}_{1}^{-1/2}(F') = \frac{1}{2}$.

Moreover, by the support property one has $0 \leq \Delta(F') \leq \Delta(F) = 1$, which can be rearranged to

$$-1 \leq -8xz \leq 3;$$

since $\beta = -\frac{1}{2}$, it follows that $8z \in \mathbb{Z}$, and since $x$ and $z$ have the same sign and can't be 0 we must have $x = 1$ and $z = \frac{1}{8}$.

This means there's only one possible actual wall, and it would be given by a subobject with $\text{ch}_{\leq 2}^{-1}(F') = \left(1, \frac{1}{2}, \frac{1}{8}\right)$. Since an element $F$ of the Gieseker moduli space is always a sheaf, from the long exact sequence in cohomology for objects in the tilted heart one finds that $F'$ must be a sheaf as well, and the map $F' \rightarrow F$ is an honest morphism of sheaves; moreover, we can assume $F'$ to be tilt-semistable. By Lemma 2.8, either $F' \cong \mathcal{O}_{Y}$ or $F' \cong \mathcal{I}_{Z}$ for $Z$ a zero-dimensional subscheme.

Recall from the proof of Proposition 2.3 that all sheaves in $\mathcal{M}_{G}(w)$ have the form $F = \mathcal{I}_{Z} \otimes \mathcal{O}_{S}(D)$. If $D \neq 0$, neither of the $F'$'s can map to $F$; indeed, a map $F' \rightarrow F$ would produce a section of $\mathcal{O}_{S}(D)$, by taking double duals and restricting to $S$. This is a contradiction since $D$ is not effective (for generalities on reflexive sheaves and Weil divisors, we refer the reader to [Sch10]).

On the other hand, an object of the type $\mathcal{I}_{p/S}$ always has a map from $\mathcal{I}_{p}$ given by the short exact sequence

$$0 \rightarrow \mathcal{I}_{p} \rightarrow \mathcal{I}_{p/S} \rightarrow \mathcal{O}(-1)[1] \rightarrow 0.$$ 

This means that all objects in $\mathcal{M}_{G}(w) \setminus \mathcal{P}_{d}$ stay stable once we cross the wall, while all the $\mathcal{I}_{p/S}$'s are destabilized and replaced by the unique extensions in the other direction

$$0 \rightarrow \mathcal{O}(-1)[1] \rightarrow E_{p} \rightarrow \mathcal{I}_{p} \rightarrow 0,$$

which are stable right after the wall since both $\mathcal{O}(-1)[1]$ and $\mathcal{I}_{p}$ are stable, and stay such in the whole chamber because there are no other walls.

This wall crossing therefore contracts the $\mathbb{P}^{d}$-bundle of the component $\mathcal{P}_{d}$ onto its base, producing the locus $\mathcal{Y}$ of the $E_{p}$'s, and leaves the rest of the moduli unaffected \hfill $\square$

Next, we show:

**Proposition 2.10.** The moduli space $\mathcal{M}_{G}(w)$ is isomorphic to $\mathcal{M}^{\text{tilt}}(w)$. 

To do so, we identify which objects in the tilt moduli space belong to $Ku(Y)$ and apply Lemma 2.2.

**Lemma 2.11.** The objects $E_p$ belong to $Ku(Y)$.

**Proof.** By definition, we need to show that $\text{Hom}^\bullet(\mathcal{O}(1), E_p) = \text{Hom}^\bullet(\mathcal{O}, E_p) = 0$. From the short exact sequence

$$0 \to \mathcal{I}_p \to \mathcal{O} \to \mathcal{C}_p \to 0,$$

it is straightforward to see that $\text{Hom}^\bullet(\mathcal{O}, \mathcal{I}_p) = 0$, and we already pointed out that $\mathcal{O}(-1)$ has no cohomology, so that $\text{Hom}^\bullet(\mathcal{O}, E_p) = 0$ using the defining sequence.

On the other hand, one computes $\text{Hom}^\bullet(\mathcal{O}(1), \mathcal{I}_p) = \text{Ext}^1(\mathcal{O}(1), \mathcal{I}_p) \cong \mathbb{C}$ and also $\text{Hom}^\bullet(\mathcal{O}(1), \mathcal{O}(-1)[1]) = \text{Ext}^2(\mathcal{O}(1), \mathcal{O}(-1)[1]) \cong \mathbb{C}$; so if we prove that the connecting morphism $\text{Ext}^1(\mathcal{O}(1), \mathcal{I}_p) \to \text{Ext}^2(\mathcal{O}(1), \mathcal{O}(-1)[1])$ is non-zero we get the desired vanishing for $\text{Hom}^\bullet(\mathcal{O}(1), E_p)$ as well.

The connecting map is given by composing $\alpha \in \text{Ext}^1(\mathcal{O}(1), \mathcal{I}_p) = \text{Hom}(\mathcal{O}(1), \mathcal{I}_p[1])$ with the unique map $\mathcal{I}_p[1] \xrightarrow{\phi} \mathcal{O}(-1)[3]$ given by the triangle defining $E_p$, to obtain a map $\beta \in \text{Ext}^2(\mathcal{O}(1), \mathcal{O}(-1)[1]) = \text{Hom}(\mathcal{O}(1), \mathcal{O}(-1)[3])$; our vanishing is proven if $\beta \neq 0$ whenever $\alpha \neq 0$.

We claim that both $\alpha$ and $\phi$ factor through $\mathbb{C}_p$: in fact, one proves that $\text{Hom}(\mathcal{O}(1), \mathcal{I}_p[1]) = \mathbb{C}$ and $\text{Hom}(\mathcal{I}_p[1], \mathcal{O}(-1)[3]) = \mathbb{C}$ by showing that these spaces are respectively isomorphic to $\text{Hom}(\mathcal{O}(1), \mathbb{C}_p)$ and $\text{Hom}(\mathbb{C}_p, \mathcal{O}(-1)[3])$ through the short exact sequence for $\mathcal{I}_p$, which exactly means that $\alpha$ and $\phi$ must factor via $\mathbb{C}_p$.

The non-vanishing of $\beta$ is now equivalent to the non-vanishing of the composition $\mathcal{O}(1) \to \mathbb{C}_p \to \mathcal{O}(-1)[3]$; but now applying the functor $\text{Hom}(-, \mathcal{O}(-1)[3])$ to the triangle $\mathcal{O}(1) \to \mathbb{C}_p \to \mathcal{I}_p[1]$ one has $\text{Hom}(\mathcal{I}_p[1], \mathcal{O}(-1)[3]) \cong \text{Ext}^1(\mathcal{O}, \mathcal{I}_p) = 0$ and therefore every map $\mathcal{O}(1) \to \mathcal{O}(-1)[3]$ is determined by the corresponding map $\mathbb{C}_p \to \mathcal{O}(-1)[3]$, hence the desired composition cannot be 0 since the map induced by $\phi$ is not. \hfill $\Box$

**Lemma 2.12.** The objects $\iota_s(\mathcal{O}_S(\ell_1 - \ell_2))$ for $S$ general belong to $Ku(Y)$.

**Proof.** By adjunction of the functors $\iota_s$ and $\iota^s$, it’s enough to check the vanishing of the spaces $\text{Hom}^\bullet(\mathcal{O}(1), \iota_s(\mathcal{O}_S(\ell_1 - \ell_2)))$ and $\text{Hom}^\bullet(\mathcal{O}_Y, \iota^s(\mathcal{O}_S(\ell_1 - \ell_2)))$ on the del Pezzo surface $S$. Let $D = \ell_1 - \ell_2$ as a divisor on the surface, and let $H$ be the pullback of the ample divisor on $Y$ to $S$; by Riemann–Roch, $\chi(D) = \chi(-H + D) = 0$. Since $D$ and $D - H$ are not effective, we have $H^0(D) = H^0(-H + D) = 0$, and by Serre duality it follows that $H^2(D) = H^2(-H + D) = 0$. Then $H^1(D) = H^1(-H + D) = 0$ must be 0 as well, and the claim is proven. \hfill $\Box$

We’re now ready to prove Proposition 2.10 and lastly Theorem 1.2:

**Proof of Proposition 2.10.** Since the class $w$ is primitive, there are no strictly semistable objects in $\mathcal{M}_G(w)$; as a consequence, also $\mathcal{M}^{\text{tilt}}(w)$ will not have any strictly semistable object, except exactly at the wall. A moduli space of Bridgeland (resp. tilt) semistable objects is a proper algebraic space over $\mathbb{C}$ if there are no strictly semistable objects (see, e.g., [BLMS17], [PT15]). Hence $\mathcal{M}^{\text{tilt}}(w)$ is proper, and so is $\mathcal{M}_S(w)$ by Remark 2.1.

Now, by Lemma 2.11 and Lemma 2.12, together with Proposition 2.9, we know that $\mathcal{M}_S(w)$ is realized as a proper dense subset of the proper space $\mathcal{M}^{\text{tilt}}(w)$, hence they must coincide. \hfill $\Box$

**Proof of Theorem 1.2.** Most of the statement is a combination of Proposition 2.3, Proposition 2.9, and Proposition 2.10. Projectivity can be checked on a case by case basis. For $d=5$ and $d=4$, $\mathcal{M}_S(w)$ is projective by the explicit description given below.

For $d=3$, projectivity follows from the fact that $\mathcal{M}_S(w) \simeq \mathcal{M}^{\text{tilt}}(w) \simeq \mathcal{M}_G(w) \setminus \mathcal{P}_3$: indeed, since $Y_3$ is a hypersurface, a hyperplane section is singular at a point $p \in Y_3$ if and only if the hyperplane is tangent at $p$. Since there is exactly one hyperplane tangent to each point, by
Proposition 2.3, the intersection of $\mathcal{P}_3$ with the rest of the moduli is a section of the $\mathbb{P}^3$-bundle, isomorphic to $Y_3$. Hence, contracting the bundle onto its base yields the desired isomorphism.

The cases $d = 2$ and $d = 1$ are proven in a similar way, we refer the reader to the proofs of Theorem 1.3 and Theorem 1.5 below for the details.

To conclude this section, we give a brief description of the moduli we just constructed for the cases $d = 5$, $4$ and $3$ (refer to Remark 1.1 for notation). These moduli have been studied in the literature for the most part and will not be addressed by the present work.

$(d = 5)$ This is just the moduli of quiver representations of the form $U_3^2 \rightarrow U_3^2$. It is isomorphic to the image of the map $\text{Hilb}_{\mathbb{P}^2}(3) \rightarrow \text{Gr}(3, 6)$ which contracts the divisor of collinear schemes to $\mathbb{P}^2 \subset \text{Gr}(3, 6)$; in particular, it is projective and irreducible of dimension 6 ([Orl91, ABCH13]). The copy of $Y_5$ can be realized by intersecting $\mathcal{M}_\sigma(w)$ with a linear section of $\text{Gr}(3, 6)$.

$(d = 4)$ The moduli space $\mathcal{M}_\sigma(w)$ is isomorphic to the moduli space of vector bundles on $C$ of rank 2, and fixed odd degree. This moduli is in particular projective and irreducible of dimension 5, and $Y_4$ appears as a subvariety of $\mathcal{M}_\sigma(w)$ given by vector bundles with fixed determinant ([BO95]).

$(d = 3)$ This case is treated in a forthcoming paper of one of the authors ([BBB+]); our moduli space is conjecturally isomorphic to the moduli of certain rank 3 vector bundles on $Y_3$, and has dimension 4; the copy of $Y_3 \subset \mathcal{M}_\sigma(w)$ is a divisor given by projecting skyscraper sheaves into the Kuznetsov component.

2.2. The Abel–Jacobi map. Let $Y$ be a Fano threefold; one defines its intermediate Jacobian $J(Y)$ as the complex tori given by (see [Voi03])

$$J(Y) = H^1(Y, \Omega^2_Y)^{\perp} / H^3(Y, Z);$$

moreover, $J(Y)$ is equipped with an Abel–Jacobi map

$$\Phi: Z^2_{\text{hom}}(Y) \longrightarrow J(Y)$$

$$Z \longrightarrow \int_\Gamma$$

sending a cycle of codimension 2 homologous to 0 to the integral over a 3-cycle $\Gamma$ such that $\partial \Gamma = Z$.

Given a smooth family $\{Z_t\}_{t \in T}$ of smooth 1-cycles in $Y$, the above construction allows us to define an analogous map $\alpha: T \rightarrow J(Y)$ after picking a base point $0 \in T$ (see [CG72]):

$$\Psi: T \longrightarrow J(Y)$$

$$Z_t \longmapsto \Phi(Z_t - Z_0)$$

Finally, following [Wel81], if $Z$ is a smooth curve on $Y$, and $T$ is a family of deformations of $Z$, the codifferential of the Abel–Jacobi map $\psi^{\perp}_{Z}$ appears in the following diagram:

$$\begin{array}{ccc}
H^0(K_Y(4)) & \longrightarrow & H^1(\Omega^2_Y) \\
\downarrow^{\text{res}} & & \downarrow^{\psi^{\perp}_{Z}} \\
H^0(K_Y(4)|_Z) & \longrightarrow & H^1(N_ZW \otimes K_Y)
\end{array}$$

where the second row is a part of the long exact sequence associated to the normal bundle sequence of $Z \subset Y \subset W$, where $W$ is a four dimensional quasi-projective space. We use
the isomorphism $H^1(N_2Y \otimes K_Y) \cong H^0(N_2Y)\vee$ and the Kodaira-Spencer isomorphism
$H^0(N_2Y)\vee \cong \Omega_{T,Z}$.

One can extend the above construction to families of derived objects by means of the second
Chern class $c_2$; in our particular setting, this yields a map from our moduli spaces to the
intermediate Jacobian:

$$
\Psi: \mathcal{M}_d(w) \longrightarrow J(Y_d).
$$

Remark 2.13. From the definition of the Abel–Jacobi map above, we see that the locus $Y \subset \mathcal{M}_d(w)$ is always contracted to a point under $\Psi$, since the objects $E_p$ all have the same second
Chern class even topologically; equivalently, one has that the Abel–Jacobi map is known to
contract rational curves, and $Y$ is rationally connected for all $d$.

We now give a brief description of the behavior of the map $\Psi$ in the cases $d = 5, 4$ and $3$, which have again been studied for the most part in the literature and will not be addressed in the
present work.

$(d = 5)$ In this case the intermediate jacobian $J(Y_5)$ reduces to a single point, hence the Abel–
Jacobi map is trivial;

$(d = 4)$ It is well known that $J(Y_4)$ is isomorphic to the Jacobian of the corresponding curve
$J(C)$, and also to the variety of lines on $Y$. The map $\Psi$ can be identified with the determin-
ant map $\det: \mathcal{M}(2, 1) \rightarrow J(C)$. Indeed, the determinant map contracts the fibers
of $\Psi$ because lines in the fibers correspond to pencils of extensions of two line bundles
$L_1$ and $L_0$ on $C (\text{Ext}^1(L_1, L_0) = \mathbb{C}^2$ if $\deg L_1 - L_0 = 1$). More precisely, such
line is given by a pencil of hyperplane sections of $Y$ that contain two fixed disjoint lines.

$(d = 3)$ We refer to ([BBB]) again; $\Psi_3$ maps $\mathcal{M}_d(w)$ isomorphically onto the theta divisor
$\Theta \subset J(Y_3)$ outside of $Y_3$, while it contracts $Y_3$ to its unique singular point $y$. Moreover,
$Y_3$ can be recovered in the blow up of $\Theta$ at $y$, by intersecting the strict transform of
$\Psi_3(\mathcal{M}_d(w))$ with the exceptional divisor.

3. The case $d = 2$

3.1. Generalities on quartic double solids. Recall that $Y_2 \xrightarrow{\pi} \mathbb{P}^3$ is a double cover of the
projective space ramified over a quartic surface (from here on, we set $Y = Y_3$ for this section,
and we’re dropping subindices everywhere); since we assume the $Y$ is smooth, we get that the
branching locus $B$ is a smooth K3 surface.

A hyperplane section $\iota: S \hookrightarrow Y$ is given by the pullback $\pi^*(P)$ of a plane in $\mathbb{P}^3$, hence
it is itself a double cover of $\mathbb{P}^2$ ramified over the quartic curve $B \cap P$. The general such $S$
is a smooth del Pezzo surface of degree 2, and it corresponds to a double cover with smooth
branching locus; when the branching locus is singular instead, we obtain a singular hyperplane
section, and this exactly happens when the plane $P$ is tangent to $B$.

Remark 3.1. As a consequence of the previous discussion, we get that a hyperplane section of
$Y$ can only be singular at a point $p$ if $p \in R$, the ramification locus, and each point $p \in R$
adopts exactly one of such hyperplane sections; another way of seeing it is by thinking of $Y$
as a quartic hypersurface in $\mathbb{P}(1, 1, 1, 1, 2)$ and use again the fact that a hyperplane section of
a hypersurface is singular at a point $p$ if and only if the hyperplane realizing it is tangent at $p$.
Being a double cover of $\mathbb{P}^3$ ramified over a quartic, the equation of $Y$ in $\mathbb{P}(1, 1, 1, 1, 2)$ can be
written as $\{e^2 - q(a, b, c, d) = 0\}$, where $e$ is the only variable of weight 2 and $q(a, b, c, d)$
is a homogeneous quartic polynomial in the other variables; on the other hand, the equation of a
hyperplane in $\mathbb{P}(1, 1, 1, 1, 2)$ cannot contain $e$, therefore it’s of the form $\alpha a + \beta b + \gamma c + \delta d = 0$. 
The tangency condition implies that \( \frac{\partial}{\partial e} (e^2 - q(a, b, c, d)) = 2e = 0 \), therefore a hyperplane will only be tangent to a point \( p \in Y \cap \{ e = 0 \} \), which is exactly the ramification locus.

We can say even more about these singularities: since the K3 is smooth, its Gauss map is finite. Hence a plane cannot be tangent to it along a curve; therefore, the corresponding surface \( S \) above it can only acquire isolated singularities corresponding to the isolated singularities of the branching quartic curve \( B \cap P \).

Since \( S \) is normal and has isolated singularities, either they are Du Val singularities or \( S \) is the cone over an elliptic curve (see [Bre80] or [HW81]); but \( S \) only has a finite number of lines, so it cannot be a cone, and therefore the singularities are all canonical; we can think of these singularities as arising from contracting \((-2)\)-curves on the blow-up of 7 points in \( \mathbb{P}^2 \) in non-general position.

Finally, \( Y \) is equipped with an involution \( \tau \) that swaps the two sheets of the cover, acting on objects in the derived category in the obvious way; the involution descends to hyperplane sections, hence each \( S \) is also preserved by it.

Following [Kuz15], we can moreover compute the Serre functor for \( Ku(Y) \) to be
\[
S_{Ku(Y)}(E) = \tau E[2].
\]

We conclude this section with a generalization of Lemma 2.12 in the case \( d = 2 \) that will be useful later:

**Lemma 3.2.** Let \( i : S \hookrightarrow Y \) be a (possibly singular) hyperplane section of \( Y \) and let \( L = \mathcal{O}_S(D) \) be the reflexive rank one sheaf on \( S \) associated to a Weil divisor \( D \neq 0 \) such that \( D.H = 0 \) and \( \chi(L) = 0 \). Then \( i_* (\mathcal{O}_S(D)) \in Ku(Y) \) and it has class \( w \).

**Proof.** The proof is identical to that of Lemma 2.12, after noticing that it only depends on \( D \) not being effective and \( \chi(L) = 0 \); indeed, \( L \) has no sections by definition of effective (Weil) divisor, and since \( S \) is Gorenstein the dualizing sheaf is still \( \mathcal{O}_S(-1) \) even for \( S \) singular, and Serre duality applies in the same way. The claim on the numerical class also follows from \( \chi(L) = 0 \) applying Grothendieck-Riemann-Roch. \( \square \)

### 3.2. The moduli space

This section aims to refine Proposition 2.3 in the case of \( d = 2 \) and prove Theorem 1.3, taking advantage of our deeper understanding of the singularities of a hyperplane section and of the Serre functor of \( Ku(Y) \). First, we have the following two lemmas:

**Lemma 3.3.** The Ext-dimension of the heart \( \mathcal{A} \subset Ku(Y) \) is equal to 2, i.e. \( \text{Ext}^i(E, F) = 0 \) for \( i \neq 0, 1, 2 \) for \( E, F \in \mathcal{A} \).

**Proof.** Since \( \mathcal{A} \) is the heart of a bounded t-structure, we have by definition that \( \text{Ext}^i(E, F) = 0 \) for \( i < 0 \). Now, using the above Serre functor we get:
\[
\text{Ext}^i(E, F) = \text{Hom}(E, F[i]) = \text{Hom}(F[i], S_{Ku(Y)}(E)) = \text{Ext}^{2-i}(F, \tau E),
\]
and our claim is proven if \( \tau E \) belongs to \( \mathcal{A} \). Recall that \( \mathcal{A} = Ku(Y) \cap \text{Coh}_{\alpha,-1/2}(Y) \), and clearly \( \tau(Ku(Y)) \subseteq Ku(Y) \) being its Serre functor up to shift; then it suffices to show that \( \tau \) preserves \( \text{Coh}_{\alpha,-1/2}(Y) \) to prove our claim.

Now the hyperplane section \( H \) is invariant under \( \tau \), so that \( \tau \) acts trivially on numerical classes of objects in \( D(Y) \), thus preserving slopes; moreover, the involution preserves inclinations of sheaves hence it preserves stability. By definition of a tilt (see Appendix A), \( \tau \) preserves the heart of the first tilt of \( \text{Coh}(Y) \); similarly, it also preserves the second tilt, and the claim is proven. \( \square \)

**Lemma 3.4.**

(a) Let \( p \in Y \) be a point and \( E_p \) be one of the objects as in (1); then
\[
\text{Ext}^i(E_p, E_p) = \begin{cases} \mathbb{C}^3, & p \notin R \\ \mathbb{C}^4, & p \in R \end{cases},
\]
where \( R \subset Y \) is the ramification locus. Moreover, for \( p \) in \( R \) there is a decomposition
\[
\text{Ext}^1(\mathcal{I}_p, \mathcal{I}_p) \to \text{Ext}^1(E_p, E_p) \to V_p
\]
where \( V_p \) is one dimensional generated by an element \( f_p \) corresponding to the tangent plane of \( R \) at \( p \).

(b) Let \( \iota: S \hookrightarrow Y \) be a (possibly singular) hyperplane section and let \( \mathcal{O}_S(D) \) be as in Lemma 3.2. Then
\[
\text{Ext}^1(\iota_*(\mathcal{O}_S(D)), \iota_*(\mathcal{O}_S(D))) = \mathbb{C}^3.
\]

Proof. For part (a), first of all notice that we can make all computations in \( \mathcal{K}u(Y) \) since \( E_p \) belongs to it and the subcategory is extension closed; from \( [E_p] = w \) we have \( \chi(E_p, E_p) = -2 \), and moreover \( \text{Hom}(E_p, E_p) = 1 \) since the object is stable in \( \mathcal{K}u(Y) \). Now using the Serre functor for \( \mathcal{K}u(Y) \) we get
\[
\text{Ext}^2(E_p, E_p) = \text{Hom}(E_p, \tau E_p) = \text{Hom}(E_p, E_{\tau(p)}) = \begin{cases} 0, & p \notin R \\ \mathbb{C}, & p \in R \end{cases}.
\]
this yields the first statement in part (a) given that the Ext dimension of \( \mathcal{A} \) is equal to 2 by Lemma 3.3 and the \( E_p \)'s all lie in \( \mathcal{A} \) being stable.

Applying the functor \( \text{Hom}(E_p, -) \) to the sequence (1) one sees \( \text{Ext}^1(E_p, E_p) \cong \text{Ext}^1(E_p, \mathcal{I}_p) \), and the latter sits in an exact sequence
\[
\text{Ext}^1(\mathcal{I}_p, \mathcal{I}_p) \to \text{Ext}^1(E_p, \mathcal{I}_p) \to \ker \left( \text{Ext}^1(\mathcal{O}(-1)[1], \mathcal{I}_p) \to \text{Ext}^2(\mathcal{I}_p, \mathcal{I}_p) \right),
\]
where \( \alpha \) is pre-composition with the map \( \epsilon_p : \mathcal{I}_p \to \mathcal{O}(-1)[2] \) of the triangle (1). Let \( V_p := \ker \alpha \). Since \( \text{Ext}^1(\mathcal{O}(-1)[1], \mathcal{I}_p) \cong H^0(\mathcal{I}_p(1)) \), elements of \( V_p \) correspond to hyperplanes through \( p \). We prove that a nonzero \( f \in \text{Ext}^2(\mathcal{O}(-1)[2], \mathcal{I}_p) \) is in \( \ker \alpha \) if and only if \( f = 0 \) is tangent to \( R \) at \( p \). Consider a triangle
\[
\mathcal{I}_p/S[1] \to \mathcal{O}(-1)[2] \xrightarrow{f} \mathcal{I}_p[2].
\]
Then \( \alpha(f) = 0 \) if and only if \( f \epsilon_p = 0 \), which happens if and only if \( \epsilon_p \) lifts to a map \( \mathcal{I}_p \to \mathcal{I}_p/S[1] \). One checks that \( \text{Hom}(\mathcal{I}_p, \mathcal{I}_p/S[1]) \to \text{Hom}(\mathcal{I}_p, \mathcal{O}(-1)[2]) \) surjects if and only if \( p \in S \) is a singular point, that is the hyperplane \( f = 0 \) is tangent to \( R \) at \( p \).

Part (b) is proved similarly; using the fact that \( \mathcal{O}_S(D) \in \mathcal{K}u(Y) \) and \( [\iota_*(\mathcal{O}_S(D))] = w \) by Lemma 3.2, we just need to show that \( \text{Hom}(\mathcal{O}_S(D), \mathcal{O}(\tau D)) = 0 \). We claim that \( \tau D = -D \), so that the vanishing of \( \text{Hom}(\mathcal{O}_S(D), \mathcal{O}_S(-D)) = \text{Hom}(\mathcal{O}_S, \mathcal{O}_S(-2D)) \) follows from the fact that \( S \) does not contain any numerically trivial divisor by construction (and thus \( 2D \neq 0 \)); to prove the claim, consider the invariant divisor \( D' = D + \tau D \); it has degree 0, but being invariant it must be realized as the pullback of a divisor from \( \mathbb{P}^2 \). Since all divisors in \( \mathbb{P}^2 \) are multiples of the hyperplane section, and the pullback of it has strictly positive degree, this multiple must be 0, hence \( D' = 0 \) and the claim is proven. \( \square \)

Proposition 3.5 (Gieseker moduli space). Let \( \iota : S \hookrightarrow Y \) be a possibly singular hyperplane section; a sheaf belonging to the moduli space of Gieseker stable sheaves \( \mathcal{M}_G(w) \) of class \( w \) for \( Y \) is either an ideal sheaf \( \mathcal{I}_p/S \) of a point in \( S \) or a rank one reflexive sheaf \( \mathcal{O}_S(D) \) associated to a Weil divisor \( D \) on \( S \).

Moreover, \( \mathcal{M}_G(w) \) has a component of dimension 5 given by \( \mathcal{P} = \mathbb{P}_2 \) which intersects other components in the locus described in Proposition 2.3, while the rest of the moduli is smooth of dimension 3.

Proof. We follow the same starting argument as Proposition 2.3, so that an element in \( \mathcal{M}_G(w) \) must be of the form \( \iota_*(F) \), with \( F = \mathcal{I}_Z \otimes L \) and \( [F] = (1, D, -1) \) for a Weil divisor with \( D.H = 0 \) such that \( L = \mathcal{O}_S(D) \). Since by construction \( [F] = (1, D, \chi_2(L) - z) \), in order to understand what happens in the case in which \( S \) is singular we need to make sense of the meaning of the quantity \( \chi_2(L) \) for a reflexive rank-one sheaf.
We thus follow [Rei87], where the author gives a Riemann-Roch formula for the Euler characteristic of a Weil divisor on a surface with at worst Du Val singularities, which is our case. One has

\[ \chi(D) = \chi(O_S) + \frac{1}{2}(D^2 - K_S \cdot D) + \delta_S(D), \]

where \( \delta_S(D) \in \mathbb{Q} \) is a number depending only on \( D \) and the singularities of \( S \); moreover, by Theorem 9 in [Rei87] again, we have \( \delta_S(D) \leq 0 \). Using the above formula, we can define the second Chern character of \( L \) consistently as

\[ \text{ch}_2(L) = \frac{D^2}{2} + \delta_S(D). \]

Now, using Hodge Index Theorem and the fact that even when singular \( S \) has no numerically trivial divisors, we conclude that \( \text{ch}_2(L) < 0 \). Therefore, in the notation of Proposition 2.3, we have \( z = 0 \) when \( D \neq 0 \) for all \( S \) and the first part of the statement is proven.

The second part is just a restatement of Proposition 2.3, with the additional information from Lemma 3.4(b) giving us the dimension and the smoothness of all the points that do not lie in the intersection locus.

We’re now ready to give a proof of Theorem 1.3, which will be broken down in several lemmas below.

**Proof of Theorem 1.3.** As before, we study the effect of the wall crossing on \( \mathcal{M}_G(w) \); first of all, we know from Proposition 3.5 that \( \mathcal{M}_G(w) \setminus \mathcal{P} \) has pure dimension 3, and it is not affected by the wall crossing by the proof of Proposition 2.9.

Moreover, Remark 3.1 implies that the intersection locus of the component \( \mathcal{P} \subset \mathcal{M}_G(w) \) with the rest of the moduli is isomorphic to the ramification locus \( R \), and Lemma 3.4(a) states that the component containing the \( E_p \)'s has dimension 3, hence after the wall crossing we obtain the component \( \mathcal{Y} \simeq Y \) given by the base of the \( \mathbb{P}^2 \)-bundle; moreover, Lemma 3.4 indeed implies that all components of \( \mathcal{M} \) have dimension 3, and at least two components meet at \( R \subset Y \) (see also 2.7).

Now by Lemma 3.6 only two components can meet there; furthermore, we can identify an open set of \( \mathcal{C} := \mathcal{M} \setminus \mathcal{Y} \) with a certain space of smooth conics on \( Y' \) up to linear equivalence (see discussion below Lemma 3.6), which proves \( \mathcal{C} \) is irreducible and therefore \( \mathcal{M} \) has only two components. Moreover, again by Lemma 3.4 we know that \( \mathcal{C} \) is smooth outside of \( R \).

Projectivity of \( \mathcal{M} \) is seen in a similar way as in the case \( d = 3 \): since the intersection locus in the Gieseker moduli is isomorphic to \( R \), we have like before that \( \mathcal{C} \simeq \mathcal{M}_G(w) \setminus \mathcal{P} \), yielding projectivity of \( \mathcal{C} \); since \( \mathcal{Y} \) is clearly projective and the two components meet along a projective intersection, it follows \( \mathcal{M} \) is projective.

Finally, the Abel–Jacobi map generically embeds the component \( \mathcal{C} \) in \( J(Y) \) by Corollary 3.8, and contracts \( \mathcal{Y} \) as in the general case. \( \square \)

**Lemma 3.6.** Let \( p \in R \) be a point in the intersection of \( Y \) and \( \mathcal{C} \) in \( \mathcal{M} := \mathcal{M}_G(w) \). The tangent cone to \( \mathcal{M} \) at \( p \) consists of two distinct hyperplanes, or of a single hyperplane with multiplicity two. In particular, no more than two components of \( \mathcal{M} \) meet at \( p \).

**Proof.** There is an identification \( T_p \mathcal{M} \simeq \text{Ext}^1(E_p, E_p) \simeq \text{Ext}^1(I_p, I_p) \oplus V_p \) as in Lemma 3.4, where \( \text{Ext}^1(I_p, I_p) \) is identified with \( T_p Y_2 \). The tangent cone to \( \mathcal{M} \) corresponds to unobstructed deformations of \( E_p \) in \( \mathcal{M} \), therefore it contains \( T_p Y \) and it is contained in the null-space \( N \subset T_p \mathcal{M} \) of the symmetric bilinear form

\[ \text{Ext}^1(E_p, E_p) \times \text{Ext}^1(E_p, E_p) \to \text{Ext}^2(E_p, E_p) \]

given by the cup product. Since \( N \) is a quadric and it contains the hyperplane \( \text{Ext}^1(I_p, I_p) \), the only possibilities are that the tangent cone of \( \mathcal{M} \) at \( p \) is the union of two distinct hyperplanes or a single hyperplane with multiplicity two. Both these possibilities imply that there are no more than two components meeting at \( p \). \( \square \)
The following construction expresses the relation between \( \mathcal{C} \) and a family of conics on \( Y \). Let \( \mathcal{C}' \) be the component of the Hilbert scheme of conics on \( Y \) containing smooth conics. Let \( Z \in \mathcal{C}' \) be a conic; its image \( \pi(Z) \) spans a hyperplane of \( \mathbb{P}^3 \) and determines a hyperplane section \( S \subset Y \). Suppose \( S \) is smooth. Then the reflexive sheaf \( \mathcal{O}_S(Z - H) \) is in the Gieseker moduli space \( \mathcal{M}_C(w) \), as in 2.3. The assignment \( Z \mapsto \iota_*(\mathcal{O}_S(Z - H)) \) then defines a dominant rational map

\[
f: \mathcal{C}' \longrightarrow \mathcal{C}
\]

which contracts pencils of linearly equivalent conics. For a general \( Y \), \( \mathcal{C}' \) is irreducible by [TM03, Lemma 1.2], and hence so is \( \mathcal{C} \). Let \( \mathcal{C}'_0 \subset \mathcal{C}' \) denote the domain of definition of \( f \). Or we can define \( \mathcal{C}'_0 = \{ Z \in \mathcal{C}' \mid S \) is smooth\}.

**Proposition 3.7.** Let \( Z \) be a smooth conic in \( \mathcal{C}'_0 \) and consider the Abel–Jacobi map \( \mathcal{C}'_0 \rightarrow J(Y) \). Its codifferential at \( Z \) has rank 3, and the Abel–Jacobi map factors through \( f: \mathcal{C}'_0 \rightarrow \mathcal{C} \).

**Proof.** The Abel–Jacobi map contracts pencils of curves, so it factors through \( \mathcal{C} \). We use diagram (3) to study the codifferential, taking \( W \) to be an open set in the weighted projective space (which can be thought as \( W = \mathbb{P}(\mathcal{O}_{\mathbb{P}^3} \oplus \mathcal{O}_{\mathbb{P}^3}(2)) \)). In any case, \( H^0(N_Z Y)^{\vee} \) has dimension 4 by [TM03, Lemma 1.2]. The bundle \( N_Z W \) can be computed as follows: let \( Z \subset \mathbb{P}^3 \) be the smooth conic image of \( Z \) under \( \pi \). The standard exact sequence \( \mathcal{O}_W(2) \rightarrow T_W \rightarrow \pi^*\mathcal{T}_{\mathbb{P}^3} \) yields the diagram

\[
\begin{array}{ccc}
\mathcal{O}_W(2) & \rightarrow & \mathcal{O}_W(2) \\
\downarrow & & \downarrow \\
T_Z & \rightarrow & T_{W|Z} \rightarrow N_Z W \\
\downarrow^\approx & & \downarrow \\
\pi^*\mathcal{T}_{\mathbb{P}^3|Z} & \rightarrow & \pi^*N_Z \mathbb{P}^3
\end{array}
\]

where all rows and columns are exact. Since \( Z \) is a complete intersection we have \( N_Z \mathbb{P}^3 \simeq \mathcal{O}_Z(2) \oplus \mathcal{O}_Z(1) \), hence \( N_Z W \otimes K_Y \simeq \mathcal{O}\mathbb{P}^2 \oplus \mathcal{O}_Z(-1) \simeq \mathcal{O}_{\mathbb{P}^3} \oplus \mathcal{O}_{\mathbb{P}^3}(-2) \). Then, the long exact sequence associated to

\[
0 \rightarrow N_Z Y \otimes K_Y \rightarrow N_Z W \otimes K_Y \rightarrow K_Y(4) \rightarrow 0
\]

implies that \( \beta_Z \) has rank 3.

To conclude that \( \psi_S \) has rank 3, it is enough to show that the restriction map \( H^0(K_Y(4)|_{S}) \rightarrow H^0(K_Y(4)|_{S}) \) is surjective. Since \( Z \) lies on a hyperplane section \( S \) of \( Y \), this can be checked in two steps: \( H^0(K_Y(4)) \rightarrow H^0(K_Y(4)|_S) \) is surjective because \( H^1(\mathcal{O}_Y(1)) = 0 \), and the surjectivity of \( H^0(K_Y(4)|_S) \rightarrow H^0(K_Y(4)|_S) \) follows from the sequence

\[
\mathcal{O}_S(2H - Z) \rightarrow \mathcal{O}_S(2H) \rightarrow \mathcal{O}_S(Z),
\]

using that \( Z = H - \xi_1 + \xi_2 \) in Pic \((S)\), where the \( \xi_i \)'s are exceptional divisors in \( S \) seen as a blow-up of \( \mathbb{P}^2 \).

**Corollary 3.8.** The Abel–Jacobi map \( \Psi: \mathcal{M}_\sigma(w) \rightarrow J(Y) \) contracts the irreducible component \( Y \) to a point \( y \in J(Y) \) and is a generic embedding on \( \mathcal{C} \).

We conclude this section with a more detailed discussion of the Abel Jacobi map under some stricter hypotheses for the ramification locus: from here on we assume the K3 surface does not contain lines, so that the Hilbert scheme of lines in \( Y \) is smooth. Under this assumption, we get the following:

**Proposition 3.9.** The differential \( \psi_p: T_p\mathcal{M} \simeq \text{Ext}^1(E_p, E'_p) \rightarrow T_y J(Y) \) of \( \Psi \) at a general point \( p \in R \) is non-zero.
Proof. Let $S_0$ be the hyperplane section of $Y$ that is singular at $p$; if $p$ is general, the singularity is an $A_1$ singularity as in Example 2.7. Let $L := E_1 \cap S_0$ (keeping the notation as in Example 2.7). In other words, $L$ is a line through $p$ determined by an exceptional divisor in $S_1$. Let $\Delta$ be a formal neighborhood of $S_0$ in the pencil parametrizing hyperplane sections of $Y$ containing $L$. Let $D$ be a flat family on $\Delta \times Y$, with central fiber $D_0 = E_p$ and general fiber a line bundle on $S_t$, $D_t = \mathcal{O}_{S_t}(L-L_t)$, where $L_t$ is a line disjoint from $E$ in $S_t$. The locus $\{L_t\}_t \subset F(Y)$ in the Hilbert scheme of lines is contained in the incidence divisor $D_C \subset F(Y)$, of lines intersecting $C := H - L$. The differential $\psi_p$ is equal to the differential of the Abel Jacobi map from $F(Y)$, restricted to $D_C$. The assumption on $R$ and [Wel81, Prop. 2.13] imply that the Abel Jacobi map is a local embedding $F(Y) \to J(Y)$, so $\psi_p$ is nonzero. 

From this, we have the following Corollary:

**Corollary 3.10.** There is a birational map $\psi: R \dasharrow S$, where $S$ is the intersection of the strict transform of $\Psi(C)$ with the exceptional divisor $\mathbb{P}^0 \simeq \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^3}(2)))$ of $Bl_y J(Y)$.

**Proof.** Combining Lemma 3.4 and Proposition 3.9, one sees that for a general point $p$ the vector space $(f_p)$ coincides with the tangent space of $\Delta'$ in $T_{\nu_0} F \simeq H^0(N_{\nu_0} Y)(\Delta'$ is the image of $\Delta$ in $F(Y)$). Then, writing diagram (3) for $\psi_{\Delta',\nu_0}$, we have

$$
\begin{array}{ccc}
H^0(\mathcal{O}_{\nu_0}(2)) & \longrightarrow & H^0(\mathcal{O}_{\mathbb{P}^3}(2)) \\
\downarrow_{\psi} & & \downarrow_{\psi_{\Delta',\nu_0}} \\
H^0(\mathcal{O}_{\nu_0}(2)) & \longrightarrow & H^0(N_{\nu_0} Y) \psi^\vee \longrightarrow (\psi_p(f_p))^\vee
\end{array}
$$

which shows that $\psi$ induces a rational map on $R$ via quadrics to $\mathbb{P}^0 \simeq \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^3}(2)))$, whose image is dense in $S$ and is generically one-to-one. 

### 3.3. A categorical Torelli theorem

As an application of the previous construction, this section is dedicated to the proof of Theorem 1.4.

#### 3.3.1. Images of stable objects

First, we prove that given an equivalence as in Theorem 1.4, we can produce another equivalence with nice properties on the objects parametrized by $\mathcal{M}'$. We start with a series of lemmas:

**Lemma 3.11.** Let $u: \mathcal{K}u(Y') \xrightarrow{\sim} \mathcal{K}u(Y)$ be an equivalence of categories, and let $E \in \mathcal{K}u(Y')$ be an object of class $w$; then up to a sign, we have $[u(E)] = w$ or $[u(E)] = 2v - w$.

**Proof.** Since $u$ is an equivalence of categories, it must preserve dimensions of Hom spaces, so in particular $\chi(u(E), u(E)) = \chi(E, E) = -2$. From the intersection matrix of the Euler form given in section 2, if $[u(E)] = av + bw$, then $\chi(u(E), u(E)) = -(a + b)^2 - b^2$. The only possible signs $(a, b)$ are $(0, \pm 1)$ and $(\pm 2, \pm 1)$. Finally, since an equivalence of categories induces a homomorphism on the Grothendieck groups, we can choose the sign uniformly for all objects.

**Lemma 3.12.** Let $0 \neq C \in \mathcal{A} \subset \mathcal{K}u(Y)$; then $\dim \text{Ext}^1(C, C) \geq 2$.

**Proof.** This follows directly from Lemma 3.3; indeed, for an object in the heart $\text{Ext}^3(C, C) = 0$, hence since $\chi(C, C) \leq -1$ and $\dim \text{Hom}(C, C) \geq 1$, we must have that $\dim \text{Ext}^1(C, C) \geq 2$. 

**Lemma 3.13.** Let $C \in \mathcal{K}u(Y)$ with $\text{hom}^1(C, C) = 3$; then up to shift $C \in \mathcal{A}$, and if additionally $[C] = w$ then $C$ is stable.

**Proof.** Consider the spectral sequence for objects in $\mathcal{K}u(Y)$ whose second page is given by

$$E_2^{pq} = \bigoplus_i \text{Hom}^p(\mathcal{H}^i(C), \mathcal{H}^{i+q}(C)) \Rightarrow \text{Hom}^{p+q}(C, C)$$

(5)
(see [BMMS12]), where the cohomology is taken with respect to the heart \( \mathcal{A} \). Since by Lemma 3.3 the Ext-dimension of \( \mathcal{A} \) is 2, it follows that \( E_2^{1,0} = E_2^{1,0} \), so that if we take \( q = 0 \), by Lemma 3.12 we get

\[
3 = \text{hom}^1(C, C) \geq \bigoplus_i \text{hom}^i(\mathcal{H}^i(C), \mathcal{H}^i(C)) \geq 2r, \]

where \( r > 0 \) is the number of non-zero cohomology objects of \( C \). Then \( r = 1 \) and \( C \in \mathcal{A} \) up to shift; if we also assume \( [C] = w \), then \( C \) must be stable since \( w \) has maximal slope and is primitive. □

Lemma 3.14. Let \( C \in \mathcal{Ku}(Y) \) of class \( [C] = w \) with the following numerics:

\[
\text{hom}^i(C, C) = \begin{cases} 
1 & i = 0 \\
4 & i = 1 \\
1 & i = 2 \\
0 & i = 3
\end{cases}
\]

then up to shift \( C \in \mathcal{A} \), and in particular \( C \) is stable.

Proof. Similarly to the proof of the previous Lemma, we get that

\[
4 = \text{hom}^1(C, C) \geq \bigoplus_i \text{hom}^i(\mathcal{H}^i(C), \mathcal{H}^i(C)) \geq 2r,
\]

which in this case could yield \( r = 1 \) or \( r = 2 \); if \( r = 1 \), we’re done. Assume by contradiction that \( r = 2 \), and call \( M \) and \( N \) the two non-zero cohomology objects of \( C \); one necessarily has \( \text{hom}^1(M, M) = \text{hom}^1(N, N) = 2 \), and since \( \chi(F, F) \leq -1 \) for all objects in \( \mathcal{Ku}(Y) \), we also get \( \text{hom}^0(M, M) = \text{hom}^0(N, N) = 1 \) and \( \text{hom}^2(M, M) = \text{hom}^2(N, N) = 0 \), yielding \( \chi(M, M) = \chi(N, N) = -1 \) in particular. This means that \( [M] \) and \( [N] \) can only be equal to \( \pm v \) or \( \pm (v - w) \); in order for their classes (with appropriate shift) to add up to \( w \), for \( M \) and \( N \) to be in the heart at the same time and for the spectral sequence to abut to the correct numerics of \( C \), we see that the only possibility is the following:

\[
M = \mathcal{H}^i(C), \quad [M] = \pm v \quad \text{and} \quad N = \mathcal{H}^{i \pm 1}(C), \quad [N] = \mp (w - v),
\]

i.e. \( M \) and \( N \) are adjacent cohomologies, and exactly one of them has class \( \pm v \) and the other has class \( \mp (w - v) \), where the signs are determined by the parity of \( j \); notice in particular that in all of these cases \( \chi(M, N) = 0 \). Now, if we gather all this information together, the table of dimensions for the second page of the spectral sequence (5) looks like this:

\[
\begin{array}{ccc}
0 & 0 & 0 \\
a & b & c \\
2 & 4 & 0 \\
d & e & f
\end{array}
\]

with zeroes elsewhere. Moreover, we know that the central column survives and indeed the whole sequence degenerates at page 3; using the hypothesis on the numerics of \( C \), we get that the next page is of the form

\[
\begin{array}{ccc}
0 & 0 & 0 \\
0 & 1 & 0 \\
g & 4 & 0 \\
0 & e & 0
\end{array}
\]

This implies right away that \( a = 0 \), \( b = 1 \), \( c = 0 \) and \( d = 0 \); moreover, the space of dimension 2 must surject onto the one of dimension \( f \) at page 2, and since the alternate sum of dimension on the line \( q = -1 \) is equal to \( \chi(M, N) = 0 \), we also have \( e = f \). Finally, by \( \text{hom}^0(C, C) = 1 \) on page 3 we get \( g + e = g + f = 1 \); but \( g = 2 - f \) from page 2, contradiction. □
Let $\Phi : D(Y) \to D(Y)$ be a functor defined with $E \mapsto L_{O_Y}(E(1))$, i.e., $L_{O_Y}(E(1))$ fits into the triangle

$$L_{O_Y}(E(1)) \to \text{Hom}^\bullet(O_Y, E(1)) \otimes O_Y \to E(1),$$

where the second map is the evaluation map.

**Lemma 3.15.** The restricted functor $\Phi : Ku(Y) \to Ku(Y)$ is an equivalence. Moreover, the induced map on $K(Y)$ maps $w \mapsto 2v - w$ and $v \mapsto v - w$.

**Proof.** Note first that $Ku(Y) = O_Y^\perp \cap O_Y(1)^\perp = O_Y(-1) \cap O_Y(-2)$. Since left mutation induces an equivalence $O_Y \to O_Y^\perp$, $\Phi$ restricts to equivalences $O_Y(-1) \to O_Y^\perp$ and $O_Y(-2) \to O_Y(-1)^\perp$, and therefore to $Ku(Y) \to Ku(Y)$. \hfill $\square$

Now if we take an object $E \in \mathcal{M}'$, then $u(E)$ has class $\pm w$ or $\pm(2v - w)$. In the latter case we can replace $u$ with $u \circ \Phi$ so that $u(E)$ has class $\pm w$. Lemmas 3.13 and 3.14 show that there exists an integer $n_E$ such that $u(E[n_E]) \in \mathcal{A}$ and is stable of class $w$ (in particular, it has phase 1). We want to prove that the above shift can be taken uniformly. First of all, notice that for two distinct objects $E$ and $F$ in $\mathcal{M}'$ we must have $\text{Hom}(E, F[1]) = \text{Ext}^1(E, F) \neq 0$, since $\text{Hom}(E, F) = 0$ by stability. Since $\text{Ext}^1(E, F) = \text{Ext}^{-1}(F, E) = 0$ by use of the Serre functor on $Ku(Y)$, and $\chi(E, F) = -2$ because of their numerical class; but then $\text{Hom}(u(E)[n_E], u(F)[n_E + 1]) \neq 0$, and also $\text{Hom}(u(F)[n_E], u(E)[n_E + 1]) \neq 0$. Call $\phi \in \mathbb{Z}$ the phase of $u(F)[n_E]$; by stability of $u(E)$ and $u(F)$ and their shifts, from the above we get $1 < \phi + 1$ and $1 < \phi$, hence $\phi = 1$ and we proved that $n_F = n_E$.

We can thus summarize the results of this section with the following Proposition:

**Proposition 3.16.** The equivalence $u : Ku(Y') \to Ku(Y)$ induces a bijection on closed points $u : \mathcal{M}'(k) \to \mathcal{M}(k)$.

**Proof.** We have shown that the assignment $E \mapsto u(E)$ sends points of $\mathcal{M}'$ to points of $\mathcal{M}$. Since $u$ is an equivalence, the induced map is a bijection on closed points. \hfill $\square$

### 3.3.2. Universal families and convolutions

Let $\mathcal{M}$ and $\mathcal{M}'$ denote the moduli spaces of objects of class $w$ in $Ku(Y)$, resp. $Ku(Y')$. As in Theorem 1.3, we will denote by $\mathcal{Y}$ the component isomorphic to $Y$ in $\mathcal{M}$ (we use the same convention in the case of $Y'$). The universal family on $\mathcal{Y}$ as a component of $\mathcal{M}$ is the object $E$ defined as the cone of the natural map

$$(6) \quad \mathcal{I} \to q^*Rq_*R\text{Hom}(p^*O_Y(-1)[1], \mathcal{I} \otimes \omega_q[3]) \otimes p^*O_Y(-1)[1] \to E'[1]$$

where $p$ and $q$ denote the projections onto $Y$ and $Y'$, respectively, and $\omega_q$ is the relative canonical bundle with respect to $q$.

In fact, one checks that $Rq_*R\text{Hom}(p^*O_Y(-1)[1], \mathcal{I} \otimes \omega_q[3])$ commutes with base change in the sense of [Lan83, Remark 1.5]. Thus, the restriction of (6) to a fiber $Y \times \{s\}$ above a closed point $s \in \mathcal{Y}$ is the triangle

$$\mathcal{I}_s \to \text{Hom}^\bullet(O_Y(-1), \mathcal{I}_s \otimes \omega_Y[3]) \otimes O_Y(-1) \to E_s[1],$$

whence $E_s \simeq E_s$ because $\text{Hom}^\bullet(O_Y(-1), \mathcal{I}_s \otimes \omega_Y[3]) \simeq \mathbb{C}$. Likewise, define $E'$ to be the universal family above $\mathcal{Y}'$.

Define the composite functor

$$\Phi : D(Y') \xrightarrow{\rho'} Ku(Y') \xrightarrow{u} Ku(Y) \xrightarrow{\epsilon} D(Y)$$

where $\rho'$ is the natural projection, $\epsilon$ the full embedding, and $u$ an exact equivalence. If $F$ is a Fourier–Mukai functor, i.e., $F \simeq \Phi_G$ for some $G \in D^b(Y \times Y')$, then one defines

$$\Phi_G \times \text{id}_{Y'} := \Phi_{G \otimes O_{\Delta_Y'}} : D^b(Y' \times Y') \to D^b(Y \times Y')$$

and the object

$$\tilde{E} := \Phi_G \times \text{id}_{Y'}(E') \in D^b(Y \times Y')$$
is a family of objects of $D(Y')$ parametrized by $Y'$, which defines a morphism $Y' \simeq Y' \to M$.

If $F$ is not a Fourier–Mukai functor, then one can construct the family $\tilde{E}$ "by hand", with the same argument as in [BMMS12, Sec. 5.2]. The main technical tool is that of convolutions, we will recall here some aspects of the argument for the convenience of the reader. A right convolution of a bounded complex

$$A_m \xrightarrow{d_m} A_{m-1} \xrightarrow{d_{m-1}} \ldots \xrightarrow{d_1} A_0$$

in a triangulated category $T$ is an object $A$ with a morphism $d_0 : A_0 \to A$ such that there is a diagram in $T$

$$\begin{array}{c}
\begin{array}{c}
A_m \\
\downarrow \text{id}
\end{array} \\
\begin{array}{c}
\begin{array}{c}
A_m \\
\circlearrowleft \\
\end{array} \\
\begin{array}{c}
A_{m-1} \\
\circlearrowleft \\
\end{array} \\
\vdots
\end{array} \\
\begin{array}{c}
\begin{array}{c}
A_0 \\
\text{id}
\end{array} \\
\begin{array}{c}
A_0 \\
\circlearrowleft \\
\end{array} \\
\begin{array}{c}
A_1 \\
\circlearrowleft \\
\end{array} \\
\vdots
\end{array} \\
\end{array}$$

where the triangles with $\circlearrowleft$ are commutative, and the others are distinguished.

If $L \in \text{Pic}(Y')$ is an ample line bundle, we can consider the (possibly infinite) resolution of $E'$:

$$(7) \quad \ldots \to \mathcal{O}_{Y'}(-N_i)^{\oplus n_i} \boxtimes (L^{\otimes -r_i})^{\oplus s_i} \to \ldots \to \mathcal{O}_{Y'}(-N_0)^{\oplus n_0} \boxtimes (L^{\otimes -r_0})^{\oplus s_0} \to E'$$

with $r_i \geq 0$, and $N_i \gg 0$ so that

$$\text{Hom}(\mathcal{O}_{Y'}, \mathcal{O}_{Y'}(-N_i)[p]) = \text{Hom}(\mathcal{O}_{Y'}(1), \mathcal{O}_{Y'}(-N_i)[p]) = 0$$

for all $p \neq 3$. Then, choose $m$ sufficiently large and define the complex

$$(8) \quad O_m^* := \{ \mathcal{O}_{Y'}(-N_m)^{\oplus n_m} \boxtimes (L^{\otimes -r_m})^{\oplus s_m} \to \ldots \to \mathcal{O}_{Y'}(-N_0)^{\oplus n_0} \boxtimes (L^{\otimes -r_0})^{\oplus s_0} \}.$$ Denote by $K_m \in \text{Coh}(Y' \times Y')$ the kernel of $O_m^* \to O_{m-1}^*$. Then the triangle

$$K_m[m] \to O_m^* \to E'$$

splits (if $m + 1 > \dim Y' + \dim Y'$, for example). Then, the object $K_m[m] \oplus E'$ is a right convolution for the complex $O_m^*$. This convolution is unique, because the terms of $O_m^*$ are coherent sheaves (and not arbitrary objects of $D^b(Y' \times Y')$, see [Kaw04, Lemma 2.1]).

Next, one considers the complex

$$(9) \quad F_m^* := \{ F(\mathcal{O}_{Y'}(-N_m)^{\oplus n_m} \boxtimes (L^{\otimes -r_m})^{\oplus s_m} \to \ldots \to F(\mathcal{O}_{Y'}(-N_0)^{\oplus n_0} \boxtimes (L^{\otimes -r_0})^{\oplus s_0} \}$$

whose terms are objects of $D^b(Y \times Y')$.

The following lemma follows from the same argument given in [BMMS12]:

**Lemma 3.17.** The complex $F_m^*$ admits a unique (up to isomorphism) split right convolution $G_m \simeq H_m \oplus E_m$ such that for some $M < m$ one has $H^i(E_m) = 0$ unless $i \in [-M, 0]$, and $H^i(H_m) = 0$ unless $i \in [-m - M, -m]$.

**Proof.** See [BMMS12, Lemma 5.2].

We denote $\tilde{E} := E_m \in D^b(Y \times Y')$.

### 3.3.3. Conclusion of the proof.

The last step of the proof is to show that the map defined in Prop. 3.16 is a morphism of projective varieties which restricts to an isomorphism $Y' \simeq Y = Y$. For a closed point $s \in Y'$, denote by $i_s$ (resp. $i_s'$) the inclusion $Y \times \{s\} \to Y \times Y'$ (resp. $Y' \times \{s\} \to Y' \times Y'$).

**Lemma 3.18.** For any closed point $s \in Y'$ we have $i_s^*(\tilde{E}) \simeq F((i_s')^*E')$. 
**Proof.** Apply the functor $i_s^*$ to the complex $F_m^*$ to get the complex
\[(10) \quad i_s^*(F_m^*) := \{ F(O_Y(-N_0))^{\oplus m} \otimes C^{\oplus m} \to F(O_Y(-N_0))^{\oplus m} \otimes C^{\oplus m} \}\]
of objects of $D^b(Y)$. One sees that the objects $i_s^*\bar{L} \oplus i_s^*H_m$ and $F((i_s')^*\mathcal{E}') \oplus F((i_s')^*K_m[m])$ are both right convolutions of $i_s^*(F_m^*)$. However, the same argument as in Lemma 3.17 shows that $i_s^*(F_m^*)$ has a unique convolution up to isomorphism, and the choice $m \gg 0$ implies $i_s^*(\bar{L}) \simeq F((i_s')^*\mathcal{E}')$ for any choice of $s \in Y'$ a closed point. \hfill \Box

**Proof of Theorem 1.4.** Whether $\bar{L}$ is constructed with a Fourier–Mukai functor or by means of convolutions, one sees that $i_s^*(\bar{L}) \simeq F((i_s')^*\mathcal{E}') = u(E_s)$ for all $s \in Y'$. In other words, $\bar{L}$ is a family of objects of $\mathcal{M}$ parametrized by $Y'$, and it yields a projective morphism $\alpha : Y' \to \mathcal{M}$ with the property that $\alpha(s) \in \mathcal{M}$ corresponds to the object $u(E_s)$ for all $s \in Y'$. Since $Y'$ is irreducible, $\alpha$ factors through one of the components of $\mathcal{M}$. We claim that $\alpha$ must factor through $\mathcal{Y}$. Granting the claim for a moment, smoothness of $\mathcal{Y}$ implies that $\alpha$ is the desired isomorphism $\mathcal{Y}' \xrightarrow{\sim} \mathcal{Y}$.

To establish the claim, observe that $\alpha$ is, in particular, a morphism dominating one of the components of $\mathcal{M}$ and $\alpha$ is birational onto its image. Since $\mathcal{Y}'$ is rationally connected and $\alpha$ preserves this property (see for example [Kol96]), its image cannot lie in $\mathcal{C}$, which is not rationally connected as a consequence of Corollary 3.8. \hfill \Box

4. The case $d = 1$

Throughout this section we set $Y = Y_1 \subset \mathbb{P}(1, 1, 2, 3)$, a sextic hypersurface. More precisely, $Y$ is constructed in the following way (see [Tih82]): let $v : \mathbb{P}^2 \to \mathbb{P}^5$ be the Veronese embedding, and let $K$ be the cone over $v(\mathbb{P}^2)$ in $\mathbb{P}^5$; consider then a cubic hypersurface $W \subset \mathbb{P}^6$ avoiding the vertex $s \in K$, and let $W = W \cap K$. Then, $Y$ can be regarded as a compactification of the double cover of $K_0 = K \setminus \{s\}$ ramified over $W$; furthermore, $K \simeq \mathbb{P}(1, 1, 1, 2)$ and projecting away from the singular point yields a $3 : 1$ cover $\pi : W \to \mathbb{P}^2$ ramified over a curve $C$ such that $\pi(C)$ has degree 12.

**Remark 4.1.** Here we assume the hypersurface $W$ to be general, in the sense that we require the curve $C$ to be irreducible and general in moduli; the curve $C$ has indeed a special role in the construction, since $Y$ only admits tangent - hence singular - hyperplane sections at points that lie in $C$ (this can be seen by tracking the above construction with finite covers, or with a similar argument to the case $d = 2$ using partial derivatives).

Following [Tih82], we now give a brief description of $F(Y)$, the Fano surface of lines in $Y$. First of all, a line $l$ in $Y$ is defined as a closed one-dimensional subscheme $L \subset Y$ with Hilbert polynomial $p(t) = t + 1$; under the generality assumptions of Remark 4.1, the scheme $F(Y)$ parametrizing lines in $Y$ is given by a smooth projective surface with a copy of $C$ embedded in it ([Tih82, Thm 4]).

The copy of $C \subset F(Y)$ is given by **singular** lines ([Tih82, §3, §8]): indeed, a line according to the above definition can either be a smooth rational curve $L$ with $L \cdot H = 1$, or a rational curve with a single node at a point $p \in C$, with non-reduced scheme structure at the point.

We’re now ready to prove Theorem 1.5:

**Proof of Theorem 1.5.** By finiteness of the Gauss map for a smooth hypersurface, the hyperplane sections of $Y$ can only have isolated singularities; arguing as in the case $d = 2$, we see that these singularities must be Du Val and therefore $\mathcal{M}_G(u) \setminus \mathcal{P}$ only contains objects of the form $\iota_*\mathcal{I}(\mathbb{P}(D))$, with $D$ possibly a Weil divisor. As in the previous case, given that singularities can only occur along $C$ by Remark 4.1, we get that after the wall crossing we obtain a component $\mathcal{Y} \simeq Y$ that intersect the rest of the moduli exactly at $C$.

We’re then only left with proving that $\mathcal{M} \setminus \mathcal{Y} := \mathcal{F}$ is isomorphic to $F(Y)$, and projectivity of $\mathcal{M}$ will also follow. We know from Proposition 2.3 that $\mathcal{F}$ has dimension 2, and we can define a morphism $F(Y) \to \mathcal{F}$ as follows. Let $\mathcal{H} \subset Y \times (\mathbb{P}^2)^\vee$ be the universal hyperplane section.
Since any line in \( Y \) is contained in a unique hyperplane section of \( Y \), there is a finite map \( F(Y) \to (\mathbb{P}^2)^Y \), so we can define \( S \subset Y \times F(Y) \) as a pullback of \( H \). Let \( \mathcal{L} \subset S \subset Y \times F(Y) \) be the universal line. The sheaf \( \mathcal{O}_S(p_Y^* H - \mathcal{L}) \) on \( Y \times F(Y) \) has fiber \( \mathcal{O}_S(H - L) \) over a smooth line \( L \in F(Y) \), and \( \mathcal{T}_{p/S} \) over a singular line, where \( p \) is the embedded point of the singular line.

Next, we perform an elementary modification on \( \mathcal{O}_S(p_Y^* H - \mathcal{L}) \) as in [AB13, Section 5]. Let \( r \) be the restriction map

\[
\mathcal{O}_S(p_Y^* H - \mathcal{L}) \xrightarrow{r} \mathcal{O}_S(p_Y^* H - \mathcal{L})_{|Y \times C} = \mathcal{U}
\]

and denote \( \mathcal{V} := p^* \mathcal{O}_Y(-1)[1]|_{Y \times C} \). Now compose \( r \) with the natural evaluation

\[
\mathcal{U} \xrightarrow{ev} q^* Rq_* R\mathcal{H}om(\mathcal{V}, \mathcal{U} \otimes \omega_\mathcal{Y}[3]) \otimes \mathcal{V}.
\]

Observe that \( ev \) restricts on fibers to the unique map \( \mathcal{T}_{p/S} \to \mathcal{O}_Y(-1)[1] \) (see Section 3.3.2 for an analogous argument). Let \( K[1] \) denote the cone of \( ev \circ r \). Then, \( K \) and \( \mathcal{O}_S(p_Y^* H - \mathcal{L}) \) are isomorphic outside \( Y \times C \), and the fiber \( K_L \) of \( K \) over a singular line \( L \in C \) fits in a distinguished triangle

\[
\mathcal{O}_Y(-1)[1] \to K_L \to \mathcal{T}_p,
\]

where \( p \) is the singular point of \( L \). In other words, \( K_L \simeq E_p \) and \( K \) is a universal family for \( F \) supported on \( F(Y) \). Then, the morphism \( F(Y) \to F \) induced by \( K \) is an isomorphism.

The component \( \mathcal{Y} \) is contracted by \( \Psi \) since it is rationally connected; the Abel–Jacobi mapping is an embedding on smooth lines by [Tih82, §10], and \( \mathcal{Y} \) is determined uniquely via \( \Psi(M) = \Psi(F(Y)) \) by [Tih82, Thm. 12].

### Appendix A. Weak stability conditions

In this section we refer to [BLMS17] and briefly summarize definitions and results on weak (and Bridgeland) stability conditions.

Let \( D \) be a triangulated category and \( K(D) \) its Grothendieck group; fix a lattice \( \Lambda \subset K(D) \) and a surjective homomorphism \( v \colon \Lambda \to \mathbb{C} \).

**Definition A.1.** The heart of a bounded t-structure is a full abelian subcategory \( \mathcal{A} \subset D \) with the following properties:

(a) For all \( E, F \in \mathcal{A} \) and \( n < 0 \) we have \( \text{Hom}(E, F[n]) = 0 \);

(b) For every \( E \in D \) there exist a filtration, i.e. objects \( E_i \in D \), integers \( k_1 > \cdots > k_m \) and triangles

\[
\begin{array}{ccccccc}
0 & \to & E_0 & \to & E_1 & \to & E_2 & \to & \cdots & \to & E_{m-1} & \to & E_m = E \\
& \searrow & & \searrow & & \searrow & & \searrow & & \searrow & & \searrow & & \searrow \\
& & A_1[k_1] & & A_2[k_2] & & A_{m-1}[k_{m-1}] & & A_m[k_m] & & & & & & \\
\end{array}
\]

such that \( A_i \in \mathcal{A} \); these objects are called the cohomologies of \( E \) and are often denoted by \( \mathcal{H}^i_{\mathcal{A}}(E) \).

**Definition A.2.** Let \( \mathcal{A} \) be an abelian category; a group homomorphism \( Z \colon K(\mathcal{A}) \to \mathbb{C} \) is called a weak stability function if for all \( E \in \mathcal{A} \) we have \( \Re Z(E) \geq 0 \), and \( \Im Z(E) = 0 \) implies \( \Re Z(E) = 0 \). Moreover \( \Im Z(E) = 0 \) implies \( \Re Z(E) < 0 \) then \( Z \) is called a stability function.

A (weak) stability function has an associated slope function

\[
\mu_Z(E) = \begin{cases} 
\frac{-\Re Z(E)}{\Im Z(E)} & \text{if } \Im Z(E) > 0 \\
\infty & \text{otherwise}
\end{cases}
\]

**Definition A.3.** An object \( E \in \mathcal{A} \) is called semistable (resp. stable) with respect to \( Z \) if for every subobject \( F \subset E \) we have \( \mu_Z(F) \leq (<) \mu_Z(E) \).
Definition A.4. Let \( D \) be a triangulated category, and let \( \Lambda \) and \( \nu \) be as above; a weak stability condition on \( D \) is a pair \( \sigma = (\mathcal{A}, Z) \) where \( \mathcal{A} \) is the heart of a bounded t-structure and \( Z \) is a group homomorphism \( Z : \Lambda \to \mathbb{C} \), satisfying the following properties:

(a) The composition \( Z \circ \nu : K(\mathcal{A}) = K(\mathcal{D}) \to \Lambda \to \mathbb{C} \) is a weak stability function on \( \mathcal{A} \);

(b) We require all \( E \in \mathcal{A} \) to have Harder–Narasimhan filtration with factors \( F_i \in \mathcal{A} \) semistable with respect to \( Z \), with strictly decreasing slopes;

(c) There exists a quadratic form \( Q \) on \( \Lambda \otimes \mathbb{R} \) that is negative definite on \( \ker Z \), such that \( Q(E) \geq 0 \) for \( E \) semistable.

If moreover \( Z \) is a stability function, then the pair \((\mathcal{A}, Z)\) is a Bridgeland stability condition.

Definition A.5. An object \( E \in D \) is called (semi)stable if there exists \( m \in \mathbb{Z} \) such that \( E[m] \in \mathcal{A} \) and \( E[m] \) is (semi)stable; in that case we also say that \( E \) is (semi)stable of phase \( -m + \mu Z(E) \).

Then any \( E \in \mathcal{D} \) has a Harder–Narasimhan filtration

\[
0 = E_0 \rightarrow E_1 \rightarrow E_2 \rightarrow \ldots \rightarrow E_{m-1} \rightarrow E_m = E
\]

such that each \( F_i \) is semistable of phase \( \phi_i \), with \( \phi_1 > \cdots > \phi_m \).

Remark A.6. For our purposes, we’ll always choose \( D = D(X) \) to be the bounded derived category of coherent sheaves on a variety \( X \) of dimension \( n \), and \( \Lambda \) to be the numerical \( K \)-group, i.e., the Grothendieck group modulo the kernel of the Euler form. Moreover, our \( Z \) will always factor through the Chern character and therefore have discrete image.

Given a weak stability condition, we can produce a new heart by tilting; indeed, given \( \sigma = (\mathcal{A}, Z) \) and a choice of slope \( \mu \in \mathbb{R} \), define

\[
T^\mu,\sigma = \{ E \in \mathcal{A} \mid \text{All HN factors } F \text{ of } E \text{ have slope } \mu(F) > \mu \}
\]

\[
\mathcal{F}^\mu,\sigma = \{ E \in \mathcal{A} \mid \text{All HN factors } F \text{ of } E \text{ have slope } \mu(F) \leq \mu \}.
\]

Proposition A.7 ([HRS96], [BLMS17]). The abelian category \( \mathcal{A}^\mu,\sigma = (T^\mu,\sigma, \mathcal{F}^\mu,\sigma[1]) \) is the heart of a bounded t-structure.

In particular, starting from the weak stability condition given by Mumford slope on \( \mathcal{A} = \text{Coh}(X) \) we construct new hearts \( \text{Coh}^\beta(X) \) for \( \mu = \beta \). In order to define new (weak) stability conditions on these hearts, we need new stability functions; recalling the notation \( \text{ch}^\beta(E) = \text{ch}(E) \cdot e^{\beta H} \), we have the following

Proposition A.8 ([MS17]). Let \( \alpha > 0 \) and \( \beta \in \mathbb{R} \); the pair given by \( \sigma_{\alpha,\beta} = (\text{Coh}^\beta(X), Z_{\alpha,\beta}) \) with

\[
Z_{\alpha,\beta}(E) = -H^{n-2}\text{ch}_2^\beta(E) + \frac{\alpha}{2} H^n\text{ch}_1^\beta(E) + iH^{n-1}\text{ch}_1^\beta(E)
\]

defines a weak stability condition on \( D(X) \).

In [BLMS17], the authors give a further construction of a weak stability condition by tilting \( \text{Coh}^\beta(X) \) again: indeed, in the notation of Proposition A.7, fix a slope \( \mu \in \mathbb{R} \) and define \( \text{Coh}(X)^\mu_{\alpha,\beta} := \text{Coh}^\beta(X)^{\mu,\sigma_{\alpha,\beta}} \) endowed with a stability function

\[
Z^\mu_{\alpha,\beta} := \frac{1}{u} Z_{\alpha,\beta},
\]

where \( u \in \mathbb{C} \) is the unique unit vector such that \( \mu = -\frac{\Re u}{\Im u} \) (we just “rotate” our original stability function).

Proposition A.9. The pair \( \sigma^\mu_{\alpha,\beta} = (\text{Coh}(X)^\mu_{\alpha,\beta}, Z^\mu_{\alpha,\beta}) \) is a weak stability condition on \( D(X) \).
Finally, again in [BLMS17], we find the following Theorem that allows us to induce a stability condition on the Kuznetsov component of \( Y \) using weak stability conditions:

**Theorem A.10.** Let \( Y \) be a Fano threefold of index 2 with \( \text{Pic}(Y) = \mathbb{Z} \), and let \( \sigma_{\alpha - \frac{1}{2}} \) be the weak stability condition constructed in Proposition A.9 for \( \mu = 0 \), \( \beta = -\frac{1}{2} \) and \( 0 < \alpha \ll 1 \); let moreover \( \mathcal{A} = K \cup (Y) \cap \text{Coh}(X)_{\alpha, \beta} \) and \( Z = Z_{\alpha, \beta}^{0} \). Then the pair \( \sigma = (\mathcal{A}, Z) \) is a Bridgeland stability condition on \( K \cup Y \).
