Abstract The equation arising from Prandtl boundary layer theory

\[
\frac{\partial u}{\partial t} - \frac{\partial}{\partial x_i} \left( a(u,x,t) \frac{\partial u}{\partial x_i} \right) - f_i(x)D_i u + c(x,t)u = g(x,t)
\]

is considered. The existence of the entropy solution can be proved by BV estimate method. The interesting problem is that, since \(a(\cdot, x, t)\) may be degenerate on the boundary, the usual boundary value condition may be overdetermined. Accordingly, only dependent on a partial boundary value condition, the stability of solutions can be expected. This expectation is turned to reality by Kružkov’s bi-variables method, a reasonable partial boundary value condition matching up with the equation is found first time. Moreover, if \(a_{x_i}(\cdot, x, t)\big|_{x \in \partial \Omega} = a(\cdot, x, t)\big|_{x \in \partial \Omega} = 0\) and \(f_i(x)\big|_{x \in \partial \Omega} = 0\), the stability can be proved even without any boundary value condition.

Key words Prandtl Boundary Layer Theory, entropy solution, Kružkov’s bi-variables method, partial boundary value condition, stability.

1. Introduction

The initial-boundary value problem of the quasilinear degenerate parabolic equation

\[
\frac{\partial u}{\partial t} - \frac{\partial}{\partial x_i} \left( a(u,x,t) \frac{\partial u}{\partial x_i} \right) - f_i(x)D_i u + c(x,t)u = g(x,t), \quad (x, t) \in \Omega \times (0, T),
\]

\[u(x,0) = u_0(x), \quad x \in \Omega,
\]

\[u(x,t) = 0, \quad (x, t) \in \partial \Omega.
\]

is considered in this paper, where \(a(u, x, t) \geq 0, \Omega \subset \mathbb{R}^N\) is a appropriately smooth open domain, \(D_i = \frac{\partial}{\partial x_i}\), the double indices of \(i\) represent the summation from 1 to \(N\) as usual.

Equation (1.1) arises from the boundary layer theory [1] etc. As the simplification of the Navier-Stokes equation, the Prandtl boundary layer equation describes the motion of a fluid with small viscosity about a solid body in a thin layer which is formed near its surface owing to the adhesion of the viscous fluid to the solid surface. In particular, we consider the motion of a fluid occupying a two dimensional region is characterized by the velocity vector \(V = (u, v)\), where \(u, v\) are the projections of \(V\) onto the coordinate
axes $x, y$, respectively, assume that the density of the fluid $\rho$ is equal to 1, then the Prandtl boundary layer equation for a non-stationary boundary layer arising in an axially symmetric incompressible flow past a solid body has the form [1]

$$
\begin{align*}
& u_t + uu_x + vu_y = \nu u_{yy} - p_x, \\
& u_x + v_y = 0, \\
& u(0, x, y) = u_0(x, y), \quad u(t, 0, y) = u_1(t, y), \\
& u(t, x, 0) = 0, \quad v(t, x, 0) = v_0(t, x), \\
& \lim_{y \to \infty} u(t, x, y) = U(t, x).
\end{align*}
$$

in a domain $D = \{0 < t < T, 0 < x < X, 0 < y < \infty\}$, where $\nu = \text{const} > 0$ is the viscosity coefficient of the incompressible fluid, $u_0 > 0, u_1 > 0$ for $y > 0, u_{0y} > 0, u_{1y} > 0$ for $y \geq 0$, where, $p = p(t, x)$ is the pressure, $U = U(t, x)$ is the velocity at the outer edge of the boundary layer which satisfies

$$
U_t + UU_x = -p_x(t, x), \quad U(t, x) > 0.
$$

By the well-known Crocco transform,

$$
\tau = t, \quad \xi = x, \quad \eta = u(t, x, y), \quad w(\tau, \xi, \eta) = u_y.
$$

we can show that $u_y = w$ satisfies the following nonlinear equation

$$
w_\tau = \nu w^2w_{\eta\eta} - \eta w_\xi + p_xw_\eta, \quad (1.4)
$$

By a linearized method, Oleinik had shown that there is a local classical solution to this equation [2]. Although there are some important papers to studied the global solutions of the Prandtl boundary layer equation [32-37], the related problems are far from being solved. For example, the compatibility problem between Navier-Stokes equation and Prandtl boundary layer equation. For another example, whether there is a global solution of equation (1.4) and whether this global solution can be deduced a global weak solution of the Prandtl boundary layer equation by the inverse transform of Crocco transform? In fact, if the domain is not the $N-$dimensional cube, whether the inverse transform of Crocco transform exists or not is still unsolved. In addition, many reaction-diffusion problems can be summed up to equation (1.1) [2].

In this paper, we will consider the global solutions of equation (1.1). After the pioneering work [3] by Vol’pert-Hudjaev, the Cauchy problem of equation (1.1) had been studied in [4-13] etc., the solutions to the Cauchy problem of equation (1.1) are well-posedness. Also, the initial-boundary value problem of equation (1.1) had been studied in many papers, many excellent and important results had been obtained in [14-16], [30-31] etc. Shall we say, there is not important problem left? I think it is too early to make such a conclusion. Besides the problems related to Prandtl boundary layer theory, since $a(u, x, t) \geq 0$ and may be degenerate in the interior of $\Omega$ or on the boundary $\partial \Omega$, everyone knows that the boundary value condition (1.3) is overdetermined, there is not an effective method to find a reasonable partial boundary value condition

$$
u(x, t) = 0, \quad (x, t) \in \Sigma_p \times (0, T), \quad (1.5)
$$
to replace (1.3), where $\Sigma_p$ is a relative open subset of $\partial \Omega$. Here, we like to suggest that the boundary value condition (1.3) or (1.5) is understood in the sense of the trace, and we expect to find an analytic expression of $\Sigma_p$ in this paper. The difficulty comes from that, since the equation has the nonlinearity, the partial boundary $\Sigma_p$ in (1.5) can not be depicted out by Fichera function as that of the linear degenerate parabolic equation [26-27].

In fact, for a nonlinear parabolic equation, how to impose a reasonable partial boundary value condition has been up in the air for a long time [14-19]. Let us give some details. In [14-16], the entropy solutions defined in these references are in $L^\infty(Q_T)$ sense, one can not define the trace on the boundary, accordingly, it is impossible to express $\Sigma_p$ in an analytic formula. Instead, the authors of [14-16] had found a kind of the entropy inequality to imply the boundary value condition (1.5) in ingenious ways. In the work by Yin-Wang [17], the degenerate non-Newtonian fluid equation

$$\frac{\partial u}{\partial t} - \text{div}(d(x)|\nabla u|^{p-2} \nabla u) - f_i(x) D_i u + c(x,t) u = g(x,t), (x,t) \in \Omega \times (0,T), \quad (1.6)$$

was considered. By means of a reasonable integral description, in [17], the boundary $\partial \Omega$ is classified into three parts: the nondegenerate boundary $\Sigma_1$, the weakly degenerate boundary $\Sigma_2$ and the strongly degenerate boundary $\Sigma_3$. Instead of the usual boundary condition (1.3), a partial boundary value condition (1.5) is imposed, where

$$\Sigma_p = \Sigma_2 \cup \Sigma_3. \quad (1.7)$$

It is pity that, since equation (1.1) is apparently different the Non-Newtonian equation (1.6), $\Sigma_p$ also can not be described as (1.7). If the domain $\Omega$ is the $N-$dimensional cube or the half space of $\mathbb{R}^N$, the equation

$$\frac{\partial u}{\partial t} = \Delta A(u) + \text{div}(b(u)), \quad (x,t) \in \Omega \times (0,T),$$

was studied in [18-19] by the author recently, a reasonable analytic expression of $\Sigma_p$ had been found in [18-19]. However, for a general domain $\Omega$, the problem remains open. We hope to make a essential progress sooner or later.

Certainly, since the subset set $D_0 = \{ x \in \Omega : a(\cdot, x, t) = 0 \}$ may have a positive measure in $\Omega$, equation (1.1) has hyperbolic characteristic in $D_0$. Thus, only in the sense of the entropy solution, the uniqueness (or the stability) of the weak solution can be obtained [1]. In this paper, with the help of the entropy solutions defined in the sense of $BV$ functions [1, 5, 18, 22], we study the well-posed problem of equation (1.1) with the initial value (1.2) and the partial boundary value condition (1.5), the key is to find a reasonable analytic expression of $\Sigma_p$ first time.

The paper is arranged as follows. After the introduction section, section 2 introduces the definition of the entropy solution and the main results. Section 3 gives the proof of the existence of the entropy solutions. Section 4 introduces the well-known Kružkov bi-variables method. Section 5 is on the stability of the entropy solutions based on the partial boundary value condition. At the end, an explanation of the definition of the entropy solution is given.

2. The definition of the entropy solution and the main results

For the completeness of the paper, we first quote the definition of $BV$ function and its properties [28].
Definition 2.1 Let \( \Omega \subset \mathbb{R}^m \) be an open set and let \( f \in L^1(\Omega) \). Define
\[
\int_\Omega |Df| = \sup \left\{ \int_\Omega f \text{div} g : g = (g_1, g_2, \ldots, g_N) \in C^1_0(\Omega; \mathbb{R}^m), |g(x)| \leq 1, x \in \Omega \right\},
\]
where \( \text{div} g = \sum_{i=1}^m \frac{\partial g_i}{\partial x_i} \).

Definition 2.2 A function of \( f \in L^1(\Omega) \) is said to have bounded variation in \( \Omega \) if
\[
\int_\Omega |Df| < \infty.
\]
We define \( BV(\Omega) \) as the space of all functions in \( L^1(\Omega) \) with bounded variation. This is equivalent to that the generalized derivatives of every function in \( BV(\Omega) \) are regular measures on \( \Omega \). Under the norm
\[
\|f\|_{BV} = \|f\|_{L^1} + \int_\Omega |Df|,
\]
\( BV(\Omega) \) is a Banach space.

Proposition 2.3 (Semicontinuity) Let \( \Omega \subset \mathbb{R}^m \) be an open set and \( \{f_j\} \) a sequence of functions in \( BV(\Omega) \) which converge in \( L^1_{\text{loc}}(\Omega) \) to a function \( f \). Then
\[
\int_\Omega |Df| \leq \lim_{j \to \infty} \inf \int_\Omega |Df_j|.
\]

Proposition 2.4 (Integration by part) Let \( C^+_R = \mathcal{B}(0, R) \times (0, R) = \mathcal{B}_R \times (0, R) \) and \( f \in BV(C^+_R) \). Then there exists a function \( f^+ \in L^1(\mathcal{B}_R) \) such that for \( H_{n-1} \)-almost all \( y \in \mathcal{B}_R \),
\[
\lim_{\rho \to 0} \rho^{-m} \int_{C^+_{\rho}(y)} \langle g(z) - f^+(y) \rangle dz = 0.
\]
Moreover, if \( C_R = \mathcal{B}_R \times (-R, R) \), then for every \( g \in C^1_0(C_R; \mathbb{R}^m) \),
\[
\int_{C^+_{\rho}} f \text{div} g dx = -\int_{C^+_{\rho}} g(y, Df) + \int_{\mathcal{B}_R} f^+ g dH_{n-1},
\]
where \( \mathcal{B}_\rho = \{ x \in \mathbb{R}^m ; |x| < \rho \} \).

Remark 2.5 The function \( f^+ \) is called the trace of \( f \) on \( \mathcal{B}_R \) and obviously
\[
f^+(y) = \lim_{\rho \to 0} \frac{1}{|C^+_{\rho}(y)|} \int_{C^+_{\rho}(y)} f(z) dz.
\]
The definition of the trace is easy generalized to a general smooth domain in \( \mathbb{R}^m \).

Secondly, we give the definition of the entropy solutions matching up with equation (1.1). For small \( \eta > 0 \), let
\[
S_\eta(s) = \int_0^s h_\eta(\tau) d\tau, \quad h_\eta(s) = \frac{2}{\eta} \left( 1 - \left| \frac{s}{\eta} \right| \right)_+.
\]
Obviously \( h_\eta(s) \in C(\mathbb{R}) \), and
\[
h_\eta(s) \geq 0, \quad |s h_\eta(s)| \leq 1, \quad |S_\eta(s)| \leq 1; \lim_{\eta \to 0} S_\eta(s) = \text{sgn} s, \lim_{\eta \to 0} s S'_\eta(s) = 0. \tag{2.1}
\]
Definition 2.6 A function $u \in BV(Q_T) \cap L^\infty(Q_T)$ is said to be the entropy solution of equation (1.1) with the initial value (1.2), provided that

1. There exist $g^i \in L^2(Q_T)$ ($i = 1, 2, \ldots, N$) such that for any $\varphi(x, t) \in C^1_0(Q_T)$
   \[
   \iint_{Q_T} \varphi(x, t) g^i(x, t) dx dt = \iint_{Q_T} \varphi(x, t) \sqrt{a(u, x, t)} \frac{\partial u}{\partial x_i} dx dt, \quad (2.2)
   \]
   where
   \[
   \sqrt{a(u, x, t)}(u, x, t) = \int_0^1 \sqrt{\alpha u^+ + (1 - \tau)u^-} \cdot x, t d\tau,
   \]
   is the composite mean value of $\sqrt{a(u, x, t)}$.

2. If $\varphi \in C^2_0(Q_T)$ and $\varphi \geq 0$, for $k \in \mathbb{R}$ and for any small $\eta > 0$ there holds
   \[
   \iint_{Q_T} \left[ I_{\eta}(u - k) \varphi_t - f_i(x) I_{\eta}(u - k) \varphi_{x_i} + A_{\eta}(u, x, t, k) \Delta \varphi - \sum_{i=1}^N S_{\eta}(u - k) \left| g^i \right|^2 \varphi \right] dx dt
   \]
   \[
   + \iint_{Q_T} \int_k^u a_{x_i}(s, x, t) S_{\eta}(s - k) ds \varphi_{x_i} dx dt
   \]
   \[
   - \iint_{Q_T} f_{x_i}(x)(u - k) \varphi S_{\eta}(u - k) dx dt + \iint_{Q_T} f_{x_i}(x) \int_k^u (s - k) h_{\eta}(s - k) ds \varphi dx dt
   \]
   \[
   - \iint_{Q_T} [c(x, t) u + g(x, t)] \varphi S_{\eta}(u - k) dx dt
   \]
   \[
   \geq 0.
   \]

3. The initial value is satisfied in the sense of that
   \[
   \lim_{t \to 0} \int_{\Omega} \left| u(x, t) - u_0(x) \right| dx = 0. \quad (2.4)
   \]

Here $\tilde{f} = \{f_i\}$,
\[
A_{\eta}(u, x, t, k) = \int_k^u a(s, x, t) S_{\eta}(s - k) ds,
\]
and
\[
I_{\eta}(u - k) = \int_0^{u - k} S_{\eta}(s) ds.
\]

Definition 2.7 If $u \in BV(Q_T) \cap L^\infty(Q_T)$ is the entropy solution of equation (1.1) with the initial value (1.2), and the partial boundary value condition (1.5) is satisfied in the sense of the trace, then we say $u$ is an entropy solution of the initial-boundary value problem of equation (1.1). Here,
\[
\Sigma_p = \left\{ x \in \partial \Omega : \sum_{i=1}^N f_i(x) n_i < 0 \right\} \bigcup \left\{ x \in \partial \Omega : \sum_{i=1}^N a_{x_i}(\cdot, x, t) n_i \neq 0 \right\} \bigcup \left\{ x \in \partial \Omega : a(\cdot, x, t) \neq 0 \right\}, \quad (2.5)
\]
and $\vec{n} = \{n_i\}$ is the inner normal vector of $\Omega$.

In what follows, we can show that if $a(\cdot, x, t) |_{x \in \partial \Omega} = 0$, then $\Sigma_p$ in the partial boundary value (1.5) can be depicted out as (2.5). Based on this fact, thirdly, we will prove the following theorems.
Theorem 2.8 If \( a(s, x, t) \in C^1(\mathbb{R}^N \times Q_T), f_i(x) \in C(\overline{\Omega}), c(x, t) \) and \( g(x, t) \) are \( C^1(\overline{Q}_T) \), \( u_0(x) \in L^\infty(\Omega) \), then equation (1.1) with the initial value condition (1.2) has an entropy solution in the sense of Definition 2.6.

Theorem 2.9 If \( a(s, x, t) \in C^1(\mathbb{R}^N \times Q_T) \) with \( a(0, x, t) = 0, (x, t) \in Q_T, f_i(x) \in C^1(\overline{\Omega}), c(x, t) \) and \( g(x, t) \) are \( C^1(\overline{Q}_T) \), \( u_0(x) \in L^\infty(\Omega) \), and there is a constant \( \delta_1 > 0 \) such that
\[
a(r, x, t) - \delta_1 \sum_{s=1}^{N+1} (a_{xs}(r, x, t))^2 \geq 0,
\]
then the initial-boundary value problem of equation (1.1) has an entropy solution in the sense of Definition 2.7.

Theorem 2.10 Suppose \( a(\cdot, x, t) \) is a \( C^1(\overline{Q}_T) \) function, \( a(s, x, t) \) is bounded when \( s \) is bounded, \( f_i(x) \in C^1(\overline{\Omega}), c(x, t) \) and \( g(x, t) \) are bounded. Suppose that when \( x \) is near to the boundary,
\[
\Delta d \leq 0,
\]
there exist constants \( \delta_2 > 0 \) such that
\[
| \sqrt{a(\cdot, x, \cdot)} - \sqrt{a(\cdot, y, \cdot)} | \leq c \cdot | x - y |^{2+\delta_2},
\]
\[
a_{xs}(\cdot, x, \cdot) = 0, x \in \partial \Omega, i = 1, 2, \ldots, N,
\]
\[
f_i(x) = 0, x \in \partial \Omega, i = 1, 2, \ldots, N.
\]
If \( u(x, t) \) and \( v(x, t) \) are two solutions of equation (1.1) with the different initial values \( u_0(x), v_0(x) \in L^\infty(\Omega) \) respectively, then
\[
\int_\Omega | u(x, t) - v(x, t) | dx \leq c \int_\Omega | u_0(x) - v_0(x) | dx.
\]
Here \( d(x) = \text{dist}(x, \partial \Omega) \) is the distance function from the boundary, \( a(\cdot, x, t) \) is regarded as the function of the variables \( (x, t) \), \( a(\cdot, x, \cdot) \) is regarded as the function of \( x \).

In general, the conditions listed in Theorem 2.10 are only the sufficient conditions, and can be replaced by the other assumptions.

If without the condition (2.7), we have

Theorem 2.11 Suppose that \( a(\cdot, x, t) \) is a \( C^1(\overline{Q}_T) \) function with that \( a(\cdot, x, t) |_{x \in \partial \Omega} = 0, a(s, x, t) \) is bounded when \( s \) is bounded, \( f_i(x) \in C^1(\overline{\Omega}), c(x, t) \) and \( g(x, t) \) are bounded. Suppose that the conditions (2.8)-(2.10) are true. If \( u(x, t) \) and \( v(x, t) \) are two solutions of equation (1.1) with the different initial values \( u_0(x), v_0(x) \in L^\infty(\Omega) \) respectively, then the stability (2.11) is true.

If the condition (2.10) is not true, we have the following stability based on the partial boundary value condition (1.5) with \( \Sigma_p \) appearing as (2.5).

Theorem 2.12 Suppose \( a(\cdot, x, t) \) is a \( C^1(\overline{Q}_T) \) function, \( a(s, x, t) \) is bounded when \( s \) is bounded, \( f_i(x) \in C^1(\overline{\Omega}), c(x, t) \) and \( g(x, t) \) are bounded. Suppose that the condition (2.7) is true. If \( u(x, t) \) and \( v(x, t) \) are two solutions of equation (1.1) with the different initial values \( u_0(x), v_0(x) \in L^\infty(\Omega) \) respectively, and with the same partial boundary value condition
\[
u(x, t) = v(x, t) = 0, (x, t) \in \Sigma_p \times (0, T),
\]
then the stability (2.11) is true. Where $\Sigma_p$ has the form (2.5).

Now, we give a simple comment on Theorem 2.11 and Theorem 2.12. For the linear degenerate parabolic equation
\[
\frac{\partial u}{\partial t} - \frac{\partial}{\partial x_i} \left( a(x) \frac{\partial u}{\partial x_i} \right) - f_i(x)D_iu + c(x,t)u = g(x,t), \quad (x,t) \in \Omega \times (0,T),
\] (2.13)
let $\vec{n} = \{n_i\}$ be the inner normal vector of $\Omega$. To ensure the well-posedness of the solutions of equation (2.13), only a partial boundary value condition (1.5) should be imposed, where the part of the boundary $\Sigma_p$ can be expressed by Fichera function [26-27]
\[
\Sigma_p = \{ x \in \partial \Omega : a(x) > 0 \} \cup \{ x \in \partial \Omega : f_i(x)n_i(x) < 0 \}.
\] (2.14)

If $a(x) |_{x \in \partial \Omega} = 0$, and the condition (2.10) is imposed, by (2.14), we have
\[
\Sigma_p = \emptyset.
\]
In the other words, the stability of the weak solutions of equation (2.13) can be obtained independent of the boundary value condition. This coincides with Theorem 2.11.

If without the condition (2.10), since $a(x) |_{x \in \partial \Omega} = 0$, (2.14) reduces to the expression (2.5). This coincides with Theorem 2.12.

Fourthly, we would like to suggest that there are many domains satisfying the condition (2.7). For examples,

i) The $N$-dimensional cube
\[
C_1 = \{ x \in \mathbb{R}^N : 0 < x_i < 1, i = 1, 2, \ldots, N \}
\]
the distance function $d$ from the boundary satisfies that when $x$ is near to the hyperplane $\{x : x_i = 0\}$,
\[
d(x) = x_i,
\]
while $x$ is near to the hyperplane $\{x : x_i = 1\}$,
\[
d(x) = 1 - x_i.
\]

ii) The $N$-dimensional unit disc
\[
D_1 = \{ x \in \mathbb{R}^N : |x| < 1 \}
\]
the distance function from the boundary is
\[
d(x) = 1 - r, \quad r^2 = x_1^2 + x_2^2 + \cdots + x_N^2,
\]
\[
d_{x_i} = -\frac{x_i}{r},
\]
\[
\Delta d = -\frac{N - 1}{r} < 0.
\]

The last but not the least, we have said before the condition (2.7) is not a necessary condition. For example, in Theorem 2.11, we have used the condition $a(\cdot, x, t)|_{x \in \partial \Omega} = 0$ to replace the condition (2.7). This is very interesting phenomena. Condition (2.7), $\Delta d < 0$ reflects the geometric characteristic of the domain $\Omega$, while, $a(\cdot, x, t)$ itself is the diffusion coefficient, the condition $a(\cdot, x, t)|_{x \in \partial \Omega} = 0$ implies the diffusion process ends at the boundary $\partial \Omega$. The results of our paper show that these two different conditions both are enough to make the solutions stable.
3. The proof of the existence

The existence of the entropy solutions of equation (1.1) can be proved by the similar way as that in [18, 19, 23], we only give the outline of the proof in what follows.

**Lemma 3.1** [24] Assume that Ω ⊂ \( \mathbb{R}^N \) is an open bounded set and \( f_k, f \in L^q(\Omega) \), as \( k \to \infty \), \( f_k \rightharpoonup f \) weakly in \( L^q(\Omega) \) (1 \( \leq q < \infty \)). Then we have

\[
\lim_{k \to \infty} \inf \| f_k \|_{L^q(\Omega)} \geq \| f \|_{L^q(\Omega)}.
\]

**Proof of Theorem 2.8** Consider the regularized problem

\[
\frac{\partial u}{\partial t} = \partial_{x_i} \left( a(u, x, t) \partial_{x_i} u \right) + \varepsilon \Delta u + f_1(x) D_i u - c(x, t) u + g(x, t), \quad (x, t) \in Q_T,
\]

with the initial-boundary conditions

\[
u(x, 0) = u_0(x), \quad x \in \Omega, \tag{3.2}
\]
\[
u(x, t) = 0, \quad (x, t) \in \partial \Omega \times (0, T). \tag{3.3}
\]

Here, \( u_0(x) \) is a mollified function of \( u_0 \). We know that there exists a classical solutions \( u_\varepsilon \), provided that both \( a(u, x, t) \) and \( b_i(u, x, t) \) satisfy the assumptions given in Theorem 2.8. For more details, one can refer to [5] or Chapter 8 of [25]. Moreover, we have

\[
| u_\varepsilon | \leq \| u_0 \|_{L^\infty} \leq c. \tag{3.4}
\]

**Step 1** Multiplying equation (2.1) with \( u_\varepsilon \), it is easy to show that

\[
\int\int_{Q_T} a(u_\varepsilon, x, t) |\nabla u_\varepsilon|^2 \, dx \, dt \leq c. \tag{3.5}
\]

Then, \( \sqrt{a(u_\varepsilon, x, t)} \frac{\partial u_\varepsilon}{\partial x_i} \) is weakly compact in \( L^2(Q_T) \). By choosing a subsequence (still denoting it as \( \sqrt{a(u_\varepsilon, x, t)} \frac{\partial u_\varepsilon}{\partial x_i} \)), we are able to show that

\[
\sqrt{a(u_\varepsilon, x, t)} \frac{\partial u_\varepsilon}{\partial x_i} \to \sqrt{a(u, x, t)} \frac{\partial u}{\partial x_i}, \text{ in } L^2(Q_T),
\]

\( u \) satisfies (1) of Definition 2.6.

**Step 2** Let \( \varphi \in C_0^2(Q_T), \ \varphi \geq 0 \). Multiplying both sides of (2.1) by \( \varphi S_0(u_\varepsilon - k) \), integrating it by part,
we can deduce that
\[
\int Q_T \eta (u_\varepsilon - k) \varphi \, dx \, dt + \int Q_T A_\eta (u_\varepsilon, x, t, k) \Delta \varphi \, dx \, dt
\]
\[
- \varepsilon \int Q_T \eta (u_\varepsilon - k) f_i(x) \varphi_i \, dx \, dt
\]
\[
- \int Q_T \eta (u_\varepsilon - k) \varphi \, dx \, dt + \int Q_T \int \eta (u_\varepsilon - k) \psi \, dx \, dt
\]
\[
- \int Q_T \int \eta (u_\varepsilon - k) \varphi \, dx \, dt
\]
\[
= 0.
\]
By Lemma 3.1, we have
\[
\liminf_{\varepsilon \to 0} \int Q_T \eta (u_\varepsilon - k) a(u_\varepsilon, x, t) \frac{\partial u_\varepsilon}{\partial x_i} \frac{\partial u_\varepsilon}{\partial x_i} \varphi \, dx \, dt \geq \sum_{i=1}^{N} \int Q_T \eta (u_\varepsilon - k) | g^i |^2 \varphi \, dx \, dt.
\]
(3.6)

Letting \( \varepsilon \to 0 \) in (3.6), it is easily to obtain (2.3).

**Step 3** At last, the initial value (1.2) is true in the sense of (2.4), its proof can be found in [21].

Thus, the existence of the entropy solution in the sense of Definition 2.6 has been proved, Theorem 2.8 follows immediately.

**Lemma 3.2** Let \( u_\varepsilon \) be the solution of the problem (3.1)-(3.3). If the assumptions given in Theorem 2.9 hold, then
\[
| \operatorname{grad} u_\varepsilon |_{L^1(\Omega)} \leq c,
\]
where \( c \) is independent of \( \varepsilon \), and
\[
| \operatorname{grad} u_\varepsilon |^2 = \sum_{i=1}^{N} \left| \frac{\partial u_\varepsilon}{\partial x_i} \right|^2 + \left| \frac{\partial u_\varepsilon}{\partial t} \right|^2.
\]

Lemma 3.2 can be proved in a similar manner as Theorem 11 of [29], we omit the details here.

By Theorem 2.8 and Lemma 3.2, we know that Theorem 2.9 is true.

4. **Kruzkov’s bi-variables method**

Similar as [1, 22], we denote that \( \Gamma_u \) is the set of all jump points of \( u \in BV(Q_T) \), \( v \) is the normal of \( \Gamma_u \) at \( X = (x, t) \), \( u^+(X) \) and \( u^-(X) \) are the approximate limits of \( u \) at \( X \in \Gamma_u \) with respect to \( (v, Y - X) > 0 \) and \( (v, Y - X) < 0 \), respectively. For the continuous functions \( p(u, x, t) \) and \( u \in BV(Q_T) \), the composite mean value of \( p \) is defined as
\[
\tilde{p}(u, x, t) = \int_{0}^{1} p(\tau u^+ + (1 - \tau) u^-, x, t) \, d\tau.
\]
If \( f(s) \in C^1(\mathbb{R}) \) and \( u \in BV(Q_T) \), then \( f(u) \in BV(Q_T) \) and
\[
\frac{\partial f(u)}{\partial x_i} = \int(u) \frac{\partial u}{\partial x_i}, \quad i = 1, 2, \cdots, N, N + 1,
\]
where \( x_{N+1} = t \).

**Lemma 4.1** Let \( u \) be a solution of (1.1). Then
\[
a(s, x, t) = 0, \quad s \in I(u^+(x, t), u^-(x, t)) \text{ a.e. on } \Gamma_u,
\]
which \( I(\alpha, \beta) \) denote the closed interval with endpoints \( \alpha \) and \( \beta \), and (4.1) is in the sense of Hausdorff measure \( H_N(\Gamma_u) \).

**Proof** Denote
\[
\Gamma_1 = \{(x, t) \in \Gamma_u, v_1(x, t) = \cdots = v_N(x, t) = 0\},
\]
\[
\Gamma_2 = \{(x, t) \in \Gamma_u, v_1^2(x, t) + \cdots + v_N^2(x, t) > 0\}.
\]

At first, we prove \( a(s, x, t) = 0, \quad s \in I(u^+(x, t), u^-(x, t)) \text{ a.e. on } \Gamma_1 \). Since any measurable subset of \( \Gamma_1 \) can be expressed as the union of Borel sets and a set of measure zero, it suffices to prove
\[
a(s) = 0, \quad s \in I(u^+(x, t), u^-(x, t)) \text{ a.e. on } U \subset \Gamma_1,
\]
where \( U \) is a Borel subset of \( \Gamma_1 \). For any bounded function \( f(x, t) \), which is measurable with respect to measure \( \frac{\partial u}{\partial x_i} \), Lemma 3.7.8 in [1] shows that
\[
\iiint_U f(x, t) \frac{\partial u}{\partial x_i} = \int_0^T dt \iiint_{U'} f(x, t) \frac{\partial u}{\partial x_i},
\]
where \( U' = \{x : (x, t) \in U\} \). Moreover, for any Borel subset \( S \subset U, S' \subset U' \), for \( i = 1, 2, \cdots, N, \)
\[
\frac{\partial u}{\partial x_i}(S) = \int_S (u^+(x, t) - u^-(x, t)) v_i dH,
\]
\[
\frac{\partial u}{\partial x_i}(S') = \int_{S'} (u^+_i(x, t) - u^-_i(x, t)) v_i dH'.
\]
(4.2) is equivalent to
\[
\iiint_U f(x, t)(u^+(x, t) - u^-(x, t)) v_i dH = \int_0^T dt \iiint_{U'} f(x, t)(u^+_i(x, t) - u^-_i(x, t)) v_i dH'.
\]
The definition of \( \Gamma_1 \) implies that the left hand side vanishes, then
\[
\int_0^T dt \iiint_{U'} f(x, t)(u^+_i(x, t) - u^-_i(x, t)) v_i dH' = 0.
\]
If we choose \( f(x, t) = \chi_u(x, t) \text{sgn}(u^+_i(x, t) - u^-_i(x, t)) \text{sgnv}_i \), where \( \chi_u(x, t) \) is the characteristic function of \( U \), sum up for \( i \) from 1 up to \( N \), then
\[
\int_G dt \iiint_{U'} (u^+_i(x, t) - u^-_i(x, t)) (| v_1^i | + \cdots + | v_N^i |) dH' = 0,
\]
where $G$ is the projection of $U$ on the $t$-axis. (4.2) implies for almost all $t \in G$,

$$\int_{U_t} (u^+_t(x,t) - u^-_t(x,t)) (|v_1'| + \cdots + |v_N'|) dH^1 = 0,$$

and hence for almost all $t \in G$,

$$v_1' = \cdots = v_N' = 0,$$

$H^1$-almost everywhere on $U_t$, which is impossible unless $\text{mes} G = 0$.

For any $\alpha, \beta$ with $0 < \alpha < \beta < T$, we choose $\psi_j(t) \in C_0^\infty(0, T)$ such that

$$0 \leq \psi_j(t) \leq 1, \quad \lim_{j \to \infty} \psi_j(t) = \chi_{[\alpha, \beta]}(t), \quad \forall t \in [0, T],$$

and choose $\varphi_n \in C_0^\infty(Q_T)$ such that

$$|\varphi_n(x,t)| \leq 1, \quad \lim_{n \to \infty} \varphi_n = \chi_U \text{ in } L^1(Q_T, |\partial u|).$$

Now, denoting that

$$A(u, x, t) = \int_0^u a(s, x, t) ds,$$

from the definition of BV-function, we have

$$\iint_{Q_T} \varphi_n(x,t) \psi_j(t) \frac{\partial u}{\partial t} dx dt = \iint_{Q_T} A(u, x, t) \Delta \varphi_n(x,t) \psi_j(t) dx dt - \iint_{Q_T} a_x(s, x, t) ds \varphi_n(x,t) \psi_j(t) dx dt - \iint_{Q_T} f_i(x) u_i \varphi_n(x,t) \psi_j(t) dx dt + \iint_{Q_T} f_i u \varphi_n(x,t) \psi_j(t) dx dt + \int_{Q_T} [g(x,t) - c(x,t)u] \varphi_n(x,t) \psi_j(t) dx dt.$$

Let $j \to \infty$. Then

$$\iint_{Q_T} \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) \frac{\partial u}{\partial t} dx dt = \iint_{Q_T} A(u, x, t) \Delta \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) dx dt - \iint_{Q_T} a_x(s, x, t) ds \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) dx dt - \iint_{Q_T} f_i(x) u_i \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) dx dt + \iint_{Q_T} f_i u \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) dx dt + \int_{Q_T} [g(x,t) - c(x,t)u] \varphi_n(x,t) \chi_{[\alpha, \beta]}(t) dx dt.$$

Clearly, this equality also holds if $[\alpha, \beta]$ is replaced by $(\alpha, \beta)$ and hence it holds even if $[\alpha, \beta]$ is replaced by any open set $I$ with $\bar{7} \subset (0, T)$. Since $G$ is a Borel set, by approximation we may conclude that

$$\iint_{Q_T} \varphi_n(x,t) \chi_G(t) \frac{\partial u}{\partial t} dx dt = \iint_{Q_T} A(u, x, t) \Delta \varphi_n(x,t) \chi_G(t) dx dt - \iint_{Q_T} a_x(s, x, t) ds \varphi_n(x,t) \chi_G(t) dx dt$$
\[-\iint_{Q_T} f_i(x)u \frac{\partial}{\partial x_i} \varphi_n(x, t)\chi_G(t) dx dt + \iint_{Q_T} f_{ix, u} \varphi_n(x, t)\chi_G(t) dx dt + \iint_{Q_T} [g(x, t) - c(x, t)u] \varphi_n(x, t)\chi_G(t) dx dt.\]

The two terms on the right hand vanish by that \(\text{mes}G = 0\), and
\[\iint_{Q_T} \varphi_n(x, t)\chi_G(t) \frac{\partial u}{\partial t} = 0.\]
Let \(n \to \infty\). Then
\[\iint_{U} \frac{\partial u}{\partial t} = \iint_{Q_T} \chi_U(x, t) \frac{\partial u}{\partial t} = 0.\]
Hence
\[\int_{U} (u^+(x, t) - u^-(x, t))v_i dH = 0,\]
which implies \(H(U) = 0\) and \(H(\Gamma_1) = 0\) by the arbitrariness of \(U\).

Secondly, we prove \(H(\Gamma_2) = 0\). Let \(U\) be any Borel subset of \(\Gamma_2\) which is compact in \(Q_T\). Since \(U\) is a set of \(N + 1\)-dimensional measure zero and \(\frac{\partial}{\partial x_i} A(u, x, t) \in L^2_{\text{loc}}(Q_T)\), we have
\[\iint_{U} \frac{\partial}{\partial x_i} A(u, x, t) dx dt = 0, \ i = 1, \cdots, N,\]
and hence
\[\int_{U} [A(u^+, x, t) - A(u^-, x, t)]v_i dH = 0, \ i = 1, \cdots, N.\]
Form this fact, it follows by the definition of \(\Gamma_2\) that
\[\int_{u^+(x, t)}^{u^-(x, t)} a(s, x, t) ds = 0, \ a.e. \ on \ \Gamma_2.\]
Thus the lemma is proved.

In this section, we apply Kružkov bi-variables method to the main equation (1.1). In details, let \(u(x, t)\) and \(v(x, t)\) be two entropy solutions of equation (1.1) with the initial values
\[u(x, 0) = u_0(x) \ \text{and} \ v(x, 0) = v_0(x),\]
respectively.

By Definition 2.6, for any nonnegative \(\varphi \in C_0^2(Q_T)\), we have
\[\iint_{Q_T} \left[ I_{\eta}(u - k)\varphi_t - f_i(x)I_{\eta}(u - k)\varphi_{x_i} + A_{\eta}(u, x, t, k)\Delta \varphi - \sum_{i=1}^{N} S^\prime_{\eta}(u - k) \mid g^i \mid^2 \varphi \right] dx dt \]
\[+ \iint_{Q_T} \int_{k}^{u} a_{x_i}(s, x, t) S_{\eta}(s - k) ds \varphi_{x_i} dx dt \]
\[= \iint_{Q_T} f_{ix}(x)(u - k)\varphi S_{\eta}(u - k) dx dt + \iint_{Q_T} f_{ix}(x) \int_{k}^{u} (s - k) h_{\eta}(s - k) ds \varphi dx dt \]
\[- \iint_{Q_T} [c(x, t)u - g(x, t)]\varphi S_{\eta}(u - k) dx dt \]
\[\geq 0,\]
and

\[
\int_{Q_T} \left[ I\eta(v-l)\varphi_x - f_1(y)I\eta(v-l)\varphi_y + A\eta(v,y,\tau,t)\Delta \varphi - \sum_{i=1}^{N} S'_\eta(v-l) \mid g^i \mid \varphi \right] dyd\tau \\
+ \int_{Q_T} \int_{l}^{v} a_y(s,y,\tau)S\eta(v-l)ds\varphi_y dyd\tau \\
- \int_{Q_T} f_{iy}(y)\varphi S\eta(v-l)dyd\tau + \int_{Q_T} f_{iy}(y) \int_{l}^{v} (s-k)h\eta(s-l)ds\varphi dyd\tau \\
- \int_{Q_T} [c(y,\tau)v-g(y,\tau)]\varphi S\eta(v-l)dyd\tau \geq 0. 
\]

Let

\[ \psi(x,t,y,\tau) = \phi(x,t)j_h(x-y,t-\tau), \]

for any \( \phi(x,t) \geq 0, \phi(x,t) \in C_0^\infty(Q_T), \) and

\[ j_h(x-y,t-\tau) = \omega_h(t-\tau)\Pi_{i=1}^{N}\omega_h(x_i-y_i). \]

Here, \( \omega_h(s) = \frac{1}{T} \omega(\frac{s}{T}), \omega(s) \in C_0^\infty(\mathbb{R}), \omega(s) \geq 0, \omega(s) = 0 \text{ if } |s| > 1, \) and \( \int_{-\infty}^{\infty} \omega(s)ds = 1. \) Moreover, for any given positive constant \( \delta, \) there holds

\[ \lim_{h \to 0} \omega_h^\delta(s)^{2+\delta} = 0. \]

We choose \( k = v(y,\tau), l = u(x,t) \) and \( \varphi = \psi(x,t,y,\tau) \) in (4.3) and (4.4). Integrating it over \( Q_T, \) using the fact of that \( S\eta(v-u) = -S\eta(v-u), \) we have

\[
\int_{Q_T} \int_{Q_T} \left\{ I\eta(u-v)(\psi_t + \psi_\tau) + A\eta(u,x,t,v)\Delta \psi + A\eta(v,y,\tau,u)\Delta \psi \right\} dyd\tau \\
+ \int_{Q_T} a_x(s,x,t)S\eta(s-v)ds\psi_x + \int_{Q_T} a_y(s,y,\tau)S\eta(s-u)ds\psi_y \\
- \int_{Q_T} \left[ \sum_{i=1}^{N} S'_\eta(u-v) \mid g^i(u,x,t) \mid ^2 + \mid g^i(v,y,\tau) \mid ^2 \right] \psi \\
- \int_{Q_T} [f_1(x)I\eta(u-v)\psi_x + f_2(y)I\eta(v-u)\psi_y] \\
- \int_{Q_T} \left[ \text{div}_{x} \int_{u}^{v} (s-u)h\eta(s-v)ds + \text{div}_{y} \int_{u}^{v} (s-v)h\eta(s-u)ds \right] \psi \\
- [c(x,t)u-c(y,\tau)\psi]S\eta(u-v)\psi + [(g(x,t) - g(y,\tau)]S\eta(u-v)\psi \right] dxdt d\tau \\
\geq 0. 
\]

We can use the facts

\[
\frac{\partial j_h}{\partial t} + \frac{\partial j_h}{\partial \tau} = 0, \quad \frac{\partial j_h}{\partial x_i} + \frac{\partial j_h}{\partial y_i} = 0, \quad i = 1, \cdots, N, \\
\frac{\partial \psi}{\partial t} + \frac{\partial \psi}{\partial \tau} = \frac{\partial \phi}{\partial t}j_h, \quad \frac{\partial \psi}{\partial x_i} + \frac{\partial \psi}{\partial y_i} = \frac{\partial \phi}{\partial x_i}j_h. 
\]
to analysis every term of the left hand side of (4.6).

The first term, we have
\[ \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} I_{\eta}(u - v) \psi_{i} dx \, dt = \int_{Q_T} u(x, t) - v(x, t) \phi_{i} dx \, dt. \]  
(4.7)

From the second term to the sixth term, by a very complicated calculations [23], by (4.1) in Lemma 4.1, using the condition (2.8) and the observation (4.5), we can deduce that

\[ \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} \left\{ I_{\eta}(u - v)(\psi_{i} + \psi_{\tau}) + A_{\eta}(u, x, t, v) \Delta_{x} \psi + A_{\eta}(v, y, \tau, u) \Delta_{y} \psi 
\right. 
\]
\[ + \int_{v}^{u} a_{x_{i}}(s, x, t) S_{\eta}(s - v) ds \psi_{x_{i}} + \int_{u}^{v} a_{y_{i}}(s, y, \tau) S_{\eta}(s - u) ds \psi_{y_{i}}, 
\]  
\[ - \sum_{i=1}^{N} S'_{\eta}(u - v) \left[ |g^{i}(u, x, t)|^{2} + |g^{i}(v, y, \tau)|^{2} \right] \psi \right\} \int_{Q_T} \int_{Q_T} \left. dx \, dt \right. \]  
(4.8)

For the seventh term, by the fact
\[ \psi_{i} = \phi_{x_{i}} j_{h} - \psi_{x_{i}}, \]
we have
\[ \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} [f_{i}(x)I_{\eta}(u - k) \psi_{x_{i}} + f_{i}(y)I_{\eta}(v - l) \psi_{y_{i}}] dx \, dt \]  
\[ = \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} [f_{i}(x) \psi_{x_{i}} + f_{i}(y) \psi_{y_{i}}] |u - v| dx \, dt \]  
\[ = \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} [f_{i}(x) \psi_{x_{i}} + f_{i}(y) (\phi_{x_{i}} j_{h} - \psi_{x_{i}})] |u - v| dx \, dt \]  
\[ = \int_{Q_T} f_{i}(x) \phi_{x_{i}} |u - v| dx \, dt. \]  
(4.9)

For the eighth term, it is obviously
\[ - \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} \left[ \operatorname{div}_{x} \bar{f} \tilde{S}_{\eta}(u - v)(u - v) + \operatorname{div}_{y} \bar{f} \tilde{S}_{\eta}(v - u)(v - u) \right] \psi dx \, dt \]  
\[ = - \int_{Q_T} \operatorname{div}_{x} \bar{f} |u - v| \phi dx \, dt. \]  
(4.10)

For the ninth term, it is obviously
\[ - \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} \left[ \operatorname{div}_{x} \bar{f} \int_{v}^{u} (s - v) h_{\eta}(s - v) ds + \operatorname{div}_{y} \bar{f} \int_{u}^{v} (s - u) h_{\eta}(s - u) ds \right] \psi dx \, dt \]  
\[ = 0. \]  
(4.11)

For the tenth term,
\[ - \lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} [c(x, t)u - c(y, \tau)v] S_{\eta}(u - v) \psi dx \, dt \]  
\[ = - \int_{Q_T} c(x, t) |u - v| \phi dx \, dt. \]  
(4.12)
For the last term,
\[
\lim_{h \to 0} \lim_{\eta \to 0} \int_{Q_T} \int_{Q_T} \int_{Q_T} \int_{Q_T} [g(x, t) - g(y, \tau)] S_u(u - v) \psi dx dt dy d\tau \\
= \int_{Q_T} \int_{Q_T} \int_{Q_T} \int_{Q_T} \left[ g(x, t) \psi - g(y, \tau) \psi \right] S_u(u - v) \phi dx dt \\
= 0.
\] (4.13)

Thus, if we let \( \eta \to 0 \) and \( h \to 0 \) in (4.6), then we have
\[
\int_{Q_T} \int_{Q_T} \left\{ \left| u(x, t) - v(x, t) \right| \phi_t + \text{sgn}(u - v)[A(u, x, t) - A(v, x, t)] \Delta \phi \\
+ \int_u^v a_{x_i}(s, x, t) \text{sgn}(s - v) ds \phi_{x_i} + \int_v^u a_{x_i}(s, x, t) \text{sgn}(s - u) ds \phi_{x_i} \\
- \left[ f_i(x) \phi_{x_i} + \text{div} \vec{f} + c(x, t) \phi \right] |u - v| \right\} dx dt \\
\geq 0.
\] (4.14)

By choosing some special test functions or some special domains \( \Omega \), one can prove the stability of the entropy solutions according to (4.14).

5. The proof of Theorem 2.10 and Theorem 2.11

**Proof of Theorem 2.10** For small enough \( \lambda \), we define
\[
\varphi_\lambda(x) = \begin{cases} 
\frac{-(d - \lambda)^2}{\lambda^2} + 1, & \text{if } 0 \leq d \leq \lambda, \\
1, & \text{if } d \geq \lambda.
\end{cases}
\] (5.1)

By a process of limit, we can choose the test function in (4.13) as
\[
\phi(x, t) = \eta(t) \varphi_\lambda(x),
\] (5.2)

where \( 0 \leq \eta(t) \in C^1_0(t) \).

When \( x \in \Omega_\lambda = \{ x \in \Omega : d(x) < \lambda \} \),
\[
\partial_{x_i} \phi(x, t) = \eta(t) \partial_{x_i} \varphi_\lambda(x) = -\eta(t) \frac{2(d - \lambda)}{\lambda^2} d_{x_i},
\]
\[
\Delta \phi = -\eta(t) \left[ \frac{2}{\lambda^2} |\nabla d|^2 + \frac{2(d - \lambda)}{\lambda^2} \Delta d \right].
\]

While in \( \Omega \setminus \Omega_\lambda \),
\[
\phi_{x_i} = 0, \Delta \phi = 0.
\]
In the first place, by the assumption of that $\Delta d \leq 0$, choosing $\lambda$ is small enough, when $x$ is near to the boundary, $d(x) < \lambda$, we have

$$\int_\Omega \text{sgn}(u - v)(A(u, x, t) - A(v, x, t))\Delta \phi dx$$

$$= -\eta(t) \int_{\Omega_{\lambda}} |A(u, x, t) - A(v, x, t)| \left[ \frac{2}{\lambda^2} |\nabla d|^2 + \frac{2(d - \lambda)}{\lambda^2} \Delta d \right] dx$$

$$\leq 0.$$  \hspace{1cm} (5.3)

In the second place, by that $|d_x| \leq |\nabla d| = 1$, and by (2.9), $a_{x_i}(s, x, t) = 0$ when $x \in \partial \Omega$,

$$\lim_{\lambda \to 0} \left| \int_{\Omega} \int_{u}^{v} a_{x_i}(s, x, t)\text{sgn}(s - v)ds \phi_{x_i} dx \right|$$

$$= \lim_{\lambda \to 0} \left| \int_{\Omega} \int_{\Omega_{\lambda}} \int_{u}^{v} a_{x_i}(s, x, t)\text{sgn}(s - v)ds \phi_{x_i} dx \right|$$

$$\leq \lim_{\lambda \to 0} \frac{c}{\lambda} \int_{\Omega_{\lambda}} \int_{u}^{v} a_{x_i}(s, x, t)\text{sgn}(s - v)ds |d\Sigma|$$

$$= \int_{\partial \Omega} \int_{u}^{v} a_{x_i}(s, x, t)\text{sgn}(s - v)ds |d\Sigma|$$

$$= 0.$$  \hspace{1cm} (5.4)

Similarly, we have

$$\lim_{\lambda \to 0} \left| \int_{\Omega} \int_{u}^{v} a_{x_i}(s, x, t)\text{sgn}(s - u)ds \phi_{x_i} dx \right| = 0.$$  \hspace{1cm} (5.5)

Moreover, by that $|d_x| \leq |\nabla d| = 1$, and by the assumption of that $f_i(x) = 0$ when $x \in \partial \Omega$, we have

$$\lim_{\lambda \to 0} \left| \int_{\Omega} f_i(x)\phi_{x_i}(u - v) dx \right|$$

$$\leq 2 \lim_{\lambda \to 0} \int_{\Omega_{\lambda}} |f_i(x)| \left| \frac{(d - \lambda)d_x}{\lambda^2} \eta(t) |u - v| \right| dx$$

$$\leq c \sum_{i=1}^{N} \lim_{\lambda \to 0} \frac{1}{\lambda} \int_{\Omega_{\lambda}} |f_i(x)|\eta(t) |u - v| dx$$

$$= c \sum_{i=1}^{N} \int_{\partial \Omega} |f_i(x)|\eta(t) |u - v| d\Sigma$$

$$= 0,$$  \hspace{1cm} (5.6)

and it is clearly that

$$\lim_{\lambda \to 0} \int_{\Omega} |\text{div} \vec{f} + c(x, t)| \phi |u - v| dx$$

$$= \int_{\Omega} |\text{div} \vec{f} + c(x, t)| \eta(t) |u - v| dx$$

$$\leq c \int_{\Omega} \eta(t) |u - v| dx.$$  \hspace{1cm} (5.7)
By (5.3)-(5.7), according to (4.12), we have
\[
\iint_{Q_T} |u(x,t) - v(x,t)| \phi_t \, dx \, dt + c \int_0^T \int_{\Omega} \eta(t) \cdot |u - v| \, dx \, dt \geq 0. \tag{5.8}
\]
Let \(0 < s < \tau < T\), and
\[
\eta(t) = \int_{\tau-t}^{s-t} \alpha_\varepsilon(\sigma) \, d\sigma, \quad \varepsilon < \min\{\tau, T-s\}.
\]
Here \(\alpha_\varepsilon(t)\) is the kernel of mollifier with \(\alpha_\varepsilon(t) = 0\) for \(t \notin (-\varepsilon, \varepsilon)\). Then
\[
c \iint_{Q_T} |u - v| \eta(t) \, dx \, dt + \int_0^T \int_{\Omega} \eta(t) |u - v| \, dx \, dt \geq 0.
\]
Let \(\varepsilon \to 0\). Then
\[
\int_{\Omega} |u(x,\tau) - v(x,\tau)| \, dx \leq \int_{\Omega} |u(x,s) - v(x,s)| \, dx + c \int_s^\tau \int_{\Omega} |u - v| \, dx \, dt. \tag{5.9}
\]
By the Gronwall inequality, we have
\[
\int_{\Omega} |u(x,\tau) - v(x,\tau)| \, dx \leq c \int_{\Omega} |u(x,s) - v(x,s)| \, dx,
\]
letting \(s \to 0\), we have the conclusion.

**Proof of Theorem 2.11** From proof of Theorem 2.10, we only need to deal with the term
\[
\int_{\Omega} \text{sgn}(u - v)(A(u, x, t) - A(v, x, t)) \Delta \phi \, dx
\]
\[
= - \eta(t) \int_{\Omega} \left| A(u, x, t) - A(v, x, t) \right| \left[ \frac{2}{\lambda^2} \| \nabla d \|^2 + \frac{2(d-\lambda)}{\lambda^2} \Delta d \right] \, dx
\]
\[
\leq - \eta(t) \int_{\Omega} \left| A(u, x, t) - A(v, x, t) \right| \frac{2(d-\lambda)}{\lambda^2} \Delta d \, dx,
\]
we have
\[
\lim_{\lambda \to 0} \left| \int_{\Omega} \left| A(u, x, t) - A(v, x, t) \right| \frac{2(d-\lambda)}{\lambda^2} \Delta d \, dx \right|
\]
\[
\leq c \lim_{\lambda \to 0} \frac{1}{\lambda} \int_{\Omega} \left| A(u, x, t) - A(v, x, t) \right| \, dx
\]
\[
= c \lim_{\lambda \to 0} \frac{1}{\lambda} \int_{\Omega} \left| \int_0^u a(s, x, t) \, ds \right| \, dx
\]
\[
= 0. \tag{5.10}
\]
Then we have the conclusion.

**Proof of Theorem 2.12** Since we have imposed the partial boundary value condition
\[
u(x, t) = 0, (x, t) \in \Sigma_p \times (0, T),
\]
with
\[
\Sigma_p = \{ x \in \partial \Omega : \sum_{i=1}^N f_i(x) n_i < 0 \} \bigcup \{ x \in \partial \Omega : \sum_{i=1}^N a_{xi}(\cdot, x, t) n_i \neq 0 \} \bigcup \{ x \in \partial \Omega : a(\cdot, x, t) \neq 0 \}, \tag{2.5}
\]

.. _17:
From proof of Theorem 2.10-Theorem 2.11, we know (5.4)(5.5) and (5.10) are still true. We only need to deal with the term

\[-f_i(x)\phi_{x_i}|u - v|\]

in (4.12). In other words, since there is not the condition (2.10), the inequality (5.6) is not true. Actually, by the partial boundary value condition (2.12) with the expression (2.5), if we denote that

\[\Omega_{1\lambda} = \{x \in \Omega_{\lambda} : f_i(x)dx_i < 0\},\]  

then we have

\[-\lim_{\lambda \to 0} \int_{\Omega} f_i(x)\phi_{x_i}|u - v|dx = -2\lim_{\lambda \to 0} \int_{\Omega_{1\lambda}} f_i(x)\frac{(d - \lambda)dx_i}{\lambda^2}\eta(t)|u - v|dx \]

\[\leq -2\lim_{\lambda \to 0} \frac{1}{\lambda} \int_{\Omega_{1\lambda}} f_i(x)dx_i\eta(t)|u - v|dx \]

\[= 2\eta(t) \int_{\Sigma_p} (-f_i(x)n_i)|u - v|d\sigma \]

\[= 0.\]  

Similar as the proof of Theorem 2.11, we have the conclusion.

6. The explanation of Definition 2.6

Let us give a simple explanation of Definition 2.6 lastly.

Let \(u_\varepsilon\) be the solution of the regularized equation

\[
\frac{\partial u}{\partial t} = \frac{\partial}{\partial x_i} \left( a(u, x, t) \frac{\partial u}{\partial x_i} \right) + \varepsilon \Delta u + f_i(x)D_iu - c(x, t)u + g(x, t), \quad (x, t) \in Q_T, \tag{6.1}
\]

with the initial-boundary value conditions (3.2)-(3.3). Multiplying both sides of (6.1) by \(\varphi S_\varepsilon(u_\varepsilon - k)\) and integrating it over \(Q_T\) yields

\[
\int_{Q_T} \frac{\partial u_\varepsilon}{\partial t} \varphi S_\varepsilon(u_\varepsilon - k)dxdt \]

\[= \int_{Q_T} \frac{\partial}{\partial x_i} \left( a(u_\varepsilon, x, t) \frac{\partial u_\varepsilon}{\partial x_i} \right) \varphi S_\varepsilon(u_\varepsilon - k)dxdt \]

\[+ \varepsilon \int_{Q_T} \Delta u_\varepsilon \varphi S_\varepsilon(u_\varepsilon - k)dxdt \]

\[+ \int_{Q_T} \frac{\partial f_i(x)u_\varepsilon}{\partial x_i} \varphi S_\varepsilon(u_\varepsilon - k)dxdt - \int_{Q_T} f_{ix}(x)u_\varepsilon \varphi S_\varepsilon(u_\varepsilon - k)dxdt \]

\[- \int_{Q_T} c(x, t)u_\varepsilon \varphi S_\varepsilon(u_\varepsilon - k)dxdt + \int_{Q_T} g(x, t)\varphi S_\varepsilon(u_\varepsilon - k)dxdt. \tag{6.2}
\]
Integration by parts, (6.2) gives

\[
\begin{align*}
&\int_Q I_\varepsilon(u_\varepsilon - k)\varphi_1 dx dt + \int_Q A_\varepsilon(u_\varepsilon, x, t, k)\triangle \varphi dx dt \\
&\quad - \int_Q f_i(x)I_\varepsilon(u_\varepsilon - k)\varphi_x dx dt - \varepsilon \int_Q \nabla u_\varepsilon \cdot \nabla \varphi S_\varepsilon(u_\varepsilon - k) dx dt \\
&\quad - \varepsilon \int_Q |\nabla u_\varepsilon|^2 S'_\varepsilon(u_\varepsilon - k)\varphi dx dt + \int_Q \int_k a_{x_i}(s, x, t)S_\varepsilon(s - k) ds \varphi_x, dx dt \\
&\quad - \int_Q a(u_\varepsilon, x, t) |\nabla u_\varepsilon|^2 h_\varepsilon(u_\varepsilon - k)\varphi dx dt \\
&\quad - \int_Q f_{ix_i}(x)(u_\varepsilon - k)\varphi S_\varepsilon(u_\varepsilon - k) dx dt + \int_Q f_{ix_i}(x) \int_k^u (s - k) h_\varepsilon(s - k) ds \varphi dx dt \\
&\quad - \int_Q c(x, t) u_\varepsilon \varphi S_\varepsilon(u_\varepsilon - k) dx dt + \int_Q g(x, t) \varphi S_\varepsilon(u_\varepsilon - k) dx dt \\
&\quad \geq 0. 
\end{align*}
\]

By discarding the terms

\[
\int_Q a(u_\varepsilon, x, t) |\nabla u_\varepsilon|^2 S'_\varepsilon(u_\varepsilon - k)\varphi dx dt,
\]

and

\[
- \varepsilon \int_Q |\nabla u_\varepsilon|^2 S'_\varepsilon(u_\varepsilon - k)\varphi dx dt
\]

in (6.3), we have

\[
\begin{align*}
&\int_Q I_\varepsilon(u_\varepsilon - k)\varphi_1 dx dt + \int_Q A_\varepsilon(u_\varepsilon, x, t, k)\triangle \varphi dx dt \\
&\quad - \int_Q f_i(x)I_\varepsilon(u_\varepsilon - k)\varphi_x dx dt - \varepsilon \int_Q \nabla u_\varepsilon \cdot \nabla \varphi S_\varepsilon(u_\varepsilon - k) dx dt \\
&\quad + \int_Q \int_k a_{x_i}(s, x, t)S_\varepsilon(s - k) ds \varphi_x, dx dt \\
&\quad - \int_Q f_{ix_i}(x)(u_\varepsilon - k)\varphi S_\varepsilon(u_\varepsilon - k) dx dt + \int_Q f_{ix_i}(x) \int_k^u (s - k) h_\varepsilon(s - k) ds \varphi dx dt \\
&\quad - \int_Q c(x, t) u_\varepsilon \varphi S_\varepsilon(u_\varepsilon - k) dx dt + \int_Q g(x, t) \varphi S_\varepsilon(u_\varepsilon - k) dx dt \\
&\quad \geq 0.
\end{align*}
\]
Let $\varepsilon \to 0$. We can get

$$
\begin{align*}
&\int_{Q_T} |u - k| \phi_t \, dx dt + \int_{Q_T} |A(u, x, t) - A(k, x, t)| \Delta \phi \, dx dt \\
&- \int_{Q_T} f(x)|u - k| \phi_x \, dx dt \\
&+ \int_{Q_T} \int_k^u a_x(s, x, t) \text{sign}(s - k) ds \phi_x \, dx dt \\
&- \int_{Q_T} f_{zz}(x)(u - k) \phi_x \, dx dt \\
&- \int_{Q_T} c(x, t) \text{sign}(u - k) \phi \, dx dt + \int_{Q_T} g(x, t) \text{sign}(u - k) \phi \, dx dt \\
&\geq 0.
\end{align*}
$$

(6.6)

The inequality (6.6) is just the classical entropy inequality used in [3][5] etc. However, the term (6.4) can not be thrown away casually. In fact, this term includes many information of the uniqueness [9-12], [18-19], [21-23][29]. The difficulty lies in that, when we let $\varepsilon \to 0$, what is the limit of the term (6.4) is very difficult to depict out, so it is almost impossible to remain the limit to the end, one has to throw it away [3][5].

In order to overcome this difficulty, instead of multiplying both sides of (6.1) by $\phi_{S_\varepsilon}(u_\varepsilon - k)$, we multiply both sides of (6.1) by $\phi_{S_\eta}(u_\varepsilon - k)$, where $\eta$ is a small positive constant independent of $\varepsilon$. Then we can employ the weak convergent theory (Lemma 3.1), the uniqueness information of the term (6.4) remains, and we can prove the uniqueness of the entropy solutions by Kružkov’s method.
