Optimal unbiased estimators via convex hulls

Nabil Kahalé *

September 9, 2019

Abstract

Necessary and sufficient conditions for the square-integrability of recently proposed unbiased estimators are established. A geometric characterization of a distribution that optimizes the performance of these estimators is given. An algorithm based on convex hulls that finds the optimal distribution truncated to its first $m$ terms in time linear in $m$ is described. The algorithm exploits a connection with a recent randomized dimension reduction method and is illustrated via a numerical example.

Keywords: unbiased, Monte Carlo simulation, efficiency, variance reduction, convex hulls.

1 Introduction

Monte Carlo methods are used in a variety of domains such as financial engineering, queuing networks, and machine learning. In general, however, Monte Carlo methods are computationally costly. Variance reduction techniques such as importance sampling, control variate methods, stratified sampling and splitting techniques can significantly improve the efficiency of Monte Carlo methods (e.g. (Glasserman 2004, Asmussen and Glynn 2007, Rubinstein and Kroese 2016)). The multilevel Monte Carlo method (MLMC), introduced by Giles (2008), dramatically reduces the computational cost of estimating an expected value arising from a stochastic differential equation. McLeish (2011), Glynn and Rhee (2014) and Rhee and Glynn (2015) provide related randomized multilevel Monte Carlo methods (RMLMC) that produce unbiased estimators for equilibrium expectations of functionals on Markov chains, and for expectations of functionals arising in stochastic differential equations. Sufficient conditions guaranteeing the square-integrability of these estimators are given in (McLeish 2011, Rhee and Glynn 2015). Jacob and Thiery (2015) study the existence of unbiased nonnegative estimators. RMLMC and related methods have been used in a variety of contexts such as the unbiased estimation of a function of the mean of a random variable (Blanchet, Chen and Glynn 2015, Moka, Kroese and Juneja 2019), the design of Markov chain Monte Carlo methods (Bardenet, Doucet and Holmes 2017, Agapiou, Roberts and Vollmer 2018, Middleton, Deligiannidis, Doucet and Jacob 2018), unbiased inference for hidden Markov models (Franks, Jasra, Law and Vihola 2018), pricing of Asian options under general models (Kahalé 2018), and stochastic optimization (Blanchet, Glynn and Pei 2019). Vihola (2018) describes stratified RMLMC methods that, under certain conditions, are shown to be asymptotically as efficient as MLMC. The randomized dimension reduction method, recently introduced in (Kahalé 2016, Kahalé 2019), is another technique that can provably achieve substantial variance reduction in high-dimensional settings, such as the estimation of the expectation of a functional of a time-varying Markov chain at a long horizon.

Using the terminology of Rhee and Glynn (2015), the “coupled sum” and “independent sum” unbiased estimators take as parameter the distribution of an integral random variable. In (Rhee

*ESCP Europe and Labex ReFi, 75011 Paris, France; e-mail: nkahale@escpeurope.eu.
an algorithm that finds in $O(m^3)$ time an $m$-truncated distribution that optimizes the efficiency of these estimators is given. On the other hand, the asymptotic efficiency of the randomized dimension reduction method is maximized in (Kahalé 2019) via a new geometric algorithm that solves an $m$-dimensional optimization problem in $O(m)$ time. Kahalé (2019) points out that the same geometric algorithm solves the optimization problem in (Rhee and Glynn 2015, Section 3) in $O(m)$ time.

The output of unbiased estimators can be analysed using well-known tools. For instance, drawing independent copies of an unbiased estimator allows the construction of normal confidence intervals (Asmussen and Glynn 2007, Section III.1). In addition, this construction is easy to parallelize. Also, Glynn and Whitt (1992) have established a central limit theorem on the average of independent copies of an unbiased estimator under a computational budget constraint. On the other hand, the output of biased estimators can be difficult to analyse, even for estimators which are asymptotically consistent (e.g. (Glasserman 2004, Section 4.5.1)). This highlights the importance of the RMLMC techniques. Motivated by these considerations and by the wide range of applications of the RMLMC methods, this note studies the coupled sum and independent sum estimators in a general framework and makes three main contributions:

1. It gives a necessary and sufficient condition for the square-integrability of the coupled sum (resp. independent sum) estimator. When this condition is met, it is shown that the corresponding estimator is unbiased and an expression for the second moment is derived. An example showing that the new conditions are strictly weaker than the sufficient condition in (Rhee and Glynn 2015) is given.

2. Under general conditions, it gives a simple geometric characterization, based on convex hulls, of distributions with infinite support that optimize the performance of the coupled sum (resp. independent sum) estimator. Rhee and Glynn (2015, Theorem 3) show that such a distribution can be found by solving a certain combinatorial problem, but do not provide the solution to this problem in the infinite support case.

3. Building on techniques developed in (Kahalé 2019), it describes an algorithm that finds an optimal $m$-truncated distribution for each of these estimators in $O(m)$ time. The algorithm, based on convex hulls, is simple to implement. Rhee and Glynn (2015) give an alternative algorithm based on dynamic programming that runs in $O(m^3)$ time. More recently, Cui, Lee, Zhu and Zhu (2019) give yet another algorithm that solves this problem in $O(m)$ time by using a dual formulation of the optimization problem.

The rest of the paper is organised as follows. §2 gives necessary and sufficient conditions for the square-integrability of the coupled sum and independent sum estimators, and presents expressions for the second moment of these estimators when these conditions are met. §3 describes a geometric characterization of distributions with infinite support that optimize the efficiency of these estimators. §4 shows how to calculate in $O(m)$ time an optimal $m$-truncated distribution. §5 describes a numerical example. §6 contains concluding remarks. Omitted proofs are in the appendix.

2 The coupled and independent sum estimators

Let $\mathbb{R}_+$ denote the set of nonnegative real numbers. For a square-integrable random variable $X$, let $\|X\| = \sqrt{E(X^2)}$. The coupled and independent sum estimators efficiently estimate the expectation of a random variable $Y$ that is approximated by random variables $Y_n$, $n \geq 0$. By convention, $Y_{-1} = 0$. Let $(\Delta_n : n \geq 0)$ be a sequence of independent random variables such that $\Delta_n$ has the same distribution as $Y_n - Y_{n-1}$ for $n \geq 0$. It is assumed throughout the paper that $Y$ and $Y_n$ are square-integrable, that $\|Y_n - Y\|$ goes to 0 as $n$ goes to infinity, and that the
expected time to generate \((Y_0, \ldots, Y_n)\) (resp. \((\tilde{\Delta}_0, \ldots, \tilde{\Delta}_n)\)) is finite, for \(n \geq 0\). Let
\[
A = \{(q_i : i \geq 0) \in \mathbb{R}^N : q_0 = 1, q_i \geq q_{i+1} > 0 \text{ for } i \geq 0, \lim_{i \to \infty} q_i = 0}\.
\]

Example 2.1 is a standard application of MLMC and RMLMC methods.

**Example 2.1.** Let \(T\) be a fixed maturity and let \((X(t) : 0 \leq t \leq T)\) be a stochastic process that solves the stochastic differential equation
\[
dX(t) = a(X(t), t) \, dt + b(X(t), t) \, dW,
\]
where \(a\) and \(b\) are real-valued functions on \(\mathbb{R} \times [0, T]\) and \(W\) is a one-dimensional Brownian motion. Suppose that, for \((x, t) \in \mathbb{R} \times [0, T]\), \(a(x, t)\) and \(b(x, t)\) can be calculated in constant time. Option pricing applications often need to estimate \(E(Y)\), where \(Y = f(X(T))\) and \(f\) is a payoff function. The process \(X\) can be approximately simulated via the Milstein discretisation scheme as follows. For \(i \geq 0\), define recursively the sequence \((X^{(i)}_k : 0 \leq k \leq 2^i)\) by setting \(X^{(i)}_0 = X(0)\) and
\[
X^{(i)}_{k+1} = X^{(i)}_k + a(X^{(i)}_k, k\Delta t) \Delta t + b(X^{(i)}_k, k\Delta t) \Delta W + \frac{1}{2} b(X^{(i)}_k, k\Delta t) \frac{\partial b}{\partial x}(X^{(i)}_k, k\Delta t)((\Delta W)^2 - \Delta t),
\]
\(0 \leq k \leq 2^i - 1\), where \(\Delta t = 2^{-i} T\) and \(\Delta W = W((k+1)\Delta t) - W(k\Delta t)\). Let \(Y_i = f(X^{(i)}_2^i)\). Under certain conditions on \(a, b\) and \(f\),
\[
||Y_i - Y||^2 \leq c 2^{-2i}, \tag{2.1}
\]
where \(c\) is a constant (e.g. \((\text{Kloeden and Platen 1992})\)). Note that \(Y_i\) can be calculated in \(O(2^i)\) time.

### 2.1 The coupled sum estimator

Let \(q \in A\) and let \(N\) be an integral random variable independent of \((Y_i : i \geq 0)\) such that \(\Pr(N \geq i) = q_i\) for \(i \geq 0\). Following McLeish (2011) and Rhee and Glynn (2015), define the coupled sum estimator as
\[
\bar{Z} = \sum_{i=0}^{N} \frac{Y_i - Y_{i-1}}{q_i}.
\]

Theorem 2.1 gives a necessary and sufficient condition for \(\bar{Z}\) to be square-integrable. Moreover, under this condition, it shows that \(\bar{Z}\) is an unbiased estimator for \(E(Y)\), and gives an expression for the second moment of \(\bar{Z}\). Note that each term in the LHS of (2.2) is nonnegative because \(q \in A\).

**Theorem 2.1.** The coupled sum estimator \(\bar{Z}\) is square-integrable if and only if
\[
\sum_{i=0}^{\infty} \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) ||Y_i - Y||^2 < \infty. \tag{2.2}
\]

Furthermore, if (2.2) holds then \(E(\bar{Z}) = E(Y)\) and
\[
||\bar{Z}||^2 = ||Y||^2 + \sum_{i=0}^{\infty} \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) ||Y_i - Y||^2. \tag{2.3}
\]

Theorem 1 in (Rhee and Glynn 2015) gives a sufficient condition for \(\bar{Z}\) to be square-integrable. More precisely, it shows that if
\[
\sum_{i=1}^{\infty} \frac{||Y_{i-1} - Y||^2}{q_i} < \infty, \tag{2.4}
\]
then $\bar{Z}$ is square-integrable, and $\bar{Z}$ is an unbiased estimator for $E(Y)$, and gives an expression for $||\bar{Z}||^2$. However, the following toy example shows that (2.4) is not a necessary condition for $\bar{Z}$ to be square-integrable.

**Example 2.2.** Assume that $Y = 0$ and $Y_i = (i + 1)^{-3/2}$, and $q_i = (i + 1)^{-2}$ for $i \geq 0$. Then (2.4) holds and so $\bar{Z}$ is square-integrable, but (2.4) does not hold.

McLeish (2011) gives alternative conditions that guarantee the unbiasedness and square-integrability of $\bar{Z}$, and provides an alternative expression for $||\bar{Z}||^2$.

### 2.2 The independent sum estimator

Let $q \in A$ and let $N$ be an integral random variable independent of ($\tilde{\Delta}_i : i \geq 0$) such that $\Pr(N \geq i) = q_i$ for $i \geq 0$. Following Rhee and Glynn (2015), define the independent sum estimator as

$$
\tilde{Z} = \sum_{i=0}^{N} \frac{\tilde{\Delta}_i}{q_i}.
$$

Theorem 2.2 below gives a necessary and sufficient condition for $\tilde{Z}$ to be square-integrable. Furthermore, if this condition is met, it shows that $\tilde{Z}$ is an unbiased estimator for $E(Y)$, and gives an expression for the second moment of $\tilde{Z}$.

**Theorem 2.2.** The independent sum estimator $\tilde{Z}$ is square-integrable if and only if

$$
\sum_{i=0}^{\infty} \left( \frac{\text{Var}(Y_i - Y_{i-1})}{q_i} + \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) (E(Y_i - Y))^2 < \infty.
$$

Furthermore, if (2.5) holds then $E(\tilde{Z}) = E(Y)$ and

$$
||\tilde{Z}||^2 = (E(Y))^2 + \sum_{i=0}^{\infty} \left( \frac{\text{Var}(Y_i - Y_{i-1})}{q_i} + \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) (E(Y_i - Y))^2.
$$

Theorem 2 in (Rhee and Glynn 2015) shows that (2.4) is a sufficient condition for the square-integrability of $\tilde{Z}$. Assuming that (2.4) holds, Theorem 2 in (Rhee and Glynn 2015) shows that $\tilde{Z}$ is square-integrable, and $\tilde{Z}$ is an unbiased estimator for $E(Y)$, and gives an expression for $||\tilde{Z}||^2$. In Example 2.2, however, (2.5) holds and so $\tilde{Z}$ is square-integrable, but (2.4) does not hold. Thus (2.4) is not a necessary condition for $\tilde{Z}$ to be square-integrable.

### 3 Optimal distribution: the infinite support case

#### 3.1 The coupled sum estimator

For $i \geq 0$, let $\bar{t}_i$ be the expected cost required to simulate the sequence $(Y_0, \ldots, Y_{i-1})$. By convention, $\bar{t}_0 = 0$. It is assumed that the sequence $\bar{t} = (\bar{t}_i : i \geq 0)$ is strictly increasing and that $\bar{t}_i$ goes to infinity as $i$ goes to infinity. Let $\bar{\tau}$ be the time required to generate $\bar{Z}$. As observed by Rhee and Glynn (2015),

$$
E(\bar{\tau}) = E(\bar{t}_{N+1}) = \sum_{i=0}^{\infty} q_i (\bar{t}_{i+1} - \bar{t}_i).
$$

Note that $E(\bar{\tau})$ is either infinite or is finite and positive. In Example 2.1 assuming that (2.1) holds, $q$ can be chosen so that $\bar{Z}$ is square-integrable and $E(\bar{\tau})$ is finite by setting $q_i = 2^{-3i/2}$. Indeed, for this choice of $q$, (2.2) holds and $E(\bar{\tau})$ is finite since $\bar{t}_i = O(2^i)$.
Glynn and Whitt (1992) show that the efficiency of an unbiased estimator is inversely proportional to the product of the variance and expected running time. Thus, maximizing the efficiency of $\bar{Z}$ amounts to finding a sequence $q \in A$ that satisfies \( (3.2) \) and minimizes $E(\bar{Z}) \text{Var}(\bar{Z})$. For $q \in A$, and any strictly increasing sequence $\vartheta = (\vartheta_0, \vartheta_1, \ldots) \in \{0\} \times \mathbb{R}_+^N$, and $\gamma = (\gamma_0, \gamma_1, \ldots) \in \mathbb{R}_+^N$, set

$$R(q; \vartheta, \gamma) = \lim_{n \to \infty} \left( \sum_{i=0}^{n} q_i (\theta_{i+1} - \theta_i) \right) (\gamma_0 + \sum_{i=1}^{n} \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right) \gamma_i).$$

Thus, $R(q; \vartheta, \gamma)$ is the limit of a nonnegative increasing sequence, and so $R(q; \vartheta, \gamma)$ is either infinite or is nonnegative and finite.

Define the sequence $\mu = (\mu_i : i \geq 0)$, where $\mu_0 = \text{Var}(Y)$ and $\mu_i = |Y_{i-1} - Y|^2$ for $i \geq 1$. For simplicity, this subsection assumes that the sequence $\mu$ is positive. The case where $Y = Y_m$ for some integer $m$ is studied in \(4.1\) By Theorem 2.1. Theorem 2.1 generalizes Theorem 3 in (Kahalé 2019) to infinite sequences.

Let $\gamma' \in \mathbb{R}_+^N$ be such that the set \(\{(\vartheta_i, \gamma_i') : i \in \mathbb{N}\}\) forms the lower hull of the set \(\{(\vartheta_i, \gamma_i) : i \in \mathbb{N}\}\). Thus $\gamma'$ is the supremum of all real sequences such that $\gamma' \leq \gamma$ and the sequence $(\theta_i)$ is increasing, where

$$\theta_i = \gamma'_{i+1} - \gamma_i' \overline{\vartheta_{i+1} - \vartheta_i}$$

$i \geq 0$.

**Theorem 3.1.** Let $\vartheta = (\vartheta_0, \vartheta_1, \ldots) \in \{0\} \times \mathbb{R}_+^N$ be a strictly increasing sequence, and let $\gamma = (\gamma_0, \gamma_1, \ldots) \in \mathbb{R}_+^N$ be a positive sequence that goes to 0 at infinity. Assume there is $q \in A$ such that $R(q; \vartheta, \gamma)$ is finite. For $i \geq 0$, set $q_i^* = \sqrt{\theta_i / \theta_0}$, where $\theta_i$ is given by \(3.3\). Then $q^* = (q_i^* : i \geq 0) \in A$ and $R(q^*; \vartheta, \gamma)$ is finite. Moreover, $q^* = \arg \min_{q \in A} R(q; \vartheta, \gamma)$ and

$$R(q^*; \vartheta, \gamma) = \left( \sum_{i=0}^{\infty} \sqrt{(\gamma'_{i+1} - \gamma_i')(\vartheta_{i+1} - \vartheta_i)} \right)^2,$$

where the series in the RHS of \(3.3\) is convergent.

Thus, if there is $q \in A$ such that $\bar{Z}$ is square-integrable and $E(\bar{Z})$ is finite, then the efficiency of $\bar{Z}$ is maximized when $Pr(N \geq i) = q_i^*$ for $i \geq 0$, where $q^*$ is the sequence described in Theorem 3.1 with $\vartheta = \bar{\vartheta}$ and $\gamma = \bar{\gamma}$.

### 3.2 The independent sum estimator

For $i \geq 0$, let $\tilde{t}_i$ be the expected cost required to simulate the sequence $(\tilde{\Delta}_0, \ldots, \tilde{\Delta}_{i-1})$. By convention, $\tilde{t}_0 = 0$. Assume that the sequence $\tilde{t} = (\tilde{t}_i : i \geq 0)$ is strictly increasing and that $\tilde{t}_i$ goes to infinity as $i$ goes to infinity. Let $\tilde{\tau}$ be the time required to generate $\bar{Z}$. Then

$$E(\tilde{\tau}) = E(\tilde{t}_{N+1}) = \sum_{i=0}^{\infty} q_i (\tilde{t}_{i+1} - \tilde{t}_i).$$
In Example 2.1 assuming that (2.1) holds, $q$ can be chosen so that $\tilde{Z}$ is square-integrable and $E(\tilde{\tau})$ is finite by setting $q_i = 2^{-3i/2}$. Indeed, for $i \geq 0$,

$$|E(Y_i - Y)| \leq ||Y_i - Y|| \leq \sqrt{2}^{-i}$$

and, for $i \geq 1$,

$$\text{Std}(Y_i - Y_{i-1}) \leq ||Y_i - Y|| + ||Y_{i-1} - Y|| \leq 3\sqrt{2}^{-i}.$$

Thus, for this choice of $q$, (2.5) holds and $E(\tilde{\tau})$ is finite since $t_i = O(2^i)$.

When $\tilde{Z}$ is square-integrable, Proposition 3.1 gives an expression for $\text{Var}(\tilde{Z})$ similar to that of $\text{Var}(\bar{Z})$ in (3.2).

**Proposition 3.1.** If $q \in A$ is such that $\tilde{Z}$ is square-integrable, then $\tilde{\mu}_0 = \sum_{j=0}^{\infty} \text{Var}(Y_j - Y_{j-1})$ is finite, and

$$\text{Var}(\tilde{Z}) = \tilde{\mu}_0 + \sum_{i=1}^{\infty} \frac{1}{q_i} - \frac{1}{q_{i-1}} \tilde{\mu}_i,$$

where, for $i \geq 1$,

$$\tilde{\mu}_i = (E(Y_{i-1} - Y))^2 + \sum_{j=i}^{\infty} \text{Var}(Y_j - Y_{j-1}).$$

Maximizing the efficiency of $\tilde{Z}$ amounts to finding a sequence $q \in A$ that satisfies (2.5) and minimizes $E(\tilde{\tau})\text{Var}(\tilde{Z})$. Suppose that $q \in A$ is such that $\tilde{Z}$ is square-integrable and $E(\tilde{\tau})$ is finite. By Proposition 3.1 and since $|E(Y_{i-1} - Y)| \leq ||Y_{i-1} - Y||$, the sequence $\tilde{\mu} = (\tilde{\mu}_i : i \geq 0)$ goes to 0 at infinity. For simplicity, assume that $\tilde{\mu}$ is positive. Using arguments similar to those used in §3.4, it can be shown that the efficiency of $\tilde{Z}$ is maximized when $\text{Pr}(N \geq i) = q_i^*$ for $i \geq 0$, where $q^*$ is the sequence described in Theorem 4.1 with $\vartheta = \tilde{\ell}$ and $\gamma = \mu$.

## 4 Optimal distribution: the truncated case

### 4.1 A truncated coupled sum estimator

Fix $m \geq 1$ and let

$$A^{(m)} = \{ (q_0, \ldots, q_m) \in \mathbb{R}^{m+1} : 1 = q_0 \geq q_1 \geq \cdots \geq q_m > 0 \}.$$  

Let $q \in A^{(m)}$ and let $S$ be an integral random variable in $\{0, \ldots, m\}$ independent of $(Y_i : 0 \leq i \leq m)$ such that $\text{Pr}(S \geq i) = q_i$ for $0 \leq i \leq m$. Set

$$\tilde{Z}^{(m)} = \sum_{i=0}^{S} \frac{Y_i - Y_{i-1}}{q_i}.$$

Let $N$ be an integral random variable with infinite support independent of $(Y_i : 0 \leq i \leq m)$ such that $\text{Pr}(N \geq i) = q_i$ for $0 \leq i \leq m$. Thus, $S$ has the same distribution as $N \land m$. By applying Theorem 2.1 to $N$ and to the sequence $(Y_{m \land n} : n \geq 0)$, with $Y = Y_m$, it follows that $\tilde{Z}^{(m)}$ is square-integrable, with $E(\tilde{Z}^{(m)}) = E(Y_m)$ and

$$||\tilde{Z}^{(m)}||^2 = ||Y_m||^2 + \sum_{i=0}^{m-1} \frac{1}{q_{i+1}} - \frac{1}{q_i}||Y_i - Y_{m}||^2$$

$$= \sum_{i=0}^{m} \frac{||Y_{i-1} - Y_m||^2 - ||Y_i - Y_m||^2}{q_i}.$$  

(4.1)
Define the sequence $\bar{\eta} = (\bar{\eta}_i : 0 \leq i \leq m + 1)$, where $\bar{\eta}_0 = \text{Var}(Y_m)$ and $\bar{\eta}_i = ||Y_{i-1} - Y_m||^2$ for $1 \leq i \leq m + 1$. Thus, $\bar{\eta}$ can be considered as the truncated counterpart of the sequence $\bar{\mu}$ defined in §3.1. Note that $\bar{\eta}_{m+1} = 0$. Assume for simplicity that $\bar{\eta}_i > 0$ for $0 \leq i \leq m$. By (4.1),

$$\text{Var}(\bar{Z}^{(m)}) = \sum_{i=0}^{m} \frac{\bar{\eta}_i - \bar{\eta}_{i+1}}{q_i}.$$ 

Let $\bar{\pi}^{(m)}$ be the expected time to simulate $\bar{Z}^{(m)}$. As $\Pr(S = i) = q_i - q_{i+1}$ for $0 \leq i \leq m$, where $q_{m+1} = 0$ by convention,

$$E(\bar{\pi}^{(m)}) = \sum_{i=0}^{m} (q_i - q_{i+1})\bar{t}_{i+1} = \sum_{i=0}^{m} q_i(\bar{t}_{i+1} - \bar{t}_i).$$

### 4.2 The optimal distribution

Maximizing the efficiency of $\bar{Z}^{(m)}$ amounts to finding a sequence $q \in A^{(m)}$ that minimizes $E(\bar{\pi}^{(m)})\text{Var}(\bar{Z}^{(m)})$. For $q \in A^{(m)}$, and any strictly increasing sequence $\theta = (\theta_0, \ldots, \theta_{m+1}) \in \{0\} \times \mathbb{R}_+^{m+1}$, and $\gamma = (\gamma_0, \ldots, \gamma_{m+1}) \in \mathbb{R}_+^{m+1} \times \{0\}$, set

$$R^{(m)}(q; \theta, \gamma) = \sum_{i=0}^{m} q_i(\theta_{i+1} - \theta_i)(\sum_{i=0}^{m} \frac{\gamma_i - \gamma_{i+1}}{q_i}).$$

Hence, $E(\bar{\pi}^{(m)})\text{Var}(\bar{Z}^{(m)}) = R^{(m)}(q; \bar{\pi}^{(m)}, \bar{\eta})$, where $\bar{\pi}^{(m)} = (\bar{t}_0, \ldots, \bar{t}_{m+1})$. Thus, we need to calculate a sequence $q \in A^{(m)}$ that minimizes $R^{(m)}(q; \bar{\pi}^{(m)}, \bar{\eta})$. Given a sequence $\gamma \in \mathbb{R}_+^{m+1} \times \{0\}$ whose first $m + 1$ components are positive, Theorem [1.1] a direct consequence of Theorem 3 in (Kahale 2019), shows how to calculate in $O(m)$ time a vector $q^*$ that minimizes $R^{(m)}(q; \bar{\pi}^{(m)}, \bar{\eta})$ under the constraint that $q \in A^{(m)}$. The vector $q^*$ clearly depends on $\bar{\pi}^{(m)}$ and on $\gamma$.

Let $\gamma' = (\gamma'_0, \ldots, \gamma'_{m+1})$ be such that the set $\{(\bar{t}_i, \gamma'_i) : 0 \leq i \leq m + 1\}$ forms the lower hull of the set $\{(\bar{t}_i, \gamma_i) : 0 \leq i \leq m + 1\}$. In other words, $\gamma'$ is the supremum of all sequences in $\mathbb{R}_+^{m+2}$ such that $\gamma' \leq \gamma$ and the sequence $(\theta_i)$ is increasing, where

$$\theta_i = \frac{\gamma'_i}{\bar{t}_{i+1} - \bar{t}_i}, \quad (4.2)$$

$0 \leq i \leq m$. For instance, if $m = 5$, with $\bar{t}_i = i$ and $\gamma = (20, 22, 14, 5, 4, 1, 0)$, then $\gamma' = (20, 15, 10, 5, 3, 1, 0)$, as illustrated in Fig. 1. The vector $\gamma'$ can be calculated in $O(m)$ time using the convex hull algorithm of Andrew (1979).

**Theorem 4.1** ([Kahale 2019]). Let $\gamma$ be a vector in $\mathbb{R}_+^{m+1} \times \{0\}$ whose first $m+1$ components are positive. For $0 \leq i \leq m$, set $q^*_i = \sqrt{\theta_i}/\theta_0$, where $\theta_i$ is given by (4.2), and let $q^* = (q^*_0, \ldots, q^*_m)$. Then $q^* = \arg\min_{q \in A^{(m)}} R^{(m)}(q; \bar{\pi}^{(m)}, \bar{\eta})$.

The proof of (Kahale 2019, Theorem 3) shows that the conclusions of Theorem [1.1] are valid for any strictly increasing sequence $\bar{\pi}^{(m)} \in \{0\} \times \mathbb{R}_+^{m+1}$.

### 4.3 The algorithm description

Combining the previously discussed elements yields an algorithm that takes as input the vectors $\bar{\pi}^{(m)}$ and $\bar{\eta}$, and outputs $q^* = \arg\min_{q \in A^{(m)}} R^{(m)}(q; \bar{\pi}^{(m)}, \bar{\eta})$ in $O(m)$ time. The first two steps of the algorithm are adapted from Andrew (1979). The algorithm first generates by backward induction a subset $B(j)$ of $\{j, \ldots, m + 1\}$, $0 \leq j \leq m$, so that the lower hull $\{(\bar{t}_i, \bar{\eta}_i) : 0 \leq i \leq m + 1\}$ of the set $\{(\bar{t}_i, \bar{\eta}_i) : 0 \leq i \leq m + 1\}$ is obtained by piece-wise interpolation of $\bar{\eta}$ on $B(0)$. More precisely, $B(0)$ contains $\{0, m + 1\}$, and if $i'$ and $i''$ are two consecutive elements of $B(0)$ with $i' \leq i \leq i''$, then $(\bar{t}_i, \bar{\eta}_i)$ lies on the segment $[(\bar{t}_{i'}, \bar{\eta}_{i'}), (\bar{t}_{i''}, \bar{\eta}_{i''})]$. The third step calculates $q^*$ via $B(0)$.
1. Set $B(m) = \{m, m + 1\}$.

2. For $j = m - 1$ down to 0, denote by $i_0 < \cdots < i_l$ the elements of $B(j + 1)$. Determine the smallest element $k$ of the set $\{0, \ldots, l - 1\}$ such that $(\bar{t}_{i_k}, \bar{\eta}_{i_k})$ lies below the segment $[(\bar{t}_j, \bar{\eta}_j), (\bar{t}_{i_{k+1}}, \bar{\eta}_{k+1})]$, if such $k$ exists, otherwise let $k = l$. Set $B(j) = \{j, i_k, \ldots, i_l\}$.

3. For $i = 0$ to $m$, let $i'$ and $i''$ be two consecutive elements of $B(0)$ with $i' \leq i < i''$. Set

$$\theta_i = \frac{\gamma_{i''} - \gamma_{i'}}{t_{i''} - t_{i'}}$$

and $q_i^* = \sqrt{\theta_i/\theta_0}$.

As pointed out in (Rhee and Glynn 2015, Vihola 2018), the vector $\bar{\eta}$ is not known exactly, in general, but can be estimated by Monte Carlo simulation.

### 4.4 A truncated independent sum estimator

Let $q \in A^{(m)}$ and let $S$ be an integral random variable in $[0, m]$ independent of $(\bar{\Delta}_i : 0 \leq i \leq m)$ such that $Pr(S \geq i) = q_i$ for $0 \leq i \leq m$. Set

$$\bar{Z}^{(m)} = \sum_{i=0}^{S} \bar{\Delta}_i.$$  

By Theorem 2.2, Proposition 3.1, and arguments similar to those used in §4.1, it follows that $\bar{Z}^{(m)}$ is square-integrable, with $E(\bar{Z}^{(m)}) = E(Y_m)$, and

$$\text{Var}(\bar{Z}^{(m)}) = \sum_{i=0}^{m} \frac{\tilde{\eta}_i - \tilde{\eta}_{i+1}}{q_i},$$  

where $\tilde{\eta}_0 = \sum_{j=0}^{m} \text{Var}(Y_j - Y_{j-1})$ and, for $1 \leq i \leq m + 1$,

$$\tilde{\eta}_i = (E(Y_{i-1} - Y_m))^2 + \sum_{j=i}^{m} \text{Var}(Y_j - Y_{j-1}).$$
condition of Rhee and Glynn (2015). A geometric characteriz ation of a distribution with infinite coupled sum and independent sum estimators. These conditio ns are weaker than the sufficient similar work-normalized variance, and thus a similar perfo rmance.

Thus, the vector \( \tilde{\eta} \) is estimated via Monte Carlo simulation using 10000 independent copies of the corresponding estimator. The variable Work refers to the total expected number of time steps simulated through the \( \tilde{\eta} \) in the algorithm described in §4.3. Here again, the vector \( \tilde{\eta} \) can be estimated by Monte Carlo simulation.

5 Numerical Experiments

The simulation experiments were implemented in the C++ programming language. The price \( X(t) \) of a stock at time \( t \) is assumed to follow the Geometric Brownian motion model (e.g. Glasserman (2004)), i.e. it satisfies the stochastic differential equation

\[
dX(t) = rX(t) \, dt + \sigma X(t) \, dW,
\]

with \( X(0) = 1 \), where \( r = 0.05 \) is the risk-free rate, \( \sigma = 0.2 \) is the volatility of the stock, and \( W \) is a Brownian motion under the risk-neutral probability. Here \( Y = f(X(T)) \), where \( T = 1 \) and \( f(x) = e^{-r} \max(x - 1, 0) \), so that \( E(Y) \) is the price of a one-year at the money call option on the stock. The model parameters are the same as those in (Rhee and Glynn 2015), and \( E(Y) \) is approximately equal to 0.104505836. The numerical experiments approximate \( Y \) via the Milstein scheme described in Example 2.1. For the coupled sum (resp. independent sum) estimator, \( q_0, \ldots, q_m \) are calculated via the algorithm described in §4.3 (resp. §4.1), with \( m = 13 \). Each component of the vectors \( \tilde{\eta} \) and \( \tilde{\eta} \) is estimated via Monte Carlo simulation using 10000 independent runs. The remaining components of \( q \) are calculated by setting \( q_i = 2^{-3(i-m)/2}q_m \), \( i \geq m+1 \). In Table 1 the estimated option price and its standard deviation Std are calculated using \( n \) independent copies of the corresponding estimator. The variable Work refers to the total expected number of time steps simulated through the \( n \) replications. The fifth column is a 90%-confidence interval for this variable. Thus, \( \text{Work} \times \text{Std}^2 \) is an estimate of the work-normalized variance. As expected, in Table 1 for each of the coupled and independent sum estimators, the variable Work is roughly proportional to \( n \), the variable Std is roughly proportional to \( n^{-1/2} \), while the work-normalized variance is roughly independent of \( n \). The two estimators have a similar work-normalized variance, and thus a similar performance.

6 Conclusion

This note establishes necessary and sufficient conditions for the square integrability of the coupled sum and independent sum estimators. These conditions are weaker than the sufficient condition of Rhee and Glynn (2015). A geometric characterization of a distribution with infinite

</table>

Let \( \tilde{\tau}^{(m)} \) be the expected time to simulate \( \tilde{Z}^{(m)} \). Then

\[
E(\tilde{\tau}^{(m)}) = \sum_{i=0}^{m} q_i (\tilde{\ell}_{i+1} - \tilde{\ell}_i).
\]

Thus, \( q^* = \arg \min_{q \in A_m} R^{(m)}(q; \tilde{\ell}^{(m)}, \tilde{\eta}) \) optimizes the performance of \( \tilde{Z}^{(m)} \). The vector \( q^* \) can be found in \( O(m) \) time by replacing \( (\tilde{\ell}^{(m)}, \tilde{\eta}) \) with \( (\tilde{\ell}^{(m)}, \tilde{\eta}) \) in the algorithm described in §4.3.
support that optimizes the performance of these estimators is presented. An algorithm based on convex hulls that finds an optimal $m$-truncated distribution in $O(m)$ time is described. The algorithm is simple to implement and is illustrated using a numerical example. Alternative RMLMC estimators not covered in this note, such as the “single term” estimator, are studied in (Rhee and Glynn 2015, Vihola 2018). Using the results in this note to broaden the range of applications of the RMLMC methods is a promising direction for future research.

A Proof of Theorem 2.1

Let us first prove the following.

Proposition A.1. Let $(\gamma_n)$, $n \geq 0$, be a nonnegative sequence that goes to 0 as $n$ goes to infinity. Then there is a strictly increasing nonnegative integral sequence $(\rho(n) : n \geq 0)$, such that

$$\gamma_{\rho(n)} \leq \gamma_j \text{ for } n \geq 0 \text{ and } j \in [\rho(0), \rho(n)].$$

(A.1)

Furthermore, if $q \in A$ and

$$\sum_{i=0}^{\infty} \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) \gamma_i < \infty,$$

(A.2)

then $\gamma_{\rho(n)}/q_{\rho(n)+1}$ goes to 0 as $n$ goes to infinity.

Proof. Assume first that there is an integer $n_0$ such that $\gamma_n > 0$ for $n \geq n_0$. Let $\rho(0) = n_0$ and, for $n \geq 1$, let

$$\rho(n) = \min \{ j > \rho(n-1) : \gamma_j \leq \gamma_{\rho(n-1)} \}.$$

By construction, (A.1) holds. Assume now that there are infinitely many integers $n$ such that $\gamma_n = 0$. Let $\rho$ be a strictly increasing sequence with $\gamma_{\rho(n)} = 0$ for $n \geq 0$. Here again, (A.1) holds.

Suppose now that $q \in A$ and that (A.2) holds. Fix $\epsilon > 0$. By (A.2), there is an integer $m$ such that, for $n > m$,

$$\sum_{i=\rho(m)}^{\rho(n)} \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) \gamma_i < \epsilon/2,$$

and so, by (A.1),

$$\left( \frac{1}{q_{\rho(n)+1}} - \frac{1}{q_{\rho(m)}} \right) \gamma_{\rho(n)} < \epsilon/2.$$

Because the sequence $q$ goes to 0 at infinity, there is an integer $m' > m$ such that $q_{\rho(n)+1} < q_{\rho(m)}/2$ for $n > m'$. Thus $\gamma_{\rho(n)}/q_{\rho(n)+1} < \epsilon$ for $n > m'$. This concludes the proof. □

For the rest of the paper, for $n \geq 0$, set $\Delta_n = Y_n - Y_{n-1}$ and

$$\bar{Z}_n = \sum_{k=0}^{n \wedge N} \frac{\Delta_k}{q_k},$$

with $\bar{Z}_{-1} = 0$. Proposition A.2 is shown in (Rhee and Glynn 2015, pp. 1027, 1030).

Proposition A.2. [Rhee and Glynn (2015)] For $-1 \leq m \leq n$, we have $E(\bar{Z}_n) = E(Y_n)$, and

$$||\bar{Z}_n - \bar{Z}_m||^2 = \sum_{i=m+1}^{n} \frac{||Y_{i-1} - Y_n||^2 - ||Y_i - Y_n||^2}{q_i}.$$

Proposition A.3. If $\bar{Z}$ is square-integrable then $||\bar{Z}_n 1\{N > n\}||^2 \leq ||\bar{Z}||^2 + 1$ for infinitely many integers $n$. 

10
Proof. Fix \( n \geq 0 \) with \( \Pr(N = n) > 0 \). Because of the independence of \( N \) and \( (Y_i : i \geq 0) \),

\[
E(\bar{Z}_n^2 \mid N > n) = \| \sum_{k=0}^{n} \Delta_k \|^2 \\
= E(\bar{Z}^2 \mid N = n).
\]

Hence

\[
\| \bar{Z}_n \{ N > n \} \|^2 \Pr(N = n) = \| \bar{Z} \{ N = n \} \|^2 \Pr(N > n).
\]

Clearly, this equation also holds if \( \Pr(N = n) = 0 \).

Assume now for contradiction that the conclusion of Proposition \( \text{A.3} \) does not hold. Then there is an integer \( m \) such that \( \| \bar{Z}_n \{ N > n \} \|^2 > \| \bar{Z} \|^2 + 1 \) for \( n \geq m \). By \( \text{(A.3)} \), for \( n \geq m \),

\[
\| \bar{Z}_n \{ N > n \} \|^2 \Pr(N = n) \leq q_m \| \bar{Z} \{ N = n \} \|^2,
\]

and so

\[
(\| \bar{Z} \|^2 + 1) \Pr(N = n) \leq q_m \| \bar{Z} \{ N = n \} \|^2.
\]

Summing over \( n \in [m, \infty) \) implies that

\[
(\| \bar{Z} \|^2 + 1) q_m \leq q_m \| \bar{Z} \|^2,
\]

leading to a contradiction. \( \square \)

Let us now prove Theorem 2.1. The first part of the proof is inspired from the proof of Theorem 1 of (Rhee and Glynn 2015). By Proposition \( \text{A.2} \) for \( -1 \leq m \leq n \),

\[
\| \bar{Z}_n - \bar{Z}_m \|^2 = \| Y_n - Y_m \|^2 q_{m+1} + \sum_{i=m+1}^{n} \| Y_i - Y_{n} \|^2 \frac{1}{q_{i+1}} - \frac{1}{q_{i}}.
\]

Suppose first that \( \text{(2.2)} \) holds. Applying Proposition \( \text{A.1} \) with \( \gamma_n = \| Y_n - Y \|^2 \) shows the existence of a strictly increasing nonnegative integral sequence \( (\rho(n) : n \geq 0) \) such that \( \text{(A.1)} \) holds. Set \( \bar{Z}_n' = \bar{Z}_{\rho(n)} \) for \( n \geq 0 \). By \( \text{(A.4)} \), for \( 0 \leq m \leq n \),

\[
\| \bar{Z}_n' - \bar{Z}_m' \|^2 = \| Y_n' - Y_m' \|^2 \frac{1}{\rho(n)} + \sum_{i=\rho(n)}^{\rho(m)} \| Y_i - Y_{\rho(n)} \|^2 \frac{1}{q_{i+1}} - \frac{1}{q_{i}}.
\]

Let us show that \( (\bar{Z}_n' : n \geq 0) \) is a Cauchy sequence in \( L^2 \). For \( \rho(0) \leq i \leq \rho(n) \),

\[
\| Y_i - Y_{\rho(n)} \|^2 \leq 2(\gamma_i + \gamma_{\rho(n)}) \leq 4\gamma_i,
\]

where the second inequality follows from \( \text{(A.1)} \). Thus, for \( 0 \leq m \leq n \),

\[
\| \bar{Z}_n' - \bar{Z}_m' \|^2 \leq 4\frac{\gamma_{\rho(n)}}{q_{\rho(n)+1}} + 4 \sum_{i=\rho(n)}^{\rho(m)} \gamma_i \frac{1}{q_{i+1}} - \frac{1}{q_{i}}.
\]

By \( \text{(2.2)} \) and Proposition \( \text{A.1} \), for any \( \epsilon > 0 \), the first term in the RHS of \( \text{(A.6)} \) is smaller than \( \epsilon \) if \( m \) is sufficiently large. Because of \( \text{(2.2)} \), the same holds for the second term. Thus, the sequence \( (\bar{Z}_n' : n \geq 0) \) is Cauchy in \( L^2 \), and so it has a limit in \( L^2 \) as \( n \) goes to infinity. Since \( \bar{Z}_n' \) converges a.s. to \( \bar{Z} \) as \( n \) goes to infinity, this implies that \( \bar{Z} \) is in \( L^2 \) and that \( \bar{Z}_n' \) converges in \( L^2 \) to \( \bar{Z} \) as \( n \) goes to infinity. Hence \( E(\bar{Z}_n') \) (resp. \( (\bar{Z}_n') \)) converges to \( E(\bar{Z}) \) (resp. \( \| \bar{Z} \| \) as
\( n \) goes to infinity. By Proposition [A.2], \( E(Z'_n) = E(Y_{\rho(n)}) \). Letting \( n \) go to infinity implies that \( E(Z) = E(Y) \). This is because \( Y_n \) converges to \( Y \) in \( L^2 \). Furthermore, applying (A.4) with \( m = -1 \) and replacing \( n \) by \( \rho(n) \) yields

\[
\|Z'_n\|^2 = \|Y_{\rho(n)}\|^2 + \sum_{i=0}^{\rho(n)-1} \|Y_i - Y_{\rho(n)}\|^2 \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right).
\]

Observe that \( \|Y_{\rho(n)}\| \) (resp. \( \|Y_i - Y_{\rho(n)}\| \)) converges to \( \|Y\| \) (resp. \( \|Y_i - Y\| \)) as \( n \) goes to infinity. Letting \( n \) go to infinity and using (A.5), (2.2), and the dominated convergence theorem yields (2.3).

Assume now that \( \bar{Z} \) is square-integrable. For \( n \geq 0 \), by linearity of expectation and the equality \( \bar{Z}_n 1\{N \leq n\} = \bar{Z}_1 1\{N \leq n\} \),

\[
\|\bar{Z}_n\|^2 = \|\bar{Z}_1\|^2 + \|\bar{Z}_n 1\{N > n\}\|^2 \leq \|\bar{Z}\|^2 + \|\bar{Z}_n 1\{N > n\}\|^2.
\]

Combining this with Proposition [A.3] shows the existence of a strictly increasing nonnegative integral sequence \( \lambda \) such that, for \( n \in \mathbb{N} \),

\[
\|\bar{Z}_{\lambda(n)}\|^2 \leq 2\|\bar{Z}\|^2 + 1.
\]

Applying once again (A.4) with \( m = -1 \) yields

\[
\|Y_{\lambda(n)}\|^2 + \sum_{i=0}^{\lambda(n)-1} \|Y_i - Y_{\lambda(n)}\|^2 \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) \leq 2\|\bar{Z}\|^2 + 1.
\]

For \( m \in \mathbb{N} \) and \( n \geq m \), because \((q_i)\) is a decreasing sequence and \( m \leq \lambda(n) \), it follows that

\[
\sum_{i=0}^{m-1} \|Y_i - Y_{\lambda(n)}\|^2 \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) \leq 2\|\bar{Z}\|^2 + 1.
\]

Letting \( n \) go to infinity shows that

\[
\sum_{i=0}^{m-1} \|Y_i - Y\|^2 \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right) \leq 2\|\bar{Z}\|^2 + 1,
\]

which implies (2.2).

**B  Proof of Theorem 2.2**

The proof is similar to that of Theorem 2.1. For \( n \geq 0 \), set

\[
\tilde{Z}_n = \sum_{k=0}^{n \wedge N} \hat{\Delta}_k q_k
\]

and let \( \tilde{Z}_{-1} = 0 \). Note that \( E(\tilde{Z}_n) = E(\tilde{Z}_n) = E(Y_n) \). Proposition B.1 is shown in (Rhee and Glynn 2015, p. 1031).

**Proposition B.1.** [Rhee and Glynn (2015)] For \(-1 \leq m \leq n\),

\[
\|\tilde{Z}_n - \tilde{Z}_m\|^2 = \sum_{i=m+1}^{n} \frac{E(\Delta_i^2 + 2\Delta_i E(Y_n - Y_i))}{q_i}.
\]
A simple calculation shows that

\[ E(\Delta_i^2 + 2\Delta_i E(Y_n - Y_i)) = Var(\Delta_i) + (E(Y_n - Y_i))^2 - (E(Y_n - Y_i))^2. \]

Hence, by Proposition B.1 for \(-1 \leq m \leq n,<n\)

\[ ||\bar{Z}_n - \bar{Z}_m||^2 = \frac{(E(Y_n - Y_m))^2}{q_{m+1}} + \sum_{i=m+1}^n \left( \frac{Var(\Delta_i)}{q_i} + (E(Y_i - Y_n))^2 \frac{1}{q_i+1} - \frac{1}{q_i} \right). \]  

(B.1)

Suppose first that (2.5) holds. Applying Proposition A.1 with \(\gamma_n = (E(Y_n - Y))^2\) shows the existence of a strictly increasing nonnegative integral sequence \((\gamma(n) : n \geq 0)\) such that \(E(Y_n - Y) \leq |E(Y_j - Y)|\) for \(\rho(0) \leq j \leq \rho(n)\). Set \(\bar{Z}'_n = \bar{Z}_\rho(n)\) for \(n \geq 0\). By (B.1), for \(0 \leq m \leq n,<n\)

\[ ||\bar{Z}'_n - \bar{Z}'_m||^2 = \frac{(E(Y_{n\rho(m)} - Y_{\rho(n)}))^2}{q_{\rho(m)+1}} + \sum_{i=\rho(m)+1}^{\rho(n)} \left( \frac{Var(\Delta_i)}{q_i} + (E(Y_i - Y_{\rho(n)}))^2 \frac{1}{q_{i+1}} - \frac{1}{q_i} \right). \]

For \(\rho(0) \leq i \leq \rho(n),<n\)

\[ |E(Y_i - Y_{\rho(n)})| \leq |E(Y_i - Y)| + |E(Y_{\rho(n)} - Y)| \leq 2|E(Y_i - Y)|. \]

Thus, for \(0 \leq m \leq n,<n\)

\[ ||\bar{Z}'_n - \bar{Z}'_m||^2 \leq \frac{4\gamma_{\rho(m)}}{q_{\rho(m)+1}} + \sum_{i=\rho(m)+1}^{\rho(n)} \left( \frac{Var(\Delta_i)}{q_i} + 4\gamma(\frac{1}{q_{i+1}} - \frac{1}{q_i}) \right). \]  

(B.2)

By (2.5) and Proposition A.1, for any \(\epsilon > 0\), the first term in the RHS of (B.2) is smaller than \(\epsilon\) if \(m\) is sufficiently large. Because of (2.5), the same holds for the second term. Thus, the sequence \((\bar{Z}'_n : n \geq 0)\) is Cauchy in \(L^2\). As in the proof Theorem 2.1, this implies that \(\bar{Z}\) is in \(L^2\), that \(E(\bar{Z}) = E(Y)\), and that \(||\bar{Z}'_n||\) converges to \(||\bar{Z}||\) as \(n\) goes to infinity. Furthermore, applying (B.1) with \(m = -1\) and replacing \(n\) by \(\rho(n)\) yields

\[ ||\bar{Z}'_n||^2 = (E(Y_{\rho(n)}))^2 + \sum_{i=0}^{\rho(n)} \left( \frac{Var(\Delta_i)}{q_i} + (E(Y_i - Y_{\rho(n)}))^2 \frac{1}{q_{i+1}} - \frac{1}{q_i} \right). \]

Letting \(n\) go to infinity and using the dominated convergence theorem implies (2.6).

Conversely, if \(\bar{Z}\) is square-integrable, then (2.5) follows from arguments similar to those used in the proof of Theorem 2.1. \(\square\)

C Proof of Proposition 3.1

Let us first prove the following proposition. The equality (C.1) means that, if one of its members is finite, so is the other one, and the two members are equal. Moreover, if one of its members is infinite, so is the other one.

Proposition C.1. Let \((\gamma_n : n \geq 0)\) be a positive decreasing sequence that goes to 0 as \(n\) goes to infinity, and let \(q \in A\). Then

\[ \sum_{i=0}^\infty \frac{\gamma_i - \gamma_{i+1}}{q_i} = \gamma_0 + \sum_{i=1}^\infty \gamma_i \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right). \]  

(C.1)
Proof. For $n \geq 0$, 
\[ \sum_{i=0}^{n} \frac{\gamma_i - \gamma_{i+1}}{q_i} = \gamma_0 - \frac{\gamma_{n+1}}{q_{n+1}} + \sum_{i=1}^{n+1} \gamma_i \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right). \]  
(C.2)

Assume first that the LHS of (C.1) is infinite. Then (C.2) implies that the RHS of (C.1) is infinite as well. Assume now that the LHS of (C.1) is finite. As $q$ is decreasing, for $0 \leq m < n$, 
\[ \sum_{i=m}^{n} \frac{\gamma_i - \gamma_{i+1}}{q_i} \geq \frac{\gamma_m - \gamma_{n+1}}{q_m}. \]

Letting $n$ go to infinity shows that 
\[ \frac{\gamma_m}{q_m} \leq \sum_{i=m}^{\infty} \frac{\gamma_i - \gamma_{i+1}}{q_i}, \]
and so $\gamma_m/q_m$ goes to 0 as $m$ goes to infinity. Letting $n$ go to infinity in (C.2) implies (C.1). \qed

Let us now prove Proposition 3.1. Assume that $q \in A$ is such that $\tilde{Z}$ is square-integrable. Since $q_i \leq 1$ for $i \geq 0$, by Theorem 2.2, $\mu_0$ is finite. For $i \geq 0$, let 
\[ \gamma_i = \sum_{j=i}^{\infty} \text{Var}(Y_j - Y_{j-1}). \]

By Theorem 2.2 and Proposition C.1
\[ \text{Var}(\tilde{Z}) = \sum_{i=0}^{\infty} \left( \frac{\gamma_i - \gamma_{i+1}}{q_i} + \left( \frac{1}{q_{i+1}} - \frac{1}{q_i} \right)(E(Y_i - Y))^2 \right) \]
\[ = \gamma_0 + \sum_{i=1}^{\infty} \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right) \gamma_i + \sum_{i=1}^{\infty} \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right)(E(Y_{i-1} - Y))^2. \]

This concludes the proof. \qed

D Proof of Theorem 3.1

The proof builds on ideas used in the proof of (Kahalé 2019, Theorem 3). It uses the following proposition, whose proof follows immediately from (3.1).

Proposition D.1. Let $\vartheta = (\vartheta_0, \vartheta_1, \ldots) \in \{0\} \times \mathbb{R}_+^N$ be a strictly increasing sequence. If $\gamma \in \mathbb{R}_+^N$ and $\gamma' \in \mathbb{R}_+^N$ are such that $\gamma' \leq \gamma$, and $q \in A$. If $R(q; \vartheta, \gamma)$ is finite then $R(q; \vartheta, \gamma') \leq R(q; \vartheta, \gamma)$, with equality if $\gamma_0 = \gamma'_0$ and, for $i \geq 1$, $(\gamma_i - \gamma'_i)(q_{i-1} - q_i) = 0$.

Let us show that $q^*$ is well-defined and belongs to $A$. Fix $i \geq 0$, and let 
\[ a_i = \min_{0 \leq k \leq i} \left( \frac{\gamma_k}{\vartheta_{i+1} - \vartheta_k} \right). \]

The sequence $(a_i(\vartheta_{i+1} - \vartheta_n) : n \geq 0)$ is an affine function of $\vartheta$ and is upper-bounded by $\gamma$, and so it is upper-bounded by $\gamma'$. Hence $\gamma'_i \geq a_i(\vartheta_{i+1} - \vartheta_i) > 0$. In the particular case where $i = 0$, this implies that $\gamma'_0 = \gamma_0$. Since $\gamma_n$ goes to 0 as $n$ goes to infinity, there is $j > i$ with $\gamma_j < \gamma'_j$. By definition of the lower hull, $\gamma_j \geq \gamma'_j \geq \gamma'_i + \vartheta_i(\vartheta_j - \vartheta_i)$, and so $\vartheta_i < 0$. Thus $q^*_i$ is well-defined and is strictly positive. On the other hand, for $n > 0$, because of the convexity properties of the lower hull, 
\[ \vartheta_n \geq \frac{\gamma'_n - \gamma'_0}{q'_n} \geq \frac{-\gamma_0}{q_n}. \]
Thus $|\theta_n| \leq \gamma_0/\vartheta_n$, and so $\theta_n$ goes to 0 as $n$ goes to infinity. As the sequence $(\theta_n : n \geq 0)$ is increasing, this implies that $q^* \in A$. Furthermore, since $\theta_n < 0$ for $n \geq 0$, the sequence $\gamma'$ is strictly decreasing.

By hypothesis, there is $q \in A$ such that $R(q; \vartheta, \gamma)$ is finite. Thus, each component of the product in the RHS of (3.1) has a finite limit as $n$ goes to infinity. By Proposition D.1, $R(q; \vartheta, \gamma') \leq R(q; \vartheta, \gamma)$, and so $R(q; \vartheta, \gamma')$ is finite as well. Since $\gamma'$ is positive, decreasing and goes to 0 at infinity, Proposition C.1 shows that

$$
\sum_{i=0}^{\infty} \frac{\gamma'_i - \gamma'_{i+1}}{q_i} = \gamma'_0 + \sum_{i=1}^{\infty} \gamma'_i \left( \frac{1}{q_i} - \frac{1}{q_{i-1}} \right),
$$

As $\gamma' \leq \gamma$, the RHS of this equation is finite. Thus,

$$
R(q; \vartheta, \gamma') = \left( \sum_{i=0}^{\infty} q_i (\vartheta_{i+1} - \vartheta_i) \right) \left( \sum_{i=0}^{\infty} \frac{\gamma'_i - \gamma'_{i+1}}{q_i} \right),
$$

and the two series in the RHS of this equation are convergent. Since, by the Cauchy-Schwartz inequality, for all nonnegative summable sequences $(x_i)$ and $(y_i)$, $i \geq 0$,

$$
(\sum_{i=0}^{\infty} \sqrt{x_i y_i})^2 \leq (\sum_{i=0}^{\infty} x_i)(\sum_{i=0}^{\infty} y_i),
$$

we conclude that

$$
\left( \sum_{i=0}^{\infty} \sqrt{(\gamma'_i - \gamma'_{i+1})(\vartheta_{i+1} - \vartheta_i)} \right)^2 \leq R(q; \vartheta, \gamma'),
$$

and that the LHS of this equation is finite. Furthermore, by the definition of $q^*$ and Proposition C.1

$$
\sqrt{\theta_0} \sum_{i=0}^{\infty} \sqrt{(\gamma'_i - \gamma'_{i+1})(\vartheta_{i+1} - \vartheta_i)} = \sum_{i=0}^{\infty} \frac{\gamma'_i - \gamma'_{i+1}}{q^*_i} = \gamma'_0 + \sum_{i=1}^{\infty} \left( \frac{1}{q'_i} - \frac{1}{q'_{i-1}} \right) \gamma'_i.
$$

The second equation follows once again from Proposition C.1. Thus the three series are convergent and have the same limit. Using (3.1) and the definition of $q^*$ implies that

$$
R(q^*; \vartheta, \gamma') = \left( \sum_{i=0}^{\infty} \sqrt{(\gamma'_i - \gamma'_{i+1})(\vartheta_{i+1} - \vartheta_i)} \right)^2.
$$

Hence, by (D.1), $R(q^*; \vartheta, \gamma') \leq R(q; \vartheta, \gamma')$. On the other hand, $(\gamma_i - \gamma'_i)(q^*_i - q'_i) = 0$ for $i \geq 1$. This is because, if $\gamma'_i < \gamma_i$, then the point $(\vartheta_i, \gamma_i)$ does not belong to the lower hull of the set $\{(\vartheta_j, \gamma_j) : j \geq 0\}$. Thus $(\vartheta_i, \gamma'_i)$ belongs to the segment $[ (\vartheta_{i-1}, \gamma'_{i-1}), (\vartheta_{i+1}, \gamma'_{i+1}) ]$, which implies that $\theta_{i-1} = \theta_i$ and $q^*_{i-1} = q'_i$. Hence, as $\gamma_0 = \gamma'_0$, Proposition D.1 shows that $R(q^*; \vartheta, \gamma) = R(q^*; \vartheta, \gamma')$. This implies (3.2) and shows that $R(q^*; \vartheta, \gamma) \leq R(q; \vartheta, \gamma)$, as desired.
