XMO and Weighted Compact Bilinear Commutators

Jin Tao, Qingying Xue, Dachun Yang* and Wen Yuan

Abstract  In this article, the authors first establish an equivalent characterization of the space XMO (\(\mathbb{R}^n\)) very recently introduced by R. H. Torres and Q. Xue, and then show that XMO (\(\mathbb{R}^n\)) is a proper subspace of the space VMO (\(\mathbb{R}^n\)) introduced by D. Sarason. Furthermore, via XMO (\(\mathbb{R}^n\)), the authors obtain a weighted compactness result for a certain type of bilinear Calderón–Zygmund operators, which contains the (inhomogeneous) Coifman–Meyer bilinear Fourier multipliers and the bilinear pseudodifferential operators as special examples.

1 Introduction

In a very recent article [21], Torres and Xue introduced a new subspace of BMO (\(\mathbb{R}^n\)), denoted by XMO (\(\mathbb{R}^n\)), which was used to study the compactness of a certain type of bilinear Calderón–Zygmund operators. The main purpose of this article is to explore the intrinsic properties of XMO (\(\mathbb{R}^n\)) and to optimize the corresponding compactness results even in the unweighted setting. In particular, we completely answer an open question raised in [21]. In what follows, we use \(L^\infty_c(\mathbb{R}^n)\) to denote the set of all essentially bounded functions on \(\mathbb{R}^n\) with compact supports. The theory of commutators of pointwise multiplication with Calderón–Zygmund operators has attracted lots of attentions and many works have been done since Coifman et al. [8] first studied the boundedness characterization of the commutator \([b, T]\) which is defined by setting, for any \(f \in L^\infty_c(\mathbb{R}^n)\),

\[ [b, T]f := bT(f) - T(bf), \]

where \(T\) is any classical Calderón–Zygmund operator with smooth kernel and \(b \in \text{BMO}(\mathbb{R}^n)\). Among those achievements are the celebrated boundedness and compactness results of Coifman et al. [8], Cordes [9], Uchiyama [23] and Janson [15] in the linear situation. In [23], Uchiyama established a characterization of CMO (\(\mathbb{R}^n\)) (see Proposition 2.4) and used it to show that the compactness of the commutators of the classical Calderón–Zygmund operators with non-degenerate homogeneous kernels holds true if and only if \(b\) is in CMO (\(\mathbb{R}^n\)), where CMO (\(\mathbb{R}^n\)) denotes the closure in BMO (\(\mathbb{R}^n\)) of indefinitely differential functions with compact supports.

*Corresponding author/September 7, 2019/Final version.
In the bilinear setting, recall that the boundedness on $L^p(\mathbb{R}^n)$ of the commutators of more generalized bilinear Calderón–Zygmund operators with $b \in \text{BMO}(\mathbb{R}^n)$ was established by Pérez and Torres [17] for any $p \in (1, \infty)$, and by Tang [19] and Lerner et al. [16] for any $p \in (1/2, 1]$. The compactness in $L^p(\mathbb{R}^n)$ of the commutators multiplying functions in $\text{CMO}(\mathbb{R}^n)$ was demonstrated by Bényi and Torres [4] for any $p \in (1, \infty)$, and by Torres et al. [22] for any $p \in (1/2, 1]$. Moreover, Chaffee et al. [5] showed that the compactness result for certain homogeneous bilinear Calderón–Zygmund operators holds true if and only if $b \in \text{CMO}(\mathbb{R}^n)$. For more related works, we refer the reader to [10, 14] and their references.

In order to investigate the possible versions in the bilinear setting of the compactness result of Cordes [9], Torres and Xue in [21] uncovered two subspaces of $\text{BMO}(\mathbb{R}^n)$, which were denoted, respectively, by $\text{MMO}(\mathbb{R}^n)$ and $\text{XMO}(\mathbb{R}^n)$. It is known that
\[
\text{CMO}(\mathbb{R}^n) \subset \text{MMO}(\mathbb{R}^n) \subset \text{XMO}(\mathbb{R}^n) \subset \text{VMO}(\mathbb{R}^n),
\]
where $\text{VMO}(\mathbb{R}^n) \subset \text{BMO}(\mathbb{R}^n)$ denotes the space of functions with “vanishing mean oscillation”. The main results in [21] state that the compactness result still holds true for the commutators of pointwise multiplication with certain bilinear Calderón–Zygmund operators whenever $b \in \text{XMO}(\mathbb{R}^n)$. This means, of course, for the compactness of these commutators, $b$ does not need to be in $\text{CMO}(\mathbb{R}^n)$. It still works in a more larger subspace $\text{XMO}(\mathbb{R}^n)$.

In what follows, let $\mathbb{N} := \{1, 2, \ldots\}$, $\mathbb{Z}_+ := \mathbb{N} \cup \{0\}$, $\mathbb{Z}_+^n := (\mathbb{Z}_+)^n$ and $\mathbb{Z}_+^{3n} := (\mathbb{Z}_+)^{3n}$. In this article, we consider the following particular type bilinear Calderón–Zygmund operator $T$, whose kernel $K$ satisfies

(i) The standard size and regularity conditions: for any multi-indices $\alpha := (\alpha_1, \ldots, \alpha_{3n}) \in \mathbb{Z}_+^{3n}$ with $|\alpha| := \alpha_1 + \cdots + \alpha_{3n} \leq 1$, there exists a positive constant $C_{(\alpha)}$, depending on $\alpha$, such that, for any $x, y, z \in \mathbb{R}^n$ with $x \neq y$ or $x \neq z$,
\[
|D^{\alpha}K(x, y, z)| \leq C_{(\alpha)}(|x - y| + |x - z|)^{-2n-|\alpha|}. \tag{1.1}
\]

Here and thereafter, $D^{\alpha} := (\frac{\partial}{\partial x_1})^{\alpha_1} \cdots (\frac{\partial}{\partial x_n})^{\alpha_{3n}}$.

(ii) The additional decay condition: there exists a positive constant $C$ such that, for any $x, y, z \in \mathbb{R}^n$ with $|x - y| + |x - z| > 1$,
\[
|K(x, y, z)| \leq C(|x - y| + |x - z|)^{-2n-2}. \tag{1.2}
\]

and, for any $f, g \in L^\infty_c(\mathbb{R}^n)$ and $x \notin \text{supp}(f) \cap \text{supp}(g)$, $T$ is supposed to have the following usual representation:
\[
T(f, g)(x) = \int_{\mathbb{R}^{2n}} K(x, y, z)f(y)g(z) \, dy \, dz,
\]
here and thereafter, $\text{supp}(f) := \{x \in \mathbb{R}^n : f(x) \neq 0\}$. The (inhomogeneous) Coifman–Meyer bilinear Fourier multipliers and the bilinear pseudodifferential operators with certain symbols satisfy the above conditions (see, for instance, [21]). Therefore, they are typical examples of the bilinear Calderón–Zygmund operators as above. We refer the reader to [3, 7, 11, 13, 12, 21] for the boundedness and more history of these operators.
Recall that the bilinear commutators with single entries are defined by setting, for any \( f, g \in L^\infty_c(\mathbb{R}^n) \) and \( x \notin \text{supp}(f) \cap \text{supp}(g) \),

\[
[T, b]_1(f, g)(x) := (bT(f, g) - T(bf, g))(x) = \int_{\mathbb{R}^{2n}} [b(x) - b(y)]K(x, y, z)f(y)g(z) \, dy \, dz
\]

and

\[
[T, b]_2(f, g)(x) := (bT(f, g) - T(bf, g))(x) = \int_{\mathbb{R}^{2n}} [b(x) - b(z)]K(x, y, z)f(y)g(z) \, dy \, dz.
\]

We now need to introduce several subspaces of the space \( BMO(\mathbb{R}^n) \). Recall that

\[
\text{CMO}(\mathbb{R}^n) := \overline{C_{c}^{\infty}(\mathbb{R}^n) \cap BMO(\mathbb{R}^n)}^{BMO(\mathbb{R}^n)}
\]

and

\[
\text{VMO}(\mathbb{R}^n) := \overline{C_{d}(\mathbb{R}^n) \cap BMO(\mathbb{R}^n)}^{BMO(\mathbb{R}^n)},
\]

where \( C_{c}^{\infty}(\mathbb{R}^n) \) denotes the set of all smooth functions on \( \mathbb{R}^n \) with compact supports and \( C_{d}(\mathbb{R}^n) \) the set of all functions on \( \mathbb{R}^n \) with uniform continuity. Here and thereafter, \( \overline{X}^{BMO(\mathbb{R}^n)} \) denotes the closure in \( BMO(\mathbb{R}^n) \) of the set \( X \).

In what follows, we use \( \vec{0}_n \) to denote the origin of \( \mathbb{R}^n \) and, for any \( \alpha := (\alpha_1, \ldots, \alpha_n) \in \mathbb{Z}^n_{+} \), we let \( D^\alpha := (\frac{\partial}{\partial x_1})^{\alpha_1} \cdots (\frac{\partial}{\partial x_n})^{\alpha_n} \). We also use \( C^{\infty}(\mathbb{R}^n) \) to denote the set of all infinitely differentiable functions on \( \mathbb{R}^n \) and \( L^{\infty}(\mathbb{R}^n) \) the set of all essentially bounded functions on \( \mathbb{R}^n \). The spaces \( \text{MMO}(\mathbb{R}^n) \) and \( \text{XMO}(\mathbb{R}^n) \) in [21] were defined in the way that

\[
\text{MMO}(\mathbb{R}^n) := A_{\infty}(\mathbb{R}^n)^{BMO(\mathbb{R}^n)},
\]

where

\[
A_{\infty}(\mathbb{R}^n) := \left\{ b \in C^{\infty}(\mathbb{R}^n) \cap L^{\infty}(\mathbb{R}^n) : \forall \alpha \neq \vec{0}_n \in \mathbb{Z}^n_{+}, \lim_{|x| \to \infty} D^\alpha b(x) = 0 \right\},
\]

and

\[
\text{XMO}(\mathbb{R}^n) := B_{\infty}(\mathbb{R}^n)^{BMO(\mathbb{R}^n)},
\]

where

\[
B_{\infty}(\mathbb{R}^n) := \left\{ b \in C^{\infty}(\mathbb{R}^n) \cap BMO(\mathbb{R}^n) : \forall \alpha \neq \vec{0}_n \in \mathbb{Z}^n_{+}, \lim_{|x| \to \infty} D^\alpha b(x) = 0 \right\}.
\]

Furthermore, we use the following set

\[
B_1(\mathbb{R}^n) := \left\{ b \in C^{1}(\mathbb{R}^n) \cap BMO(\mathbb{R}^n) : \lim_{|x| \to \infty} |\nabla b(x)| = 0 \right\}
\]

to define

\[
X_1\text{MO}(\mathbb{R}^n) := \overline{B_1(\mathbb{R}^n)}^{BMO(\mathbb{R}^n)},
\]

where \( C^{1}(\mathbb{R}^n) \) denotes the set of all functions \( f \) on \( \mathbb{R}^n \) whose gradients \( \nabla f := (\frac{\partial f}{\partial x_1}, \ldots, \frac{\partial f}{\partial x_n}) \) are continuous. By the fact that \( C_{c}^{\infty}(\mathbb{R}^n) \subset B_{\infty}(\mathbb{R}^n) \subset B_1(\mathbb{R}^n) \subset C_{d}(\mathbb{R}^n) \), then it is easy to see that

\[
\text{CMO}(\mathbb{R}^n) \subset \text{XMO}(\mathbb{R}^n) \subset X_1\text{MO}(\mathbb{R}^n) \subset \text{VMO}(\mathbb{R}^n).
\]
It was shown in [21] that

\[ \text{CMO}(\mathbb{R}^n) \subsetneq \text{MMO}(\mathbb{R}^n) \subsetneq \text{XMO}(\mathbb{R}^n). \]

Meanwhile, an open question was posed by Torres and Xue in [21] as follows:

**Question 1.1.** Which one of the following two possibilities

\[ \text{XMO}(\mathbb{R}^n) \subsetneq \text{VMO}(\mathbb{R}^n) \quad \text{or} \quad \text{XMO}(\mathbb{R}^n) = \text{VMO}(\mathbb{R}^n) \]

holds true?

Torres and Xue in [21] conjectured that the latter might be true. However, in this article, we show that the relationship \( \text{XMO}(\mathbb{R}^n) \subsetneq \text{VMO}(\mathbb{R}^n) \) holds true, which gives a complete answer to Question 1.1. Indeed, we have

\[ \text{CMO}(\mathbb{R}^n) \subsetneq \text{XMO}(\mathbb{R}^n) = \text{X}_1\text{MO}(\mathbb{R}^n) \subsetneq \text{VMO}(\mathbb{R}^n), \]

where \( \text{XMO}(\mathbb{R}^n) \supsetneq \text{X}_1\text{MO}(\mathbb{R}^n) \) is not obvious. To show this, we establish the following equivalent characterization, which is the first main result of this article. In what follows, the symbol \( a \to 0^+ \) means that \( a \in (0, \infty) \) and \( a \to 0^- \); the symbol \( Q \) means a cube that \( Q \) has finite side length, all its sides parallel to the coordinate axes, but \( Q \) is not necessary to be open or closed, and \( Q + x := \{ y + x : y \in Q \} \) for any \( x \in \mathbb{R}^n \); for any cube \( Q \subset \mathbb{R}^n \) and \( f \in L^1_{\text{loc}}(\mathbb{R}^n) \) (the set of all locally integrable functions), the mean oscillation \( O(f; Q) \) is defined by setting

\[
O(f; Q) := \frac{1}{|Q|} \int_Q \left| f(x) - \frac{1}{|Q|} \int_Q f(y) \, dy \right| \, dx.
\]

**Theorem 1.2.** The following statements are mutually equivalent:

(i) \( f \in \text{X}_1\text{MO}(\mathbb{R}^n); \)

(ii) \( f \in \text{BMO}(\mathbb{R}^n) \) and enjoys the properties that

\[
\text{(ii)}_1 \quad \lim_{a \to 0^+} \sup_{|Q|=a} O(f; Q) = 0;
\]

\[
\text{(ii)}_2 \quad \text{for any cube } Q \subset \mathbb{R}^n, \quad \lim_{|x| \to \infty} O(f; Q + x) = 0.
\]

(iii) \( f \in \text{XMO}(\mathbb{R}^n). \)

As a consequence of Theorem 1.2, we have

**Corollary 1.3.** \( \text{XMO}(\mathbb{R}^n) \subsetneq \text{VMO}(\mathbb{R}^n). \)
Thus, Corollary 1.3 completely answers the open question asked by Torres and Xue in [21].

In order to state another main results of this article, we need to introduce a class of multiple weights. Recall that, usually, a non-negative measurable function $w$ on $\mathbb{R}^n$ is called a weight on $\mathbb{R}^n$. For any given $p := (p_1, p_2) \in (1, \infty) \times (1, \infty)$, let $p$ satisfies $\frac{1}{p} = \frac{1}{p_1} + \frac{1}{p_2}$. Following [1], we call $w := (w_1, w_2)$ a vector $A_p(\mathbb{R}^n)$ weight, denoted by $w := (w_1, w_2) \in A_p(\mathbb{R}^n)$, if

$$[w]_{A_p(\mathbb{R}^n)} := \sup_Q \left[ \frac{1}{|Q|} \int_Q w(x) \, dx \right] \left( \frac{1}{|Q|} \int_Q [w_1(x)]^{1/p_1'} \, dx \right)^{p_1} \left( \frac{1}{|Q|} \int_Q [w_2(x)]^{1/p_2'} \, dx \right)^{p_2} < \infty,$$

where $w := w_1^{p_1/p} w_2^{p_2/p}$, $p := \frac{1}{p_1} + \frac{1}{p_2}$ and the supremum is taken over all cubes $Q$ of $\mathbb{R}^n$. In what follows, for any given weight $w$ on $\mathbb{R}^n$ and measurable subset $E \subseteq \mathbb{R}^n$, the symbol $L^p_w(E)$ denotes the set of all measurable functions $f$ on $E$ such that

$$\|f\|_{L^p_w(E)} := \left[ \int_E |f(x)|^p w(x) \, dx \right]^{1/p} < \infty.$$

Now, we state our second main result of this article via XMO ($\mathbb{R}^n$) as follows.

**Theorem 1.4.** Let $p := (p_1, p_2) \in (1, \infty) \times (1, \infty)$, $w \in XMO(\mathbb{R}^n)$ and $T$ be a bilinear Calderón–Zygmund operator whose kernel satisfies (1.1) and (1.2). Then, for any $i \in \{1, 2\}$, the bilinear commutator $[T, b_i]$ as in (1.3) and (1.4) is compact from $L^{p_1}_{w_1}(\mathbb{R}^n) \times L^{p_2}_{w_2}(\mathbb{R}^n)$ to $L^p_w(\mathbb{R}^n)$.

**Remark 1.5.** We have the following several comments towards the results in Theorem 1.4.

(i) By usual modifications, Theorem 1.4 can be extended to multilinear case with notational complications. Furthermore, observe that the proof of Theorem 1.4 mainly relies on the boundedness of Calderón–Zygmund operators and the Hardy–Littlewood maximal operators. Therefore, Theorem 1.4 can also be extended to Morrey spaces; see, for instance, [20].

(ii) Comparing with the classical compactness results (see, for instance, [1]), since we require additional decay (1.2) for the Calderón–Zygmund kernel in Theorem 1.4, we can delete condition (iii) in Proposition 2.4 below, which changes CMO ($\mathbb{R}^n$) into XMO ($\mathbb{R}^n$) by Theorem 1.2.

(iii) The corresponding compactness result in [21] requires the kernel $K$ satisfying both (1.1) and the following additional estimates: for any given $\alpha \in \mathbb{Z}^n$, with $|\alpha| \leq 1$, and for any given $N \in \{1, 2, 3\}$, there exists a positive constant $C_{(\alpha, N)}$, depending on $\alpha$ and $N$, such that, for any $|x - y| + |x - z| > 1$,

$$(1.5) \quad |D^\alpha K(x, y, z)| \leq C_{(\alpha, N)} (|x - y| + |x - z|)^{-2n-N}.$$

But, our assumption (1.2) in Theorem 1.4 only needs $\alpha = 0_3$ and $N = 2$ in (1.5). Thus, in this sense, even the unweighted case of Theorem 1.4 also improves the corresponding result in [21].
This article is organized as follows.

In Section 2, we first notice the nontriviality of XMO ($\mathbb{R}^n$) when $n = 1$, namely,

$$\text{XMO} (\mathbb{R}) \subsetneq \text{VMO} (\mathbb{R})$$

(see Proposition 2.1). Based on its calculation, we further show that XMO ($\mathbb{R}^n$) have a similar equivalent characterization as VMO ($\mathbb{R}^n$) and CMO ($\mathbb{R}^n$) (see Theorem 1.2). Inspired by Uchiyama [23], we first approximate a given function $f \in \text{XMO} (\mathbb{R}^n)$ via an exceptional simple function $g_\varepsilon$ based on a dyadic family $\mathcal{F}$, which behaves like a sunflower (dense inside and sparse outside), that is to say, $\mathcal{F}$ consists of numerous small equal-size dyadic cubes near the origin, and farther away from the origin, the larger the dyadic cubes in $\mathcal{F}$ are. Furthermore, by the convolution of $g_\varepsilon$ and an even function $\varphi$ with delicate dilation, we obtain the desired approximation element in $B_\infty (\mathbb{R}^n)$ and finally finish the proof of Theorem 1.2. As a corollary, we obtain

$$\text{X}^1 \text{MO} (\mathbb{R}^n) = \text{XMO} (\mathbb{R}^n) \subsetneq \text{VMO} (\mathbb{R}^n)$$

(see Corollary 1.3), which completely answer the open question raised in [21].

In Section 3, we give the proof of Theorem 1.4. Since a general $A_p$ weight is not invariant under translations, the method in [21] can not be applied to the weighted setting directly. Hence, to overcome this difficulty, a main new idea is to change the dominations of the translation-invariant positive operators in [21] into the dominations of the maximal functions and the smooth truncated Calderón–Zygmund operators. To this end, we use several smooth truncated techniques and the density arguments of compact operators. We point out that, using this method, we can also optimize [21, Theorem 1.1] from “$K$ satisfies (1.5)” to “$K$ satisfies (1.2)” even in the unweighted case.

Throughout this article, we denote by $C$ and $\tilde{C}$ positive constants which are independent of the main parameters, but they may vary from line to line. Moreover, we use $C_{(\gamma, \beta, \ldots)}$ to denote a positive constant depending on the indicated parameters $\gamma, \beta, \ldots$. Constants with subscripts, such as $C_0$ and $A_1$, do not change in different occurrences. Moreover, the symbol $f \lesssim g$ represents that $f \leq Cg$ for some positive constant $C$. If $f \lesssim g$ and $g \lesssim f$, we then write $f \sim g$. We also use the following conventions: If $f \leq Cg$ and $g = h$ or $g \leq h$, we then write $f \sim h$. We use $f \lesssim g$ and $g \lesssim f$, rather than $f \lesssim g = h$ or $f \lesssim g \leq h$. Let $\mathbb{N} := \{1, 2, \ldots\}$ and $\mathbb{Z}_+ := \mathbb{N} \cup \{0\}$. For any $p \in [1, \infty]$, let $p'$ denote its conjugate index, that is, $p'$ satisfies $1/p + 1/p' = 1$. For any cube $Q \subset \mathbb{R}^n$ and $f \in L^1_{\text{loc}} (\mathbb{R}^n)$, let

$$\int_Q := \frac{1}{|Q|} \int_Q f(y) \, dy;$$

moreover, the mean oscillation $O(f; Q)$ is defined by setting

$$O(f; Q) := \int_Q \left| f(x) - f_Q \right| \, dx.$$

## 2 Characterization and non-triviality of XMO ($\mathbb{R}^n$)

In this section, we investigate the equivalent characterization of XMO ($\mathbb{R}^n$) and begin with the following concise counterexample on the real line.
**Proposition 2.1.** There exists some \( f \in \text{VMO}(\mathbb{R}) \setminus \text{XMO}(\mathbb{R}) \).

**Proof.** For any \( x \in \mathbb{R} \), let \( f(x) := \sin(x) \). Then \( f \) is uniformly continuous and \( f \in L^\infty(\mathbb{R}) \subset \text{BMO}(\mathbb{R}) \). Thus, \( f \in \text{VMO}(\mathbb{R}) \). We claim that, for any \( g \in B_1(\mathbb{R}^n) \),

\[
\|f - g\|_{\text{BMO}(\mathbb{R})} \geq \frac{1}{2\pi}.
\]

Indeed, for any \( k \in \mathbb{N} \), let

\[
I_k := \left[ 2k\pi - \frac{\pi}{2}, 2k\pi + \frac{\pi}{2} \right].
\]

Since \( g \in B_1(\mathbb{R}^n) \), it follows that \( \lim_{|x| \to \infty} g'(x) = 0 \) and hence we can choose \( k \) large enough such that, for any \( y \in I_k \),

\[
|g'(y)| < \frac{4}{\pi^2} < \frac{\sqrt{2}}{\pi}.
\]

Therefore, by the mean value theorem and the fundamental theorem of calculus, we have

\[
O(f - g; I_k) = \frac{1}{|I_k|} \int_{I_k} \left| (f - g)(x) - (f - g)_{I_k} \right| \, dx \geq \frac{1}{|I_k|} \int_{I_k} \left| (f - g)(x) - (f - g)(\xi_k) \right| \, dx = \frac{1}{|I_k|} \int_{I_k} \left| \int_{\xi_k}^x (f - g)'(y) \, dy \right| \, dx = \frac{1}{|I_k|} \int_{\xi_k}^x \left| \cos(y) - g'(y) \right| \, dy \, dx,
\]

where \( \xi_k \in I_k \) is independent of \( x \), but it may depend on \( k \). Without loss of generality, we may assume that \( \xi_k \in [2k\pi - \frac{\pi}{2}, 2k\pi] \). Then, from (2.3), we deduce that

\[
O(f - g; I_k) \geq \frac{1}{\pi} \int_{2k\pi}^{2k\pi + \frac{\pi}{2}} \left| \int_{\xi_k}^x \left| \cos(y) - g'(y) \right| \, dy \right| \, dx.
\]

By the fact that \( \xi_k \in [2k\pi - \frac{\pi}{2}, 2k\pi] \) and \( x \in [2k\pi, 2k\pi + \frac{\pi}{2}] \), we know that \( \frac{x + \xi_k}{2} \in [2k\pi - \frac{\pi}{4}, 2k\pi + \frac{\pi}{4}] \) and \( \frac{x - \xi_k}{2} \in [0, \frac{\pi}{2}] \). Therefore,

\[
\cos\left(\frac{x + \xi_k}{2}\right) \geq \frac{\sqrt{2}}{2} \quad \text{and} \quad \sin\left(\frac{x - \xi_k}{2}\right) \geq \frac{2}{\pi} \frac{x - \xi_k}{2} = \frac{x - \xi_k}{\pi}.
\]

From (2.2) and (2.5), it follows that

\[
\int_{\xi_k}^x \left| \cos(y) - g'(y) \right| \, dy > \int_{\xi_k}^x \left| \cos(y) - \frac{\sqrt{2}}{\pi} \right| \, dy = \sin(x) - \sin(\xi_k) - \frac{\sqrt{2}}{\pi} (x - \xi_k) = 2 \cos\left(\frac{x + \xi_k}{2}\right) \sin\left(\frac{x - \xi_k}{2}\right) - \frac{\sqrt{2}}{\pi} (x - \xi_k) \geq 2 \frac{\sqrt{2}}{\pi} \frac{x - \xi_k}{\pi} - \frac{\sqrt{2}}{\pi} (x - \xi_k) \geq 0.
\]
By (2.4), (2.6), \( \xi_k \in [2k\pi - \frac{\pi}{2}, 2k\pi] \) and (2.2), we conclude that

\[
\mathcal{O}(f - g; I_k) \geq \frac{1}{\pi} \int_{2k\pi}^{2k\pi + \frac{\pi}{2}} \int_{\xi_k}^{\xi_k + \frac{\pi}{2}} \left[ \cos(y) - g'(y) \right] \, dy \, dx \\
= \frac{1}{\pi} \int_{2k\pi}^{2k\pi + \frac{\pi}{2}} \left[ \sin(x) \sinh \left( \frac{4}{\pi^2} (x - 2k\pi) \right) \right] \, dx \\
= \frac{1}{\pi} \left( 1 - \frac{4}{\pi^2} \int_0^{\frac{\pi}{2}} z \, dz \right) = \frac{1}{\pi} \left[ 1 - \frac{4}{\pi^2} \left( \frac{\pi}{2} \right)^2 \right] = \frac{1}{2}\pi.
\]

This implies that the inequality (2.1) holds true, which completes the proof of Proposition 2.1. \( \square \)

**Remark 2.2.** One can modify the above calculation from \( \mathbb{R} \) to \( \mathbb{R}^n \), but this process may be tedious. However, if, for any \((x_1, \ldots, x_n) \in \mathbb{R}^n\), let

\[
f(x_1, \ldots, x_n) := \prod_{k=1}^n \sin(x_k)
\]

then, by Theorem 1.2, we immediately know that

\[
f \in \text{VMO}(\mathbb{R}^n) \setminus \text{XMO}(\mathbb{R}^n);
\]

see the proof of Corollary 1.3 below.

In what follows, we need to use the following equivalent characterizations of VMO \((\mathbb{R}^n)\) and CMO \((\mathbb{R}^n)\) established by Sarason [18] and Uchiyama [23], respectively.

**Proposition 2.3. (\cite[Theorem 1]{18})** Let \( f \in \text{BMO}(\mathbb{R}^n) \). Then \( f \in \text{VMO}(\mathbb{R}^n) \) if and only if

\[
\lim_{a \to 0^+} \sup_{Q \subset a} \mathcal{O}(f; Q) = 0.
\]

**Proposition 2.4. (\cite[p. 166]{23})** Let \( f \in \text{BMO}(\mathbb{R}^n) \). Then \( f \in \text{CMO}(\mathbb{R}^n) \) if and only if \( f \) satisfies the following three conditions:

(i) \[
\lim_{a \to 0^+} \sup_{Q \subset a} \mathcal{O}(f; Q) = 0;
\]

(ii) for any cube \( Q \subset \mathbb{R}^n \),

\[
\lim_{|x| \to \infty} \mathcal{O}(f; Q + x) = 0;
\]

(iii) \[
\lim_{a \to \infty} \sup_{Q \subset a} \mathcal{O}(f; Q) = 0.
\]

Observe that, in the proof of Proposition 2.1, the mean oscillations \( \{\mathcal{O}(f; I_k)\}_{k \in \mathbb{N}} \) violate Proposition 2.4(ii), which leads us to consider the limit condition (ii) of Theorem 1.2(ii).

Now, we are in the position to give the proof of Theorem 1.2.
Proof of Theorem 1.2. We first prove (i) \implies (ii). By the density argument, it suffices to prove that, for any \( f \in B_1(\mathbb{R}^n) \), both (ii)_1 and (ii)_2 of Theorem 1.2(ii) hold true. Indeed, for any \( x, y \in \mathbb{R}^n \), by the mean value theorem, we obtain
\[
|f(x) - f(y)| = |\nabla f(\xi) \cdot (x - y)| \leq \|\nabla f\|_{L^\infty(\mathbb{R}^n)} |x - y|,
\]
where \( \xi \) is on the segment \( \overline{xy} \) connecting \( x \) and \( y \), and \( \|\nabla f\|_{L^\infty(\mathbb{R}^n)} < \infty \) because \( f \in B_1(\mathbb{R}^n) \). This implies that \( f \in C_0(\mathbb{R}^n) \) and hence \( f \in \text{VMO}(\mathbb{R}^n) \). From this and Proposition 2.3, it follows that \( f \) satisfies (ii)_1 of Theorem 1.2(ii). Moreover, for any fixed cube \( Q \subseteq \mathbb{R}^n \), by the mean value theorem again, we conclude that
\[
O(f; Q) = \frac{1}{|Q|} \int_Q |f(x) - f(y)| \frac{dx}{dy} \leq \frac{1}{|Q|^2} \int_Q \int_Q |f(x) - f(y)| \frac{dy dx}{Q} 
\]
\[
\leq \left( \sup_{\xi \in Q} |\nabla f(\xi)| \right) |Q|.
\]
Thus, for the given cube \( Q \) and any \( x \in \mathbb{R}^n \), we have
\[
O(f; Q + x) \leq \left( \sup_{\xi \in Q + x} |\nabla f(\xi)| \right) |Q + x| \sim \left( \sup_{\xi \in Q + x} |\nabla f(\xi)| \right) |Q| = 0
\]
as \( |x| \to \infty \), which shows that \( f \) satisfies (ii)_2 of Theorem 1.2(ii). This finishes the proof that (i) \implies (ii).

Now, we are going to prove (ii) \implies (iii). Let \( f \in \text{BMO}(\mathbb{R}^n) \) satisfies both (ii)_1 and (ii)_2 of Theorem 1.2(ii). To prove \( f \in \text{XMO}(\mathbb{R}^n) \), for any fixed \( \epsilon \in (0, \infty) \), it suffices to show that, there exist a simple function \( g_\epsilon \) satisfying
\[
\|f - g_\epsilon\|_{\text{BMO}(\mathbb{R}^n)} \leq \epsilon
\]
and a function \( h_\epsilon \in B_\infty(\mathbb{R}^n) \) satisfying
\[
\|g_\epsilon - h_\epsilon\|_{\text{BMO}(\mathbb{R}^n)} \leq \epsilon.
\]

The remainder of the proof that (ii) \implies (iii) consists of the following three steps:

**Step i)** Construct a family \( \mathcal{F} \) of disjoint dyadic cubes and introduce a simple function \( g_\epsilon \) via \( \mathcal{F} \).

**Step ii)** Show that (2.7) holds true.

**Step iii)** Define \( h_\epsilon \) via \( g_\epsilon \), and then show that (2.8) holds true and \( h_\epsilon \in B_\infty(\mathbb{R}^n) \).

We proceed in order and begin with **Step i**. For the above given \( \epsilon \in (0, \infty) \), by (ii)_1 of Theorem 1.2(ii), we know that there exists a negative integer \( j(\epsilon; 0) \in \mathbb{Z}_- := \{ -1, -2, \ldots \} \) such that, for any cube \( Q \) with the side length \( \ell(Q) < 2^{j(\epsilon; 0)+1} \),
\[
O(f; Q) < \epsilon.
\]
Here and thereafter, we denote the side length of a cube \( Q \) by \( \ell(Q) \). Besides, we always use \( Q(x, r) \) to represent the cube centered at \( x \) with the side length \( 2r \), and \( D \) to represent the family of all classical dyadic cubes in \( \mathbb{R}^n \). By (ii) of Theorem 1.2(ii), we find that there exists some \( j(\varepsilon; 1) \in \mathbb{Z} \) with \( j(\varepsilon; 1) > j(\varepsilon; 0) \) such that, for any \( x \in \mathbb{R}^n \) with \( |x| \geq j(\varepsilon; 1) \),

\[
O(f; Q(x, 2^{j(\varepsilon;0)+1})) < 2^{j(\varepsilon;0)} \varepsilon < 2^{-1} \varepsilon < \varepsilon.
\]

Repeating the above procedure, we obtain, for any \( k \in \mathbb{N} \), there exists some \( j(\varepsilon; k) \in \mathbb{Z} \) with \( j(\varepsilon; k) > j(\varepsilon; k - 1) > \cdots > j(\varepsilon; 0) \) such that, for any \( x \in \mathbb{R}^n \) with \( |x| \geq 2^{j(\varepsilon; k)} \),

\[
O(f; Q(x, 2^{j(\varepsilon;0)+k})) < 2^{j(\varepsilon;0)+k} \varepsilon < \varepsilon.
\]

Now, define \( \{F_k\}_{k \in \mathbb{N}} \) and \( F \) as follows:

\[
F_1 := \{ Q \subset Q(\bar{0}_n, 2^{j(\varepsilon;1)}) : Q \in D \text{ with } \ell(Q) = 2^{j(\varepsilon;0)} \};
\]

\[
F_2 := \{ Q \subset Q(\bar{0}_n, 2^{j(\varepsilon;2)}) \setminus Q(\bar{0}_n, 2^{j(\varepsilon;1)}) : Q \in D \text{ with } \ell(Q) = 2^{j(\varepsilon;0)+1} \};
\]

\[
\vdots
\]

\[
F_k := \{ Q \subset Q(\bar{0}_n, 2^{j(\varepsilon;k)}) \setminus Q(\bar{0}_n, 2^{j(\varepsilon;k-1)}) : Q \in D \text{ with } \ell(Q) = 2^{j(\varepsilon;0)+k-1} \};
\]

\[
\vdots
\]

and

\[
F := \bigcup_{k \in \mathbb{N}} F_k,
\]

here and thereafter, for any subset \( A \) of \( \mathbb{R}^n \), we use \( \overline{A} \) to denote its closure in \( \mathbb{R}^n \). Then, for any \( k \in \mathbb{N} \), \( F_k \) contains disjoint cubes with the same side length and hence \( F \) is a family of disjoint dyadic cubes. Next, we introduce the simple function \( g_\varepsilon \) associated with \( F \) as follows. Since the cubes in \( F \) are disjoint, it follows that, for any \( x \in \mathbb{R}^n \), there exists a unique cube \( Q(x) \in F \) such that \( Q(x) \ni x \); let

\[
g_\varepsilon(x) := f_{Q(x)} := \frac{1}{|Q(x)|} \int_{Q(x)} f(y) \, dy.
\]

Then \( g_\varepsilon \) is a simple function on \( \mathbb{R}^n \). This finishes Step i).

**Step ii** To estimate \( \|f - g_\varepsilon\|_{\text{BMO}(\mathbb{R}^n)} \), we first claim that, for any \( x, y \in \mathbb{R}^n \) with \( Q(x) \cap Q(y) \neq \emptyset \),

\[
|g_\varepsilon(x) - g_\varepsilon(y)| \leq \varepsilon.
\]

Indeed, if both \( x \) and \( y \) lie in the same cube \( Q \in F \), then, by the definition of \( g_\varepsilon \), we know that \( g_\varepsilon(x) = g_\varepsilon(y) \) and hence (2.13) holds true trivially. If \( x \) and \( y \) lie in different dyadic cubes \( Q(x) \) and \( Q(y) \), respectively, then, from the construction of \( F \), it follows that \( Q(x) \) and \( Q(y) \) must be adjacent, namely, \( Q(x) \cap Q(y) \) is a point, segment or surface. Anyhow, \( |Q(x)| \) and \( |Q(y)| \) are comparable and hence there exists a larger dyadic cube \( Q(x,y) \in D \) such that

\[
Q(x) \subset Q(x,y) \quad \text{and} \quad Q(y) \subset Q(x,y),
\]
whose side length

\[
\ell(Q_{(x,y)}) = 2 \max[\ell(Q_{(x)}), \ell(Q_{(y)})] \sim \ell(Q_{(x)}) \sim \ell(Q_{(y)}),
\]

where \(\ell(Q_{(x)})\) and \(\ell(Q_{(y)})\) denote the side lengths of \(Q_{(x)}\) and \(Q_{(y)}\), respectively. From the definition of \(\mathcal{F}\) and (2.11), we deduce that

\[
O(f; Q_{(x,y)}) < \epsilon
\]

and hence

\[
(2.14) \quad |g_\epsilon(x) - g_\epsilon(y)| \leq |f_{Q_{(x)}} - f_{Q_{(x,y)}}| + |f_{Q_{(y)}} - f_{Q_{(x,y)}}| \leq 2 \left[ \frac{|Q_{(x,y)}|}{|Q_{(x)}|} + \frac{|Q_{(x,y)}|}{|Q_{(y)}|} \right] O(f; Q_{(x,y)})
\]

\[
\leq O(f; Q_{(x,y)}) \leq \epsilon.
\]

Thus, (2.13) also holds true in this case. This finishes the proof of the above claim.

Now, we estimate \(\|f - g_\epsilon\|_{\BMO(\mathbb{R}^n)} = \sup_{Q} O(f - g_\epsilon; Q)\) via considering different side lengths \(\ell(Q)\) in the supremum.

When \(\ell(Q) \in (0, 2^{j(\epsilon;0)}),\) by the definition of \(\mathcal{F}\), \(Q\) intersects at most \(2^n\) different cubes in \(\mathcal{F}\). From this, the definition of \(g_\epsilon\) and (2.13), we deduce that

\[
(2.15) \quad \frac{1}{|Q|^2} \int_Q \int_Q |g_\epsilon(x) - g_\epsilon(y)| \, dx \, dy \leq \epsilon.
\]

Combining (2.9) with (2.15), we obtain

\[
O(f - g_\epsilon; Q) \leq O(f; Q) + O(g_\epsilon; Q) < \epsilon + \frac{1}{|Q|^2} \int_Q \int_Q |g_\epsilon(x) - g_\epsilon(y)| \, dx \, dy \leq \epsilon.
\]

When \(\ell(Q) \in [2^{j(\epsilon;0)}, 2^{j(\epsilon;0)+1})\), we consider the following two cases:

**Case i)** \(Q \cap Q(\overline{Q}_n, 2^{j(\epsilon;1)}) = \emptyset\), namely, \(Q \subset Q(\overline{Q}_n, 2^{j(\epsilon;1)})\). In this case, by the definition of \(\mathcal{F}_1\), \(Q\) intersects at most \(3^n\) different cubes in \(\mathcal{F}_1\). This, together with the definition of \(g_\epsilon\) and (2.9), implies that

\[
O(f - g_\epsilon; Q) \leq \frac{2}{|Q|} \int_Q |f(x) - g_\epsilon(x)| \, dx = \sum_{Q, \epsilon \in \mathcal{F}_1: Q \cap Q_{(x,y)} \neq \emptyset} \frac{2}{|Q|} \int_Q |f(x) - g_\epsilon(x)| \, dx
\]

\[
= 2 \sum_{Q, \epsilon \in \mathcal{F}_1: Q \cap Q_{(x,y)} \neq \emptyset} \frac{|Q|}{|Q|} \int_Q |f(x) - f_{Q_{(x,y)}}| \, dx
\]

\[
< 2\epsilon \sum_{Q, \epsilon \in \mathcal{F}_1: Q \cap Q_{(x,y)} \neq \emptyset} \frac{|Q|}{|Q|} \leq \epsilon.
\]

**Case ii)** \(Q \cap Q(\overline{Q}_n, 2^{j(\epsilon;1)}) \neq \emptyset\). In this case, the distance between the center of \(Q\) and the boundary of \(Q(\overline{Q}_n, 2^{j(\epsilon;1)})\) is less than \(\ell(Q) < 2^{j(\epsilon;0)+1}\). Therefore, there exists some \(x_Q \in \mathbb{R}^n\) such that \(Q \subset Q(x_Q; 2^{j(\epsilon;0)+1})\) and \(|x_Q| > j(\epsilon; 1)\). Thus, by (2.10), we find that

\[
(2.16) \quad O(f; Q) \leq 2 \frac{2^{j(\epsilon;0)+1}}{|Q|} O(f, Q(x_Q; 2^{j(\epsilon;0)+2})) \leq \epsilon.
\]
Meanwhile, by the definition of $\mathcal{F}$, $Q$ intersects at most $3^n$ different cubes in $\mathcal{F}$. Therefore, (2.16) still holds true. Combining (2.16) and (2.15), we obtain

$$O(f - g_\cdot;Q) \leq O(f;Q) + O(g_\cdot;Q) \leq \epsilon + \frac{1}{|Q|^2} \int_Q \int_Q |g_\cdot(x) - g_\cdot(y)| \, dx \, dy \leq \epsilon.$$ 

Combining Case i) and Case ii), we finally conclude that $O(f - g_\cdot;Q) \leq \epsilon$ when $\ell(Q) \in [2^{j(\epsilon,0)}, 2^{j(\epsilon,0)+1})$.

Observer that, geometrically, $\mathcal{F}$ is self-similar. Thus, for any $k \in \mathbb{N}$, the above estimations when $\ell(Q) \in [2^{j(\epsilon,0)}, 2^{j(\epsilon,0)+1})$ can be modified into the case $\ell(Q) \in [2^{j(\epsilon,0)+k-1}, 2^{j(\epsilon,0)+k})$ with the implicit positive constant depending only on dimension $n$. This finishes Step ii).

**Step iii)** Let $\varphi \in C_0^\infty(\mathbb{R}^n)$ be a non-negative even function with $\int_{\mathbb{R}^n} \varphi(x) \, dx = 1$ and

$$\text{supp} \, (\varphi) \subseteq B(0,1) := \{x \in \mathbb{R}^n : |x| \leq 1\}.$$ 

Let $h_\cdot := g_\cdot * \varphi_{2^{j(\epsilon,0)}}$, where $\varphi_{2^{j(\epsilon,0)}}(\cdot) := 2^{-n(j(\epsilon,0))} \varphi(2^{-j(\epsilon,0)} \cdot)$. Notice that, for any $x, y \in \mathbb{R}^n$ with $|x - y| \leq 2^{j(\epsilon,0)}$ by the definition of $\mathcal{F}$, we know that $Q(x) \cap Q(y) \neq \emptyset$. Then, for any $x \in \mathbb{R}^n$, by (2.13), we have

$$|g_\cdot(x) - h_\cdot(x)| = \left| \int_{\mathbb{R}^n} [g_\cdot(x) - g_\cdot(y)] \varphi_{2^{j(\epsilon,0)}}(x - y) \, dy \right|$$

$$\leq \int_{B(x,2^{j(\epsilon,0)})} |g_\cdot(x) - g_\cdot(y)| \varphi_{2^{j(\epsilon,0)}}(x - y) \, dy$$

$$\leq \epsilon \int_{B(x,2^{j(\epsilon,0)})} \varphi_{2^{j(\epsilon,0)}}(x - y) \, dy \sim \epsilon,$$

where $B(x,2^{j(\epsilon,0)})$ denotes the ball centered at $x$ with radius $2^{j(\epsilon,0)}$. Hence

$$\|g_\cdot - h_\cdot\|_{\text{BMO}(\mathbb{R}^n)} \leq 2 \|g_\cdot - h_\cdot\|_{L^n(\mathbb{R}^n)} \leq \epsilon,$$

which shows that (2.8) holds true.

It remains to show that $h_\cdot \in B_\infty(\mathbb{R}^n)$. Indeed, by $\varphi \in C_0^\infty(\mathbb{R}^n)$, (2.7), (2.8) and $f \in \text{BMO}(\mathbb{R}^n)$, we know that $h_\cdot \in C^\infty(\mathbb{R}^n)$ and $h_\cdot \in \text{BMO}(\mathbb{R}^n)$. Thus, to prove $h_\cdot \in B_\infty(\mathbb{R}^n)$, it suffices to show that, for any given $\alpha \in \mathbb{Z}_+^n$ and $\alpha \neq \vec{0}_n$, any $x \in \mathbb{R}^n$ and $|x| > E(\alpha, n)$ with $E(\alpha, n) \in (0, \infty)$ being determined below,

$$|D^\alpha h_\cdot(x)| \leq \epsilon.$$ 

Indeed, when $\alpha \in \mathbb{Z}_+^n$ and $|\alpha| \in \{2m - 1\}_{m \in \mathbb{N}}$, from the fact that $\varphi$ is even, we deduce that $D^\alpha \varphi$ is odd and hence

$$\int_{\mathbb{R}^n} D^\alpha \varphi(x) \, dx = 0.$$ 

Meanwhile, in this case, for any $x \in \mathbb{R}^n$ with $|x| > E(\alpha, n) := \sqrt{n} 2^{j(\epsilon,|\alpha|)}$ and any $y \in B(x, 2^{j(\epsilon,0)})$, by the definition of $\mathcal{F}$, we have $Q(x) \cap Q(y) = \emptyset$ and $Q(x) \cap Q(y) \neq \emptyset$, which, combined with (2.14), the definition of $\mathcal{F}$ and (2.11), further implies that

$$|g_\cdot(y) - g_\cdot(x)| \leq O(f; Q(x,y)) \leq 2^{|\alpha| j(\epsilon,0)} \epsilon.$$
where $Q_{(x,y)} \supset (Q_{(x)} \cup Q_{(y)})$ is the dyadic cube comparable with both $Q_{(x)}$ and $Q_{(y)}$ [see the first paragraph of Step ii) above] and the implicit positive constant only depends on $n$. By (2.17) and (2.18), we conclude that, for any $\alpha \in \mathbb{Z}_+^n$ with $|\alpha| \in \{2m-1\}_{m \in \mathbb{N}}$, and any $x \in \mathbb{R}^n$ with $|x| > E_{(\alpha,n)},$

\begin{equation}
|D^\alpha h_\epsilon(x)| \leq \left| \int_{\mathbb{R}^n} g_\epsilon(y)D^\alpha \varphi_2(x-y) dy \right| = \left| \int_{B(x,2\|x\|)} g_\epsilon(y)D^\alpha \varphi_2(x-y) dy \right|
\end{equation}

\begin{equation}
= \left| \int_{B(x,2\|x\|)} [g_\epsilon(y) - f_{Q_{(x)}}]D^\alpha \varphi_2(x-y) dy \right|
\end{equation}

\begin{equation}
\leq \int_{B(x,2\|x\|)} O(f; Q_{(x,y)})|D^\alpha \varphi_2(x-y)| dy
\end{equation}

\begin{equation}
\leq 2^{|\alpha|}\epsilon \int_{B(x,2\|x\|)} |D^\alpha \varphi_2(x-y)| dy
\end{equation}

\begin{equation}
\leq 2^{|\alpha|}\epsilon 2^{-|\alpha|}||D^\alpha \varphi||_{L^1(\mathbb{R}^n)} \leq \epsilon,
\end{equation}

where the implicit positive constant is independent of $\epsilon$ and $x$.

When $\alpha \in \mathbb{Z}_+^n$ and $|\alpha| \in \{2m\}_{m \in \mathbb{N}}$, we claim that $|D^\alpha h_\epsilon(x)| \leq \epsilon$ as well, for any given $\alpha \in \mathbb{Z}_+^n$ with $|\alpha| \in \{2m\}_{m \in \mathbb{N}}$ and any $|x| > E_{(\alpha,n)} := \sqrt{2^{|\alpha|}}$, with the implicit positive constant independent of $\epsilon$ and $x$. Indeed, let $\psi \in C^\infty(\mathbb{R}^n)$ and $M$ be a positive constant. By the Taylor remainder theorem, we conclude that, for any $x := (x_1, \ldots, x_n) \in \mathbb{R}^n$ with $|x| > M$ and $y \in \mathcal{R}_x := \{y := (y_1, \ldots, y_n) \in \mathbb{R}^n : x_i y_i \geq 0, \forall i = 1, \ldots, n\}$,

\begin{equation}
\psi(x+y) = \psi(x) + \sum_{i=1}^n \frac{\partial}{\partial x_i} \psi(x) y_i + \sum_{\beta \in \mathbb{Z}_+^n : |eta|=2} R_\beta(x,y) y^\beta,
\end{equation}

where, for any $\beta := (\beta_1, \ldots, \beta_n) \in \mathbb{Z}_+^n$ and $|eta| = 2$,

\begin{equation}
R_\beta(x,y) := \frac{|eta|}{\beta!} \int_0^1 (1-t)^{|eta|-1} D^\beta \psi(x + ty) dt,
\end{equation}

with $\beta! := \beta_1! \cdots \beta_n!$, satisfies

\begin{equation}
|R_\beta(x,y)| \leq \max_{\beta \in \mathbb{Z}_+^n : |eta|=2} \frac{1}{\beta!} \sup_{|z| \leq M} |D^\beta \psi(z)| \leq \max_{\beta \in \mathbb{Z}_+^n : |eta|=2} ||D^\beta \psi||_{L^\infty(\{|z| > M\})}
\end{equation}

by using the following observation that, for any $t \in [0,1]$, $|x + ty| \geq |x| > M$. To estimate $||\frac{\partial}{\partial x_i} \psi||_{L^\infty(\{|z| > M\})}$, let

\begin{equation}
y \in \mathcal{R}_x^{(1)} := \{y := (y_1, \ldots, y_n) \in \mathbb{R}^n : x_i y_i \geq 0, y_1 \neq 0, y_1 = 0, \forall i = 2, \ldots, n\};
\end{equation}

then $|x+y| \geq |x| > M$ and (2.20) becomes

\begin{equation}
\psi(x+y) = \psi(x) + \frac{\partial}{\partial x_1} \psi(x) y_1 + R_{(2,0,\ldots,0)}(x,y) y_1^2.
\end{equation}
which implies that
\[
\left| \frac{\partial}{\partial x_1} \psi(x) \right| \leq |\psi(x + y) - \psi(x)| y_1^{-1} + |R_{(2,0,...,0)}(x, y)| y_1 \\
\leq 2\|\psi\|_{L^\infty(|z| > M)} y_1^{-1} + \max_{\beta \in \mathbb{Z}_+^n: |\beta| = 2} \|D^\beta \psi\|_{L^\infty(|z| > M)} y_1.
\]

From the arbitrariness of both \( x \in \mathbb{R}^n : |x| > M \) and \( |y_1| \in (0, \infty) \), and the AM-GM inequality\(^1\), we then deduce that
\[
(2.21) \quad \left\| \frac{\partial}{\partial x_1} \psi \right\|_{L^\infty(|z| > M)} \leq \inf_{|y_1| > 0} \left[ 2\|\psi\|_{L^\infty(|z| > M)} y_1^{-1} + \max_{\beta \in \mathbb{Z}_+^n: |\beta| = 2} \|D^\beta \psi\|_{L^\infty(|z| > M)} y_1 \right]^{1/2}.
\]

By the same technique, we know that (2.21) also holds true with \( \frac{\partial}{\partial x_i} \psi \) replaced by \( \frac{\partial}{\partial x_i} \psi \) for any \( i \in \{2, \ldots, n\} \). Based on this, we can now estimate \( \|D^\alpha h_\varepsilon\|_{L^\infty(|z| > E_{(a, \alpha)})} \) for any given \( \alpha := (\alpha_1, \ldots, \alpha_n) \in \mathbb{Z}_+^n \) with \( |\alpha| \in \{2m\}_{m \in \mathbb{N}} \). Without loss of generality, we may assume that \( \alpha_1 \neq 0 \), and let \( \tilde{\alpha} := (\alpha_1 - 1, \alpha_2, \ldots, \alpha_n) \). Applying (2.21) with \( \psi := D^\tilde{\alpha} h_\varepsilon \) and \( M := E_{(\tilde{\alpha}, a)} = \sqrt{n}2^{j(|\tilde{\alpha}|+1)} \), we have
\[
\|D^\alpha h_\varepsilon\|_{L^\infty(|z| > E_{(a, \alpha)})} = \left\| \frac{\partial}{\partial x_1} D^\tilde{\alpha} h_\varepsilon \right\|_{L^\infty(|z| > E_{(a, \alpha)})} \\
\leq \sqrt{2\|D^\tilde{\alpha} h_\varepsilon\|_{L^\infty(|z| > E_{(a, \alpha)})}} \max_{\beta \in \mathbb{Z}_+^n: |\beta| = |\alpha| + 1} \|D^\beta h_\varepsilon\|_{L^\infty(|z| > E_{(\alpha, \alpha)})} \\
= \sqrt{2\|D^\tilde{\alpha} h_\varepsilon\|_{L^\infty(|z| > \sqrt{n}2^{j(|\tilde{\alpha}|+1)})}} \max_{\beta \in \mathbb{Z}_+^n: |\beta| = |\alpha| + 1} \|D^\beta h_\varepsilon\|_{L^\infty(|z| > \sqrt{n}2^{j(|\alpha|+1)})} \\
\leq \sqrt{2\|D^\tilde{\alpha} h_\varepsilon\|_{L^\infty(|z| > \sqrt{n}2^{j(|\alpha|+1)})}} \max_{\beta \in \mathbb{Z}_+^n: |\beta| = |\alpha| + 1} \|D^\beta h_\varepsilon\|_{L^\infty(|z| > E_{(\tilde{\alpha}, a)})}.
\]

From this and (2.19), we deduce that, for any \( \alpha := (\alpha_1, \ldots, \alpha_n) \in \mathbb{Z}_+^n \) with \( |\alpha| \in \{2m\}_{m \in \mathbb{N}} \),
\[
(2.22) \quad \|D^\alpha h_\varepsilon\|_{L^\infty(|z| > E_{(a, \alpha)})} \leq \varepsilon,
\]
where the implicit positive constant is independent of \( \varepsilon \). This finishes the proof of the above claim.

Combining (2.19) and (2.22), we conclude that \( h_\varepsilon \in B_{\infty}(\mathbb{R}^n) \), which completes Step iii) and hence the proof that (ii) \( \implies \) (iii).

(iii) \( \implies \) (i) is obvious from definitions of XMO \((\mathbb{R}^n)\) and X1MO \((\mathbb{R}^n)\). This finishes the proof of Theorem 1.2. \( \square \)

By Theorem 1.2, we can now completely answer the open question raised in [21].

\(^1\)the inequality of arithmetic and geometric means, namely, for any \( a, b \in [0, \infty) \), \( \frac{a+b}{2} \geq \sqrt{ab} \) and, moreover, the equality holds true when \( a = b \).
Proof of Corollary 1.3. To show this corollary, it suffices to prove that there exists some \( f \in \text{VMO}(\mathbb{R}^n) \setminus \text{XMO}(\mathbb{R}^n) \). For any \( x := (x_1, \ldots, x_n) \in \mathbb{R}^n \), define

\[
f(x_1, \ldots, x_n) := \prod_{k=1}^{n} \sin(x_k).
\]

Then it is easy to show that \( f \) is uniform continuous and bounded in \( \mathbb{R}^n \), which implies that \( f \in \text{VMO}(\mathbb{R}^n) \).

Now, we claim that \( f \) violates (ii) of Theorem 1.2(ii) and hence \( f \notin \text{XMO}(\mathbb{R}^n) \). Indeed, let \( Q_0 := [-\frac{n}{2}, \frac{n}{2}]^n \) and, for any \( k \in \mathbb{N} \), let \( Q_k := 2k\pi + Q_0 \). Then, for any \( k \in \mathbb{N} \), we have

\[
\int_{Q_k} f(x_1, \ldots, x_n) \, dx_1 \cdots dx_n = \int_{2k\pi - \frac{\pi}{2}}^{2k\pi + \frac{\pi}{2}} \sin(x_1) \, dx_1 \cdots \int_{2k\pi - \frac{\pi}{2}}^{2k\pi + \frac{\pi}{2}} \sin(x_n) \, dx_n = 0
\]

and hence

\[
O(f; Q_0 + 2k\pi) = O(f; Q_k) = \int_{Q_k} |f(x) - f_{Q_k}| \, dx = \int_{Q_k} |f(x)| \, dx = \left[ \frac{1}{\pi} \int_{2k\pi - \frac{\pi}{2}}^{2k\pi + \frac{\pi}{2}} |\sin(t)| \, dt \right]^n = \left( \frac{2}{\pi} \right)^n,
\]

which can not tend to 0 as \( k \to \infty \). Thus, the above claim holds true, which completes the proof of Corollary 1.3.

□

Proposition 2.5. Proposition 2.4(ii) can be replaced by

\[(ii')\]

\[
\lim_{R \to \infty} \sup_{Q \cap B(0, R) = 0} O(f; Q) = 0,
\]

where \( Q(0, R) \) denotes the cube centered at \( 0 \) with the side length \( 2R \). However, (ii)2 of Theorem 1.2(ii) can not be replaced by (ii')

Proof. Indeed, Uchiyama [23] stated Proposition 2.4 via (i), (ii) and (iii), while, in his proof, he proved that Proposition 2.4 with (ii) replaced by (\( ii' \)) is true. Indeed, this equivalence is a direct consequence of the following observation:

(i) + (ii) + (iii) of Proposition 2.4 \( \implies \) Proposition 2.5(ii') \( \implies \) Proposition 2.4(ii).

To show (ii)2 of Theorem 1.2(ii) can not replaced by Proposition 2.5(ii'), for simplicity, we only calculate a typical example in \( \mathbb{R} \). Indeed, let \( f(x) := \log(|x|) \) for any \( x \in \mathbb{R} \) with \( |x| \geq 1 \), and extend \( f \) to \( \mathbb{R} \) smoothly. Then \( f \in \mathcal{C}^1(\mathbb{R}) \cap \text{BMO}(\mathbb{R}) \) and \( \lim_{|x| \to \infty} f''(x) = 0 \), which implies \( f \in B_1(\mathbb{R}) \subset X_{1}\text{MO}(\mathbb{R}) \). On the other hand, for any \( k \in \mathbb{Z}_+ \) and interval \( I_k := [e^k, e^{k+1}] \), we have

\[
f_{k} = \int_{I_k} f(x) \, dx = \frac{1}{e^{k+1} - e^k} \int_{e^k}^{e^{k+1}} \log(x) \, dx = \frac{1}{(e - 1)e^k} \left[ (k+1)e^{k+1} - e^{k+1} - (ke^k - e^k) \right]
\]
\[
\frac{1}{e-1} [(k+1)e - e - (k-1)] = \frac{1}{e-1} (ke - k + 1) = k + \frac{1}{e-1}
\]
and hence
\[
\mathcal{O}(f; I_k) = \int_{I_k} |f(x) - f_{I_k}| \, dx = \frac{1}{(e-1)e^k} \int_{e^k}^{e^{k+1}} \left| \log(x) - \left( k + \frac{1}{e-1} \right) \right| \, dx
\]
\[
= \frac{1}{(e-1)e^k} \left\{ \int_{e^k}^{e^{k+1}} \left[ - \log(x) + \left( k + \frac{1}{e-1} \right) \right] \, dx + \int_{e^k}^{e^{k+1}} \left[ \log(x) - \left( k + \frac{1}{e-1} \right) \right] \, dx \right\}
\]
\[
= \frac{1}{(e-1)e^k} \left\{ (k+1)e^{k+1} - \left( k^2 + \frac{2}{e-1} \right) e^k - \left( k^2 + \frac{2}{e-1} \right) \right\}
\]
\[
= \frac{1}{e-1} \left\{ (k+1)e - e - k - 1 - 2 \left( k + \frac{1}{e-1} \right) e^{k+1} \left( e^{\frac{1}{e-1}} - 1 \right) \right\}
\]
\[
= \frac{2}{e-1} \left( e^{\frac{1}{e-1}} - 1 \right),
\]
which violates (ii') as long as \( k \) satisfies \( e^k > R \). This finishes the proof of Proposition 2.5.

\textbf{Remark 2.6.} Observe that the counterexample in Proposition 2.5 is unbounded, it is still unknown whether or not (ii)_1 of Theorem 1.2(ii)+Proposition 2.5(ii') is an equivalent characterization of MMO \((\mathbb{R}^n)\).

\section{Proof of Theorem 1.4}

In this section, we prove Theorem 1.4 via several smooth truncated techniques. Some of the ideas come from [6]; see also [20]. To begin with, we introduce the following smooth truncated function. Let \( \varphi_1 \in C^\infty([0, \infty)) \) satisfy
\[
0 \leq \varphi_1 \leq 1 \quad \text{and} \quad \varphi_1(x) = \begin{cases} 1, & x \in [0, 1], \\ 0, & x \in [2, \infty). \end{cases}
\]
Moreover, for any \( \eta \in (0, \infty) \), let
\[
K_\eta(x, y, z) := K(x, y, z) \left[ 1 - \varphi_1 \left( \frac{2}{\eta} |x - y| + |x - z| \right) \right]
\]
and, for any \( f, g \in C_c^\infty(\mathbb{R}^n) \) and \( x \notin \text{supp} (f) \cap \text{supp} (g) \),
\[
T_\eta(f, g)(x) := \int_{\mathbb{R}^n} K_\eta(x, y, z) f(y) g(z) \, dy \, dz.
\]
Then
\[
[T_\eta b] (f, g)(x) = \int_{\mathbb{R}^{2n}} [b(x) - b(y)] K_\eta(x, y, z) f(y) g(z) \, dy \, dz.
\]
Recall that the bilinear Hardy–Littlewood maximal operator $\mathcal{M}$ is defined by setting, for any $f, g \in L^1_{\text{loc}}(\mathbb{R}^n)$ and $x \in \mathbb{R}^n$,

$$
\mathcal{M}(f, g)(x) := \sup_{\text{cube } Q \ni x} \int_Q |f(y)| dy \int_Q |g(z)| dz,
$$

where the supremum is taken over all the cubes $Q$ of $\mathbb{R}^n$ containing $x$. On $[T, b]_1$ and $[T_\eta, b]_1$, we have the following estimate via $\mathcal{M}$.

**Lemma 3.1.** There exists a positive constant $C$ such that, for any $b \in B_\infty(\mathbb{R}^n)$, $\eta \in (0, \infty)$, $f, g \in L^1_{\text{loc}}(\mathbb{R}^n)$ and $x \in \mathbb{R}^n$,

$$
\left| [T, b]_1(f, g)(x) - [T_\eta, b]_1(f, g)(x) \right| \leq C\eta \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \mathcal{M}(f, g)(x).
$$

**Proof.** For any $x \in \mathbb{R}^n$, by (3.1) through (3.4) and (1.1), we have

$$
\begin{align*}
\left| [T, b]_1(f, g)(x) - [T_\eta, b]_1(f, g)(x) \right| & = \left| \int_{\mathbb{R}^{2n}} \left[ b(x) - b(y) \right] K(x, y, z) \phi_1 \left( \frac{2}{\eta} [x - y] + \frac{1}{\eta} [x - z] \right) f(y) g(z) dy dz \right| \\
& \leq \int_{|x-y|+|x-z| \leq \eta} \left[ b(x) - b(y) \right] [K(x, y, z)] f(y) g(z) dy dz \\
& \leq \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \sum_{j=0}^\infty \int_0^\infty \int_{Q(x, \frac{4j}{27})} f(y) g(z) dy dz \\
& \leq \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \eta \sum_{j=0}^\infty \frac{1}{2j} \int_{Q(x, \frac{4j}{27})} f(y) dy \int_{Q(x, \frac{4j}{27})} g(z) dz \\
& \leq \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \eta \sum_{j=0}^\infty \frac{1}{2j} \mathcal{M}(f, g)(x) \sim \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \eta \mathcal{M}(f, g)(x),
\end{align*}
$$

where $Q(x, \frac{4j}{27})$ denotes the cube centered at $x$ with the side length $2\frac{4j}{27}$. This finishes the proof of Lemma 3.1. \qed

We also need the following result on the relative compactness of a set in weighted Lebesgue spaces, which is just [24, Theorem 1].

**Lemma 3.2.** Let $w$ be a weight on $\mathbb{R}^n$. Assume that $w^{-1/(p_0-1)}$ is also a weight on $\mathbb{R}^n$ for some $p_0 \in (1, \infty)$. Let $p \in (0, \infty)$ and $E$ be a subset of $L^p_w(\mathbb{R}^n)$. Then $E$ is relatively compact in $L^p_w(\mathbb{R}^n)$ if the set $E$ satisfies the following three conditions:

(i) $E$ is bounded, namely,

$$
\sup_{f \in E} \|f\|_{L^p_w(\mathbb{R}^n)} < \infty;
$$

(ii) $E$ is uniformly integrable, namely,

$$
\sup_{f \in E} \int_{\mathbb{R}^n} f^p \frac{w}{w^*} dy < \infty;
$$

(iii) $E$ is uniformly local, namely,

$$
\sup_{f \in E} \int_{B(0,2)} w \int_{B(x,1)} f^p dy \frac{w}{w^*} dx < \infty.
$$
Moreover, using Lemma 3.1 and the boundedness of that

\[ \|f\|_{L^p_c(|x| > A)} < \epsilon; \]

(ii) \( \mathcal{E} \) uniformly vanishes at infinity, namely, for any \( \epsilon \in (0, \infty) \), there exists some positive constant \( A \) such that, for any \( f \in \mathcal{E} \),

\[ \|f\|_{L^p_c(|x| > A)} < \epsilon; \]

(iii) \( \mathcal{E} \) is uniformly equicontinuous, namely, for any \( \epsilon \in (0, \infty) \), there exists some positive constant \( \rho \) such that, for any \( f \in \mathcal{E} \) and \( t \in \mathbb{R}^n \) with \( |t| \in [0, \rho) \),

\[ \|f(\cdot + t) - f(\cdot)\|_{L^p_c(\mathbb{R}^n)} < \epsilon. \]

Remark 3.3. If \( w \) is a classical \( A_p(\mathbb{R}^n) \) weight for some \( p \in (1, \infty) \), then the sufficiency of Lemma 3.2 was first obtained in [6, Theorem 5], which is needed in the proof of Theorem 1.4.

Let \( w := (w_1, w_2) \in A_p(\mathbb{R}^n) \) and \( w := w_1^{p/p_1}w_2^{p/p_2} \) be as in Theorem 1.4. From [16, Theorem 3.6], it follows that \( w \in A_{2p}(\mathbb{R}^n) \). By this and Remark 3.3, we are now able to use Lemma 3.2 to prove Theorem 1.4 as follows.

Proof of Theorem 1.4. Without loss of generality, it may suffice to prove this theorem for the first entry \([T_\eta, b]_1\). When \( b \in \text{XMO}(\mathbb{R}^n) = X_1 \text{MO}(\mathbb{R}^n) \) (see Theorem 1.2), from the definition of \( X_1 \text{MO}(\mathbb{R}^n) \), we deduce that, for any \( \epsilon \in (0, \infty) \), there exists \( b^{(\epsilon)} \in B_1(\mathbb{R}^n) \) such that \( \|b - b^{(\epsilon)}\|_{\text{BMO}(\mathbb{R}^n)} < \epsilon \). Then, by the boundedness of \([T, b]_1 \) from \( L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \) to \( L^p_w(\mathbb{R}^n) \) (see [16, Theorem 3.18] and also [2] for more general results), we obtain, for any \( (f, g) \in L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \),

\[ \frac{\left\| [T, b]_1(f, g) - [T, b^{(\epsilon)}]_1(f, g) \right\|_{L^p_w(\mathbb{R}^n)}}{\left\| [T, b]_1(f, g) \right\|_{L^p_w(\mathbb{R}^n)}} \leq \frac{\left\| b - b^{(\epsilon)} \right\|_{\text{BMO}(\mathbb{R}^n)}}{\left\| [T, b]_1(f, g) \right\|_{L^p_w(\mathbb{R}^n)}} \leq \epsilon \|f\|_{L^{p_1}_w(\mathbb{R}^n)}\|g\|_{L^{p_2}_w(\mathbb{R}^n)} \]

Moreover, using Lemma 3.1 and the boundedness of \( M \) from \( L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \) to \( L^p_w(\mathbb{R}^n) \) ([16, Theorem 3.3]), we conclude that

\[ \lim_{\eta \to 0} \left\| [T, b]_1 - [T_\eta, b]_1 \right\|_{L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \to L^p_w(\mathbb{R}^n)} = 0, \]

where \( \left\| [T, b]_1 - [T_\eta, b]_1 \right\|_{L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \to L^p_w(\mathbb{R}^n)} \) denotes the operator norm of \([T, b]_1 - [T_\eta, b]_1\) from \( L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \to L^p_w(\mathbb{R}^n) \). Thus, to prove that \([T, b]_1\) is compact for any \( b \in \text{XMO}(\mathbb{R}^n) \), by [25, p. 278, Theorem (iii)], it suffices to show that \([T_\eta, b]_1\) is compact for any \( b \in B_1(\mathbb{R}^n) \) and \( \eta \in (0, \epsilon) \) small enough. To this end, by the definition of compact operators, Lemma 3.2 and Remark 3.3(ii), we know that it suffices to show that, for any fixed \( b \in B_1(\mathbb{R}^n) \), \( \eta \in (0, \epsilon) \) small enough and \( \mathcal{E} \subset L^{p_1}_w(\mathbb{R}^n) \times L^{p_2}_w(\mathbb{R}^n) \) bounded, \([T_\eta, b]_1\mathcal{E}\) satisfies (i), (ii) and (iii) of Lemma 3.2. In what follows, we show these in order.

To begin with, we show that \([T_\eta, b]_1\mathcal{E}\) satisfies Lemma 3.2(i). To this end, we first claim that \( T_\eta \) is a Calderón–Zygmund operator, namely, \( K_\eta \) satisfies (1.1). Indeed, from \( 0 \leq \varphi \leq 1 \) and hence \( |K_\eta| \leq |K| \), it follows that the size condition [\( \alpha := \tilde{O}_{3\eta} \) in (1.1)] holds true trivially. When \( |\alpha| = 1 \),
without loss of generality, we may assume that \( \alpha := (1, 0, \ldots, 0) \). Then, for any \( x, y, z \in \mathbb{R}^n \) with \( x \neq y \) or \( x \neq z \), by (3.1) and (1.1), we have

\[
\left| \frac{\partial}{\partial x_1} K_\eta(x, y, z) \right| \leq \left| \frac{\partial}{\partial x_1} K(x, y, z) \right| \left| 1 - \varphi_1 \left( \frac{2}{\eta} |x - y| + |x - z| \right) \right|
\]

\[
+ |K(x, y, z)| \left| \frac{\partial}{\partial x_1} \left[ 1 - \varphi_1 \left( \frac{2}{\eta} |x - y| + |x - z| \right) \right] \right|
\]

\[
\leq \left| \frac{\partial}{\partial x_1} K(x, y, z) \right| + |K(x, y, z)| \left| \varphi'_1 \left( \frac{2}{\eta} |x - y| + |x - z| \right) \right| \left| \frac{2}{\eta} \left| \frac{1}{|x - y| + |x - z|} \right| \right|
\]

\[
\leq \frac{1}{(|x - y| + |x - z|)^{2n+1}} + \frac{2}{\eta} \left| \frac{1}{|x - y| + |x - z|} \right|
\]

\[
\varphi'_1 \left( \frac{2}{\eta} |x - y| + |x - z| \right) \left| \frac{1}{|x - y| + |x - z|} \right|
\]

\[
\leq \frac{1}{(|x - y| + |x - z|)^{2n+1}}.
\]

Therefore, \( K_\eta \) satisfies (1.1) and hence \( T_\eta \) is a Calderón–Zygmund operator and, moreover, the kernel constant is independent of \( \eta \). From this, \( b \in \text{XMO} (\mathbb{R}^n) \subset \text{BMO} (\mathbb{R}^n) \), the boundedness characterization of Calderón–Zygmund commutators in weighted Lebesgue spaces ([16, Theorem 3.18]), and \((f, g) \in E \) bounded, we deduce that

\[
\left\| \left[ T_\eta, b \right] (f, g) \right\|_{L^p_{\text{loc}}(\mathbb{R}^n)} \leq \|f\|_{L^p_{\text{loc}}(\mathbb{R}^n)} \|g\|_{L^p_{\text{loc}}(\mathbb{R}^n)} < \infty,
\]

which implies that \( \left[ T_\eta, b \right] E \) satisfies Lemma 3.2(i).

Next, we show that \( \left[ T_\eta, b \right] \) satisfies Lemma 3.2(ii). In what follows, we use the symbol \( E \gg D \) to denote that \( E \) is much larger than \( D \). For fixed \( A \gg 1 \) and fixed \( x \in \mathbb{R}^n \) with \( |x| > A \), we first split the truncated function \( 1 - \varphi_1 \) into the following two parts. Let \( \varphi_2, \varphi_3 \in C^\infty([0, \infty)) \) satisfy

\[
0 \leq \varphi_2, \varphi_3 \leq 1, \quad \varphi_2 + \varphi_3 = 1 - \varphi_1,
\]

\[
\varphi_2(x) = \begin{cases} 1, & x \in \left[ \frac{2}{\eta}, \frac{A}{2} \right], \\ 0, & x \in [0, 1] \cup \left[ \frac{A}{2} + 1, \infty \right] \end{cases} \quad \text{and} \quad \varphi_3(x) = \begin{cases} 0, & x \in \left[ \frac{A}{2}, \frac{A}{2} + 1 \right], \\ 1, & x \in \left[ \frac{A}{2} + 1, \infty \right]. \end{cases}
\]

Accordingly, for any \((f, g) \in L^{p_1}_{\text{loc}}(\mathbb{R}^n) \times L^{p_2}_{\text{loc}}(\mathbb{R}^n) \) and \( x \in \mathbb{R}^n \), we split \( \left[ T_\eta, b \right] (f, g)(x) \) into the following three parts:

\[
\left[ T_\eta, b \right] (f, g)(x) = \int_{\mathbb{R}^n} \left[ b(x) - b(y) \right] K_\eta(x, y, z) f(y) g(z) \, dy \, dz
\]

\[
= \int_{\mathbb{R}^n} \nabla b(\xi) \cdot (x - y) K_\eta(x, y, z)
\]
\[
\times [\varphi_1 + \varphi_2 + \varphi_3](|x-y| + |x-z|) f(y)g(z) \, dy \, dz
\]
\[
\leq \int_{\mathbb{R}^{2n}} |\nabla b(\xi)||x-y| |K_\eta(x, y, z)\varphi_1(|x-y| + |x-z|) f(y)g(z)| \, dy \, dz
\]
\[
+ \int_{\mathbb{R}^{2n}} |\nabla b(\xi)||x-y| |K_\eta(x, y, z)\varphi_2(|x-y| + |x-z|) f(y)g(z)| \, dy \, dz
\]
\[
+ \int_{\mathbb{R}^{2n}} |\nabla b(\xi)||x-y| |K_\eta(x, y, z)\varphi_3(|x-y| + |x-z|) f(y)g(z)| \, dy \, dz
\]
\[
= : L_1(x) + L_2(x) + L_3(x),
\]
where we applied the mean value theorem to \(b(x) - b(y)\), and \(\xi\) is on the segment \(\overline{xy}\) connecting \(x\) and \(y\). We then estimate \(L_1(x)\) to \(L_3(x)\) in order.

To estimate \(L_1(x)\) as well as \(\|L_1\|_{L_{n1}^p([|x| > A_1])}\), we notice that \(\xi \in \overline{xy}\) and hence

\[
|x - \xi| \leq |x - y|.
\]

Meanwhile, by (3.1), we know that \(\text{supp} (\varphi_1) \subset [0, 2]\) and hence

\[
|x - y| + |x - z| \leq 2.
\]

From (3.8), (3.9) and \(|x| > A \gg 1\), it follows that

\[
|x - \xi| \geq |x| - |x - \xi| \geq |x| - |x - y| \geq |x| - (|x - y| + |x - z|) \geq |x| - 2 > \frac{A}{2}.
\]

By (3.10), (1.1), \(0 \leq \varphi \leq 1\) and hence \(|K_\eta| \leq |K|\), we conclude that, for any \((f, g) \in L_{n1}^{p_1}(\mathbb{R}^n) \times L_{n2}^{p_2}(\mathbb{R}^n)\) and \(x \in \mathbb{R}^n\),

\[
L_1(x) \leq \sup_{|\xi| > \frac{A}{2}} |\nabla b(\xi)| \int_{\mathbb{R}^{2n}} \frac{|x-y| \varphi_1(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n}} f(y)g(z) \, dy \, dz
\]
\[
\leq \sup_{|\xi| > \frac{A}{2}} |\nabla b(\xi)| \int_{\mathbb{R}^{2n}} \frac{\varphi_1(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n-1}} f(y)g(z) \, dy \, dz
\]
\[
:= \sup_{|\xi| > \frac{A}{2}} |\nabla b(\xi)| \int_{\mathbb{R}^{2n}} K_1(x, y, z) f(y)g(z) \, dy \, dz =: \sup_{|\xi| > \frac{A}{2}} |\nabla b(\xi)| J_1(x).
\]

We now claim that \(J_1\) is a Calderón–Zygmund operator, namely, \(K_1\) satisfies (1.1). Indeed, by (3.1), we have, for any \(x, y, z \in \mathbb{R}^n\) with \(x \neq y\) or \(x \neq z\),

\[
|K_1(x, y, z)| = \frac{\varphi_1(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n-1}} = \frac{(|x-y| + |x-z|)\varphi_1(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n}}
\]
\[
\leq \frac{2}{(|x-y| + |x-z|)^{2n}}
\]

and hence the size condition \([\alpha = 0_{2n} \text{ in (1.1)}]\) holds true. When \(|\alpha| = 1\), without loss of generality, we may assume that \(\alpha := (1, 0, \ldots, 0)\). Then, for any \(x, y, z \in \mathbb{R}^n\) with \(x \neq y\) or \(x \neq z\), we obtain

\[
\left| \frac{\partial}{\partial x_1} K_1(x, y, z) \right| \leq \frac{|\varphi_1'(|x-y| + |x-z|)(\frac{y_1-z_1}{|x-y|} + \frac{y_1-z_1}{|x-z|})(|x-y| + |x-z|)^2|}{(|x-y| + |x-z|)^{2n+1}}
\]
by (3.5) and (3.6), we obtain, for any \( x \)
and hence (3.10) still holds true. By (3.10), (1.2), 0
we now claim that \( J \)
and hence the size condition
Therefore, \( \mathcal{K}_1 \) satisfies (1.1) and hence \( J_1 \) is a Calderón–Zygmund operator, which shows the above
claim. From this claim, the boundedness of Calderón–Zygmund operators in weighted Lebesgue
spaces ([16, Corollary 3.9]) and (3.11), we deduce that, for any \( (f, g) \in L^p_{w_1}(\mathbb{R}^n) \times L^p_{w_2}(\mathbb{R}^n) \),
\[
(3.12) \quad \| L_1 \|_{L^p_w(|x|>A)} \leq \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_{L^p_w(\mathbb{R}^n)} \leq \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_w \| f \|_{L^p_{w_1}(\mathbb{R}^n)} \| g \|_{L^p_{w_2}(\mathbb{R}^n)}.
\]
Next, we estimate \( L_2(x) \) as well as \( \| L_2 \|_{L^p_w(|x|>A)} \). By (3.5) and (3.6), we know that supp \( \varphi_2 \subset \) 
and hence
\[
(3.13) \quad |x - y| + |x - z| \leq \frac{A}{2}.
\]
From (3.8), (3.9) and \( |x| > A \gg 1 \), we deduce that
\[
|\xi| \geq |x| - |x - \xi| \geq |x| - |x - y| \geq |x| - (|x - y| + |x - z|) \geq |x| - \frac{A}{2} > \frac{A}{2}.
\]
and hence (3.10) still holds true. By (3.10), (1.2), 0 \( \leq \varphi \leq 1 \) and hence \( |K_\alpha| \leq |K| \), we further
conclude that, for any \( (f, g) \in L^p_{w_1}(\mathbb{R}^n) \times L^p_{w_2}(\mathbb{R}^n) \) and \( x \in \mathbb{R}^n \),
\[
(3.14) \quad L_2(x) \leq \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_w \int_{\mathbb{R}^{2n}} \frac{|x - y| |x - y| + |x - z|}{(|x - y| + |x - z|)^{2n+2}} |f(y)g(z)| \, dy \, dz
\]
\[
\leq \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_w \int_{\mathbb{R}^{2n}} \varphi_2(|x - y| + |x - z|) |f(y)g(z)| \, dy \, dz
\]
\[
:= \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_w \int_{\mathbb{R}^{2n}} \mathcal{K}_2(x, y, z) |f(y)g(z)| \, dy \, dz =: \sup_{|k| > \frac{1}{2}} \| \nabla b(\xi) \|_w J_2(x).
\]
We now claim that \( J_2 \) is also a Calderón–Zygmund operator, namely, \( \mathcal{K}_2 \) satisfies (1.1). Indeed,
by (3.5) and (3.6), we obtain, for any \( x, y, z \in \mathbb{R}^n \) with \( x \neq y \) or \( x \neq z \),
\[
|\mathcal{K}_2(x, y, z)| = \frac{|\varphi_2(|x - y| + |x - z|)}{|(x - y) + |x - z|^{2n+1}} \leq \frac{1}{(|x - y| + |x - z|)^{2n}}
\]
and hence the size condition \( \alpha = \tilde{\alpha}_{3n} \) in (1.1) holds true. When \( |\alpha| = 1 \), without loss of generality,
we may assume that \( \alpha := (1, 0, \ldots, 0) \). Then, for any \( x, y, z \in \mathbb{R}^n \) with \( x \neq y \) or \( x \neq z \), it holds
true that
\[
\left| \frac{\partial}{\partial x_1} \mathcal{K}_2(x, y, z) \right| \leq \frac{|\varphi'_2(|x - y| + |x - z|)(\frac{|x - z|}{|x - y|} + \frac{|x - z|}{|x - z|})|}{(|x - y| + |x - z|)^{2n+1}}
\]
operator, which shows the above claim. By this claim, the boundedness of Calderón–Zygmund
and (3.14), we find that, for any (|z| = \infty),
we deduce that, for any (|z| = \infty),
where the implicated positive constant is independent of A. Therefore, \mathcal{K}_2 satisfies (1.1) and
hence J_2 is a Calderón–Zygmund operator, which shows the above claim. Using this claim, the
boundedness of Calderón–Zygmund operators in weighted Lebesgue spaces ([16, Corollary 3.9])
and (3.14), we find that, for any (|z| = \infty),

\begin{align}
\|L_2\|_{L^p_1(\mathbb{R}^n)} \leq \sup_{|\xi| = \frac{1}{2}} |\nabla b(\xi)| \|J_2\|_{L^p_1(\mathbb{R}^n)} \leq \sup_{|\xi| = \frac{1}{2}} |\nabla b(\xi)| \|f\|_{L^p_1(\mathbb{R}^n)} \|g\|_{L^p_2(\mathbb{R}^n)}
\end{align}

with the implicated positive constant independent of A.

Now, we estimate L_3(x) as well as \|L_3\|_{L^p_1(\mathbb{R}^n)} \times L^p_2(\mathbb{R}^n). From (1.2), 0 \leq \varphi \leq 1 and hence |K_I| \leq |K|, we deduce that, for any \((f, g) \in L^p_1(\mathbb{R}^n) \times L^p_2(\mathbb{R}^n)\) and \(x \in \mathbb{R}^n\),

\begin{align}
L_3(x) &\leq \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \int_{\mathbb{R}^{2n}} \frac{|x-y| \varphi_3(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n+2}} |f(y)g(z)| \, dy \, dz \\
&\leq \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \int_{\mathbb{R}^{2n}} \frac{\varphi_3(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n+1}} |f(y)g(z)| \, dy \, dz \\
&=: \|\nabla b\|_{L^\infty(\mathbb{R}^n)} \mathcal{K}_3(x, y, z)|f(y)g(z)| \, dy \, dz =: \|\nabla b\|_{L^\infty(\mathbb{R}^n)} J_3(x).
\end{align}

We now claim that J_3 is also a Calderón–Zygmund operator, namely, \mathcal{K}_3 satisfies (1.1) with the
kernel constant \(O(A^{-1})\). Indeed, by (3.5) and (3.6), we have, for any \(x, y, z \in \mathbb{R}^n\) with \(x \neq y\) or \(x \neq z\),

\begin{align}
|\mathcal{K}_3(x, y, z)| = \frac{|\varphi_2(|x-y| + |x-z|)}{(|x-y| + |x-z|)^{2n+1}} \leq \frac{2}{A(|x-y| + |x-z|)^{2n}}
\end{align}

and hence the size condition \(|\alpha = 0_{3n}\) in (1.1) holds true with the kernel constant \(O(A^{-1})\). When \(|\alpha| = 1\), without loss of generality, we may assume that \(\alpha := (1, \overbrace{0, \ldots, 0}^{3n-1 \text{ times}})\). Then, for any \(x, y, z \in \mathbb{R}^n\) with \(x \neq y\) or \(x \neq z\),

\begin{align}
\left| \frac{\partial}{\partial x_1} \mathcal{K}_3(x, y, z) \right| &\leq \frac{|\varphi_2'(|x-y| + |x-z|)|}{(|x-y| + |x-z|)^{2n+1}} \left( \frac{2}{A(|x-y| + |x-z|)^{2n}} \right) \\
&+ \frac{|\varphi_2'(|x-y| + |x-z|)|}{(|x-y| + |x-z|)^{2n+1}} \left( \frac{2}{A(|x-y| + |x-z|)^{2n}} \right) \\
&\leq \frac{|\varphi_3'\|_{L^\infty(\mathbb{R}^n)} + \frac{4}{2} \times \frac{1}{A}}{(|x-y| + |x-z|)^{2n+1}} \leq \frac{1}{A(|x-y| + |x-z|)^{2n+1}}.
\end{align}

Thus, \mathcal{K}_3 satisfies (1.1) with the kernel constant \(O(A^{-1})\) and hence J_3 is a Calderón–Zygmund
operator, which shows the above claim. By this claim, the boundedness of Calderón–Zygmund
operators in weighted Lebesgue spaces ([16, Corollary 3.9]) and (3.16), we conclude that, for any \((f, g) \in L_{w_1}^{p_1}(\mathbb{R}^n) \times L_{w_2}^{p_2}(\mathbb{R}^n),\)

\[
\|L_3\|_{L^p_{\infty}(\{\|x\|>A\})} \leq \|\nabla b\|_{L^p_\omega(\mathbb{R}^n)} \|J_2\|_{L^p_\omega(\mathbb{R}^n)} \leq \frac{\|\nabla b\|_{L^p_\omega(\mathbb{R}^n)} \|f\|_{L_{w_1}^{p_1}(\mathbb{R}^n)} \|g\|_{L_{w_2}^{p_2}(\mathbb{R}^n)}}{A}.
\]

To sum up, for any \(\epsilon \in (0, \infty),\) there exists a positive constant \(A\) large enough such that both

\[
\sup_{|\xi| > \frac{3}{2}} |\nabla b(\xi)| \leq \epsilon \quad \text{and} \quad \frac{\|\nabla b\|_{L^p_\omega(\mathbb{R}^n)}}{A} \leq \epsilon
\]

hold true, where the implicit positive constants are independent of \(A\) and \(\epsilon.\) From this, (3.7), (3.12), (3.15), (3.17), \(b \in B_1(\mathbb{R}^n)\) and \((f, g) \in \mathcal{E}\) bounded, we deduce that

\[
\left\| \left[ T_{\eta}, b \right] (f, g) \right\|_{L^p_{\infty}(\{\|x\|>A\})} \leq \sum_{k=1}^3 \|L_k\|_{L^p_{\infty}(\{\|x\|>A\})} < \epsilon,
\]

which implies that \([T_{\eta}, b] \mathcal{E}\) satisfies Lemma 3.2(ii).

It remains to prove that \([T_{\eta}, b] \mathcal{E}\) also satisfies Lemma 3.2(iii). Recall that \(\eta\) is a fixed positive constant small enough. Let \(t \in \mathbb{R}^n\) satisfy \(|t| \in (0, \eta/8).\) Then, for any \((f, g) \in L_{w_1}^{p_1}(\mathbb{R}^n) \times L_{w_2}^{p_2}(\mathbb{R}^n)\) and \(x \in \mathbb{R}^n,\) we have

\[
\left[ T_{\eta}, b \right] (f, g)(x) - \left[ T_{\eta}, b \right] (f, g)(x + t) = \int_{\mathbb{R}^n} [b(x) - b(y)] K_\eta(x, y, z) f(y) g(z) dy dz
\]

\[
- \int_{\mathbb{R}^n} [b(x + t) - b(y)] K_\eta(x + t, y, z) f(y) g(z) dy dz
\]

\[
= [b(x) - b(x + t)] \int_{\mathbb{R}^n} K_\eta(x, y, z) f(y) g(z) dy dz
\]

\[
+ \int_{\mathbb{R}^n} [b(x + t) - b(y)] \left[ K_\eta(x, y, z) - K_\eta(x + t, y, z) \right] f(y) g(z) dy dz
\]

\[
=: L_4(x) + L_5(x).
\]

Since we have shown that \(K_\eta\) satisfies (1.1) with the kernel constant independent of \(\eta\) [see the proof of \([T_{\eta}, b] \mathcal{E}\) satisfying Lemma 3.2(ii) above]. From this, the mean value theorem and the boundedness of Calderón–Zygmund operators in weighted Lebesgue spaces ([16, Corollary 3.9]), it follows that, for any \((f, g) \in L_{w_1}^{p_1}(\mathbb{R}^n) \times L_{w_2}^{p_2}(\mathbb{R}^n),\)

\[
\|L_4\|_{L^p_{\infty}(\mathbb{R}^n)} \leq |t| \|\nabla b\|_{L^p_\omega(\mathbb{R}^n)} \|f\|_{L_{w_1}^{p_1}(\mathbb{R}^n)} \|g\|_{L_{w_2}^{p_2}(\mathbb{R}^n)}.
\]

To estimate \(L_5,\) we first observe that, for any \(x, y, z, t \in \mathbb{R}^n\) with \(|x - y| + |x - z| < \frac{3}{4}r\) and \(|t| < \frac{3}{8}r,\)

\[
\varphi_\eta \left( \frac{2}{\eta} |x - y| + |x - z| \right) = 0 = \varphi_\eta \left( \frac{2}{\eta} |x + t - y| + |x + t - z| \right)
\]

and hence

\[
K_\eta(x, y, z) = 0 = K_\eta(x + t, y, z).
\]
Besides, for any \( x, y, z, t \in \mathbb{R}^n \) with \(|x - y| + |x - z| \geq \frac{3}{4} \) and \(|t| < \frac{9}{16}\), we have

\[
|t| \leq \frac{1}{4}(|x - y| + |x - z|).
\]

This, together with the mean value theorem and (1.1), implies that

\[
|K_\eta(x, y, z) - K_\eta(x + t, y, z)| = |\nabla_x K_\eta(\zeta, y, z)| \leq \frac{|t|}{(|x - y| + |x - z| - 2|t|)^{2n+1}}
\]

\[
\leq \frac{|t|}{(|x - y| + |x - z| - 2|t|)^{2n+1}} \leq \frac{|t|}{(|x - y| + |x - z|)^{2n+1}},
\]

where \( \nabla_x K_\eta(\cdot, y, z) \) denotes the gradient of \( K_\eta(\cdot, y, z) \) on the first variable with \( y, z \) fixed, and \( \zeta \) is in the segment connecting \( x \) and \( x + t \). By (3.18), the mean value theorem, (3.20) and (3.21), we have, for any \((f, g) \in L^p_{w_1}(\mathbb{R}^n) \times L^p_{w_2}(\mathbb{R}^n)\) and \( x \in \mathbb{R}^n \),

\[
|L_S(x)| \leq |t|^2 \|
abla b\|_{L^\infty(\mathbb{R}^n)} \int_{1-3|y|+|x-z|>\frac{t}{2}} \frac{|f(y)g(z)|}{(|x - y| + |x - z|)^{2n+1}} \, dy \, dz
\]

\[
\leq |t|^2 \|
abla b\|_{L^\infty(\mathbb{R}^n)} \sum_{k=0}^{\infty} \frac{1}{(2^k \eta)^{2n+1}} \int_{2^k \eta < |x-y|+|x-z| \leq 2^{k+1} \eta} f(y)g(z) \, dy \, dz
\]

\[
\leq |t|^2 \|
abla b\|_{L^\infty(\mathbb{R}^n)} \sum_{k=0}^{\infty} \frac{1}{2^k \eta} \int_{Q(x,2^{k+1} \eta)} |f(y)| \, dy \int_{Q(x,2^{k+1} \eta)} |g(z)| \, dz
\]

\[
\leq \frac{|t|^2}{\eta} \|
abla b\|_{L^\infty(\mathbb{R}^n)} \mathcal{M}(f, g)(x)
\]

and hence, by the boundedness of \( \mathcal{M} \) from \( L^p_{w_1}(\mathbb{R}^n) \times L^p_{w_2}(\mathbb{R}^n) \) to \( L^p(\mathbb{R}^n) \) ([16, Theorem 3.3]), we further conclude that, for any \((f, g) \in L^p_{w_1}(\mathbb{R}^n) \times L^p_{w_2}(\mathbb{R}^n)\),

\[
|L_S| \leq |t|^2 \|
abla b\|_{L^\infty(\mathbb{R}^n)} \|f\|_{L^p_{w_1}(\mathbb{R}^n)} \|g\|_{L^p_{w_2}(\mathbb{R}^n)}.
\]

Combining (3.18), (3.19) and (3.22), we conclude that, for any \( b \in B_1(\mathbb{R}^n) \) and \((f, g) \in \mathcal{E}\) bounded,

\[
\lim_{|t| \to 0} \left\| [T_\eta, b]_1(f, g)(\cdot) - [T_\eta, b]_1(f, g)(\cdot + t) \right\|_{L^p(\mathbb{R}^n)} = 0,
\]

which implies that \([T_\eta, b]_1 \mathcal{E}\) also satisfies Lemma 3.2(iii). Thus, \([T_\eta, b]_1 \mathcal{E}\) satisfies (i), (ii) and (iii) of Lemma 3.2 and hence \([T_\eta, b]_1\) is a compact operator for any \( b \in B_1(\mathbb{R}^n) \) and \( \eta \in (0, \infty) \) small enough. This finishes the proof of Theorem 1.4. \( \square \)
