September 10, 2019

Abstract

The quantum dynamics of a damped and forced harmonic oscillator described by a Lindblad master equation is analyzed. The master equation is converted into a matrix-vector representation and the resulting non-Hermitian Schrödinger equation is solved by Lie-algebraic techniques allowing the construction of the general solution for the density operator.

1 Introduction

The open system dynamics of the density operator \( \hat{\rho}(t) \), a positive operator with trace \( \hat{\rho}(0) = 1 \), is described by the Lindblad master equation

\[
\frac{d\hat{\rho}}{dt} = -i [\hat{H}, \hat{\rho}] + \frac{\mu}{2} (2\hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}^\dagger\hat{\rho}\hat{a} - \hat{a}^\dagger\hat{a}\hat{\rho}) + \frac{\nu}{2} (2\hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}^\dagger\hat{\rho}\hat{a} - \hat{a}^\dagger\hat{a}\hat{\rho}).
\]

(1)

for a forced harmonic oscillator with Hamiltonian

\[
\hat{H} = \omega (\hat{a}^\dagger\hat{a} + 1/2) - f(t) (\hat{a}^\dagger + \hat{a})
\]

(2)

*Electronic address: h.j.korsch@gmail.com
with a time-dependent force \( f(t) \in \mathbb{R} \), where \( \hat{a}^\dagger \) and \( \hat{a} \) are the familiar bosonic creation and destruction operators with commutator \([\hat{a}, \hat{a}^\dagger] = 1\). The damping coefficients \( \mu \) and \( \nu \) (with \( \mu > \nu \geq 0 \)) describe phenomenologically the coupling to an environment representing (homogeneous) loss and (inhomogeneous) pumping of particles, respectively. In the following it will be convenient to introduce the parameters

\[
\gamma' = (\mu + \nu)/2 \geq 0 \quad \text{and} \quad \gamma = (\mu - \nu)/2 \geq 0
\]

(3)
denoted as diffusion and dissipation constants [1]. We will use units with \( \hbar = 1 \) throughout.

The case of a force-free harmonic oscillator has been studied in detail in [2], where a general solution is derived, i.e. a solution \( \hat{\rho}(t) \) for an arbitrary initial condition \( \hat{\rho}(0) \). For the forced oscillator, a special class of solutions of the form

\[
\hat{\rho}(t) = b(t) e^{-|\beta(t)|^2/b(t)} e^{\beta(t)\hat{a}^\dagger} e^{\sigma(t)\hat{a}} e^{\beta^*(t)\hat{a}^\dagger}
\]

(4)
could be constructed in a recent study by the author [3] allowing for example to describe the convergence to the limit cycle distribution \( \hat{\rho}_{lc}(t) \) for a harmonic force. The parameters in (4) are given by

\[
b(t) = 1 - u(t), \quad u(t) = e^{\sigma(t)}
\]

(5)

Alternatively the states (4) can be rewritten using the relations [4]

\[
e^{z\hat{a}^\dagger} e^{w\hat{a}} = e^{z\hat{a}} e^{w\hat{a}^\dagger} e^{-zw/2} = e^{w\hat{a}^\dagger} e^{z\hat{a}^\dagger} e^{zw/2}, \quad e^{y\hat{a}} e^{x\hat{a}^\dagger} = e^{x\hat{a}^\dagger} e^{y\hat{a}}
\]

(6)
as

\[
\hat{\rho}(t) = \hat{D}(\alpha(t)) \hat{\rho}_{th}(t) \hat{D}^\dagger(\alpha(t))
\]

(7)
in terms of the thermal distribution

\[
\hat{\rho}_{th}(t) = \frac{1}{Z(t)} e^{\sigma(t)\hat{a}^\dagger\hat{a}}
\]

(8)
with the partition function

\[ Z = \text{trace } e^{\sigma \hat{a} \dagger \hat{a}} = \frac{1}{1-e^\sigma} = \frac{1}{b} \quad (9) \]

and the unitary displacement operator

\[ \hat{D}(\alpha) = e^{\alpha \hat{a} \dagger - \alpha^* \hat{a}} \quad \text{with} \quad |\alpha\rangle = \hat{D}(\alpha)|0\rangle, \quad (10) \]

which generates a coherent state \( |\alpha\rangle \) from the oscillator ground state. These states are known as single mode thermal coherent states \[ ? \] describing a thermal mixed state displaced in phase space. As shown in \[ 3 \] such a thermal coherent state is form-invariant under the Lindblad evolution.

Often the driving force is time-periodic, \( f(t+T) = f(t) \), as for example in the celebrated case of harmonic driving, and one can look for a time-periodic solution \( \hat{\rho}(t+T) = \hat{\rho}(t) \). Such a Floquet-solution can be found as a thermal coherent state \( (7) \) with time-periodic coefficients. Periodicity of \( u(t) \) requires \( u(t) = \nu/\mu \) and therefore \( b(t) = 2\gamma/\mu \) and \( \sigma(t) = \log(\nu/\mu) \). The remaining parameter, the displacement \( \alpha(t) \), must be a periodic solution \( \alpha^{(\ell c)}(t) \) of the differential equation \( (5) \), as for example

\[ \alpha^{(\ell c)}(t) = \frac{f_0}{2} \left( \frac{e^{i\Omega t}}{\omega + \Omega - i\gamma} + \frac{e^{-i\Omega t}}{\omega - \Omega - i\gamma} \right) \quad (11) \]

for \( f(t) = f_0 \cos \Omega t \). It should be noted, of course, that this periodic distribution agrees with the long-time limit, the limit cycle distribution

\[ \hat{\rho}^{(\ell c)}(t) = \frac{2\gamma}{\mu} e^{\log \frac{\nu}{\mu}} \left( |\alpha^{(\ell c)}(t)|^2 + \hat{n} - \alpha^{(\ell c)}(t)\hat{a}^\dagger - \alpha^{(\ell c)}(t)^* \hat{a} \right) \quad (12) \]

as discussed in \[ 3 \].

In the present notes we will construct the general solution of the Lindblad dynamics in three steps: First the system is transformed into a matrix-vector representation, a Schrödinger-like picture with a non-Hermitian Hamiltonian \( \hat{\mathcal{H}} \), which can also be viewed as two interacting forced harmonic oscillators with decay. In a second step this system is solved using Lie-algebraic techniques and finally transformed back to the original density matrix representation.
2 Matrix – vector transformation

Linear operators acting on Hilbert space form a linear space and an element $A$ of this space can also be denoted by a ket-vector $|A\rangle$. One can define a scalar product of two elements $A$ and $B$ of this space as

$$\langle A|B \rangle = \text{trace } A^\dagger B.$$  \hspace{1cm} (13)

The linear operators on this Liouville space are also called superoperators. The Lindblad dynamics of the density operator can be transformed into a vector representation using the Kronecker product (see the book by Steeb and Hardy [5] as well as [6]). Here we follow the application by Fujii [2] to the force-free and time-independent harmonic oscillator. It should be noted that a similar technique has also been developed by Ban [?] (see also [?]). The result is a Schrödinger-like equation for the vector $|\rho(t)\rangle$ representing the density operator $\hat{\rho}(t)$, namely

$$i\frac{d|\rho\rangle}{dt} = \hat{\mathcal{H}}|\rho\rangle.$$  \hspace{1cm} (14)

The (super)Hamiltonian $\hat{\mathcal{H}}$ is given by

$$\hat{\mathcal{H}} = \hat{\mathcal{H}}_0 + i\hat{G},$$  \hspace{1cm} (15)

where $\hat{\mathcal{H}}_0$ is a representation of the Hamiltonian and $\hat{G}$ of the Lindblad term. Following Fujii [2] one can use the tensor or Kronecker product $\otimes$, a bilinear product of (quadratic) matrices satisfying for instance

$$(A_1 \otimes B_1)(A_2 \otimes B_2) = (A_1 A_2) \otimes (B_1 B_2), \quad (A \otimes B)^\dagger = A^\dagger \otimes B^\dagger,$$  \hspace{1cm} (16)

which implies

$$(A \otimes B)^n = A^n \otimes B^n$$  \hspace{1cm} (17)

and

$$e^{A \otimes B} = \sum_n \frac{1}{n!} (A \otimes B)^n = \sum_n \frac{1}{n!} A^n \otimes B^n.$$  \hspace{1cm} (18)

If one of these matrices is equal to the unit matrix $I$ this yields

$$e^{A \otimes I} = e^A \otimes I, \quad e^{I \otimes A} = I \otimes e^A.$$  \hspace{1cm} (19)
Furthermore we see from
\[(A \otimes I)(I \otimes B) = A \otimes B = (I \otimes B)(A \otimes I)\] (20)
that \(A \otimes I\) and \(I \otimes B\) commute and hence
\[e^{A \otimes I + I \otimes B} = e^{A \otimes I} e^{I \otimes B} = (e^A \otimes I)(I \otimes e^B) = e^A \otimes e^B.\] (21)

An important application of the Kronecker product, which will be employed in the following, is the transformation of matrix differential equations
\[\frac{dX}{dt} = AXB \quad \iff \quad \frac{d\vec{x}}{dt} = (A \otimes B^T) \vec{x},\] (22)
\[\frac{dX}{dt} = AX + XB \quad \iff \quad \frac{d\vec{x}}{dt} = (A \otimes I + I \otimes B^T) \vec{x},\] (23)
where the \(B^T\) is the transpose of \(B\) and
\[X = (x_{jk}) \quad \iff \quad \vec{x} = (x_{11}, x_{12}, \ldots, x_{21}, \ldots)^T\] (24)
as well as
\[AXB \quad \iff \quad (A \otimes B^T) \vec{x}, \quad AX +XB \quad \iff \quad (A \otimes I + I \otimes B^T) \vec{x}.\] (25)

Applying this transformation to the damped harmonic oscillator in eqs. (1) and (2), the Hamiltonian appears as
\[\hat{H}_0 = \omega (\hat{n} \otimes \hat{1} - \hat{1} \otimes \hat{n}) - f(\hat{a}^\dagger \otimes \hat{1} + \hat{a} \otimes \hat{1} - \hat{1} \otimes \hat{a}^\dagger - \hat{1} \otimes \hat{a})\] (26)
and the representation of the Lindblad term is
\[\hat{G} = \mu \hat{a} \otimes \hat{a} + \nu \hat{a}^\dagger \otimes \hat{a}^\dagger - \gamma' (\hat{n} \otimes \hat{1} + \hat{1} \otimes \hat{n} + \hat{1} \otimes \hat{1}) + \gamma \hat{1} \otimes \hat{1}\] (27)
with \(\hat{a}^T = \hat{a}^\dagger\) and the number operator \(\hat{n} = \hat{a}^\dagger \hat{a}\) (compare [2]). Note that \(\hat{H}_0\) and \(\hat{G}\) are both Hermitian. This can now be rewritten in terms of the operators
\[\hat{K}_0 = \hat{n} \otimes \hat{1} + \hat{1} \otimes \hat{n} + \hat{1} \otimes \hat{1}, \quad \hat{K}_+ = \hat{a}^\dagger \otimes \hat{a}^\dagger, \quad \hat{K}_- = \hat{a} \otimes \hat{a}\] (28)
with \(\hat{K}_0 = \hat{K}_0^\dagger, \quad \hat{K}_- = \hat{K}_+^\dagger\), which satisfy the \(su(1, 1)\) commutator relations
\[[\hat{K}_0, \hat{K}_\pm] = \pm 2\hat{K}_\pm, \quad [\hat{K}_+, \hat{K}_-] = -\hat{K}_0\] (29)
as can be easily shown using (16). (Note that in [2] \( \hat{K}_0 \) is denoted by \( 2\hat{K}_3 \).)

In addition we define

\[
\hat{I} = \hat{1} \otimes \hat{1} \quad \text{and} \quad \hat{N} = \hat{n} \otimes \hat{1} - \hat{1} \otimes \hat{n}
\]  

(30)

(denoted by \( \hat{K}_0 \) in [2]), which commute with \( \hat{K}_0 \) and \( \hat{K}_\pm \), and

\[
\hat{A} = \hat{a} \otimes \hat{1} \quad \text{and} \quad \hat{B} = \hat{1} \otimes \hat{a}
\]  

(31)

with \( \hat{A}^\dagger = \hat{a}^\dagger \otimes \hat{1} \), \( \hat{B}^\dagger = \hat{1} \otimes \hat{a}^\dagger \) and

\[
\hat{K}_+ = \hat{a}^\dagger \otimes \hat{a}^\dagger = (\hat{a}^\dagger \otimes \hat{1})(\hat{1} \otimes \hat{a}^\dagger) = \hat{A}^\dagger \hat{B}^\dagger
\]  

(32)

\[
\hat{K}_- = \hat{a} \otimes \hat{a} = (\hat{a} \otimes \hat{1})(\hat{1} \otimes \hat{a}) = \hat{A} \hat{B}
\]  

(33)

\[
\hat{K}_0 = (\hat{a}^\dagger \hat{a}) \otimes \hat{1} + \hat{1} \otimes (\hat{a}^\dagger \hat{a}) + \hat{1} \otimes \hat{1}
\]  

(34)

\[
= (\hat{a}^\dagger \otimes \hat{1})(\hat{a} \otimes \hat{1}) + (\hat{1} \otimes \hat{a}^\dagger)(\hat{1} \otimes \hat{a}) + \hat{1} \otimes \hat{1} = \hat{A}^\dagger \hat{A} + \hat{B}^\dagger \hat{B} + \hat{I}.
\]

The commutators can be easily determined as

\[
[\hat{A}, \hat{B}] = [\hat{A}, \hat{B}^\dagger] = [\hat{A}^\dagger, \hat{B}] = [\hat{A}^\dagger, \hat{B}^\dagger] = 0,
\]  

(35)

\[
[\hat{A}, \hat{A}^\dagger] = [\hat{B}, \hat{B}^\dagger] = \hat{1} \otimes \hat{1} = \hat{I}
\]  

(36)

as well as

\[
[\hat{K}_0, \hat{A}] = -\hat{A}, \quad [\hat{K}_+, \hat{A}] = -\hat{B}^\dagger, \quad [\hat{K}_-, \hat{A}] = 0
\]  

(37)

\[
[\hat{K}_0, \hat{A}^\dagger] = \hat{A}^\dagger, \quad [\hat{K}_+, \hat{A}^\dagger] = 0, \quad [\hat{K}_-, \hat{A}^\dagger] = \hat{B}
\]  

(38)

\[
[\hat{K}_0, \hat{B}] = -\hat{B}, \quad [\hat{K}_+, \hat{B}] = -\hat{A}^\dagger, \quad [\hat{K}_-, \hat{B}] = 0
\]  

(39)

\[
[\hat{K}_0, \hat{B}^\dagger] = \hat{B}^\dagger, \quad [\hat{K}_+, \hat{B}^\dagger] = 0, \quad [\hat{K}_-, \hat{B}^\dagger] = \hat{A}
\]  

(40)

and

\[
[\hat{N}, \hat{A}] = -\hat{A}, \quad [\hat{N}, \hat{A}^\dagger] = \hat{A}^\dagger, \quad [\hat{N}, \hat{B}] = \hat{B}, \quad [\hat{N}, \hat{B}^\dagger] = -\hat{B}^\dagger.
\]  

(41)

We then obtain

\[
\hat{H}_0 = \omega \hat{N} - f(\hat{A}^\dagger + \hat{A} - \hat{B}^\dagger - \hat{B}),
\]  

(42)

\[
\hat{G} = \mu \hat{K}_- + \nu \hat{K}_+ - \gamma' \hat{K}_0 + \gamma \hat{I}.
\]  

(43)
3 Lie algebraic solution

In this section we construct a solution of the Schrödinger-like equation (14) for the vector $|\rho(t)\rangle$, or, preferably, for the time-evolution operator defined by $|\rho(t)\rangle = \hat{U}(t)|\rho(0)\rangle$, namely

$$i \frac{d}{dt} \hat{U}(t) = \hat{H} \hat{U}(t)$$

(44)

with $\hat{U}(0) = \hat{I}$ for the non-Hermitian Hamiltonian $\hat{H} = \hat{H}_0 + i \hat{G}$ and

$$\hat{H}_0 = \omega \hat{N} - f(t) (\hat{A}^\dagger + \hat{B}^\dagger - \hat{B} - \hat{A}),$$

(45)

$$\hat{G} = \mu \hat{K}_0 + \nu \hat{K}_+ - \gamma' \hat{K}_0 + \gamma \hat{I},$$

(46)

where the operators $\hat{K}_0$ and $\hat{K}_\pm$ satisfy the $su(1,1)$ commutator relations (29) and $\hat{N}$ in eq. (30) can be written as

$$\hat{N} = \hat{A}^\dagger \hat{A} - \hat{B}^\dagger \hat{B}.$$

(47)

One observes that the algebra generated by the nine operators closes and can be decomposed as a semidirect sum $R \subset S$ of the simple $su(1,1)$ algebra $S = \{\hat{K}_0, \hat{K}_+, \hat{K}_-\}$ and the radical $R = \{\hat{A}^\dagger, \hat{A}, \hat{B}^\dagger, \hat{B}, \hat{I}, \hat{N}\}$ (see, e.g., [7] and references therein). In fact, the algebra is identical to the algebra $\tilde{L}_9$ in [7] and one can easily modify the solution described there in detail for the closely related algebra $L_9$.

For the further analysis we will need the $\hat{\Gamma}_j$-evolved operators $\hat{\Gamma}_k$ of our algebra, i.e. the operators

$$e^{x \hat{\Gamma}_j} \hat{\Gamma}_k e^{-x \hat{\Gamma}_j} = \hat{\Gamma}_k + x [\hat{\Gamma}_j, \hat{\Gamma}_k] + \frac{x^2}{2!} [\hat{\Gamma}_j, [\hat{\Gamma}_j, \hat{\Gamma}_k]] + \ldots.$$ 

(48)

Here we find, for example,

$$e^{x \hat{A}} \hat{A}^\dagger e^{-x \hat{A}} = \hat{A}^\dagger + x [\hat{A}, \hat{A}^\dagger] + \frac{x^2}{2!} [\hat{A}, [\hat{A}, \hat{A}^\dagger]] + \ldots = \hat{A}^\dagger + x,$$

(49)

because of $[\hat{A}, \hat{A}^\dagger] = 1$, and

$$e^{x \hat{A}^\dagger} \hat{A} e^{-x \hat{A}^\dagger} = \hat{A} + x [\hat{A}^\dagger, \hat{A}] + \frac{x^2}{2!} [\hat{A}^\dagger, [\hat{A}^\dagger, \hat{A}]] + \ldots = \hat{A} - x.$$

(50)
Table 1: $\hat{\Gamma}_j$-evolved $\hat{\Gamma}_k$, i.e. the operators $e^{x\hat{\Gamma}_j}\hat{\Gamma}_k e^{-x\hat{\Gamma}_j}$.

</tbody>
</table>

The same relations are also valid for $\hat{B}$ and $\hat{B}^\dagger$ and some more are listed in table 1 (see also the similar table II in [7]). For future reference we also note the relations

$$e^{x\hat{N}} e^{y\hat{A}} e^{-x\hat{N}} = e^y e^{-x\hat{A}}, \quad e^{x\hat{N}} e^{y\hat{A}^\dagger} e^{-x\hat{N}} = e^y e^{x\hat{A}^\dagger},$$

(51)

$$e^{x\hat{N}} e^{y\hat{B}} e^{-x\hat{N}} = e^y e^{x\hat{B}}, \quad e^{x\hat{N}} e^{y\hat{B}^\dagger} e^{-x\hat{N}} = e^y e^{-x\hat{B}^\dagger},$$

(52)

which follow from those in table 1 by expanding the exponential function.

Separating the Hamiltonian as $\hat{H} = \hat{H}_S + \hat{H}_R$ with

$$\hat{H}_S = i\mu \hat{K}_- + i\nu \hat{K}_+ - ig' \hat{K}_0 \in S$$

(53)

$$\hat{H}_R = \omega \hat{N} - f (\hat{A}^\dagger + \hat{A} - \hat{B}^\dagger - \hat{B}) + ig \hat{I} \in R,$$ 

(54)

the time-evolution operator can be factorized as

$$\hat{U} = \hat{U}_S \hat{U}_R$$

(55)

where $\hat{U}_S$ and $\hat{U}_R$ are solutions of

$$i \frac{d}{dt} \hat{U}_S = \hat{H}_S \hat{U}_S, \quad i \frac{d}{dt} \hat{U}_R = (\hat{U}_S^{-1} \hat{H}_R \hat{U}_S) \hat{U}_R,$$ 

(56)

as discussed in [7]. Note that $\hat{U}_S^{-1} \hat{H}_R \hat{U}_S \in R$, because $R$ is the radical.

We first have to construct $\hat{U}_S$, which can be conveniently obtained as the exponential product

$$\hat{U}_S(t) = e^{d_+(t)\hat{K}_+} e^{d_0(t)\hat{K}_0} e^{d_-(t)\hat{K}_-},$$ 

(57)
where the $d$-coefficients are time-dependent, satisfying three coupled differential equations [7]. In the present case, however, $H_S$ does not depend on time, and therefore we have

$$
\hat{U}_S(t) = e^{-iH_S t} = e^{\mu t K_- + \nu t K_+ - \gamma t K_0}.
$$

(58)

This can be rewritten in the product form (57) using the disentangling relations [2] with parameters

$$
d_+(t) = \frac{\nu}{\gamma \lambda(t)} \sinh(\gamma t), \quad d_-(t) = \frac{\mu}{\gamma \lambda(t)} \sinh(\gamma t)
$$

(59)

$$
\lambda(t) = e^{-d_0(t)} = \cosh(\gamma t) + \frac{\gamma'}{\gamma} \sinh(\gamma t).
$$

(60)

Note that $d_\pm$, $d_0$ and $\lambda$ are real valued.

In the next step, one has to construct $\hat{U}_R(t)$. First we calculate

$$
\hat{\mathcal{H}}'_R = \hat{U}^{-1}_S \hat{\mathcal{H}}_R \hat{U} = \hat{U}^{-1}_S (\omega \hat{N} - f(\hat{A}^\dagger + \hat{A} - \hat{B}^\dagger - \hat{B}) + i\gamma \hat{I}) \hat{U}_S.
$$

(61)

The first and the last term in the sum (61) are trivial, $\hat{U}^{-1}_S \hat{N} \hat{U}_S = \hat{N}$ and $\hat{U}^{-1}_S \hat{I} \hat{U}_S = \hat{I}$, because $\hat{N}$ and $\hat{I}$ commute with $K_0$ and $K_\pm$. The other terms can be easily evaluated with help of table [1] as for example

$$
\hat{U}^{-1}_S \hat{A}^\dagger \hat{U}_S = e^{-d_- K_-} e^{-d_0 K_0} e^{-d_+ K_+} \hat{A}^\dagger e^{d_+ K_+} e^{d_0 K_0} e^{d_- K_-}
$$

$$
= e^{-d_- K_-} e^{-d_0 K_0} \hat{A}^\dagger e^{d_0 K_0} e^{d_- K_-}
$$

$$
= e^{-d_0} e^{-d_- K_-} \hat{A}^\dagger e^{d_- K_-} = e^{-d_0} (\hat{A}^\dagger - d_- \hat{B})
$$

(62)

and in the same way

$$
\hat{U}^{-1}_S \hat{A} \hat{U}_S = (e^{d_0} - d_+ d_- e^{-d_0}) \hat{A} + d_+ e^{-d_0} \hat{B}^\dagger,
$$

(63)

$$
\hat{U}^{-1}_S \hat{B}^\dagger \hat{U}_S = e^{-d_0} (\hat{B}^\dagger - d_- \hat{A}),
$$

(64)

$$
\hat{U}^{-1}_S \hat{B} \hat{U}_S = (e^{d_0} - d_+ d_- e^{-d_0}) \hat{B} + d_+ e^{-d_0} \hat{A}^\dagger,
$$

(65)

and therefore one obtains

$$
\hat{\mathcal{H}}'_R = \omega \hat{N} - f (1 - d_+) e^{-d_0} (\hat{A}^\dagger - \hat{B}^\dagger)
$$

$$
- f (e^{d_0} + (1 - d_+) d_- e^{-d_0})(\hat{A} - \hat{B}) + i\gamma \hat{I}
$$

$$
= c_1 \hat{N} + c_2 \hat{A} + c_3 \hat{A}^\dagger + c_4 \hat{B} + c_5 \hat{B}^\dagger + c_6 \hat{I},
$$

(66)
with
\[c_1 = \omega, \quad c_2 = -c_4 = -f(e^{d_0} + (1 - d_+)d_-e^{-d_0}),
\]
\[c_3 = -c_5 = -f(1 - d_+)e^{-d_0}, \quad c_6 = i\gamma. \quad (67)\]

One can easily show that
\[e^{d_0} + (1 - d_+)d_-e^{-d_0} = (1 - d_+)e^{-d_0} = e^{\gamma t} \quad (68)\]
and with
\[c_2 = c_3 = -c_4 = -c_5 = -f(t)e^{\gamma t} = c(t) \in \mathbb{R} \quad (69)\]
we obtain
\[\dot{\mathcal{H}}_R = \omega \dot{N} + c(t)(\dot{A} + \dot{A}^\dagger - \dot{B} - \dot{B}^\dagger) + i\gamma \dot{I}. \quad (70)\]

For the product of exponentials
\[\dot{U}_R = e^{g_1 \dot{N}}e^{g_2 \dot{A}^\dagger}e^{g_3 \dot{A}^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} \quad (71)\]
we find using \(e^{xN}\dot{A} = e^{-x}\dot{A}e^{xN}\), \(e^{xN}\dot{A}^\dagger = e^{x\dot{A}^\dagger}e^{xN}\) and \(e^{xN}\dot{B} = e^{-x}\dot{B}e^{xN}\), \(e^{xN}\dot{B}^\dagger = e^{-x}\dot{B}^\dagger e^{xN}\) (see table 1) as well as \(e^{x\dot{A}^\dagger} = (\dot{A}^\dagger + x)e^{x\dot{A}}\) and \(e^{x\dot{B}^\dagger} = (\dot{B}^\dagger + x)e^{x\dot{B}}\) (see eq. [50])
\[
\frac{d\dot{U}_R}{dt} = \dot{g}_1 \dot{N}e^{g_1 \dot{N}}e^{g_2 \dot{A}^\dagger}e^{g_3 \dot{A}^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} + \dot{g}_2 e^{g_1 \dot{N}}\dot{A}e^{g_2 \dot{A}^\dagger}e^{g_3 \dot{A}^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} \\
+ \dot{g}_3 e^{g_1 \dot{N}}\dot{A}^\dagger e^{g_2 \dot{A}^\dagger^\dagger}e^{g_3 \dot{A}^\dagger^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} + \dot{g}_4 e^{g_1 \dot{N}}\dot{A}^\dagger e^{g_2 \dot{A}^\dagger^\dagger}e^{g_3 \dot{A}^\dagger^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} \\
+ \dot{g}_5 e^{g_1 \dot{N}}e^{g_2 \dot{A}^\dagger^\dagger^\dagger}e^{g_3 \dot{A}^\dagger^\dagger^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} + \dot{g}_6 e^{g_1 \dot{N}}e^{g_2 \dot{A}^\dagger^\dagger^\dagger^\dagger}e^{g_3 \dot{A}^\dagger^\dagger^\dagger^\dagger^\dagger}e^{g_4 \dot{B}^\dagger}e^{g_5 \dot{B}^\dagger}e^{g_6 \dot{I}} \\
= (\dot{g}_1 \dot{N} + \dot{g}_2 \dot{e}^{-g_1} \dot{A} + \dot{g}_3 \dot{e}^{g_1} \dot{A}^\dagger + \dot{g}_4 \dot{e}^{-g_1} \dot{B} + \dot{g}_5 \dot{e}^{g_1} \dot{B}^\dagger + \dot{g}_3 \dot{g}_2 + \dot{g}_5 \dot{g}_4 + \dot{g}_6)\dot{U}_R. \quad (72)\]

Inserting this and (66) into \(i\frac{d\dot{U}_R}{dt} = \dot{\mathcal{H}}_R^\dagger \dot{U}_R\) and comparing both sides, we see that the \(g_j(t)\) satisfy the differential equations
\[
\dot{g}_1 = -ic_1, \quad \dot{g}_2 = -ic_2g_1, \quad \dot{g}_3 = -ic_3g_1, \quad \dot{g}_4 = -ic_4g_1, \\
\dot{g}_5 = -ic_5g_1, \quad \dot{g}_6 = -i(c_6 - c_3g_2g_1 - c_5g_4g_1), \quad (73)\]
with \( g_j(0) = 0 \). These equations can be solved by quadrature, and, using \( c_1 = \omega, c_6 = i \gamma \) and relations (69) for the \( c_2, \ldots c_5 \), we have

\[
\begin{align*}
    g_1(t) &= -i \omega t, \\
    g_2(t) &= -i \int_0^t c(t') e^{-i \omega t'} dt', \\
    g_3(t) &= -i \int_0^t c(t') e^{i \omega t'} dt', \\
    g_4(t) &= +i \int_0^t c(t') e^{i \omega t'} dt', \\
    g_5(t) &= i \int_0^t c(t') e^{-i \omega t'} dt', \\
    g_6(t) &= \gamma t + i \int_0^t c(t') (g(t') e^{-i \omega t'} - g^*(t') e^{i \omega t'}) dt' \in \mathbb{R}
\end{align*}
\]

and with

\[
    g(t) = g_3(t) = -g_2^*(t) = -g_4(t) = g_5^*(t)
\]

we finally obtain

\[
    \hat{U}_R(t) = e^{-i \omega t N} e^{-g(t) \hat{A} e^{g(t) \hat{A}^\dagger} e^{-g(t) \hat{B} e^{g(t) \hat{B}^\dagger} e^{g_6(t) I}}}
\]

We have therefore constructed the time-evolution operator \( \hat{U}(t) = \hat{U}_S(t) \hat{U}_R(t) \).

## 4 Back transformation

In order to derive the desired solution \( \hat{\rho}(t) \) of the Lindblad equation, we return from the vector to the matrix representation. First we will consider only \( \hat{U}_S \). Inserting \( \hat{K}_0 \) and \( \hat{K}_\pm \) as well as

\[
    e^{d_0 \hat{K}_0} = e^{d_0 (\hat{n} \otimes 1 + 1 \otimes \hat{n} + 1 \otimes 1)} = e^{d_0} \otimes e^{d_0 \hat{n}} \otimes e^{d_0 \hat{n}}
\]

according to (21) yields

\[
    U_S = e^{d_+ \hat{K}^+} e^{d_0 \hat{K}_0} e^{d_- \hat{K}^-} = e^{d_+ \hat{n}^\dagger} \otimes \hat{n}^\dagger e^{d_0 \hat{K}_0} e^{d_- \hat{n} \otimes \hat{n}}
\]

Rewriting the operator in this sum as

\[
    (\hat{a}^\dagger \otimes \hat{a}^\dagger) (e^{d_0 \hat{n}} \otimes e^{d_0 \hat{n}}) (\hat{a} \otimes \hat{a})^k = (\hat{a}^j e^{d_0 \hat{n}} \otimes e^{d_0 \hat{n}})(\hat{a}^k \otimes \hat{a}^k)
\]

\[
    = (\hat{a}^j e^{d_0 \hat{n}} \hat{a}^k) \otimes (\hat{a}^j e^{d_0 \hat{n}} \hat{a}^k) = (\hat{a}^j e^{d_0 \hat{n}} \hat{a}^k) \otimes (\hat{a}^j e^{d_0 \hat{n}} \hat{a}^k)^T
\]

(82)
and using $\hat{a}^T = \hat{a}^T$ and $\hat{n}^T = \hat{n}$ leads to

$$U_S(t) = e^{d_0 \hat{a}} \otimes \sum_{j,k} \frac{d_j^j d_k^k}{j!k!}(\hat{a}^{ij} e^{d_0 \hat{n} \hat{a}}^k) \otimes (\hat{a}^{\dagger k} e^{d_0 \hat{n} \hat{a}}^j)^T$$ \hspace{1cm} (83)

and hence

$$|\rho(t)\rangle = U_S(t)|\rho(0)\rangle = e^{d_0 \hat{a}} \otimes \sum_{j,k} \frac{d_j^j d_k^k}{j!k!}(\hat{a}^{ij} e^{d_0 \hat{n} \hat{a}}^k) \otimes (\hat{a}^{\dagger k} e^{d_0 \hat{n} \hat{a}}^j)^T|\rho(0)\rangle.$$ \hspace{1cm} (84)

This vector representation can be transformed back to the original matrix space as

$$\hat{\rho}(t) = e^{d_0 \hat{a}} \sum_{j,k} \frac{d_j^j d_k^k}{j!k!} \hat{a}^{ij} e^{d_0 \hat{n} \hat{a}}^k \hat{\rho}(0) \hat{a}^{\dagger k} e^{d_0 \hat{n} \hat{a}}^j$$

$$= e^{d_0 \hat{a}} \sum_{j} \frac{d_j^j}{j!} \hat{a}^{ij} e^{d_0 \hat{n} \hat{a}}^j \left( \sum_{k} \frac{d_k^k}{k!} \hat{a}^{\dagger k} \hat{\rho}(0) \hat{a}^{\dagger k} \right) e^{d_0 \hat{n} \hat{a}}^j$$ \hspace{1cm} (85)

(compare eq. (25)). For the force-free case we have

$$\hat{U}(t) = e^{d_+ \hat{K} + d_0 \hat{K}_0 e^{d_- \hat{K} - e^{g_1 \hat{N} e^{g_0 \hat{I}}}}$$ \hspace{1cm} (86)

with $g_1 = -i\omega t$ and $g_6 = \gamma t$. The operators $\hat{N}$ and $\hat{I}$ commute with the $\hat{K}_j$ and this can be rewritten as $\hat{U}(t) = e^{d_+ \hat{K} + e^{\hat{X}} e^{d_- \hat{K}} -}$ with

$$\hat{X} = g_6 \hat{I} + g_1 \hat{N} + d_o \hat{K}_0$$

$$= (d_o + g_0)(\hat{1} \otimes \hat{1}) + (d_o + g_1)(\hat{n} \otimes \hat{1})(d_o - g_1)(\hat{1} \otimes \hat{n}).$$ \hspace{1cm} (87)

In the same way as above we obtain

$$U(t) = e^{d_0 + g_6} \sum_{j,k} \frac{d_j^j d_k^k}{j!k!}(\hat{a}^{ij} e^{d_0 + g_1 \hat{a}^{\dagger k} \hat{\rho}(0)} \hat{a}^{\dagger k} e^{d_0 - g_1 \hat{a}^{\dagger k} \hat{\rho}(0)} \hat{a}^{\dagger k} e^{d_0 \hat{n} \hat{a}^j)^T}$$ \hspace{1cm} (88)

and therefore with $e^{-d_0} = \lambda$, $g_1 = -i\omega t$ and $g_6 = \gamma t$

$$\hat{\rho}(t) = e^{d_0 + g_6} \sum_{j,k} \frac{d_j^j d_k^k}{j!k!} \hat{a}^{ij} e^{d_0 + g_1 \hat{a}^{\dagger k} \hat{\rho}(0)} \hat{a}^{\dagger k} e^{d_0 - g_1 \hat{a}^{\dagger k} \hat{\rho}(0)} \hat{a}^{\dagger k} e^{d_0 \hat{n} \hat{a}^j)^T}$$

$$= \frac{e^{\gamma t}}{\lambda} \sum_{j} \frac{d_j^j}{j!} \hat{a}^{ij} e^{(-i\omega t - \log \lambda) \hat{n}} \left( \sum_{k} \frac{d_k^k}{k!} \hat{a}^{\dagger k} \hat{\rho}(0) \hat{a}^{\dagger k} \right) e^{(i\omega t - \log \lambda) \hat{n} \hat{a}^j}$$ \hspace{1cm} (89)
in agreement with the formula derived in [2].

Finally we will consider the general forced harmonic oscillator with time evolution operator

\[ \dot{U}(t) = US(t)UR(t) \quad \text{with} \quad UR(t) = e^{g_1 N} e^{g_3 A} e^{g_4 B} e^{g_5 B^\dagger} . \tag{90} \]

The term \( e^{g_1 N} e^{g_0 i} \) can be treated exactly as described above and the remaining terms can be rewritten as

\[ e^{g_2 A} e^{g_3 A^\dagger} e^{g_4 B} e^{g_5 B^\dagger} = e^{g_2 A} \otimes e^{g_3 A^\dagger} \otimes e^{g_4 B} \otimes e^{g_5 B^\dagger} = (e^{g_2 A} e^{g_3 A^\dagger}) \otimes (e^{g_4 A} e^{g_5 A^\dagger}) = (e^{g_2 A} e^{g_4 A^\dagger})^T . \tag{91} \]

Combining this with \([88]\), we have

\[ \dot{U}(t) = e^{d_0 + g_0} \sum_{j,k} \frac{d_j^k}{j!k!} (\hat{a}^j \hat{e}^{(d_0 + g_1)\hat{n}} \hat{a}^k \hat{e}^{g_2 A} \hat{e}^{g_3 A^\dagger} \hat{e}^{g_4 A} \hat{e}^{g_5 A^\dagger} \hat{e}^{f} \hat{e}^{(d_0 - g_1)\hat{n}} \hat{a}^j) \tag{92} \]

and therefore with \( e^{d_0} = 1/\lambda \)

\[ \rho(t) = e^{d_0 + g_0} \sum_{j,k} \frac{d_j^k}{j!k!} (\hat{a}^j \hat{e}^{(d_0 + g_1)\hat{n}} \hat{a}^k \hat{e}^{g_2 A} \hat{e}^{g_3 A^\dagger} \hat{e}^{g_4 A} \hat{e}^{g_5 A^\dagger} \hat{e}^{f} \hat{e}^{(d_0 - g_1)\hat{n}} \hat{a}^j) \]

\[ \times \left( \sum_k \frac{d_k^j}{k!} \hat{a}^k \hat{e}^{g_2 A} \hat{e}^{g_3 A^\dagger} \hat{e}^{g_4 A} \hat{e}^{g_5 A^\dagger} \hat{e}^{f} \hat{e}^{(d_0 - g_1)\hat{n}} \hat{a}^j \right) \tag{93} \]

or, inserting the \( g_j \) from eq. (78) and using the Baker-Hausdorff formula [6], we have

\[ e^{g_2 A} e^{g_3 A^\dagger} \hat{\rho}(0) e^{g_4 A} e^{g_5 A^\dagger} = e^{-g^* \hat{a}} e^{g \hat{a}^\dagger} \hat{\rho}(0) e^{g \hat{a}^\dagger} e^{-g^* \hat{a}} \]

\[ = e^{-|g|^2} e^{-g^* \hat{a} + g \hat{a}^\dagger} \hat{\rho}(0) e^{g^* \hat{a} - g \hat{a}^\dagger} \tag{94} \]

and obtain finally the general solution

\[ \hat{\rho}(t) = \frac{d}{\lambda} \sum_j \frac{d_j^i}{j!} (\hat{a}^i \hat{e}^{(-\omega t - \log \lambda)\hat{n}}) \left( \sum_k \frac{d_k^j}{k!} \hat{a}^k \hat{\rho}_0 (t) \hat{a}^j \right) \hat{e}^{(\omega t - \log \lambda)\hat{n}} \hat{a}^i \tag{95} \]
with \( \delta(t) = g_0(t) - |g(t)|^2 \) and

\[
\hat{\rho}_0^{(f)}(t) = \hat{D}(g(t))\hat{\rho}(0)\hat{D}^\dagger(g(t)),
\]

(96)

where \( \hat{D}(g) = e^{g\hat{a} - g^*\hat{a}} \) is the displacement operator (10). Note that this equation closely resembles the general density operator (89) for the force-free system. The only difference is the normalization factor \( e^0 \) and the replacement of \( \hat{\rho}(0) \) by \( \hat{\rho}_0^{(f)}(t) \), which describes an initial state displaced in phase space. One should furthermore note that \( \hat{\rho}(t) \) is Hermitian if \( \hat{\rho}(0) \) is, and that eq. (95) simplifies for special choices of the initial distribution similar as in the force-free case (2,3).

The final density operator (95) depends on the parameters \( \lambda(t) \) and \( d_{\pm}(t) \), which are given in eqs. (60), (59), just as for the force-free system. The force \( f(t) \) enters only via the parameters

\[
g(t) = i \int_0^t f(t') e^{(\gamma + i\omega)t'} \, dt',
\]

(97)

\[
\delta(t) = \gamma t + i \int_0^t f(t')(g^*(t') e^{(\gamma + i\omega)t'} - g(t') e^{(\gamma - i\omega)t'}) \, dt' - |g(t)|^2,
\]

(98)

given in eqs. (76) and (77), where \( c(t) = -f(t) e^{\gamma t} \) defined in (69) has been inserted.

For a harmonic driving \( f(t) = f_0 \cos(\Omega t) \) the integrals above can be evaluated in closed form as

\[
g(t) = \frac{f_0}{2} \left( \frac{e^{(i\omega + i\Omega + \gamma)t} - 1}{\omega + \Omega - i\gamma} + \frac{e^{(i\omega - i\Omega + \gamma)t} - 1}{\omega - \Omega - i\gamma} \right),
\]

(99)

\[
\delta(t) = \gamma t + \text{real} \left( J(t) \right) - |g(t)|^2
\]

(100)

with

\[
J(t) = f_0^2 \left( \frac{e^{2(\gamma - i\Omega)t} - 1}{(\gamma + i\omega - i\Omega)(\gamma - i\Omega)} + \frac{e^{2(\gamma + i\Omega)t} - 1}{(\gamma + i\omega + i\Omega)(\gamma + i\Omega)} \right.
\]

\[
- \frac{4(\omega - i\gamma)}{(\omega - i\gamma)^2 - \Omega^2} \left( i \left( e^{2\gamma t} - 1 \right) + \frac{2}{f_0} g^*(t) \right) \right).
\]

(101)

We will close with a brief look at the density (95) in the long time limit in order to extract the limit cycle distribution from this general solution. We
observe, that in this limit the dynamics ‘forgets’ the initial state so that we will, for simplicity, assume $\hat{\rho}(0) = |0\rangle\langle 0|$, which leads to

$$\hat{\rho}(t) = \hat{D}(g(t))|0\rangle\langle 0|\hat{D}^\dagger(g(t)) = |g(t)\rangle\langle g(t)|.$$ (102)

For such a coherent state distribution formula (95) simplifies considerably with the result

$$\hat{\rho}(t) = (1 - d_+) e^{\log d_-} e^{-2\gamma t} e^{-\log d_+ (g(t)e^{-(\gamma + i\omega)t}\hat{a}^\dagger + g^* (t)e^{-(\gamma - i\omega)t}\hat{a} - \hat{n})}$$ (103)

(see eq. (4.3) in [2] or eq. (24) in [3]). For long times we have $d_+ \to \nu/\mu$ and $g(t) \to e^{(\gamma + i\omega)t} \alpha(t)$ and therefore

$$\hat{\rho}(t) = \frac{2\pi}{\mu} e^{\log \frac{\nu}{\mu}} (|\alpha(t)|^2 + \hat{n} - \alpha(t)\hat{a}^\dagger - \alpha^*(t)\hat{a})$$ (104)

in agreement with formula (12) in the introduction.
