COUNTING FINITE-DIMENSIONAL ALGEBRAS OVER FINITE FIELDS

NIKOLAAS D. VERHULST

Abstract. In this paper, we describe an elementary method for counting the number of non-isomorphic algebras of a fixed dimension over a given finite field. We show how this method works for the explicit example of 2-dimensional algebras over the field \( F_2 \).

Introduction

Classifying finite dimensional algebras over a given field is usually a very hard problem. The first general result was a classification of 2-dimensional algebras over the base field \( \mathbb{R} \), which appeared in 1992 (\cite{1}). This was generalised by Petersson (\cite{3}), who managed to give a full classification of 2-dimensional algebras over an arbitrary base field. The methods employed in these papers are quite involved and rely on a large amount of previous work by many illustrious authors.

Our aim in this paper is to give perhaps not a classification but at least a way to compute the exact number of non-isomorphic \( n \)-dimensional algebras over a fixed finite field by elementary means. Indeed, nothing more complicated than linear algebra and some very basic results about group actions will be needed: we describe isomorphism classes of \( n \)-dimensional \( K \)-algebras as orbits of a certain \( \text{GL}_n(K) \)-action on \( \text{Mat}_n(K)^n \) and use a basic result about group actions to count these orbits. In the last section, we work out a concrete example.

1. Notation and basics

Fix a field \( K \). In this article, an algebra is understood to be a \( K \)-vector space \( A \) equipped with a multiplication, i.e. a bilinear map \( A \times A \rightarrow A \). If \( a, b \) are in \( K \), we will write \( ab \) for the image of \( (a, b) \) under this map. We do not assume algebras to have a unit or to be associative. By the dimension of an algebra we mean its dimension as a \( K \)-vector space. Two algebras \( A \) and \( A' \) will be called isomorphic if there exists a \( K \)-linear bijection \( f : A \rightarrow A' \) with \( f(ab) = f(a)f(b) \) for all \( a, b \) in \( A \). The isomorphism class of an algebra \( A \) will be denoted by \([A]\). For \( n \in \mathbb{N} \), we define \( \text{Alg}_n(K) \) to be the set of isomorphism classes of \( n \)-dimensional algebras.

Given a vector \( \mathcal{M} = (M_i)_{i=1,\ldots,n} \) of \( n \times n \)-matrices over \( K \), we can define an algebra \( \text{alg}(\mathcal{M}) \) which is \( K^n \) as a \( K \)-vector space and for which multiplication is defined to be the unique bilinear map \( K^n \times K^n \rightarrow K^n \) with

\[
e_i e_j = \sum_k (M_i)_{jk} e_k
\]

where the \( e_i \) are the canonical basis vectors of \( K^n \). Intuitively, this means that multiplying an element \( a \in A \) with \( e_i \) is multiplying the coordinate vector of \( a \) (with respect to the canonical basis) with \( M_i \) and interpreting the result again as a coordinate vector (with respect to the canonical basis). This allows us to define the map

\[
\text{alg} : \text{Mat}_n(K)^n \rightarrow \text{Alg}_n(K), \mathcal{M} \mapsto [\text{alg}(\mathcal{M})]
\]

which will play an important role in this paper.
Proposition 1.1. The map \( \text{alg} \) defined above is surjective.

Proof. Let \( A \) be an \( n \)-dimensional algebra with basis \( a_1, \ldots, a_n \). There are \( \alpha_{ij,k} \) in \( K \) such that \( a_i a_j = \sum_k \alpha_{ij,k} a_k \) for all \( 1 \leq i, j \leq n \). Define the matrix \( M_i \) by putting \( (M_i)_{jk} = \alpha_{ij,k} \) and set \( \mathcal{M} = (M_i)_{i=1,\ldots,n} \in \text{Mat}_n(K)^n \). There is a unique linear map \( \text{alg}(\mathcal{M}) \to A, e_i \mapsto a_i \) which is clearly bijective and which, by construction, preserves multiplication. Hence \( [A] = [\text{alg}(\mathcal{M})] \). \qed

On the other hand, \( \text{alg} \) is clearly not injective, since for any \( \mathcal{M} = (M_i)_{i=1,\ldots,n} \) and \( \alpha \in K^* \), for example, we have \( [\text{alg}(\mathcal{M})] = [\text{alg}(\alpha \mathcal{M})] \).

2. A group action on \( \text{Mat}_n(K)^n \)

Recall that for a given set \( X \) and a group \( G \) with neutral element \( e \), a (right) \( G \)-action on \( X \) is a map \( \phi : X \times G \to X \) such that

1. \( \phi(x, e) = x \) for any \( x \in X \),
2. \( \phi(x, g') = \phi(x, g)g' \) for all \( g, g' \in G, x \in X \).

If \( \phi \) is a \( G \)-action on \( X \), then the \( \phi \)-orbit of an element \( x \in X \) is the set \( G(x) = \{ \phi(x, g) \mid g \in G \} \). The set of orbits is denoted by \( X/G \). The fixpoints of a \( g \in G \) are the elements of \( X^g = \{ x \in X \mid \phi(x, g) = x \} \).

Lemma 2.1. The map

\[
\phi : \text{Mat}_n(K)^n \times \text{GL}_n(K) \to \text{Mat}_n(K)^n, \quad \left( \begin{bmatrix} M_1 \\ \vdots \\ M_n \end{bmatrix}, G \right) \mapsto \begin{bmatrix} G^{-1} \sum_i G_{i1} M_i G \\ \vdots \\ G^{-1} \sum_i G_{in} M_i G \end{bmatrix}
\]

is a \( \text{GL}_n(K) \)-action on \( \text{Mat}_n(K)^n \).

Proof. It is clear that \( \phi(M, \mathbb{I}_n) = M \) for all \( M \in \text{Mat}_n(K)^n \). Take \( \mathcal{M} = (M_i)_{i=1,\ldots,n} \in \text{Mat}_n(K)^n \) and \( G, G' \in \text{GL}_n(K) \). We have to show \( \phi(M, GG') = \phi(\phi(M, G), G') \). The term on the right is

\[
\phi \left( \begin{bmatrix} G^{-1} \sum_i G_{i1} M_i G \\ \vdots \\ G^{-1} \sum_i G_{in} M_i G \end{bmatrix}, G' \right)
\]

which is the term on the left. \qed

Lemma 2.2. Two elements \( \mathcal{M}, \mathcal{M}' \) of \( \text{Mat}_n(K)^n \) are in the same \( \phi \)-orbit if and only if \( \text{alg}(\mathcal{M}) \) and \( \text{alg}(\mathcal{M}') \) are isomorphic.

Proof. Assume \( \text{alg}(\mathcal{M}) \) and \( \text{alg}(\mathcal{M}') \) to be isomorphic for some \( \mathcal{M} = (M_i)_{i=1,\ldots,n} \) and \( \mathcal{M}' = (M'_i)_{i=1,\ldots,n} \) in \( \text{Mat}_n(K)^n \). Take an isomorphism \( f : \text{alg}(\mathcal{M}) \to \text{alg}(\mathcal{M}') \). Since \( \text{alg}(\mathcal{M}) \) and \( \text{alg}(\mathcal{M}') \), considered as \( K \)-vector spaces, are just \( K^n \), there must be a \( G \in \text{GL}_n(K) \) such that \( f(x) = Gx \) for all \( x \in \text{alg}(\mathcal{M}') \). As \( f \) is an isomorphism, we find

\[
G \sum_i x_i M_i y = f(xy) = Gx \cdot Gy = \sum_i \left( \sum_j G_{ij} x_j M'_i \right) G_{ij} y
\]

for arbitrary \( x, y \in \text{alg}(\mathcal{M}') \). In particular, if \( x = e_i \), we find \( GM_i y = \sum_i G_{ij} M'_i Gy \) for all \( y \), so \( M_i = G^{-1} \sum_i G_{ij} M'_i G \) showing \( \phi(\mathcal{M}', G) = \mathcal{M} \).
Suppose now that, for given $\mathcal{M}$ and $\mathcal{M}'$ in $\text{Mat}_n(K)^n$, there is some $G \in \text{GL}_n(K)$ with $\phi(\mathcal{M}', G) = \mathcal{M}$. $G$ induces a function $f : K^n \to K^n, x \mapsto Gx$ which is bijective as $G$ is invertible. To prove that $f$ is an isomorphism between $\text{alg}(\mathcal{M})$ and $\text{alg}(\mathcal{M}')$, it suffices to show $f(e_i e_j) = f(e_i) f(e_j)$ for all $i, j$ since $f$ is linear. We find
\[
f(e_i) f(e_j) = (Ge_i)(Ge_j) = \left(\sum_k G_{ki} M_k G\right) e_j = GG^{-1} \left(\sum_k G_{ki} M_k G\right) e_j = GM_i e_j = f(e_i e_j),
\]
the penultimate equality following from $\phi(\mathcal{M}', G) = \mathcal{M}$. □

3. Counting orbits

From now on, we assume $K$ to be a finite field with $q$ elements. As a consequence of proposition 2.2, we find that $\text{alg}$ induces a well-defined, injective map $\text{alg} : \text{Mat}_n(K)^n / \text{GL}_n(K) \to \text{Alg}_q(K), G(\mathcal{M}) \mapsto [\text{alg}(\mathcal{M})]$ which is also surjective by [1.1]. The number of isomorphism classes of $n$-dimensional $K$-algebras therefore equals the number of $\phi$-orbits of $\text{Mat}_n(K)^n$. The following well-known result result from the theory of group actions will help us count the latter:

**Proposition 3.1** (Burnside’s lemma). Suppose $\phi$ is an action of a finite group $G$ on a finite set $X$. Then
\[
|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|.
\]

*Proof.* Cfr. e.g. [5], p.58. □

To use this lemma, we need to know the number of fixpoints of a given invertible matrix $M$. For that, we need the following definition:

**Definition 3.2.** For a matrix $M \in \text{Mat}_{k,l}(K)$, the *vectorisation* of $M$ is the vector $\text{vec}(M) \in K^{kl}$ obtained by stacking the columns of $M$, the first column being on top. For an element $\mathcal{M} = (M_i)_{i=1,...,n} \in \text{Mat}_n(K)^n$, we write $\text{Vec}(\mathcal{M})$ for the single vector consisting of the vectorisations of all the $M_i$. For more on the vectorisation operation, we refer to [2].

**Lemma 3.3.** For an invertible matrix $M$, we have
\[
|X^M| = q^{\dim \text{Eig}_1(M^T \otimes M^T \otimes M^{-1})}
\]
where $\text{Eig}_1(A)$ denotes the eigenspace of the matrix $A$ with eigenvalue 1.

*Proof.* Suppose $N = (N_i)_{i=1,...,n}$ is a fixpoint of $M$, i.e.
\[
N_j = M^{-1} \sum_i M_{ij} N_i M \quad \text{for all } l.
\]

It is known (see e.g. [2]) that, for arbitrary $A, B$ in $\text{Mat}_n(K)$, $M^{-1} A M = B$ is equivalent to $\text{vec}(B) = (M^T \otimes M^{-1}) \text{vec}(A)$. From this, we conclude:

$\text{Vec}(M^{-1} N_i M)_{i=1,...,n} = (\mathbb{1}_n \otimes M^T \otimes M^{-1}) \text{Vec}(N)$.

We have furthermore that $\text{Vec}(\sum_i M_{ij} O_i)_{i=1,...,n} = (M^T \otimes \mathbb{1}_n \otimes \mathbb{1}_n) \text{Vec}(O)$ for any $O = (O_i)_{i=1,...,n} \in \text{Mat}_n(K)^n$. Consequently, [1] is equivalent to
\[
\text{Vec}(N) = (M^T \otimes \mathbb{1}_n \otimes \mathbb{1}_n) (\mathbb{1}_n \otimes M^T \otimes M^{-1}) \text{Vec}(N)
\]

$= (M^T \otimes M^T \otimes M^{-1}) \text{Vec}(N),
$
so \( N \) is a fixpoint of \( M \) if and only if \( \text{Vec}(N) \) is an eigenvector of \( M^T \otimes M^T \otimes M^{-1} \) with eigenvalue 1.

\[ \square \]

**Theorem 3.4.** The number of non-isomorphic \( n \)-dimensional \( K \)-algebras is

\[
[\text{Alg}_n(K)] = \frac{1}{|\text{GL}_n(K)|} \sum_{M \in \text{GL}_n(K)} q^{\dim \text{Eig}_1(M^T \otimes M^T \otimes M^{-1})}.
\]

**Proof.** By lemma 2.2 the number of non-isomorphic \( n \)-dimensional \( k \)-algebras is the number of \( \phi \)-orbits. By 3.1 and 3.3 this is equal to the given formula. \( \square \)

Note that, for any invertible \( M \), we have

\[ \dim \text{Eig}_1(M^T \otimes M^T \otimes M^{-1}) \leq n^3 \]

and that equality holds precisely when \( M = \mathbb{1}_n \). This gives an obvious lower bound on the number of non-isomorphic \( n \)-dimensional algebras over the field with \( q \) elements:

\[ q^{n^3} \frac{1}{(q^n - 1) \cdots (q^n - q^{n-1})}. \]

For a fixed \( n \), this bound will become sharp as \( q \) tends to infinity.

4. **Example: the case \( n = 2, q = 2 \)**

Any element of \( \text{GL}_2(K) \) has, counting multiplicities, two eigenvalues in the algebraic closure of \( K \). Clearly, either both or none are elements of \( K \) which makes counting invertible matrices with eigenvalues in \( K \) considerably easier. Indeed, the only possible Jordan normal forms for a \( 2 \times 2 \) matrix are

\[
J_1 = \begin{bmatrix} \alpha & 0 \\ 0 & \beta \end{bmatrix} \quad \text{and} \quad J_2 = \begin{bmatrix} \alpha & 1 \\ 0 & \alpha \end{bmatrix}
\]

for some \( \alpha, \beta \) in the algebraic closure of \( K \). Since \( M = SJS^{-1}, M' = S'J'S'^{-1} \) implies \( M \otimes M' = (S \otimes S')(J \otimes J')(S^{-1} \otimes S'^{-1}) \) and since the Jordan normal form of \( M \) is also the Jordan normal form of \( M^T \), it follows that every \( M^T \otimes M^T \otimes M^{-1} \) must be conjugate either to

\[
M_{\alpha, \beta} = \begin{bmatrix}
\alpha & \alpha \\
\alpha & \alpha^2 \beta^{-1} \\
\alpha^2 \beta^{-1} & \alpha^{-1} \beta^2 \\
\alpha^{-1} \beta^2 & \beta \\
\end{bmatrix}
\]

or to

\[
N_{\alpha} = \begin{bmatrix}
\alpha & -1 & 1 & -\alpha^{-1} & 1 & -\alpha^{-1} & \alpha^{-1} & -\alpha^{-2} \\
\alpha & 1 & 1 & -\alpha^{-1} & -\alpha^{-1} \\
\alpha & -1 & 1 & 1 & -\alpha^{-1} & -\alpha^{-1} \\
\alpha & 1 & 1 & -\alpha^{-1} & -\alpha^{-1} \\
\alpha & -1 & 1 & -\alpha^{-1} & -\alpha^{-1} \\
\alpha & 1 & 1 & -\alpha^{-1} & -\alpha^{-1} \\
\end{bmatrix}
\]

for some \( \alpha, \beta \in \overline{K} \). Note that \( \dim \text{Eig}_1(N_1) = 3 \) unless the characteristic of \( K \) is 2, in which case \( \dim \text{Eig}_1(N_1) = 4 \). If \( \alpha \neq 1 \), we obviously have \( \dim \text{Eig}_1(N_\alpha) = 0 \).
For $M_{\alpha,\beta}$, the dimension of the eigenspace associated to 1 depends heavily on $\alpha$ and $\beta$, ranging from 8 if $\alpha = \beta = 1$ to 0 if $1 \notin \{\alpha, \beta, \alpha^2 \beta^{-1}, \alpha^{-1} \beta^2\}$.

We will do the computations explicitly for the concrete example of $K = \mathbb{F}_2$. There are 6 invertible matrices, namely

\[ I_2, \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}. \]

The identity obviously yields a contribution of $2^8$. The next three are conjugate to $J_2$ with $\alpha = 1$, therefore yielding a contribution of $2^4$ each. The last two have no eigenvalues over $K$. Their eigenvalues are the roots $t_1, t_2$ of the polynomial $x^2 + x + 1$. As these roots satisfy $t_2^2 = t_2, t_2^2 = t_1$, both matrices give a contribution of $2^2$. This gives a total of $2^8 + 3 \cdot 2^4 + 2 \cdot 2^2 = 312$ which divided by the total number of invertible matrices gives $312/6 = 52$. This number fits the formulae which were obtained, using completely different methods, by Petersson and Scherer in [4].

5. Outlook

Theorem 3.4 suggest the following question: how many invertible $n \times n$-matrices $M$ have

$$\dim \text{Eig}(M^T \otimes M^T \otimes M^{-1}, 1) = k$$

for a given $k \in \mathbb{N}$? If $q$ and $n$ are fixed, this is a finite problem and can therefore be calculated, but this is rather tedious and time-consuming. Having a closed formula in $q$ and $n$ would be nice.

On the algebraic side, it would be interesting to see whether the method described in this paper can also be used to count certain subclasses of algebras, like alternating algebras, associative algebras, or division algebras.
