Extended Mean Field Games with Singular Controls

Guanxing Fu∗

September 11, 2019

Abstract

This paper establishes the existence of equilibrium result of a class of mean field games with singular controls, which arise in optimal portfolio liquidation and optimal exploitation of exhaustible resource. The interaction is through both states and controls. A relaxed solution approach is used. We prove the existence of equilibria by first considering the corresponding mean field games with continuous controls instead of singular controls and then taking approximation.

AMS Subject Classification: 93E20, 91B70, 60H30.

Keywords: mean field game, singular control, relaxed control, Skorokhod $M_1$ topology.

1 Introduction

Mean field games (MFGs) with singular controls were introduced in [20], in which we consider general MFGs with singular controls and establish the existence of equilibria result by a probabilistic approach. Analytically, [24] and [25] characterized the equilibria of MFGs with singular controls of bounded velocity and mean field fuel follower games in infinite horizon, respectively. By now, all results on MFGs with singular controls are based on models with the interaction through states and there is no result on MFGs with singular controls under strategic interaction, to the best of our knowledge. In this paper, motivated by optimal portfolio liquidation and optimal exploitation of exhaustible resource (see Section 2) we consider the following MFGs with singular controls

1. For fixed probability measures $\mu := (\mu^{(1)}, \mu^{(2)}, \mu^{(3)})$ in some suitable space solve the optimization problem: minimize $J(u, Z^{(1)}, Z^{(2)}; \mu)$ such that

$$dX_t^{(i)} = b^{(i)}(t, X_t^{(i)}) dt + d(\kappa^{(i)} Z_t^{(i)} + \eta^{(i)} Z_t^{(i)}) + \sigma^{(i)}(t)dW_t^i, \quad i = 1, 2$$

and

$$dX_t^{(3)} = b^{(3)}(t, X_t^{(3)}, u_t) dt + \alpha^{(1)} dZ_t^{(1)} - \alpha^{(2)} dZ_t^{(2)} + l(t, u_t)\tilde{N}(dt).$$

2. Search for the fixed point $\mu = (L(Z^{(1)}), L(Z^{(2)}), L(X^{(3)}))$ where $Z^{(1)}$, $Z^{(2)}$ and $X^{(3)}$ are the optimal control and state from 2,
where

\[ J(u, Z^{(1)}, Z^{(2)}) = \mathbb{E} \left[ \int_0^T h(X^{(1)}_s) \cdot d(\kappa^{(1)}_s\mu^{(1)}_s + \eta^{(1)}_s Z^{(1)}_s)^c + \sum_{0 \leq t \leq T} \int_0^{\Delta X^{(1)}_t} h(x) + x \, dx \right. \]

\[ + \int_0^T h(X^{(2)}_s) \cdot d(\kappa^{(2)}_s\mu^{(2)}_s + \eta^{(2)}_s Z^{(2)}_s)^c + \sum_{0 \leq t \leq T} \int_0^{\Delta X^{(2)}_t} h(x) + x \, dx \]

\[ + \int_0^T f(t, X^{(1)}_t, X^{(2)}_t, X^{(3)}_t, \mu_t, u_t) \, dt + g(X^{(1)}_T, X^{(2)}_T, X^{(3)}_T) \right]. \tag{1.2} \]

In (1.1) and (1.2), \( \tilde{N} \) is a compensated Poisson process and \( W^{(1)} \) and \( W^{(2)} \) are two Brownian motions defined on some probability space. \( u \) is the regular (absolutely continuous) control and \( Z^{(1)} \) and \( Z^{(2)} \) are singular controls, whose trajectories are non-decreasing. \( \Delta X_t \) is the jump of \( X \) at \( t \). \( \mu^{(i)} \) is the first moment of \( \mu^{(i)} \), \( i = 1, 2 \) and \( L(\cdot) \) is the law of \( \cdot \).

Differently from standard MFGs as introduced in [31] and [27], where the interaction is only through the control, the interaction of MFG (1.1) is not only through states \( X^{(1)} \), \( X^{(2)} \) and \( X^{(3)} \), but also through singular controls \( Z^{(1)} \) and \( Z^{(2)} \). Strictly speaking, our MFG (1.1) belongs to extended MFGs; see [11] for results based on probabilistic and analytical approaches, respectively. We apply the relaxed solution method (probabilistic compactification method) \(^1\) to establish the existence of equilibrium result.

The application of the relaxed solution method in MFGs stems from [29]. Later it is used to prove existence of equilibria for MFGs with common noise [10], MFGs with singular controls [20], MFGs with controlled jumps [4], MFGs with absorption [7, 8], MFGs with finite states [14] among others. The idea of this method is first establishing the upper hemi-continuity of the representative agent’s best response correspondence to a given \( \mu \) using Berge’s maximum theorem, and then to apply the Kakutani-Fan-Glicksberg fixed point theorem in order to establish the existence of some measure-valued process \( \mu^* \) such that the law of the agents state or strategy process under a best response to \( \mu^* \) coincides with that process; for details, one can refer to the lecture note [30].

In addition to [20], the work highly related to the current paper is [4] since our state \( X^{(3)} \) in (1.1) is a reminiscence of MFGs with controlled jumps. However, the existence of singular control makes the problem essentially different from [4]. In particular, Skorokhod \( J_1 \) topology used in [4] does not work for (1.1). Motivated by [20] (one dimensional case) and [22] (multidimensional case), the suitable topology is Skorokhod \( M_1 \) topology. Bacially speaking, there are two \( M_1 \) topologies, the strong one and the weak one. They coincide with each other for one dimensional paths, which are the usual objectives in the literature; see [3] among others. For multidimensional paths weak \( M_1 \) has an advantage over the strong \( M_1 \) since the oscillation function for weak \( M_1 \) is always 0 for monotone paths; see [2] among others. So in this paper, by \( M_1 \) topology we always mean weak \( M_1 \) topology unless otherwise stated. For the detailed definition and properties of weak \( M_1 \) topology, one could refer to the book [34, Chapter 12]; see also the recent interesting work [16, Section 3] for a summary.

Due to the regularity of singular controls, the relaxed solution method, which might not work for extended MFGs with regular controls, still works for (1.1). Consequently, the states in (1.1) are allowed to be degenerate. The property of degeneracy is important in applications like optimal liquidation; see Section 2. The difficulty comes from the possible simultaneous jumps of two singular controls and the Poisson process in different directions. The Skorokhod space endowed with \( M_1 \) topology is not a vector space in the sense that if \( x_n \to x \) and \( y_n \to y \) in \( M_1 \), it is not necessarily true that \( x^n + y^n \to x + y \) in \( M_1 \). One

\(^1\)The relaxed solution method we apply is in the sense of [29], which is different from [6].
possible condition to make it true is $x$ and $y$ do not admit simultaneous jumps in different directions, i.e., $\Delta x t \Delta y t \geq 0$. Thus, the jumps in different directions of singular controls and the Poisson integral make it difficult to implement convergence and relative compactness arguments under $M_1$ topology. To circumvent this difficulty, we take a two-step strategy: in step 1, instead of considering $Z^{(1)}$ and $Z^{(2)}$ we consider their continuous counterparts $k \int_{-1/k}^{1/k} Z^{(1)}_s ds$ and $k \int_{-1/k}^{1/k} Z^{(2)}_s ds$. The resulting MFG indexed by $k$ admits only one jump resource, which is the Poisson process. Although in this step Skorokhod $J_1$ topology works as well, we prefer to proceed with $M_1$ topology because the same argument will be frequently used in step 2, in which we show the sequence of equilibria indexed by $k$ from step 1 helps construct an equilibrium of (1.1) by approximation. The approximation from step 1 to step 2 holds only under $M_1$ but not $J_1$ topology as $M_1$ topology allows convergence of unmatched jumps. Note that the approximant $k \int_{-1/k}^{1/k} Z_s ds$ was also used in [20], where we want to establish a relationship between MFG with singular controls and MFG with regular controls. In [20], we assume processes do not admit jumps at the terminal time $T$. In the current paper we drop this assumption by considering a slightly different MFG on a possibly larger horizon in step 1 and assume the coefficients to be trivially extended to this larger horizon in step 2.

The rest of the paper is organized as follows: we introduce two motivating examples in Section 2. In Section 3 we introduce the model setup and our two main results: the existence of equilibrium result of (1.1) with finite fuel constraint and the existence of equilibrium result of (1.1) with general singular controls but in one dimension. The proofs of the first and the second main results are given in Section 4 and Section 5 respectively.

2 Motivation

2.1 Optimal Portfolio Liquidation

In classic liquidation models, a large trader would like to unwind her open position by submitting market orders in blocked shape into the order book. Due to the limited liquidity, the large orders would move the order book in an unfavorable direction, making the immediate execution costly. However, slow trading may result in high inventory risk due to the market uncertainty. Thus, the trader needs to make a decision of the trading rate in order to minimize her trading cost (or maximize her net profit). One can refer to [3, 20] among others for liquidation with singular controls. Recently, liquidation models beyond single player especially MFGs of optimal liquidation has drawn a lot of attention; see e.g. [9, 12, 13, 19, 21, 28], the common nature of which is the trading price is influenced not only by the individual trader’s strategy but also by the aggregation of the competitors’ strategies.

So far MFGs of optimal liquidation has only focused on absolutely continuous strategies. In the first example, we introduce a model of optimal portfolio liquidation with singular controls, which is a variant of [20]. Instead of describing the trading price, it is more convenient to consider the spread directly. We assume the buy spread $X^{(1)}$ and the sell spread $X^{(2)}$ of a representative player follow the dynamics

$$X^{(1)}_t = \chi^{(1)}(t) - \int_0^t \rho^{(1)} X^{(1)}_s \, ds + \kappa^{(1)} \nu^{(1)}_t \, + \eta^{(1)} Z^{(1)}_t + \int_0^t \sigma^{(1)}(s) \, dW^{(1)}_s, \quad (2.1)$$

respectively,

$$X^{(2)}_t = \chi^{(2)}(t) - \int_0^t \rho^{(2)} X^{(2)}_s \, ds + \kappa^{(2)} \nu^{(2)}_t + \eta^{(2)} Z^{(2)}_t + \int_0^t \sigma^{(2)}(s) \, dW^{(2)}_s. \quad (2.2)$$

Here, $Z^{(1)}$ and $Z^{(2)}$ are the accumulative market buy and sell orders until time $t$, respectively. $\nu^{(1)}$ and $\nu^{(2)}$ are the aggregated (mean-field) market buy and sell orders of competitors. We assume players trade
different stocks and the aggregation of strategies influences the representative player’s spread through a spillover effect. \( \rho^{(1)} \) and \( \rho^{(2)} \) describe the resilience of the order book. In addition to submitting market orders in the traditional venue, the representative player also submits passive orders into the dark pool, where the execution is uncertain. Thus, the current position \( X^{(3)} \) follows

\[
X_t^{(3)} = y + Z_t^{(1)} - Z_t^{(2)} + \int_0^t u_s \, dN_s,
\]

where \( N \) is a Poisson process, and \( u \) is the net amount of passive orders submitted into the dark pool.

By selling \( Z^{(2)} \) and buying \( Z^{(1)} \) blocked shares of orders, the liquidity cost together with the cost crossing the spread is

\[
\int_0^T \left( X_{s-}^{(1)} + \frac{1}{2} \Delta (\kappa^{(1)} \nu_s^{(1)} + \eta^{(1)} Z_s^{(1)}) \right) \, dZ_s^{(1)} + \int_0^T \left( X_{s-}^{(2)} + \frac{1}{2} \Delta (\kappa^{(2)} \nu_s^{(2)} + \eta^{(2)} Z_s^{(2)}) \right) \, dZ_s^{(2)}.
\]

The cost of spillover effect is

\[
\frac{\kappa^{(1)}}{\eta^{(1)}} \int_0^T \left( X_{s-}^{(1)} + \frac{1}{2} \Delta (\kappa^{(1)} \nu_s^{(1)} + \eta^{(1)} Z_s^{(1)}) \right) \, d\nu_s^{(1)} + \frac{\kappa^{(2)}}{\eta^{(2)}} \int_0^T \left( X_{s-}^{(2)} + \frac{1}{2} \Delta (\kappa^{(2)} \nu_s^{(2)} + \eta^{(2)} Z_s^{(2)}) \right) \, d\nu_s^{(2)}.
\]

The ratio coefficients \( \kappa^{(1)}/\eta^{(1)} \) and \( \kappa^{(2)}/\eta^{(2)} \), coming from the dynamics of the spreads, reflect the weight of influence between the aggregation and the individual strategy. In mathematics, it makes the total cost continuous, where the total (scaled) cost is

\[
\mathbb{E} \left[ \int_0^T \left( X_{s-}^{(1)} + \frac{1}{2} \Delta (\kappa^{(1)} \nu_s^{(1)} + \eta^{(1)} Z_s^{(1)}) \right) \, d(\kappa^{(1)} \nu_s^{(1)} + \eta^{(1)} Z_s^{(1)}) \\
+ \int_0^T \left( X_{s-}^{(2)} + \frac{1}{2} \Delta (\kappa^{(2)} \nu_s^{(2)} + \eta^{(2)} Z_s^{(2)}) \right) \, d(\kappa^{(2)} \nu_s^{(2)} + \eta^{(2)} Z_s^{(2)}) \\
+ \int_0^T \lambda_s (X_s^{(3)})^2 \, ds + \int_0^T \gamma_s u_s \, ds + \int_0^T \lambda \nu_s^2 \, ds + \varrho (X_T^{(3)})^2 \right] \rightarrow \min,
\]

where the quadratic terms \( \int_0^T \lambda_s (X_s^{(3)})^2 \, ds \) and \( \varrho (X_T^{(3)})^2 \) are inventory penalization, the term \( \int_0^T \lambda \nu_s^2 \, ds \) prevents aggressive predation from competitors and the term \( \int_0^T \gamma_s u_s \, ds \) is the cost arising from adverse selection.

### 2.2 Optimal Exploitation of Exhaustible Resources

In the second example, we consider a MFG of optimal exploitation of exhaustive resource. A model with infinite horizon and without game nature was introduced in [18]. We introduce a model among infinite players with mean-field interaction and finite horizon. The problem describes how an energy company determines her exploitation amount optimally in order to maximize her net profit, in face of the competition with a continuum of companies producing similar and alternative energy.

The reservoir of the resource is described as

\[
X_t = x - Z_t,
\]

where \( Z_t \) is the accumulative amount of exploitation until time \( t \). The market price of the resource is determined by three parts: the first part is generated from the market itself and noise traders. It is

\[\text{Note that the coefficient } \lambda \text{ can be price-sensitive so that the quadratic term } \int_0^T \lambda \nu_s^2 \, ds \text{ might not be exogenous.}\]
assumed to be a mean-reverting dynamic. When there is no exploitation activity, the price would recover to the mean level. The second part comes from the company’s sales. Once selling, the company moves the price in an undesirable direction due to the illiquidity of the exhaustible resource. The third part arises from the alternative products. Any exploitation of the alternative resource would make the price of the resource decline. We assume the price impact to be in a linear form. Hence, the actual market price of the resource follows the dynamic

\[ dP_t = (a - bP_t) \, dt + \sigma \, dW_t - \eta \, dZ_t - \kappa \, d\nu_t, \]

(2.3)

where \( \nu \) is the aggregated (mean field) exploitation of the alternative products. This price dynamic can be compared with [15, equation (1)]. The net profit is

\[ \mathbb{E} \left[ \int_0^T P_t \, d(\eta Z_t + \kappa \nu_t) + \sum_{0 \leq t \leq T} \left( P_t - \Delta(\eta Z_t + \kappa \nu_t) - \frac{1}{2} (\Delta(\eta Z_t + \kappa \nu_t))^2 \right) - \int_0^T f(t, X_t, m_t) \, dt \right] \rightarrow \max, \]

(2.4)

where the possibly nonlinear term \( \int_0^T f(t, X_t, m_t) \, dt \) reflects the market uncertainty and \( m \) is the average of the reservoir of alternative products. (2.4) is equivalent to

\[ \mathbb{E} \left[ \int_0^T \mathcal{P}_t \, d(\eta Z_t + \kappa \mu_t) + \sum_{0 \leq t \leq T} \left( \mathcal{P}_t - \Delta(\eta Z_t + \kappa \nu_t) + \frac{1}{2} (\Delta(\eta Z_t + \kappa \nu_t))^2 \right) + \int_0^T f(t, X_t, m_t) \, dt \right] \rightarrow \min, \]

where

\[ d\mathcal{P}_t = (-a - b\mathcal{P}_t) \, dt - \sigma \, dW_t + \eta \, dZ_t + \kappa \, d\nu_t. \]

3 Extended MFGs with Singular Controls

Space and Filtration. Throughout the paper, denote by \( \mathcal{D}([0, T]; \mathbb{R}^d) \) the Skorokhod space of all functions from \([0, T] \) to \( \mathbb{R}^d \) with càdlàg path, by \( \mathcal{C}([0, T]; \mathbb{R}^d) \subset \mathcal{D}([0, T]; \mathbb{R}^d) \) the subset of all continuous functions and by \( \mathcal{A}^\infty([0, T]; \mathbb{R}^d) \subset \mathcal{D}([0, T]; \mathbb{R}^d) \) the subset of all non-decreasing functions with \( z \leq m \) and \( m \in (0, \infty) \). To incorporate the initial and final jumps of elements in \( \mathcal{D}([0, T]; \mathbb{R}^d) \), we identify trajectories on \([0, T] \) with ones on the whole real line by the following trivially extended space

\[ \tilde{\mathcal{D}}_{0,T}(\mathbb{R}; \mathbb{R}^d) := \{ x \in \mathcal{D}(\mathbb{R}; \mathbb{R}^d) : x_t = 0 \text{ for } t < 0 \text{ and } x_t = x_T \text{ for } t > T \}. \]

Correspondingly, we can define \( \tilde{\mathcal{C}}_{0,T}(\mathbb{R}; \mathbb{R}^d) \) and \( \tilde{\mathcal{A}}^m_{0,T}(\mathbb{R}; \mathbb{R}^d) \). For any metric space \((S, \rho)\), denote by \( \mathcal{M}_+(S; \rho) \) the set of all finite non-negative measures on \( S \) and by \( \mathcal{P}(S; \rho) \subset \mathcal{M}_+(S; \rho) \) the set of all probability measures on \( S \) and by \( \mathcal{P}_p(S; \rho) \) the subset of probability measures with finite \( p \)-th moment. When the metric \( \rho \) is clear from the context, we write \( \mathcal{P}(S) \) and \( \mathcal{P}(S) \) for short. Denote by \( \mathcal{U}([0, T] \times U) \subset \mathcal{M}_+(\mathbb{R}; \mathcal{X} \times U) \) the set of all measures on \([0, T] \times U\) with the first marginal Lebesgue measure on \([0, T]\) and the second marginal a probability measure on \( U \), where \( U \) is some metric space. Similarly, we identify \( \mathcal{U}([0, T] \times U) \) with \( \tilde{\mathcal{U}}_{0,T}(\mathbb{R} \times U) \), where

\[ \tilde{\mathcal{U}}_{0,T}(\mathbb{R} \times U) = \{ q \in \mathcal{U}(\mathbb{R} \times U) : 1_{(-\infty, 0]} q = \delta_{u_0}(du) dt \text{ and } 1_{(T, \infty)} q = \delta_{u_T}(du) dt \} \]

for some fixed \( u_0, u_T \in U \). Each element \( q \in \tilde{\mathcal{U}}_{0,T}(\mathbb{R} \times U) \) admits the disintegration \( q(dt, du) = q_t(du) dt \). When there is no confusion, we write \( \tilde{\mathcal{D}}_{0,T}, \tilde{\mathcal{C}}_{0,T}, \tilde{\mathcal{A}}^m_{0,T} \) and \( \tilde{\mathcal{U}}_{0,T} \) for simplicity. As usual, let the canonical space be defined as the product space

\[ \Omega^m := \tilde{\mathcal{D}}_{0,T} \times \tilde{\mathcal{D}}_{0,T} \times \tilde{\mathcal{D}}_{0,T} \times \tilde{\mathcal{U}}_{0,T} \times \tilde{\mathcal{A}}^m_{0,T} \times \tilde{\mathcal{A}}^m_{0,T} \]

(3.1)
and let \((X^{(1)}, X^{(2)}, X^{(3)}, Q, Z^{(1)}, Z^{(2)})\) be the coordinate processes on \(\Omega^m\), i.e.,

\[
X^{(1)}(\omega) = x^{(1)}, \quad X^{(2)}(\omega) = x^{(2)}, \quad X^{(3)}(\omega) = x^{(3)}, \quad Q(\omega) = q, \quad Z^{(1)} = z^{(1)}, \quad Z^{(2)} = z^{(2)}
\]

for each \(\omega = (x^{(1)}, x^{(2)}, x^{(3)}, q, z^{(1)}, z^{(2)}) \in \Omega^m\). Note that by [29 Lemma 3.2] (see also [20 Section 2.1.2]) \(Q\) can be identified by an predictable disintegration in the following sense

\[
Q(dt, du) = Q_t(du)dt.
\]

The space \(\Omega^m\) is equipped with the product \(\sigma\)-algebra \(\mathcal{F}_t = \mathcal{F}^{X^{(1)}_t} \times \mathcal{F}^{X^{(2)}_t} \times \mathcal{F}^{X^{(3)}_t} \times \mathcal{F}^{Z^{(1)}_t} \times \mathcal{F}^{Z^{(2)}_t}\), where \(\mathcal{F}^{X^{(i)}_t}\) is the \(\sigma\)-algebra generated by the \(\Pi\) system \(\{\{x \in \tilde{D}_{0,T} : (x_{t_1}, \ldots, x_{t_n}) \in A_1 \times \cdots \times A_n\} : t_1 \leq \cdots \leq t_n \leq t, A_j \in \mathcal{B}(\mathbb{R}^d), n \in \mathbb{N}\}\). \(\mathcal{F}^{Z^{(1)}_t}\) and \(\mathcal{F}^{Z^{(2)}_t}\) are the \(\sigma\)-algebras generated by the \(\Pi\) system \(\{\{z \in \tilde{A}^{m}_{0,T} : (z_{t_1}, \ldots, z_{t_n}) \in A_1 \times \cdots \times A_n\} : t_1 \leq \cdots \leq t_n \leq t, A_j \in \mathcal{B}(\mathbb{R}^d), n \in \mathbb{N}\}\). For \(\nu \in \mathcal{P}_p(\tilde{D}_{0,T})\), \(\mathcal{P}_p(\tilde{A}^{m}_{0,T})\) are Polish when endowed with the \(M_1\) topology, and \((\mathcal{P}_p(S), \mathcal{W}_{p,(S,\nu)})\) is Polish as well if \((S, \nu)\) is Polish. Endowed with the following metric induced by Wasserstein metric \(\mathcal{W}_{p,(S,\nu)}\), the spaces \(\tilde{D}_{0,T}\) and \(\tilde{A}^{m}_{0,T}\) are Polish:

\[
\mathcal{W}_{p,[0,T] \times U}(q_1, q_2) = \mathcal{W}_{p,[0,T] \times U}(q_1, q_2) + \sum_{n=0}^{\infty} \frac{1}{(n+1)!} \mathcal{W}_{p,[T+n,T+n+1] \times U}(q_1, q_2).
\]

If there is no confusion about the space we will write \(\tilde{W}_p\) for simplicity.

**Convention.** We use the convention that \(C\) is a generic constant which may vary from line to line. For a stochastic process \(X\) by \(X \in \tilde{D}_{0,T}\) we mean \(X(\omega) \in \tilde{D}_{0,T}\) a.s.; other analogous notation can be understood in the same way. For simplicity of notation, from now on unless otherwise stated, whenever we mention \(W, \mu, Z\) and \(X\), we mean \((W^{(1)}, W^{(2)}), (\mu^{(1)}, \mu^{(2)}), (Z^{(1)}, Z^{(2)}), (X^{(1)}, X^{(2)}, X^{(3)})\) respectively; the same convention holds for other variants of \((W, \mu, Z, X)\) like \((\tilde{W}, \tilde{\mu}, \tilde{Z}, \tilde{X}), (W^k, \mu^k, Z^k, X^k)\) etc. Moreover, for each \(\nu \in \mathcal{P}_p(\tilde{D}_{0,T})\), put \(\nu_t = \nu \circ \pi_t^{-1}\), where \(\pi_t : x \in \tilde{D}_{0,T} \rightarrow x_t\) and \(\nabla := \int x \nu(dx)\). As usual, for stochastic processes we make the time-argument a subscript while for the coefficients the time argument is in the parentheses. Finally, when \(m = \infty\), we write \(\Omega^\infty, \tilde{A}^{\infty}_{0,T}\) and \(\mathcal{R}^\infty\) as \(\Omega, \tilde{A}_{0,T}\) and \(\mathcal{R}\) for simplicity.

**Definition 3.1.** A probability measure \(P\) is called a relaxed control with respect to \(\mu \in \mathcal{P}_p(\tilde{A}^{m}_{0,T}) \times \mathcal{P}_p(\tilde{A}^{m}_{0,T}) \times \mathcal{P}_p(\tilde{D}_{0,T})\) if

1. \((X, Q, Z)\) are coordinate processes on the canonical space \(\Omega^m\);
2. there exists an adapted process \(Y \in \tilde{D}_{0,T}\) such that
   
   \[ P(Y = X^{(3)} - \alpha^{(1)} Z^{(1)} + \alpha^{(2)} Z^{(2)} = 1, \]

   \[ 2. \text{ } \mathcal{M}^{\phi, X^{(1)}_t, Z^{(1)}_t, \nu^{(1)}} \text{ and } \mathcal{M}^{\phi, X^{(2)}_t, Z^{(2)}_t, \nu^{(2)}} \text{ are continuous } P \text{ martingales, for each } \phi \in C^2_p(\mathbb{R}^d; \mathbb{R}), \]

   \[ 3. \text{ } \mathcal{M}^{\phi, X^{(3)}_t, Y_t, Q} \text{ is } P \text{ martingale with càdlàg path, for each } \phi \in C^2_p(\mathbb{R}^d; \mathbb{R}), \]

where

- \(C^2_p(\mathbb{R}^d; \mathbb{R})\) is the space of all continuous and bounded functions from \(\mathbb{R}^d\) to \(\mathbb{R}\) with continuous and bounded first- and second-order derivatives,
• for $t \in [0, T]$

$$
\mathcal{M}_t^{\phi, X^{(i)}, Z^{(i)}, \mu^{(i)}} := \phi(X_t^{(i)}) - \int_0^t \mathbb{L}^{(i)}(s, X_s^{(i)}) ds - \int_0^t \nabla \phi(X_s^{(i)}) \cdot d(\kappa^{(i)} \nu_s^{(i)} + \eta^{(i)} Z_s^{(i)}) - \sum_{0 \leq s \leq t} (\phi(X_s) - \phi(X_{s-}) - \nabla \phi(X_{s-}) \cdot \Delta X_s), \ i = 1, 2,
$$

with $\mathbb{L}^{(i)}(s, x) = b^{(i)}(x, s) \cdot \nabla \phi(x) + \frac{1}{2} Tr(a^{(i)}(s) \Delta \phi(x))$, $a^{(i)} = \sigma^{(i)}(\sigma^{(i)})^T$, $i = 1, 2$,

• and for $t \in [0, T]$

$$
\mathcal{M}_t^{\phi, X^{(3)}, Y, \mu} := \phi(Y_t) - \int_0^t \int_U \mathcal{L}(s, X_s^{(3)}, Y_{s-}, u) Q_s(du) ds,
$$

with $\mathcal{L}(s, x, y, u) := \nabla \phi(y) \cdot b^{(3)}(x, s, u) + (\phi(y + l(s, u)) - \phi(y) - \nabla \phi(y) \cdot l(s, u)) \lambda_s$.

Remark 3.2. (1) In [20], the probability measure $\mathbb{P}$ on canonical space is called a control rule. Here we do not distinguish control rule and relaxed control since there is no confusion.

(2) The definition of relaxed controls (control rules) is different from [20]. The current definition can avoid considering the simultaneous jumps of singular controls and the Poisson process in the definition of $\mathcal{M}^{\phi, X^{(3)}, Y, \mu}$. Definition 3.1 is linked to the weak solution of SDEs given by the following proposition. The proof is the same as [4, Lemma 2.1].

Proposition 3.3. The probability measure $\mathbb{P}$ on $\Omega^m$ is a relaxed control if and only if there is an extension of $(\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P}), (\bar{\Omega}, \mathcal{F}, \mathbb{F}, \mathbb{P})$, on which a tuple of adapted stochastic processes $(X, Z, \mu, \mathbb{Q}, W, \mathbb{N})$ is defined such that

$$
dX_t^{(i)} = b^{(i)}(t, X_t^{(i)}) dt + d\left(\eta^{(i)} Z_t^{(i)} + \kappa^{(i)} \mu_t^{(i)}\right) + \sigma^{(i)}(t) dW_t^{(i)}, \ i = 1, 2,
$$

and

$$
dX_t^{(3)} = \int_U b^{(3)}(t, X_t^{(3)}, u) \mathcal{Q}(dt, du) + \alpha^{(1)}(t) dZ_t^{(1)} - \alpha^{(2)}(t) dZ_t^{(2)} + \int_U l(t, u) \mathbb{N}(dt, du),
$$

where $W^{(1)}$ and $W^{(2)}$ are two Brownian motions, and $\mathbb{N}$ is a compensated Poisson random measure with intensity $\lambda \mathbb{Q}(dt, du)$. Moreover, two tuples are related by $\mathbb{P} \circ (X, \mathbb{Q}, Z)^{-1} = \mathbb{P} \circ (X, \mathbb{Q}, Z)^{-1}$.

For each fixed measure $\mu \in \mathcal{P}_{p}(\mathcal{A}_{0,T}^m) \times \mathcal{P}_{p}(\mathcal{A}_{0,T}^m) \times \mathcal{P}_{p}(\mathcal{O}_{0,T})$, the corresponding set of relaxed controls is denoted by $\mathcal{R}^m(\mu)$, the cost functional corresponding to a relaxed control $\mathbb{P} \in \mathcal{R}^m(\mu)$ is

$$
J(\mathbb{P}; \mu) = \mathbb{E}^\mathbb{P} \left[ \int_0^T h(X_t^{(1)}) \cdot d(\kappa^{(1)} \nu_s^{(1)} + \eta^{(1)} Z_s^{(1)}) + \sum_{0 \leq t \leq T} \int_0^{\Delta X_t^{(1)}} h(X_t^{-} + x) dx \\
+ \int_0^T h(X_t^{(2)}) \cdot d(\kappa^{(2)} \nu_s^{(2)} + \eta^{(2)} Z_s^{(2)}) + \sum_{0 \leq t \leq T} \int_0^{\Delta X_t^{(2)}} h(X_t^{-} + x) dx \\
+ \int_0^T f(t, X_t, \mu_t, u_t) dt + g(X_T) \right]
$$

and the (possibly empty) set of optimal relaxed controls is denoted by

$$
\mathcal{R}^{m,*}(\mu) := \arg\inf_{\mathbb{P} \in \mathcal{R}^m(\mu)} J(\mathbb{P}; \mu).
$$

If a probability measure $\mathbb{P}$ satisfies the fixed point property

$$
\mathbb{P} \in \mathcal{R}^{m,*} \left(\mathbb{P} \circ (Z^{(1)})^{-1}, \mathbb{P} \circ (Z^{(2)})^{-1}, \mathbb{P} \circ (X^{(3)})^{-1}\right),
$$

then
then we call $\mathbb{P}$ or the associated tuple $(\Omega^m, \mathcal{F}, \mathcal{F}_t, \mathbb{P}, X, Q, Z)$ a relaxed solution to the MFG with singular controls (1.1). Moreover, if $\mathbb{P} \in \mathcal{R}^{m^*,} \mathbb{P} = (Z^{(1)})^{-1}, \mathbb{P} \circ (Z^{(2)})^{-1}, \mathbb{P} \circ (X^{(3)})^{-1}$ and $\mathbb{P}(Q(dt, du)) = \delta_{\bar{u}_t}(du)\mathbb{P}(dt) = 1$ for some progressively measurable process $\bar{u}$, then we call $\mathbb{P}$ or the associated tuple $(\Omega^m, \mathcal{F}, \mathcal{F}_t, \mathbb{P}, X, \bar{u}, Z)$ a strict solution.

To guarantee the existence of a relaxed solution to (1.1), we make the following assumptions.

$A_1$. The $\mathbb{R}^d$ valued functions $b^{(1)}$, $b^{(2)}$ and $b^{(3)}$ are measurable in $t \in [0, T]$ and there exists a positive constant $C_1$ such that $\|b^{(1)}(t, x)\| + \|b^{(2)}(t, x)\| + \|b^{(3)}(t, x, u)\| \leq C_1(1 + \|x\|)$ and $\|b^{(1)}(t, x) - b^{(1)}(t, y)\| + \|b^{(2)}(t, x) - b^{(2)}(t, y)\| + \|b^{(3)}(t, x, u) - b^{(3)}(t, y, u)\| \leq C_1\|x - y\|$, for any $(t, x, y, u) \in [0, T] \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d$. Moreover, $b^{(3)}$ is continuous in $u$.

$A_2$. The function $f$ is measurable in $t \in [0, T]$ and are continuous with respect to $(x, \nu, u) \in \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d) \times U$. $g$ is continuous in $x \in \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d$. $h(y) := (h_1(y_1), \ldots, h_d(y_d))$ for each $y \in \mathbb{R}^d$ and each $h_i \in C^1(\mathbb{R})$, the space of continuous functions on $\mathbb{R}$ with continuous derivatives.

$A_3$. For $\bar{p} > p \geq 1$, there exist a positive constant $C_2$ such that for each $(t, x, y, \nu, u) \in [0, T] \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d) \times U$

$$|h_i(y)| + |h'_i(y)| \leq C_2 (1 + \|y\|^p), \quad i = 1, \ldots, d,$$

$$|g(x)| \leq C_2 (1 + \|x\|^\bar{p}),$$

and

$$|f(t, x, \nu, u)| \leq C_2 (1 + \|x\|^\bar{p} + \|u\|_U + W_{\nu}^p(\nu, \delta_0)).$$

$A_4$. $(\alpha^{(1)}, \alpha^{(2)}, \kappa^{(1)}, \kappa^{(2)}, \eta^{(1)}, \eta^{(2)}) \in \mathbb{R}^6$. $(\sigma^{(1)}, \sigma^{(2)}) : [0, T] \rightarrow \mathbb{R}^{d \times d} \times \mathbb{R}^{d \times d}$ are bounded and measurable. Denote $a^{(1)} = \sigma^{(1)}(\alpha^{(1)})^T$ and $a^{(2)} = \sigma^{(2)}(\alpha^{(2)})^T$. $\lambda : [0, T] \rightarrow (0, \infty)$ are measurable and bounded. $l$ is a bounded and measurable functions on $[0, T] \times U$ and continuous in $u$. Moreover, $\kappa^{(i)} \eta^{(i)} \geq 0$, $i = 1, 2$.

$A_5$. The functions $f$ is locally Lipschitz continuous with $\mu$ uniformly in $(t, x, u)$, i.e., there exists $C_3 > 0$ such that for each $(t, x, u) \in [0, T] \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \times U$ and $\nu^1, \nu^2 \in \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d) \times \mathbb{P}_p(\mathbb{R}^d)$ there holds

$$|f(t, x, \nu^1, u) - f(t, x, \nu^2, u)| \leq C_3 \left(1 + L(W_{\nu}(\nu^1, \delta_0), W_{\nu}(\nu^2, \delta_0))\right) W_{\nu}(\nu^1, \nu^2),$$

where $L(W_{\nu}(\nu^1, \delta_0), W_{\nu}(\nu^2, \delta_0))$ is locally bounded with $W_{\nu}(\nu^1, \delta_0)$ and $W_{\nu}(\nu^2, \delta_0)$.

$A_6$. $U$ is a compact metrizable space.

The following two theorems are our two main results. The proofs of them are given in Section 4 and Section 5 respectively.

**Theorem 3.4** (Existence with finite fuel constraint). Under assumptions $A_1$-$A_6$, there exists a relaxed solution to MFGs with singular controls (1.1) for each $0 < m < \infty$.

**Theorem 3.5** (Existence with general singular controls in one dimensional space). In addition to assumptions $A_1$-$A_4$ and $A_4$-$A_6$, we assume the following assumption $A_7$ holds instead of $A_3$.

$A_7$. The dimension index $d = 1$ and $\eta^{(1)} \eta^{(2)} \neq 0$. Moreover, there exists a positive constant $C_4$ such that
for each \( x \in \mathbb{R} \), the following coercive conditions hold

\[
\begin{align*}
-C_4(1 - |y|^p) & \leq h(y) \leq C_4(1 + |y|^p) \\
-C_4(1 - |x|^{p+1}) & \leq -h(x)\bar{b}^{(i)}(t, x) \leq C_4(1 + |x|^{p+1}), \quad i = 1, 2 \\
-C_4(1 - |x|^{p+1}) & \leq g(x) \leq C_4(1 + |x|^{p+1}) \\
-C_4(1 - \|x\|^{p+1}) & \leq f(t, x, \nu, u) \leq C_2 \left( 1 + \|x\|^{p+1} + |u|_U^{p+1} + \mathcal{W}_p^{p+1}(\nu, \delta_0) \right).
\end{align*}
\]

Then there exists a relaxed solution to (1.1) when \( m = \infty \).

Remark 3.6. (1) A typical example satisfying assumptions \( A_1-A_7 \) is the example in Section 2.1. Note that the example in Section 2.2 does not satisfy \( \eta^{(1)} \neq 0 \). But as we can see, all the proofs in Section 4 and Section 5 applied directly to the second example, where there is only one singular control.

(2) By [20, Remark 2.8], additional convexity assumption implies that a strict solution of MFG can be constructed from a relaxed solution.

(3) In Theorem 3.4 and Theorem 3.5 we consider all processes starting from 0 for simplicity. The extension to general and different initial values is straightforward. Other extensions like mean field dependent terminal cost \( g(X_T, \mu_T) \) could be considered as well. We do not aim at giving minimal assumptions under which our result is true.

4 Existence of Equilibria with Finite Fuel Constraint

In this whole section (Section 2.1 and 2.2), we prove the existence of a relaxed solution to MFGs under a finite fuel constraint. That is, unless stated otherwise in this section, we restrict the set of admissible singular controls to the set

\[
\tilde{A}_{0,T}^m := \{ z \in \tilde{A}_{0,T} : \|z_T\| \leq m \}, \tag{4.1}
\]

for some \( m \in (0, \infty) \). By [33, Theorem 12.12.2], the set \( \tilde{A}_{0,T}^m \) is \((\tilde{D}_{0,T}, M_1)\) compact.

As mentioned in the introduction, due to the possible simultaneous jumps of \( Z^{(1)} \), \( Z^{(2)} \) and the Poisson process, it is difficult to show the tightness of \( X^{(3)} \). We circumvent the difficulty by splitting the proof of Theorem 4.4 into two parts. In Section 4.1 we prove the existence of equilibria to our MFG by smoothing the singular controls \( Z^{(1)} \) and \( Z^{(2)} \). Thus, the tightness of \( X^{(3)} \) can be obtained in Section 4.1. The general case is considered in Section 4.2 using an approximation argument. Note that the tightness of \( X^{(3)} \) is necessary in Section 4.1 while we do not need it in Section 4.2.

Precisely, in Section 4.1 instead of singular control \( Z \) we consider its continuous counterpart \( Z_t^{[k]} := k \int_{t-1/k}^t Z_s \, ds \). Since \( T+1 \) is definitely a continuous point of \( Z^{(i)} \), by [34, Theorem 12.9.3(ii)], it holds that

\[
Z^{(i),[k]} \to Z^{(i)} \text{ in } (\tilde{A}_{0,T+1}, M_1), \quad i = 1, 2. \tag{4.2}
\]

The convergence in (4.2) is not necessarily in \((\tilde{A}_{0,T}^m, M_1)\) since \( T \) might be a discontinuous time point of \( Z^{(i)} \). So in Section 4.1 the canonical space is chosen as

\[
\Omega^{m,\alpha} := \tilde{D}_{0,T+1} \times \tilde{D}_{0,T+1} \times \tilde{D}_{0,T+1} \times \tilde{U}_0,T \times \tilde{A}_{0,T}^m \times \tilde{A}_{0,T}^m.
\]

Let \( X^o \) be the coordinate projection onto \( \tilde{D}_{0,T+1} \times \tilde{D}_{0,T+1} \times \tilde{D}_{0,T+1} \times \tilde{U}_0,T \times \tilde{A}_{0,T}^m \times \tilde{A}_{0,T}^m \). Correspondingly, we extend the time-domain of coefficients from \([0, T]\) to \([0, T+1]\), i.e., there exists \( \gamma = (\bar{b}^{(1)}, \bar{b}^{(2)}, \bar{b}^{(3)}, \bar{c}^{(1)}, \bar{c}^{(2)}, \bar{\lambda}, \bar{\tilde{t}}) \) satisfying the same assumptions as \( A_1-A_6 \) with \([0, T]\) replaced by \([0, T+1]\) such that

\[
\gamma(t, \cdot) = \gamma(t, \cdot), \quad \text{on } t \in [0, T], \tag{4.3}
\]
where \( \gamma = b^{(1)}, b^{(2)}, b^{(3)}, \sigma^{(1)}, \sigma^{(2)}, \lambda, I \). In Section 3.1, we work with \( \tilde{\gamma} \). But for simplicity, we use the notation \( \gamma \) instead of \( \tilde{\gamma} \). Moreover, in Section 4.1, we consider terminal cost \( g(X^T_{T+1}) \) instead of \( g(X_T) \); see Section 4.1 for details.

In order to make MFG in Section 4.1 converge to the original MFG (1.1), in Section 4.2 we make a further assumption that the coefficients are trivially extended from \([0, T]\) to \([0, T+1]\), i.e.,

\[
\tilde{\gamma}(t, \cdot) = \begin{cases} 
\gamma(t, \cdot), & \text{if } t \in [0, T] \\
0, & \text{elsewhere,}
\end{cases}
\] (4.4)

Again, for the simplicity of notation, we identify \( \tilde{\gamma} \) with \( \gamma \). The trivial extension (4.4) requires the time dependence of coefficients but it does not lose the generality; see Remark 4.13.

### 4.1 Existence of Equilibria with \( Z^{[k]} \)

In this part, we replace \( Z \) by \( Z^{[k]} \). Due to the continuity of \( Z^{[k]} \), the corresponding MFG and the definition of relaxed controls become less complicated. More precisely, we consider the following MFGs

1. For fixed \( \mu \in \mathcal{P}_p(A^{m,c}_{0,T+1}) \times \mathcal{P}_p(A^{m,c}_{0,T+1}) \times \mathcal{P}_p(D_{0,T+1}) \), solve the optimization problem:
   
   \[
   \min \mathbb{E} \left[ \int_0^{T+1} h(X^{(1)}_s) \cdot d(k^{(1)}_s \bar{\mu}^{(1)}_s + \eta^{(1)}_s Z^{(1),[k]}_s) \\
   + \int_0^{T+1} h(X^{(2)}_s) \cdot d(k^{(2)}_s \bar{\mu}^{(2)}_s + \eta^{(2)}_s Z^{(2),[k]}_s) + \int_0^T f(t, X_t, \mu_t, u_t) \, dt + g(X_{T+1}) \right]
   \] (4.5)

   such that

   \[
   X^{(i)}_t = \int_0^t b^{(i)}(s, X^{(i)}_s) \, ds + k^{(i)}_s \bar{\mu}^{(i)}_s + \eta^{(i)}_s Z^{(i),[k]}_s + \int_0^t \sigma^{(i)}_s \, dW^s, \quad i = 1, 2
   \]

   and

   \[
   X^{(3)}_t = \int_0^t b^{(3)}(s, X^{(3)}_s, u_s) \, ds + \alpha^{(1)}_s Z^{(1),[k]}_t - \alpha^{(2)}_s Z^{(2),[k]}_t + \int_0^t l(s, u_s) \tilde{N}(ds),
   \]

   for \( t \in [0, T+1] \);

2. search for fixed points \( \mu = (\mathbb{P} \circ (Z^{(1),[k]})^{-1}, \mathbb{P} \circ (Z^{(2),[k]})^{-1}, \mathbb{P} \circ (X^{(3)})^{-1}) \),

   where \( Z \) and \( X \) are the optimal control and state from 2.

Here \( \tilde{A}^{m,c}_{0,T+1} \) is the set of all elements in \( A^{m,c}_{0,T+1} \) with continuous trajectories. Denote by \( \mathcal{R}^{m,[k]}(\mu) \) and \( \mathcal{R}^{m,[k] \ast}(\mu) \) the set of all relaxed controls and optimal relaxed controls corresponding to (4.5), respectively and \( \mathbb{P} \in \mathcal{R}^{m,[k]}(\mu) \) if and only if it is a probability measure supported on \( \Omega^{m,c} \) and it satisfies Definition 3.1 with Item 2, modified as Item 2’:

2’. there exists an adapted process \( Y \in \tilde{D}_{0,T+1} \) such that

1) \( \mathbb{P} \left( Y = X^{(3)} - \alpha^{(1)}_r Z^{(1),[k]} + \alpha^{(2)}_r Z^{(2),[k]} \right) = 1, \)

   and for each \( \phi \in C^0_b(\mathbb{R}^d; \mathbb{R}) \)

2) \( \left( M^{\phi, X^{(1)}, Z^{(1)}, \mu^{(1)}}, 0 \leq t \leq T+1 \right) \) and \( \left( M^{\phi, X^{(2)}, Z^{(2)}, \mu^{(2)}}, 0 \leq t \leq T+1 \right) \) are continuous \( \mathbb{P} \) martingale,

3) \( \left( M^{\phi, X^{(0)}, Y, \mathbb{Q}}, 0 \leq t \leq T+1 \right) \) is a \( \mathbb{P} \) martingale with càdlàg path,
where for \( t \in [0, T + 1] \) and for \( i = 1, 2 \)
\[
\mathcal{M}^i, X^{o,(i)}, Z^{j,(i)}, u^{(i)}, k := \phi(X_t^{o,(i)}) - \int_0^t L_t^{(i)} \phi(s, X_s^{o,(i)}) \, ds - \int_0^t \nabla \phi(s, X_s^{o,(i)}) \cdot d(K^{(i)}_t)_{p_s} + \eta^{(i)}(Z_s^{i,[k]}),
\]
(4.6)
and
\[
\mathcal{M}^i, X^{o,(i)}, Y, Q := \phi(Y_t) - \int_0^t \int_U \mathcal{L}(s, X_s^{o,(i)}, Y_s, u) \, Q_s(du) \, ds.
\]
(4.7)

The cost functional corresponding to \( \mathbb{P} \in \mathcal{R}^{m,[k]}(\mu) \) is defined as
\[
\mathcal{J}^0(\mathbb{P}; \mu) = \mathbb{E}^\mathbb{P} \left[ \int_0^{T+1} h(X_s^{o,(1)}) \cdot d(K^{(1)}_s)_{p_s} + \eta^{(1)}(Z_s^{1,[k]}) + \int_0^{T+1} h(X_s^{o,(2)}) \cdot d(K^{(2)}_s)_{p_s} + \eta^{(2)}(Z_s^{2,[k]}) \right.
\]
\[
+ \int_0^T \int_U f(t, X_t^o, \mu_t, u) \, Q_t(du) \, dt + g(X_T^o) \right].
\]

Remark 4.1. By the continuity of \( Z^{[n]} \), the result in the current section (Section 4.1) holds with \( J_1 \) topology. But in Section 4.2 from \( Z^{[n]} \) to \( Z \), only \( M_1 \) topology works and \( J_1 \) topology does not work any more. Moreover, the argument with \( M_1 \) topology in Section 4.1 will be also used in Section 4.2 and Section 5. So in Section 4.3 the analysis is still based on \( M_1 \) topology. Moreover, we notice that it is unnecessary to extend the integral horizon of \( f \) in (4.5).

In the current section, we prove the existence of equilibria for (4.5) for each fixed \( k \). The following result shows that the class of all possible relaxed controls is relatively compact. In a subsequent step this will allow us to apply Berge’s maximum theorem.

**Lemma 4.2.** Under assumptions \( A_1, A_4 \) and \( A_6 \), the set \( \bigcup_{\mu \in \mathcal{P}_p(\hat{\mathcal{A}}_{0,T+1}^m) \times \mathcal{P}_p(\hat{\mathcal{A}}_{0,T+1}^c) \times \mathcal{P}_p(\bar{\mathcal{D}}_{0,T+1})} \mathcal{R}^{m,[k]}(\mu) \) is relatively compact in \( \mathcal{W}_p \), for each fixed \( k \).

**Proof.** Let \( \{\mu^n\}_{n \geq 1} \) be any sequence in \( \mathcal{P}_p(\hat{\mathcal{A}}_{0,T+1}^m) \times \mathcal{P}_p(\hat{\mathcal{A}}_{0,T+1}^c) \times \mathcal{P}_p(\bar{\mathcal{D}}_{0,T+1}) \) and \( \mathbb{P}^n \in \mathcal{R}^{[k]}(\mu^n), n \geq 1 \).

Since \( U \) and \( \mathcal{A}_{0,T}^m \) are compact by assumption and [34] Theorem 12.12.2, respectively, \( \{\mathbb{P}^n \circ (\hat{X}^{(i)})^{-1}\}_{n \geq 1} \) and \( \{\mathbb{P}^n \circ (Z^{(i)})^{-1}\}_{n \geq 1} \) are tight, \( i = 1, 2 \). Since \( \mathcal{X}_{0,T} \) and \( \mathcal{A}_{0,T}^m \) are compact, these sequences are relatively compact in the topology induced by Wasserstein metric; see [33] Definition 6.8(3)].

It remains to prove the relative compactness of \( \{\mathbb{P}^n \circ (\hat{X}^{(i)})^{-1}\}_{n \geq 1} \) for \( i = 1, 2, 3 \). Since \( \mathbb{P}^n \in \mathcal{R}([k])(\mu^n) \), it follows from Proposition [34] that there exist extensions \( (\mathcal{X}^n, \mathcal{F}^n, \bar{\mathcal{F}}^n, \mathcal{Q}^n) \) of the canonical path space \( \mathcal{X}_0^o \) and processes \( (X^n, Z^n, Q^n, W^n, N^n) \) defined on it, such that for \( t \in [0, T + 1] \)
\[
dX^{(i),n}_t = b^{(i)}(t, X^{(i),n}_t) \, dt + d(K^{(i)}_t)_{p_t} + \eta^{(i)}(Z^{(i),n,[k]}_t) + \sigma^{(i)}(t) \, dW^{(i),n}_t, \quad i = 1, 2,
\]
and
\[
dX^{(3),n}_t = \int_U b^{(3)}(t, X^{(3),n}_t, u) \, Q_t^u(du) \, dt + d(K^{(3)}_t)_{p_t} + \alpha^{(1)}(t) \, dZ^{(1),n,[k]}_t - \alpha^{(2)}(t) \, dZ^{(2),n,[k]}_t + \int_U l(t, u) \, \bar{N}_n(du, dt) \quad (4.8)
\]
and
\[
\mathbb{P}^n = \mathbb{P}^n \circ (X^n, Q, Z)^{-1} = \mathbb{P}^n \circ (X^n, Q^n, Z^n)^{-1},
\]
where \( Z^{n,[k]}_t = k \int_{t-1/k}^t Z^n_s \, ds \) and \( N^n \) is a Poisson random measure on \( [0, T] \times U \) with intensity \( Q^n_t(du) \lambda_t \, dt \).

Relative compactness of \( \{\mathbb{P}^n \circ (\hat{X}^{(i)})^{-1}\}_{n \geq 1} \) now reduces to relative compactness of \( \{\mathbb{P}^n \circ (X^{(i),n})^{-1}\}_{n \geq 1} \), \( i = 1, 2, 3 \). By assumption \( A_1, A_4 \) and the boundedness of singular controls, we have
\[
\sup_{i=1,2,3} \sup_n \mathbb{E}^{\mathbb{P}^n} \left[ \sup_{0 \leq t \leq T} \|X^{(i),n}_t\|^{\bar{p}} \right] \leq \bar{C}_1 < \infty; \quad (4.9)
\]
Moreover, by the monotonicity of \( \kappa \mathcal{P}^{(i), n} + \eta Z^{(i), n} \), we have for any \( t_1 < t_2 < t_3 \) and for \( i = 1, 2 \) that
\[
\left\| X_{t_2}^{(i), n} - [X_{t_1}, t_3] X_{t_3}^{(i), n} \right\| = \max_{1 \leq j \leq d} \left| X_{t_2}^{(i), n, j} - [X_{t_1}, t_3] X_{t_3}^{(i), n, j} \right|
= \max_{1 \leq j \leq k} \inf_{\lambda \in [0, 1]} \left| X_{t_2}^{(i), n, j} - \lambda X_{t_1}^{(i), n, j} - (1 - \lambda) X_{t_3}^{(i), n, j} \right|
\leq \left\| \int_{t_1}^{t_2} b^{(i)} (t, X_{t}^{(i), n}) dt \right\| + \left\| \int_{t_2}^{t_3} b^{(i)} (t, X_{t}^{(i), n}) dt \right\| + \left\| \int_{t_1}^{t_2} \sigma^{(1)} (s) dW_s \right\| + \left\| \int_{t_2}^{t_3} \sigma^{(2)} (s) dW_s \right\|
\]
which implies the existence of \( K (\delta) \) with \( \lim_{\delta \to 0} K (\delta) = 0 \) such that
\[
\mathbb{Q}^n (\tilde{w} (X^{(i), n}, \delta) \geq \eta) \leq \frac{\mathbb{E}^{\mathbb{Q}^n} [\tilde{w} (X^{(i), n}, \delta)]}{\eta} \leq \frac{k (\delta)}{\eta},
\]
where \( \tilde{w} \) is the extended oscillation function of \( M_1 \) topology; see [20; Appendix B].

Finally, by the linear growth of \( b^{(3)} \), boundedness of \( l \), and compactness of \( U \) and \( \tilde{A}_{0, T} \), and the uniform bound (3.10), it holds that
\[
\sup_n \sup_{\tau} \mathbb{E}^{\mathbb{Q}^n} \| X_{\tau + \delta}^{n, (3)} - X_{\tau}^{n, (3)} \|^2 \leq \bar{C}_2 \delta
\]
where \( \tau \) is the stopping time taking values in \( [0, T] \) and \( \bar{C}_2 \) is independent of \( \mathbb{Q}^n \). Thus, Aldous’ tightness criterion ([5; Theorem 16.10]) implies that tightness of \( \mathbb{Q}^n \circ (X^{(3), n})^{-1} \) in \( J_1 \) topology thus in \( M_1 \) topology.

The next result states that the cost functional is continuous on the graph
\[
\text{Gr} \mathcal{R}^{m, [k]} := \{ (\mu, \mathbb{P}) \in \mathcal{P}_p (\tilde{A}_{0, T + 1}^m) \times \mathcal{P}_p (\tilde{A}_{0, T + 1}^c) \times \mathcal{P}_p (\tilde{A}_{0, T + 1}^c) \times \mathcal{P}_p (\Omega^n) : \mathbb{P} \in \mathcal{R}^{m, [k]} (\mu) \}
\]
of the multi-function \( \mathcal{R} \). This, too, will be needed to apply Berge’s maximum theorem below.

**Lemma 4.3.** Suppose that \( A_1 \cdot A_0 \) hold. Then \( J^a : \text{Gr} \mathcal{R}^{m, [k]} \to \mathbb{R} \) is continuous.

**Proof.** By Lemma 3.3, we have
\[
J^a (\mathbb{P}; \mu) = \mathbb{E}^\mathbb{P} \left[ \int_0^{T + 1} \sum_{j=1}^d h_j (\tilde{X}^{(1)}_{j,t}) d (\kappa^{(1)} \mathcal{P}^{(1)}_{j,t} + \eta^{(1)} Z^{(1)}_{j,t}) + \int_0^{T + 1} \sum_{j=1}^d h_j (\tilde{X}^{(2)}_{j,t}) d (\kappa^{(2)} \mathcal{P}^{(2)}_{j,t} + \eta^{(2)} Z^{(2)}_{j,t}) \right]
+ \int_0^T f (t, \tilde{X}, \mu, u) Q_1 (du) dt + g (\tilde{X}_{T + 1})
\]
where \( (\mathbb{P}, \tilde{X}, \tilde{Z}, \tilde{Q}) \) are defined as in Lemma 3.3 satisfying
\[
\mathbb{P} \circ (X^a, Q, Z)^{-1} = \mathbb{P} \circ (\tilde{X}, \tilde{Q}, \tilde{Z})^{-1}.
\]
Recall \( a^{(i)} = \sigma^{(i)} (\sigma^{(i)})^T \). Itô’s formula yields
\[
\mathbb{E} \left[ \int_0^{T + 1} h_j (\tilde{X}^{(i)}_{j,t}) d \tilde{X}_{j,t}^{(i)} \right] = \mathbb{E} \left[ \int_{X_{j,0}^{(i)}}^{X_{j,T + 1}^{(i)}} h_j (x) dx \right] - \mathbb{E} \left[ \frac{1}{2} \int_0^{T + 1} a_{jj}^{(i)} (t) h_j' (\tilde{X}_{j,t}^{(i)}) dt \right],
\]

12
which together with (4.11) to (4.12) implies that

\[
J^o(\mathbb{P}; \mu) = \mathbb{E}^\mathbb{P} \left[ \sum_{j=1}^d \int_{X^o,j,T+1}^{X^o,j+1} h_j(x) \, dx - \int_0^{T+1} h(X^o,t) \cdot b^1(t, X^o(t)) \, dt - \frac{1}{2} \sum_{j=1}^d \int_0^{T+1} d_{j,j}^{(1)}(t) h_j'(X^o,j,t) \, dt \\
+ \sum_{j=1}^d \int_{X^o,j,T+1}^{X^o,j+1} h_j(x) \, dx - \int_0^{T+1} h(X^o,t) \cdot b^2(t, X^o(t)) \, dt - \frac{1}{2} \sum_{j=1}^d \int_0^{T+1} d_{j,j}^{(2)}(t) h_j'(X^o,j,t) \, dt \\
+ \int_0^T \int f(t, X^o, t, u) Q_t(du) \, dt + g(X^o,T) \right].
\]

Note that \( f \) and \( g \) are have \( \tilde{p} \)-th order growth while \( \mathbb{P}^n \to \mathbb{P} \) in \( \mathcal{W}_p \). So next we prove for any \((\mathbb{P}^n, \mu^n) \in \text{Gr} \mathcal{R}^{m,k} \to (\mathbb{P}, \mu) \in \text{Gr} \mathcal{R}^{m,k} \), it holds that for any \( \bar{p} > p \)

\[
\sup_n \mathbb{E}^\mathbb{P}^n \left[ \|X^n\|_{T+1}^{\bar{p}} \right] < \infty.
\]

Firstly, for \( i = 1, 2, 3 \)

\[
\sup_n \int_{\mathbb{R}^d} \|x\|^p \mu_i^n(dx) \leq \sup_n \int dM_i(x, 0)^p \mu^n(dx) < \infty,
\]

since \( \mu^{(i), n} \to \mu^{(i)} \) in \( \mathcal{W}_p \). Thus, Proposition \[3.3] implies the existence of \( \mathbb{Q}^n, X^n \) and \( Z^n \) such that the following estimate hold for \( i = 1, 2, 3 \) by the assumptions of the coefficients

\[
\mathbb{E}^\mathbb{Q}^n \left[ \sup_{0 \leq s \leq t} \|X^{n,(i)}(s)\|^{\bar{p}} \right] = \mathbb{E}^\mathbb{Q}^n \left[ \sup_{0 \leq s \leq t} \|X^{n}(s)\|^{\bar{p}} \right] \\
\leq C + C \int_0^t \mathbb{E}^\mathbb{Q} \left[ \|X^{n,(i)}(s)\|^{\bar{p}} \right] \, ds + C \mathbb{E}^\mathbb{Q} \left[ \|Z_T^{(i), n}\|^{\bar{p}} \right] + C \int_0^t \|\mu^{(i), n}(s)\|^{\bar{p}} \, ds + \mathbb{E}^\mathbb{P} \left[ \sup_{0 \leq s \leq t} \left| \int_0^s \sigma^{(i)}(s) \, dW_s^{(i)} \right|^{\bar{p}} \right] \\
\leq C + C \int_0^t \mathbb{E}^\mathbb{Q} \left[ \|X^{n,(i)}(s)\|^{\bar{p}} \right] \, ds + Cm^{\bar{p}} + C \int_{\mathbb{D}_0,T+1}^t dM_i(x, 0)^{\mu^{(i), n}(dx)} \, \bar{p} \\
\leq C + Cm^{\bar{p}} + Cm + C \int_0^t \mathbb{E}^\mathbb{Q} \left[ \|X^{n,(i)}(s)\|^{\bar{p}} \right] \, ds.
\]

Grönwall inequality implies

\[
\sup_n \mathbb{E}^\mathbb{Q}^n \left[ \|X^{n,(i)}\|_{T+1}^{\bar{p}} \right] < \infty.
\]

Similarly, we also have

\[
\sup_n \mathbb{E}^\mathbb{Q}^n \left[ \|X^{n,(3)}\|_{T+1}^{\bar{p}} \right] < \infty.
\]

Finally, note that \( x^n \to x \) in \( \mathbb{D}_0,T+1, M_1 \) is equivalent to \( x^n \to x_j \) in \( \mathbb{D}_0,T+1, M_j \) for each \( j = 1, \cdots, d \) by \[34] Theorem 12.5.2. Then the joint continuity can be verified by the same argument in \[20] Lemma 3.3, Step 2].

**Proposition 4.4.** Suppose that \( A_1, A_4 \) and \( A_6 \) hold. For any sequence \( \{\mu^n\}_{n \geq 1} \subseteq \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \) and \( \mu \in \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}_{0,T+1}) \) with \( \mu^n \to \mu \) in \( \mathcal{W}_p(\tilde{A}_{0,T+1}) \times \mathcal{W}_p(\tilde{A}_{0,T+1}) \) if \( \mathbb{P}^n \in \mathcal{R}^{m,k}(\mu^n) \) and \( \mathbb{P}^n \to \mathbb{P} \) in \( \mathcal{W}_{p,T} \), then \( \mathbb{P} \in \mathcal{R}^{m,k}(\mu) \).

**Proof.** In order to verify \( \mathbb{P} \in \mathcal{R}^{m,k}(\mu) \), it is equivalent to check the items in the definition of relaxed controls. Notice first that, for each \( n \), there exists a stochastic process \( Y^n \in \mathbb{D}_0,T+1 \) such that

\[
\mathbb{P}^n \left( X^{(3)} = Y^n + \alpha^{(1)} Z_{(1)} + \alpha^{(2)} Z_{(2)} \right) = 1.
\]
and the corresponding martingale problem is satisfied. By Lemma 3.3, for each \( n \) there exists a probability space \((\Omega^n, \mathcal{F}^n, Q^n)\) that supports random variables \((\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n)\), a Poisson random measure \(N^n\) with intensity \(Q^n_t(du)\lambda_t dt\), and two Brownian motions \(W^{(1),n}\) and \(W^{(2),n}\) such that

\[
\mathbb{P}^n \circ (X^n, Q, Z, Y^n)^{-1} = \mathbb{Q}^n \circ (\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n, \tilde{Y}^n)^{-1},
\]  

(4.13)

where

\[
\left\{
\begin{align*}
\tilde{Y}^n &= \int_0^1 \int \beta(3) (s, \tilde{X}^n_i, n) \tilde{Q}^n_t(du)ds + \int_0^1 \int l(1)(s, u) \tilde{N}^n(du, ds), \\
\tilde{X}^n &= Y^n - \alpha(1)^n d\tilde{Z}^{(1),n,[k]} - \alpha(2)^n d\tilde{Z}^{(2),n,[k]}, \\
\tilde{X}^{(i)} &= \int_0^1 b^{(i)}(s, \tilde{X}^{(i),n}) ds + \kappa^{(i)} \tilde{p}^{(i),n} + \eta^{(i)} \tilde{Z}^{(i),n,[k]} + \int_0^1 \sigma^{(i)}(s) dW^{(i),n}, \quad i = 1, 2.
\end{align*}
\right.
\]

Thus, the relative compactness of \(\tilde{Y}^n\) (thus the relative compactness of \(Y^n\)) follows from the same argument as Lemma 3.2. Therefore, taking a subsequence if necessary, the sequence \((X^n, Q, Z, Y^n)\) of random variables taking values in \(\Omega^{m,o} \times \tilde{D}_{0,T+1}\) has a weak limit \((\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y})\) defined on some probability space. By Skorokhod’s representation theorem, there exists a probability space \((\Omega, \tilde{F}, \tilde{Q})\) that supports random variables \((\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n, \tilde{Y}^n)\) and \((\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y})\) such that

\[
\text{Law}(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n, \tilde{Y}^n) = \text{Law}(X^n, Q, Z, Y^n), \quad \text{Law}(\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y}) = \text{Law}(\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y})
\]

(4.14)

and as elements in the product space \(\Omega^{m,o} \times \tilde{D}_{0,T+1}\)

\[
(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n, \tilde{Y}^n) \rightarrow (\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y}) \quad \tilde{Q}\text{-a.s.}
\]

(4.15)

In particular,

\[
\tilde{Q} \left( \tilde{X}^{(3)} = \tilde{Y} + \alpha(1)^n \tilde{Z}^{(1),n,[k]} - \alpha(2)^n \tilde{Z}^{(2),n,[k]} \right) = 1.
\]

Since \(\mathbb{P}^n \rightarrow \mathbb{P}\), we have \(\mathbb{P} \circ (X^n, Q, Z)^{-1} = \mathbb{Q} \circ (\tilde{X}, \tilde{Q}, \tilde{Z})^{-1}\). Hence, there exists a stochastic process \(Y \in \tilde{D}_{0,T+1}\) such that

\[
\mathbb{P} \left( X^{o,(3)} = Y + \alpha(1)^n \tilde{Z}^{(1),n,[k]} - \alpha(2)^n \tilde{Z}^{(2),n,[k]} \right) = 1,
\]

(4.16)

and

\[
\mathbb{P} \circ (X^n, Q, Z, Y)^{-1} = \mathbb{Q} \circ (\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{Y})^{-1}.
\]

Finally, we verify \(\mathcal{M}_0^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),[k]}\), \(\mathcal{M}_0^{\phi,X^n(2),Z^{(2)}}, \mu^{(2),[k]}\) and \(\mathcal{M}_0^{\phi,X^n(3),Y},Q\) are martingales under \(\mathbb{P}\), where \(\mathcal{M}_0^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),[k]}\), \(\mathcal{M}_0^{\phi,X^n(2),Z^{(2)}}, \mu^{(2),[k]}\) and \(\mathcal{M}_0^{\phi,X^n(3),Y},Q\) are defined in (4.6) and (4.7), respectively. Firstly we verify the martingale property related to (4.6). Note that \(\mu^n \rightarrow \mu\) in \(\mathcal{P}_p(A_{0,T+1}^{m,c}) \times \mathcal{P}_p(A_{0,T+1}^{m,c}) \times \mathcal{P}_p(\tilde{D}_{0,T+1})\) implies

\[
\tilde{p}^{(i)} \rightarrow p^{(i)} \quad \text{in uniform topology}, \quad i = 1, 2.
\]

(4.17)

Thus, we have for any \(s < t\) and any \(F_s\)-measurable continuous and bounded function \(F\) defined on the canonical space \(\Omega^{m,o}\)

\[
0 = \mathbb{E}^{\mathbb{P}} \left( \mathcal{M}_t^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),n,[k]} - \mathcal{M}_s^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),n,[k]} \right) F \quad (\text{since } \mathbb{P} \in \mathcal{R}(\mathbb{R}^{[k]}(\mu^n)))
\]

by (4.6) and

\[
\mathbb{E}^{\mathbb{Q}} \left( \mathcal{M}_t^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),n,[k]} - \mathcal{M}_s^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),n,[k]} \right) F(X^n, \tilde{Q}^n, \tilde{Z}^n)
\]

by (4.16) and (4.17)

\[
\mathbb{E}^{\mathbb{P}} \left( \mathcal{M}_t^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),[k]} - \mathcal{M}_s^{\phi,X^n(1),Z^{(1)}}, \mu^{(1),[k]} \right) F(\tilde{X}, \tilde{Q}, \tilde{Z})
\]

by (4.10)

The same result holds for \(\mathcal{M}_0^{\phi,X^n(2),Z^{(2)}}, \mu^{(2),[k]}\).
Next we check the martingale property of $\mathcal{M}^{\phi,X_n,(3),Y,Q}$. Since $\tilde{Y}^n \to \tilde{Y}$ in $M_{t}$ topology $\tilde{Q}$ a.s., there exists $\tilde{\Omega} \subseteq \tilde{\Omega}$ with full measure such that for each $\tilde{\omega} \in \tilde{\Omega}$, $\tilde{Y}_t^n(\tilde{\omega}) \to \tilde{Y}_t(\tilde{\omega})$ for almost every $t \in [0,T]$, which together with Step 2 in the proof of [20] Lemma 3.3] implies that for each $\tilde{\omega} \in \tilde{\Omega}$ and for each $F$ that is continuous and bounded

$$\lim_{n \to \infty} \int_0^{T+1} \left| M_{t}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q} F(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n) - M_{t}^{\phi,X_n,(3),\tilde{Y},\tilde{Q}} F(\tilde{X}, \tilde{Q}, \tilde{Z}) \right| \, d\tilde{\omega} = 0.$$ 

By the boundedness or linear growth of the coefficients in $\mathcal{M}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n$ and $\mathcal{M}^{\phi,Y_n,(3),\tilde{Y},\tilde{Q}}$, and the boundedness of $F$, we have

$$\lim_{n \to \infty} \mathbb{E}^Q \left[ \int_0^{T+1} \left| M_{t}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n F(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n) - M_{t}^{\phi,X_n,(3),\tilde{Y},\tilde{Q}} F(\tilde{X}, \tilde{Q}, \tilde{Z}) \right| \, dt \right] = 0.$$ 

Thus, up to a subsequence, we have for almost every $t \in [0,T+1]$ that

$$\lim_{n \to \infty} \mathbb{E}^Q \left[ M_{t}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n F(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n) - M_{t}^{\phi,X_n,(3),\tilde{Y},\tilde{Q}} F(\tilde{X}, \tilde{Q}, \tilde{Z}) \right] = 0,$$

which implies that for almost every $s,t \in [0,T+1]$ and $s < t$, and for each $F$ that is continuous, bounded and $\mathcal{F}^s$-measurable

$$0 = \mathbb{E}^P \left[ \left( M_{t}^{\phi,X_n,(3),Y_n,Q} - M_{s}^{\phi,X_n,(3),Y_n,Q} \right) F(X^n, Q,Z) \right] \quad \text{(since } \mathbb{P}^n \in \mathcal{R}^{(k)}(\mu^n))$$

by (4.13) $\mathbb{E}^Q \left[ \left( M_{t}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n - M_{s}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n \right) F(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n) \right] = 0,$

by (4.13) $\mathbb{E}^Q \left[ \left( M_{t}^{\phi,Y_n,(3),\tilde{Y},\tilde{Q}} - M_{s}^{\phi,Y_n,(3),\tilde{Y},\tilde{Q}} \right) F(\tilde{X}, \tilde{Q}, \tilde{Z}) \right]$.

By the right continuity of the trajectory of $\mathcal{M}^{\phi,X_n,(3),Y,Q}$, we have for any $0 \leq s < t < T + 1$

$$\mathbb{E}^P \left[ \left( M_{t}^{\phi,X_n,(3),Y,Q} - M_{s}^{\phi,X_n,(3),Y,Q} \right) F(X^n, Q,Z) \right] = 0.$$ 

When $t = T + 1$, the convergence in (4.18) is still true. Indeed, firstly [20] Lemma 3.3] implies

$$\int_0^{T+1} \int_U \mathcal{L} \phi(s, \tilde{X}^n, u) \tilde{Q}_s^n(du)ds \to \int_0^{T+1} \int_U \mathcal{L} \phi(s, \tilde{X}_s^n, \tilde{Y}_s, u) \tilde{Q}_s(du)ds \quad Q \text{ a.s.}.$$ 

Secondly, $\tilde{Y}^n \to \tilde{Y}$ in $(\tilde{D}_{0,T+1}, M_{t})$ topology $Q$ a.s. implies that

$$\tilde{Y}_{T+1}^n \to \tilde{Y}_{T+1}, \quad Q \text{ a.s.}.$$ 

Thus, by dominated convergence it holds that

$$\mathbb{E}^Q \left[ M_{T+1}^{\phi,X_n,(3),n} \tilde{Y}^n, \tilde{Q}^n F(\tilde{X}^n, \tilde{Q}^n, \tilde{Z}^n) \right] \to \mathbb{E}^Q \left[ M_{T+1}^{\phi,Y_n,(3),\tilde{Y},\tilde{Q}} F(\tilde{X}, \tilde{Q}, \tilde{Z}) \right].$$ 

The next corollary shows that the correspondence $\mathcal{R}^{(k)}$ is continuous in the sense of [1] Definition 17.2, Theorem 17.20, 17.21].

**Corollary 4.5.** Suppose that $A_1$, $A_4$ and $A_6$ hold. Then, $\mathcal{R}^{m,[k]} : \mathcal{P}_P(\tilde{A}_{0,T+1}) \times \mathcal{P}_P(\hat{A}_{0,T+1}) \times \mathcal{P}_P(\tilde{D}_{0,T+1}) \to 2^{\mathcal{P}_P(\Omega^{m})}$ is continuous and compact-valued.
Proof. Lemma 1.2, Proposition 4.4 and [1] Theorem 17.20 imply that \( R^{m,[k]} \) is upper hemi-continuous and compact-valued. The lower hemi-continuity of \( R^{m,[k]} \) can be verified in the same manner as [29] Lemma 4.4.

Corollary 4.6. Under assumptions \( A_1 - A_6 \), \( R^{m,[k],*}(\mu) \neq \emptyset \) for each \( \mu \in \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \) and \( R^{m,[k],*} \) is upper hemi-continuous.

Proof. Note that by assumptions \( A_1 \) and \( A_4 \) for each \( \mu \in \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \) the set \( R^{m,[k]}(\mu) \) is nonempty. Corollary 4.3 implies that \( R^{m,[k]} \) is compact-valued and continuous. By Lemma 4.3 \( J : \text{Gr} R^{k} \to \mathbb{R} \) is jointly continuous. Thus, [1] Theorem 17.31 yields that \( R^{m,[k],*} \) is nonempty valued and upper hemi-continuous.

Theorem 4.7. Under assumptions \( A_1 - A_6 \) and the finite-fuel constraint \( Z \in \tilde{A}^{m,c}_{0,T} \times \tilde{A}^{m,c}_{0,T} \), there exists a relaxed solution to \([4.9]\).

Proof. Let us now define a set-valued map \( \psi \) by

\[
\psi : \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \to \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \times \mathcal{P}_p(\Omega^{m,c}),
\]

\[
\mu \mapsto \left\{ \mathbb{P} \circ (Z(1),[k])^{-1}, \mathbb{P} \circ (Z(2),[k])^{-1}, \mathbb{P} \circ (X^{o,(3)})^{-1} : \mathbb{P} \in R^{m,[k],*}(\mu) \right\},
\]

(4.19)

\( \tilde{A}^{m,c}_{0,T+1} \) is compact if endowed with the uniform topology, which is equivalent to \( M_1 \) in this case. Thus, Let \( S \) be defined as for \( \bar{p} > p \)

\[
S = \left\{ \mathbb{P} \circ (X^{o,(3)})^{-1} \in \mathcal{P}_p(\tilde{D}_{0,T+1}) : \mathbb{P} \in \mathcal{P}_p(\Omega^{m,c}), \text{ for any } X^{(3)} - \text{stopping time } \tau, \mathbb{E}^\mathbb{P}_\tau \| X^{o,(3)}_\tau - X^{s,(3)}_\tau \|^2 \leq C_2 \delta, \mathbb{E}^\mathbb{P}_\tau \| X^{o,(3)}_\tau \|^p_{\bar{p}+1} \leq C_1 \right\},
\]

where \( C_1 \) and \( C_2 \) are the given by [10] and [11], respectively, and a non-negative random variable is called a \( X^{o,(3)} \)-stopping time if \( \{ \tau \leq t \} \in \sigma(X^{o,(3)}_t, s \leq t) \) for each \( t \). By [5] Theorem 16.10, \( S \) is relatively compact.

Clearly, \( \psi \) maps \( \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \times S \) into the power set of itself and \( \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times S \) is non-empty, compact and convex. Moreover, by Corollary 4.6 \( \psi \) is non-empty valued and upper hemi-continuous. Indeed, the non-emptiness is obvious and to check the upper hemi-continuity we take any \( \mu^n \to \mu \) in \( \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times S \), Corollary 4.6 implies the existence of subsequences \( \mathbb{P}^{n_i} \in R^{m,[k],*}(\mu^{n_i}) \) such that \( \mathbb{P}^{n_i} \to \mathbb{P} \in R^{k,*}(\mu) \), which implies \( \mathbb{P}^{n_i} \circ (X^{i})^{-1} \to \mathbb{P} \circ (X^{o,(3)})^{-1} \). Moreover, Skorokhod representation implies the existence of the process \( (Q_i, \mathfrak{F}_i, \mathfrak{F}_i) \) and \( R_{n,i} := (R^{(1)},n_i, R^{(2)},n_i) \) and \( R_{n,i} := (R^{(1)}, R^{(2)}) \) defined on it such that for \( i = 1,2 \) it holds that \( \mathbb{P}^{n_i} \circ (Z^{i})^{-1} = Q \circ (R^{(i),n_i})^{-1}, \mathbb{P} \circ (Z^{i})^{-1} = Q \circ (R^{(i)})^{-1} \) and \( R^{n,i} \to R \) in \( (\tilde{A}^{m,c}_{0,T+1}, M_1) \times (\tilde{A}^{m,c}_{0,T+1}, M_1) \) \( \mathbb{P} \)-a.s., which implies \( R^{n,i} \to R^{[k]} \) in \( (\tilde{A}^{m,c}_{0,T+1}, M_1) \times (\tilde{A}^{m,c}_{0,T+1}, M_1) \) \( \mathbb{Q} \)-a.s. by [34] Theorem 12.5.2(iii)], where \( R^{n,i} = \int_0^t f_{t,1/k} R^{n,i} ds \) and \( R^{n,i} = \int_0^t f_{t,1/k} R^{i} ds \). Since both \( R^{n,i} \) and \( R^{i} \) are continuous, it holds that \( R^{n,i} \to R^{[k]} \) in uniform topology \( \mathbb{Q} \)-a.s. by [34] Theorem 12.5.2(iv)]. Thus, for any continuous function \( \phi \) defined on \( \tilde{A}^{m,c}_{0,T+1} \) with \( |\phi(y)| \leq C(1 + \|y\|^p_{\bar{p}+1}) \), there holds for \( i = 1,2 \) by dominated convergence

\[
\int_{\tilde{A}^{m,c}_{0,T+1}} \phi(y) \mathbb{P}^{n_i} \circ (Z^{i})^{-1} (dy) = \mathbb{E}^{\mathbb{P}^{n_i}} \phi(Z^{i})^{n,i} = \mathbb{E}^{\mathbb{Q}} \phi(R^{(i),n_i})^{[k]}
\]

\[
\to \mathbb{E}^{\mathbb{Q}} \phi(R^{[k]}) = \mathbb{E}^{\mathbb{P}} \phi(Z^{(i)[k]}) = \int_{\tilde{A}^{m,c}_{0,T+1}} \phi(y) \mathbb{P} \circ (Z^{(i)[k]})^{-1} (dy),
\]

which implies the upper hemi-continuity of \( \psi \). Therefore, [1] Corollary 17.55 is applicable by embedding \( \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{A}^{m,c}_{0,T+1}) \times \mathcal{P}_p(\tilde{D}_{0,T+1}) \) into \( \mathcal{M}(\tilde{C}_{0,T+1}) \times \mathcal{M}(\tilde{C}_{0,T+1}) \times \mathcal{M}(\tilde{D}_{0,T+1}) \), the respective product spaces of all bounded signed measures on \( \tilde{C}_{0,T+1} \) and \( \tilde{D}_{0,T+1} \) endowed with weak convergence topology.
4.2 Approximation.

In this section, the extension \(\text{(4.2)}\) is valid throughout. All the limits taken in this section is as \(k \to \infty\).

In Section \(\text{(4.1)}\) we have shown for each fixed \(k\), there is an equilibrium \(\mathbb{P}^m,*,\in \mathcal{R}^m,*,(\mu^m,*,*)\), where \(\mu^m,*:=(\mu^{(1)},m,*,\mu^{(2)},m,*,\mu^{(3)},m,*,\mu^{(4)},m,*)\):=\((\mathbb{P}^m,*)\circ(Z^{(1)},*)^{-1},\mathbb{P}^m,*)\circ(Z^{(2)},*)^{-1},\mathbb{P}^m,*)\circ(X^{(3)},*)^{-1}\). In this section, we establish the existence of equilibria of \(\text{(4.1)}\) by constructing \(\mathbb{P}^m,*,\in \mathcal{R}^m,*,(\mu^m,*)\) with \(\mu^m,*= (\mu^{(1)},m,*,\mu^{(2)},m,*,\mu^{(3)},m,*) = (\mathbb{P}^m,*)\circ(Z^{(1)},*)^{-1},\mathbb{P}^m,*)\circ(Z^{(2)},*)^{-1},\mathbb{P}^m,*)\circ(X^{(3)},*)^{-1}\), from the sequence \((\mathbb{P}^m,*)_k\).

By Proposition \(\text{(4.3)}\) \(\mathbb{P}^m,*,(\mu^m,*)\) implies the existence of \((\hat{\Omega}_k,\hat{\mathcal{F}}_k,\hat{\mathbb{P}}^k)\) and \((\hat{X}_k,\hat{Q}_k,\hat{Z}_k,\hat{W}_k,\hat{V}_k)\) such that

\[
\hat{X}^{(i),k}_t = \int_0^t b^{(i)}(s,\hat{X}^{(i),k}_s)ds + \kappa^{(i)}(s,\hat{\mu}^{(i)},m,*) + \eta^{(i)}(s,\hat{\mathcal{Z}}^{(i),k}_s) + \int_0^t \sigma^{(i)}(s,\hat{W}^{(i),k}_s), \quad t \in [0,T+1], \quad i = 1,2, \tag{4.20}
\]

\[
\hat{X}^{(3),k}_t = \int_0^t \int_U b^{(3)}(s,\hat{X}^{(3),k}_s,u)\hat{Q}^k(s,du)ds + \int_0^t l(s,u)\hat{N}^k(ds,du) + \alpha^{(1)}(s,\hat{\mathcal{Z}}^{(1),k}_s) - \alpha^{(2)}(s,\hat{\mathcal{Z}}^{(2),k}_s), \quad t \in [0,T+1]
\]

and

\[
\hat{\mathbb{P}}^k \circ (\hat{X}_k,\hat{Q}_k,\hat{Z}_k)^{-1} = \mathbb{P}^m,*,(X^{(1)}_*,Q,Z)^{-1}. \tag{4.21}
\]

Let

\[
\hat{Y}^{(k)}_t := \hat{X}^{(3),k}_t - \alpha^{(1)}(s,\hat{\mathcal{Z}}^{(1),k}_s) + \alpha^{(2)}(s,\hat{\mathcal{Z}}^{(2),k}_s)
\]

\[
\hat{Y}^{(k)}_t = \int_0^t \int_U b^{(3)}(s,\hat{X}^{(3),k}_s,u)\hat{Q}^k(s,du)ds + \int_0^t l(s,u)\hat{N}^k(ds,du), \quad t \in [0,T+1]. \tag{4.22}
\]

Thus, we have

\[
\hat{\mathbb{P}}^k \circ (\hat{Y}_k,\hat{X}^{(1),k}_k,\hat{X}^{(2),k}_k,\hat{Z}^{(1),k}_k,\hat{Z}^{(2),k}_k,\hat{Q}^k)^{-1} = \mathbb{P}^m,*,(Y^{(k)},X^{(1)},X^{(2)},Z^{(1)},Z^{(2)},Q)^{-1},
\]

where \(\mathbb{P}^m,*(Y^{(k)}=X^{(3)}-\alpha^{(1)}Z^{(1),k}+\alpha^{(2)}Z^{(2),k})=1\). The same arguments as Lemma \(\text{(1.2)}\) yields the relative compactness of \(\hat{\mathbb{P}}^k \circ (\hat{Y}_k,\hat{X}^{(1),k}_k,\hat{X}^{(2),k}_k,\hat{Z}^{(1),k}_k,\hat{Z}^{(2),k}_k,\hat{Q}^k)^{-1}\), which implies a weak limit \((\bar{Y},\bar{X}^{(1)},\bar{X}^{(2)},\bar{Z}^{(1)},\bar{Z}^{(2)},\bar{Q})\). Skorokhod representation theorem implies that there exists a probability space \((\bar{\Omega},\bar{\mathcal{F}},\bar{\mathbb{P}})\), two sequences of stochastic processes

\[
(Y^{(k)},X^{(1),k}_k,X^{(2),k}_k,Z^{(1),k}_k,Z^{(2),k}_k) \quad \text{and} \quad (Y,\bar{X}^{(1)},\bar{X}^{(2)},\bar{Z}^{(1)},\bar{Z}^{(2)},\bar{Q})
\]

such that

\[
(Y^{(k)},X^{(1),k}_k,X^{(2),k}_k,Z^{(1),k}_k,Z^{(2),k}_k) \Rightarrow (Y^{(k)},X^{(1),k}_k,X^{(2),k}_k,Z^{(1),k}_k,Z^{(2),k}_k,\bar{Q}), \tag{4.23}
\]

\[
(Y,\bar{X}^{(1)},\bar{X}^{(2)},\bar{Z}^{(1)},\bar{Z}^{(2)},\bar{Q}) \Rightarrow (Y,\bar{X}^{(1)},\bar{X}^{(2)},\bar{Z}^{(1)},\bar{Z}^{(2)},\bar{Q}) \quad \bar{\mathbb{P}} \text{ a.s.} \tag{4.24}
\]

Let

\[
\hat{X}^{(3),k} := Y^{(k)} + \alpha^{(1)}Z^{(1),k} - \alpha^{(2)}Z^{(2),k} \quad \text{and} \quad \bar{X}^{(3)} := Y + \alpha^{(1)}Z^{(1)} - \alpha^{(2)}Z^{(2)}. \tag{4.25}
\]

\[\text{Note that } (\hat{\Omega}_k,\hat{\mathcal{F}}_k,\hat{\mathbb{P}}^k) \text{ and } (\hat{X}_k,\hat{Q}_k,\hat{Z}_k,\hat{W}_k,\hat{V}_k) \text{ should depend on } m. \text{ Since } m \text{ is a fixed finite number in this section, we drop this dependence for simplicity and only keep the dependence on } m \text{ for the optimal ones, e.g. } \mu^{m,*} \text{ and } \mathbb{P}^{m,*}.\]
Thus, (4.24) and (4.25) imply the following convergence result
\[
\mathbb{E}^{\mathbb{Q}} \left[ \int_0^{T+1} \left\| \overline{X}_t^{(k)} - \overline{X}_t^{(3)} \right\|^p \, dt \right] \to 0 \quad \text{and} \quad \overline{X}_{T+1}^{(3),k} \to \overline{X}_{T+1}^{(3)} \quad \mathbb{Q} \text{ a.s.} \quad (4.26)
\]

Moreover, (4.21), (4.22), (4.23) and (4.25) imply that
\[
\mathbb{Q} \circ \left( \tilde{Y}^k, \tilde{X}^{(1),k}, \tilde{X}^{(2),k}, \tilde{X}^{(3),k}, \tilde{Z}^{(1),k}, \tilde{Z}^{(2),k}, \tilde{Q}^k \right)^{-1} = \mathbb{P}^k \circ \left( \hat{Y}^k, \hat{X}^{(1),k}, \hat{X}^{(2),k}, \hat{X}^{(3),k}, \hat{Z}^{(1),k}, \hat{Z}^{(2),k}, \hat{Q}^k \right)^{-1} = \mathbb{P}^{m,\mu} \circ \left( \gamma^k, X^{(1),k}, X^{(2),k}, X^{(3),k}, Z^{(1),k}, Z^{(2),k}, Q^k \right)^{-1}. \quad (4.27)
\]

Define \((\mu^{(1),m,*}, \mu^{(2),m,*}, \mu^{(3),m,*}) := \left( \mathbb{Q} \circ \left( Z^{(1)} \right)^{-1}, \mathbb{Q} \circ \left( Z^{(2)} \right)^{-1}, \mathbb{Q} \circ \left( X^{(3)} \right)^{-1} \right) \) and \(\mathbb{P}^{m,*} := \mathbb{Q} \circ \left( X^{(2)}, X^{(3)}, Q, Z^{(1)}, Z^{(2)} \right)^{-1}. \quad (4.28)\)
and
\(\mathbb{P}^{m,*} := \mathbb{Q} \circ \left( X^{(2)}, X^{(3)}, Q, Z^{(1)}, Z^{(2)} \right)^{-1}. \quad (4.29)\)

The next lemma shows the admissibility of \(\mathbb{P}^\ast\).

**Lemma 4.8.** Assume assumptions \(A_1, A_4\) and \(A_6\) hold. Let \(\mu^{m,*}\) and \(\mathbb{P}^{m,*}\) be defined as (4.28) and (4.29), respectively. Then we have \(\mathbb{P}^{m,*} \in \mathcal{R}^m(\mu^{m,*})\).

**Proof.** The proof is split into two steps. In Step 1, we verify \(\mathbb{P}^{m,*}\) is supported on the original canonical space \(\Omega^m\) and we recall \(\Omega^m = \overline{D}_{0,T} \times \overline{D}_{0,T} \times \overline{D}_{0,T} \times \overline{D}_{0,T} \times \overline{A}_{0,T} \times \overline{A}_{0,T}\). In Step 2, we verify the martingale properties.

**Step 1.** By the definition of \(\mathbb{P}^{m,[k],*}\) and the equation (4.21), \(\hat{Z}^k \in \tilde{A}_{0,T}^m \times \tilde{A}_{0,T}^m\). The trivial extension (4.4) and (4.22) imply \(\tilde{Y}^k \in \tilde{D}_{0,T}\). So the vector of stochastic processes \((\tilde{Y}^k, \hat{X}^{(1),k}, \hat{X}^{(2),k}, \hat{Z}^{(1),k}, \hat{Z}^{(2),k}, \tilde{Q}^k)\) in fact takes values in the product space \(\overline{D}_{0,T} \times \overline{D}_{0,T+1} \times \overline{D}_{0,T+1} \times \overline{A}_{0,T} \times \overline{A}_{0,T} \times \overline{\U}_0\) a.s., so does \((\tilde{Y}^k, \tilde{X}^{(1),k}, \tilde{X}^{(2),k}, \tilde{X}^{(3),k}, \tilde{Z}^{(1),k}, \tilde{Z}^{(2),k} \tilde{Q}^k)\) by (4.23).

Since \(\overline{D}_{0,T}, \tilde{D}_{0,T}^m\) and \(\overline{\U}_0\) are closed, the convergence (4.24) implies \(\tilde{Z} \in \tilde{A}_{0,T}^m \times \tilde{A}_{0,T}^m, \tilde{Y} \in \tilde{D}_{0,T}\) and \(\tilde{Q} \in \tilde{\U}_0\). Thus, (4.25) implies \(\tilde{X}^{(3),k} \in \tilde{D}_{0,T+1}\) and \(\tilde{X}^{(3)} \in \tilde{D}_{0,T}\). It remains to prove \((\tilde{X}^{(1),k}, \tilde{X}^{(2),k}) \in \overline{D}_{0,T} \times \overline{\U}_0\). By (4.23) and the trivial extension (4.4) there exists \(\tilde{K}^{(1),k} \in \tilde{C}_{0,T}\) such that \(\tilde{X}^{(1),k} + k(1)\tilde{Z}^{(1),k}, \tilde{X}^{(2),k} + k(1)\tilde{Z}^{(2),k}\) and the same argument as Lemma 4.2 implies the relative compactness of \(\mathbb{P}^k \circ \hat{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k})^{-1}\) with a weak limit denoted by \((\tilde{X}', \tilde{K}', \tilde{Z}')\). Skorokhod representation implies
\[
(\tilde{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k}) \overset{d}{=} (\tilde{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k}) \quad \text{and} \quad (\tilde{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k}) \overset{d}{=} (\tilde{X}', \tilde{K}', \tilde{Z}')
\]
and \((\tilde{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k}) \to (\tilde{X}^{(1),k}, \tilde{K}^{(1),k}, \tilde{Z}^{(1),k}) \in \overline{D}_{0,T+1} \times \overline{C}_{0,T} \times \overline{A}_{0,T}\), which together with (4.20) yield
\[
\tilde{X}^{(1)} = \tilde{K}^{(1)} + k(1)\tilde{Z}^{(1)} + \eta(1)\tilde{Z}^{(1)}.
\]
Thus, \(\tilde{X}^{(1)} \in \tilde{D}_{0,T}\). Note that by the uniqueness of the limit \(\tilde{X}^{(1)} \overset{d}{=} \tilde{X}^{(1)}\), which implies \(\tilde{X}^{(1)} \in \tilde{D}_{0,T}\). The same holds for \(\tilde{X}^{(2)}\).
Step 2. In this step, we check $M^{\phi,X^{(3)},Y,Q}$ is a $(\mathbb{P}^*,(\mathcal{F}_t))_{0 \leq t \leq T}$ martingale. The martingale property of $M^{\phi,X^{(3)},Z^{(1)},\mu^*}$ and $M^{\phi,X^{(3)},Z^{(2)},\mu^*}$ can be obtained similarly.

For any $n$, any bounded and continuous function $\Phi$, by (4.24), (4.26) and dominated convergence it holds up to a subsequence

$$
\lim_{k \to \infty} \int_0^{T+1} \int_0^{T+1} \cdots \int_0^{T+1} \left| M^{\phi,X^{(3)},\nu^{(k)}}_t \nu^{(k)} \Phi(\zeta_{t_1}, \cdots, \zeta_{t_n}) - M^{\phi,X^{(3)},\nu^{(k)}}_s \nu^{(k)} \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \right| dt_1 \cdots dt_n dt = 0 \text{ a.s.,}
$$

where

$$
\zeta_i := (X^i, Z^i) \quad \text{and} \quad \bar{\zeta} := (X, Z).
$$

(4.30)

Boundedness and linear growth of the coefficients, compactness of $U$, (4.30) and dominated convergence yield that

$$
\lim_{k \to \infty} \mathbb{E} \left[ \int_0^{T+1} \int_0^{T+1} \cdots \int_0^{T+1} \left| M^{\phi,X^{(3)},\nu^{(k)}}_t \nu^{(k)} \Phi(\zeta_{t_1}, \cdots, \zeta_{t_n}) - M^{\phi,X^{(3)},\nu^{(k)}}_s \nu^{(k)} \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \right| dt_1 \cdots dt_n dt \right] = 0.
$$

(4.32)

Thus, for almost every $(s, t_1, \cdots, t_n) \in [0, T+1]^{n+2}$ with $(t_1, \cdots, t_n) \in [s, T+1] \times [0, s]^n$, any continuous and bounded function $\Phi$ on $(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d)^n$ and any continuous and bounded function $\varphi$ which is defined on $\mathcal{U}_0, T$ and $F_2$ measurable we have

$$
0 = \mathbb{E}^{\mu^{\times},*} \left( M^{\phi,X^{(3)},Y,Q}_t - M^{\phi,X^{(3)},Y,Q}_s \right) \Phi(\zeta_s, \cdots, \zeta_t) \varphi(Q)
$$

by (4.24)

$$
\mathbb{E}^{\mu^{\times}} \left( M^{\phi,X^{(3)},\nu^{(k)}}_t \nu^{(k)} \Phi(\bar{\zeta}_{t_1}, \cdots, \bar{\zeta}_{t_n}) - M^{\phi,X^{(3)},\nu^{(k)}}_s \nu^{(k)} \Phi(\bar{\zeta}_{s_1}, \cdots, \bar{\zeta}_{s_n}) \right) \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \varphi(Q)
$$

by (4.26)

$$
\mathbb{E}^{\mu^{\times}} \left( M^{\phi,X^{(3)},Y,Q}_t - M^{\phi,X^{(3)},Y,Q}_s \right) \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \varphi(Q)
$$

by (4.29)

$$
\mathbb{E}^{\mu^{\times},*} \left( M^{\phi,X^{(3)},Y,Q}_t - M^{\phi,X^{(3)},Y,Q}_s \right) \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \varphi(Q)
$$

where \( \bar{\zeta} \) and \( \bar{\zeta}^k \) are defined as (4.31), and \( \zeta^o, \bar{\zeta}^k \) and \( \zeta \) are defined as follows

$$
\zeta^o := (X^o, Z^o), \quad \bar{\zeta}^k := (X^k, Z^k) \quad \text{and} \quad \zeta := (X, Z).
$$

By the right continuity of $M^{\phi,X^{(3)},Y,Q}$ and $X^{(3)}$ we have for any $(t_1, \cdots, t_n) \in [s, T+1] \times [0, s]^n$

$$
\mathbb{E}^{\mu^{\times},*} \left( M^{\phi,X^{(3)},Y,Q}_t - M^{\phi,X^{(3)},Y,Q}_s \right) \Phi(\zeta_{s_1}, \cdots, \zeta_{s_n}) \varphi(Q) = 0.
$$

Finally, using continuous function to approximate indicator function and monotone class theorem we get $M^{\phi,X^{(3)},Y,Q}$ is a $(\mathbb{P}^*,(\mathcal{F}_t))_{0 \leq t \leq T}$ martingale.

Lemma 4.9. For $i = 1, 2$, up to a subsequence $(\mathbb{P}^{m,[k]}^*, (Z^{(i)}[k])^{-1})_k$ converges to $\mu^{(i),m,*}$ as defined in (1.28), in $\mathbb{P}^B(\mathcal{A}_{0,T+1}^m)$. In particular, we have the convergence of the first order moment, i.e.,

$$
\int_{\mathcal{A}_{0,T+1}^m} x \mathbb{P}^{m,[k]}^* \circ (Z^{(i)}[k])^{-1} (dx) \to \int_{\mathcal{A}_{0,T+1}^m} x \mu^{(i),m,*} (dx), \quad \text{in } (\mathcal{A}_{0,T+1}^m, M_1).
$$

19
Proof. The definition of Wasserstein metric, boundedness of $Z$, the convergence (4.2) and (4.27)-(4.29) imply
\[
\mathcal{W}_{p}^{p} \left( \mathbb{P}^{m,[k],*} \circ (Z^{(i)}, [k])^{-1}, \mathbb{P}^{m,*} \circ (Z^{(i)})^{-1} \right) \leq \mathbb{E}^T \left[ d_{W,M} (Z^{(i),k,[k]}, Z^{(i)})^p \right] \to 0,
\]
from which the convergence of first order moments follows. \hfill \Box

Next lemma shows that the cost functional in (1.1) can be rewritten into the form that is more convenient for the convergence argument.

**Lemma 4.10.** Under assumptions $A_1$-$A_4$, the cost functional in (1.1) can be rewritten as follows
\[
J(\mathbb{P}, \mu^{m,*}) = \mathbb{E}^p \left[ \sum_{j=1}^{d} \int_{X_{t,j,0}^{(1)}}^{X_{T,j,t}^{(1)}} h(x) \, dx - \int_{0}^{T} h(X_{t,j}^{(1)}) \cdot b^{(1)}(t, X_{t,j}^{(1)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a^{(1)}_{j,j}(t) h_{j}'(X_{j,t,j}^{(1)}) \, dt \right. \\
\left. + \sum_{j=1}^{d} \int_{X_{t,j,0}^{(2)}}^{X_{T,j,t}^{(2)}} h(x) \, dx - \int_{0}^{T} h(X_{t,j}^{(2)}) \cdot b^{(2)}(t, X_{t,j}^{(2)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a^{(2)}_{j,j}(t) h_{j}'(X_{j,t,j}^{(2)}) \, dt \right. \\
\left. + \int_{0}^{T} \int_{U} f(t, X_{t,j}^{m,*}, u) Q_{t}(du) \, dt + g(X_{T+1}) \right].
\]

**Proof.** By Itô’s formula, we have
\[
\int_{X_{t,j,0}^{(1)}}^{X_{T,j,t}^{(1)}} h_{j}(x) \, dx \\
= \int_{0}^{T} h_{j}(X_{j,s}^{(1)}) h_{j}'(s, X_{s}^{(1)}) \, ds + \int_{0}^{T} h_{j}(X_{j,s}^{(1)}) \left( \kappa^{(1)} \mu^{(1),m,*} + \eta^{(1)} Z_{j,s}^{(1)} \right) \, ds \\
+ \frac{1}{2} \sum_{0 \leq t \leq T} \left( \int_{X_{j,t}^{(1)}}^{X_{j,t}^{(1)}} h_{j}(x) \, dx - h_{j}(X_{j,s}^{(1)}) \Delta X_{j,s}^{(1)} \right) + \text{martingale}
\]
\[
= \int_{0}^{T} h_{j}(X_{j,s}^{(1)}) h_{j}'(s, X_{s}^{(1)}) \, ds + \frac{1}{2} \int_{0}^{T} h_{j}'(X_{s}^{(1)}) a_{j,j}(s) \, ds \\
+ \int_{0}^{T} h_{j}(X_{j,s}^{(1)}) \left( \kappa^{(1)} \mu^{(1),m,*} + \eta^{(1)} Z_{j,s}^{(1)} \right) + \sum_{0 \leq t \leq T} \left( \int_{0}^{\Delta X_{j,t}^{(1)}} h_{j}(y + X_{j,t}^{(1)}) \, dy \right) + \text{martingale.}
\]

(4.33)

Taking (4.33) into the cost functional we get
\[
J(\mathbb{P}; \mu^{m,*}) = \mathbb{E}^p \left[ \sum_{j=1}^{d} \int_{X_{t,j,0}^{(1)}}^{X_{T,j,t}^{(1)}} h_{j}(x) \, dx - \int_{0}^{T} h(X_{t,j}^{(1)}) \cdot b^{(1)}(t, X_{t,j}^{(1)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a^{(1)}_{j,j}(t) h_{j}'(X_{j,t,j}^{(1)}) \, dt \right. \\
\left. + \sum_{j=1}^{d} \int_{X_{t,j,0}^{(2)}}^{X_{T,j,t}^{(2)}} h_{j}(x) \, dx - \int_{0}^{T} h(X_{t,j}^{(2)}) \cdot b^{(2)}(t, X_{t,j}^{(2)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a^{(2)}_{j,j}(t) h_{j}'(X_{j,t,j}^{(2)}) \, dt \right. \\
\left. + \int_{0}^{T} \int_{U} f(t, X_{t,j}^{m,*}, u) Q_{t}(du) \, dt + g(X_{T}) \right].
\]

By $X_T = X_{T+1}$, the desired result follows. \hfill \Box
From now on, for simplicity we define for any \((\mathbb{P}, \mu, X, Q)\)

\[
\mathcal{J}(\mathbb{P}, X, Q, \mu) := \mathbb{E}^\mathbb{P} \left[ \sum_{j=1}^{d} \int_{X_j(t)}^{X_j(T)} h_j(x) \, dx - \int_{0}^{T} h(X_t^{(1)}) \cdot b(1)(t, X_t^{(1)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a_{jj}^{(1)}(t) h_j'(X_j(t)) \, dt \\
+ \sum_{j=1}^{d} \int_{X_j(t)}^{X_j(T)} h_j(x) \, dx - \int_{0}^{T} h(X_t^{(2)}) \cdot b(2)(t, X_t^{(2)}) \, dt - \frac{1}{2} \sum_{j=1}^{d} \int_{0}^{T} a_{jj}^{(2)}(t) h_j'(X_j(t)) \, dt \\
+ \int_{\mathcal{U}} f(t, X_t, \mu_t, u) \, Q_t(du) \, dt + g(X_{T+1}) \right].
\]

In particular, by (4.42) it holds that

\[
J^a(\mathbb{P}; \mu) = \mathcal{J}(\mathbb{P}, X^a, Q, \mu).
\] (4.34)

With the help of Lemma 4.10, the next Lemma shows any admissible relaxed control corresponding to \(\mu_{m,*}^{m,*}\) inducing a finite cost can be approximated by a sequence of admissible relaxed controls corresponding to \(\mu_{m,[k],*}^{m,*}\).

**Lemma 4.11.** For any \(\mathbb{P} \in \mathcal{R}^{m,*}(\mu_{m,*}^{m,*})\) with \(J(\mathbb{P}; \mu_{m,*}^{m,*}) < \infty\), we can find a sequence \(\mathbb{P}_k \in \mathcal{R}^{m,[k]}(\mu_{m,[k],*}^{m,*})\) such that

\[
J^a(\mathbb{P}_k; \mu_{m,[k],*}^{m,*}) \to J(\mathbb{P}; \mu_{m,*}^{m,*}),
\]

where \(\mu_{m,*}^{m,*}\) is defined in (4.29).

**Proof.** The admissibility of \(\mathbb{P}\) implies the existence of \((\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})\) and \((\tilde{X}, \tilde{Q}, \tilde{Z}, \tilde{W}, \tilde{N})\) such that

\[
\tilde{X}^{(1)} = \int_{0}^{T} \tilde{b}^{(1)}(s, \tilde{X}^{(1)}_s) \, ds + \tilde{\kappa}^{(1)}(\mathbb{P}_{m,*}^{m,*}) + \tilde{\eta}^{(1)}(\tilde{Z}^{(1)}) + \int_{0}^{T} \sigma^{(1)}(s) \, d\tilde{W}^{(1)}_s,
\] (4.35)

\[
\tilde{X}^{(2)} = \int_{0}^{T} \tilde{b}^{(2)}(s, \tilde{X}^{(2)}_s) \, ds + \tilde{\kappa}^{(2)}(\mathbb{P}_{m,*}^{m,*}) + \tilde{\eta}^{(2)}(\tilde{Z}^{(2)}) + \int_{0}^{T} \sigma^{(2)}(s) \, d\tilde{W}^{(2)}_s,
\] (4.36)

\[
\tilde{X}^{(3)} = \int_{\mathcal{U}} \tilde{b}^{(3)}(s, \tilde{X}^{(3)}_s, u) \, \tilde{Q}_s(du) \, ds + \int_{\mathcal{U}} \int_{\mathbb{R}^d} l(s, u) \, \tilde{N}(ds, du) + \alpha^{(1)}(\tilde{Z}^{(1)}) - \alpha^{(2)}(\tilde{Z}^{(2)})
\]
(4.37)

and

\[
\tilde{\mathbb{P}} \circ (\tilde{X}, \tilde{Q}, \tilde{Z})^{-1} = \mathbb{P} \circ (X, Q, Z)^{-1}.
\] (4.38)

Let \(\tilde{X}^{(i),k}, \tilde{X}^{(2),k}\) and \(\tilde{X}^{(3),k}\) be the unique strong solution to the following dynamics, respectively,

\[
\tilde{X}^{(i),k} = \int_{0}^{T} \tilde{b}^{(i)}(s, \tilde{X}^{(i),k}_s) \, ds + \tilde{\kappa}^{(i)}(\mathbb{P}_{m,*}^{m,[k],*}) + \tilde{\eta}^{(i)}(\tilde{Z}^{(i)[k]}) + \int_{0}^{T} \sigma^{(i)}(s) \, d\tilde{W}^{(i)}_s, \quad i = 1, 2
\] (4.39)

and

\[
\tilde{X}^{(3),k} = \int_{\mathcal{U}} \tilde{b}^{(3)}(s, \tilde{X}^{(3),k}_s, u) \, \tilde{Q}_s(du) \, ds + \int_{\mathcal{U}} \int_{\mathbb{R}^d} l(s, u) \, \tilde{N}(ds, du) + \alpha^{(1)}(\tilde{Z}^{(1)[k]}) - \alpha^{(2)}(\tilde{Z}^{(2)[k]}),
\] (4.40)

where we recall \(\mu_{m,[k],*}^{m,*}\) is the mean field aggregation from Section 4.1. Define

\[
\mathbb{P}^k \circ (X^a, Q^a, Z^a)^{-1} := \tilde{\mathbb{P}} \circ \left( \tilde{X}^{k}, \tilde{Q}, \tilde{Z} \right)^{-1},
\] (4.41)

which together with the equations (4.39)–(4.40) implies the admissibility of \(\mathbb{P}^k\), i.e., \(\mathbb{P}^k \in \mathcal{R}^{m,[k]}(\mu_{m,[k],*}^{m,*})\). Moreover, by Lemma 4.9 and the fact \(\tilde{Z}^{(i)[k]} \to \tilde{Z}^{(i)}\) in \((\mathcal{D}_{0,T+1}, M_1)\) \(\tilde{\mathbb{P}}\) a.s., we have the following convergence from (4.39)–(4.40)

\[
\mathbb{E}^{\mathbb{P}} \left[ \int_{0}^{T} \left\| \tilde{X}_t^k - \tilde{X}_t \right\|_p^p \, dt \right] \to 0 \text{ and } \tilde{X}_{T+1}^k \to \tilde{X}_{T+1} \text{ by (4.3) } \tilde{X}_T.
\] (4.42)
Therefore,
\[
J^o(\mathbb{P}^k; \mu^{m,[k]}_*) \overset{\text{by } 4.37}{=} \mathcal{J}(\mathbb{P}^k, \mu^{m,[k]}_*, X^o, Q) \overset{\text{by } 4.31}{=} \mathcal{J}(\hat{\mathbb{P}}, \mu^{m,[k]}_*, X^k, \hat{Q}) \overset{\text{by } 4.32}{=} \mathcal{J}(\hat{\mathbb{P}}, \mu^{m,*}, X, \hat{Q}) \overset{\text{by Lemma } 4.10}{=} J(\mathbb{P}; \mu^{m,*}).
\]

The following theorem shows \(\mu^*\) defined in (4.28) is an equilibrium of (1.1).

**Theorem 4.12.** Under Assumptions \(A_1 - A_6\), it holds that \(\mathbb{P}^{m,*} \in \mathcal{R}^{m,*}(\mu^{m,*})\).

**Proof.** Let \(\mathbb{P}^k\) be the probability measure constructed in Lemma 4.11. Thus, Lemma 4.11 and optimality of \(\mathbb{P}^{m,[k]}\) imply
\[
J(\mathbb{P}; \mu^{m,*}) \overset{\text{by Lemma } 4.11}{=} J^o(\mathbb{P}^k; \mu^{m,[k]}_*) \geq J^o(\mathbb{P}^{m,*}; \mu^{m,[k]}_*) = \mathcal{J}(\mathbb{P}^{m,*}, \mu^{m,[k]}_*, X^o, Q) \overset{\text{by } 4.29}{=} \mathcal{J}(\hat{\mathbb{P}}, \mu^{m,*}, \hat{Q}) \overset{\text{by } 4.29}{=} J(\mathbb{P}; \mu^{m,*}).
\]

**Remark 4.13.** The trivial extension (4.4) makes the coefficients dependent on the time variable. MFG (1.1) with coefficients that are independent of time can also be considered. Indeed, note that in Section 4.1 and Section 4.2 we do not assume any continuity of the coefficients w.r.t. the time variable, so that we can consider the following coefficients
\[
\tilde{\gamma}(s, x) := \gamma(s, x),
\]
where \(\gamma(s) = 1\) when \(0 \leq s \leq T\) and \(\gamma(s) = 0\) when \(T < s \leq T + 1\). Then \(\tilde{\gamma}\) satisfies all assumptions as well as (4.4). With the coefficients \(\tilde{\gamma}\), (1.1) admits equilibria, which is consistent with the equilibria of (1.1) with coefficients \(\gamma\).

## 5 Existence of Equilibria with General Singular Controls

In this section, we prove Theorem 3.3. From Section 4 for each \(m \in (0, \infty)\) there exists an equilibrium \(\mathbb{P}^{m,*}\) for MFGs with finite fuel constraint, i.e., \(\mathbb{P}^{m,*} \in \mathcal{R}^{m,*}(\mu^{m,*})\), where \(\mu^{m,*} = (\mathbb{P}^{m,*} \circ (Z^{(1)})^{-1}, \mathbb{P}^{m,*} \circ (Z^{(2)})^{-1}, \mathbb{P}^{m,*} \circ (X^{(3)})^{-1})\). We have the following uniform bound for \(p + 1\) moments of \(Z^{(1)}\) and \(Z^{(2)}\) under \(\mathbb{P}^{m,*}\). This is sufficient for the relative compactness of \(\{\mathbb{P}^{m,*} \circ (Z^{(1)})^{-1}\}_m\) and \(\{\mathbb{P}^{m,*} \circ (Z^{(2)})^{-1}\}_m\).

**Lemma 5.1.** Under assumptions \(A_1, A_2, A_4, A_6\) and \(A_7\), we have the following uniform estimate
\[
\sup_m \mathbb{E}^{\mathbb{P}^{m,*}}[|Z_T^{(1)}|^{p+1} + |Z_T^{(2)}|^{p+1}] < \infty.
\]

**Proof.** By the linear growth of \(b^{(i)}\), boundedness of \(\sigma^{(i)}\) and Proposition 3.3, we have under \(\mathbb{P}^{m,*}\)
\[
\mathbb{E}^{\mathbb{P}^{m,*}}[|Z^{(i)}_T|^{p+1}] \leq C \left(1 + \mathbb{E}^{\mathbb{P}^{m,*}} \left[\sup_{0 \leq t \leq T} |X_t^{(i)}|^{p+1}\right] + \mathbb{E}^{\mathbb{P}^{m,*}} \left[|Z_T^{(i)}|^{p+1}\right]\right), \quad i = 1, 2. \tag{5.1}
\]
Take a probability measure \(\mathbb{P}_0 \in \mathcal{R}^m(\mu^{m,*})\) such that \(\mathbb{P}_0(Z \equiv 0, Q \equiv \delta_{u_0}) = 1\). Under \(\mathbb{P}_0\) it holds by the linear growth of \(b^{(i)}\), boundedness of \(\sigma^{(i)}\) and Proposition 3.3
\[
\mathbb{E}^{\mathbb{P}_0} \left[\sup_{0 \leq t \leq T} |X_t^{(i)}|^{p+1}\right] \leq C \left(1 + \mathbb{E}^{\mathbb{P}^{m,*}}[|Z_T^{(i)}|^{p+1}]\right), \quad i = 1, 2. \tag{5.2}
\]
Moreover, by the boundedness of $l$, linear growth of $b^{(3)}$, Proposition 3.3 implies that

$$
E^{P_0} \left[ \sup_{0 \leq t \leq T} |X^{(3)}_t|^{p+1} \right] \leq C < \infty.
$$

(5.3)

By Lemma 4.10, assumptions $A_1$, $A_3$, $A_4$, $A_6$ and $A_7$, and estimates (5.1)–(5.3), we have the following upper estimate of $J(P_0; \mu^{m,*})$ and lower estimate of $J(P^{m,*}; \mu^{m,*})$

$$
J(P_0; \mu^{m,*}) \leq C \left( 1 + \int_0^T E^{P_0}|X^{(1)}_t|^{p+1} + E^{P_0}|X^{(2)}_t|^{p+1} + E^{P_0}|X^{(3)}_t|^{p+1} \, dt \right)
$$

$$
+ E^{P_0}(X^{(1)}_T)^{p+1} + E^{P_0}(X^{(2)}_T)^{p+1} + \int_0^T \mathcal{W}^{p+1}(|\mu^{m,*}(\mu^{m,*}), \delta_0) \, dt \right)
$$

$$
\leq C \left( 1 + \left| E^{\mu^{m,*}}[Z^{(1)}_T] \right|^{p+1} + \left| E^{\mu^{m,*}}[Z^{(2)}_T] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(1)}_T|] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(2)}_T|] \right|^{p+1} \right)
$$

respectively,

$$
J(P^{m,*}; \mu^{m,*}) \geq - C + C \left( E^{\mu^{m,*}}[|X^{(1)}_T|^{p+1}] + E^{\mu^{m,*}}[|X^{(2)}_T|^{p+1}] \right)
$$

$$
\geq - C + C \left( E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] + E^{\mu^{m,*}}[|Z^{(2)}_T|^{p+1}] \right) - C \left( \left| E^{\mu^{m,*}}[Z^{(1)}_T] \right|^{p+1} + \left| E^{\mu^{m,*}}[Z^{(2)}_T] \right|^{p+1} \right).
$$

(5.4)

By the optimality of $P^{m,*}$ w.r.t. $\mu^{m,*}$, it holds $J(P^{m,*}; \mu^{m,*}) \leq J(P_0; \mu^{m,*})$, which implies by (5.4) and (5.5)

$$
E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] + E^{\mu^{m,*}}[|Z^{(2)}_T|^{p+1}]
$$

$$
\leq C \left( 1 + \left| E^{\mu^{m,*}}[Z^{(1)}_T] \right|^{p+1} + \left| E^{\mu^{m,*}}[Z^{(2)}_T] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(1)}_T|] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(2)}_T|] \right|^{p+1} \right)
$$

$$
\leq C \left( 1 + \left| E^{\mu^{m,*}}[Z^{(1)}_T 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} + \left| E^{\mu^{m,*}}[Z^{(2)}_T 1\{|Z^{(2)}_T| \geq K\}] \right|^{p+1}
$$

$$
+ \left| E^{\mu^{m,*}}[|Z^{(1)}_T 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(2)}_T 1\{|Z^{(2)}_T| \geq K\}] \right|^{p+1} \right).
$$

Note that $E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] = 0$ implies $E^{\mu^{m,*}}[Z^{(1)}_T 1\{|Z^{(1)}_T| \geq K\}] = 0$ and $E^{\mu^{m,*}}[|Z^{(2)}_T 1\{|Z^{(2)}_T| \geq K\}] = 0$.

When $E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] \neq 0$, by the fact that

$$
\lim_{K \to \infty} \left| E^{\mu^{m,*}}[Z^{(1)}_T 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} = \lim_{K \to \infty} \left| E^{\mu^{m,*}}[|Z^{(1)}_T| 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} = 0,
$$

we can choose $K$ large enough such that

$$
C \left( \left| E^{\mu^{m,*}}[Z^{(1)}_T 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} + \left| E^{\mu^{m,*}}[Z^{(2)}_T 1\{|Z^{(2)}_T| \geq K\}] \right|^{p+1}
$$

$$
+ \left| E^{\mu^{m,*}}[|Z^{(1)}_T| 1\{|Z^{(1)}_T| \geq K\}] \right|^{p+1} + \left| E^{\mu^{m,*}}[|Z^{(2)}_T| 1\{|Z^{(2)}_T| \geq K\}] \right|^{p+1} \right)
$$

$$
\leq \frac{1}{2} \left( E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] + E^{\mu^{m,*}}[|Z^{(2)}_T|^{p+1}] \right),
$$

which implies

$$
E^{\mu^{m,*}}[|Z^{(1)}_T|^{p+1}] + E^{\mu^{m,*}}[|Z^{(2)}_T|^{p+1}] \leq 2C,
$$

where $C$ and $K$ are independent of $m$. \qed
First of all, we prove for each $m$ that $(\hat{X}^{(1)}, \hat{X}^{(2)}, \hat{Q}, \hat{Z}^{(1)}, \hat{Z}^{(2)}, \hat{W}, \hat{\nu})$ is relatively compact. Denote by $\mathbb{P}$ the weak limit. Skorohod representation implies the existence of $(\Omega, \mathbb{F}, \mathbb{Q})$ and two tuples of stochastic processes $(X^{(1)}, X^{(2)}, Q, Z^{(1)}, Z^{(2)}, \mathbb{F})$ and $(X^{(1)}, X^{(2)}, Q^m, Z^{(1)}, Z^{(2)}, \mathbb{F}^m)$ such that

$$
\begin{align*}
Q \circ (X^{(1)}, X^{(2)}, Q, Z^{(1)}, Z^{(2)}, Y)^{-1} &= \mathbb{P}^{m, \ast} \circ (X^{(1)}, X^{(2)}, Q, Z^{(1)}, Z^{(2)}, Y)^{-1}, \\
Q \circ (X^{(1)}, X^{(2)}, Q^m, Z^{(1)}, Z^{(2)}, Y^m) &= \mathbb{P}^m, \\
(X^{(1)}, X^{(2)}, Q^m, Z^{(1)}, Z^{(2)}, Y^m) &\rightarrow (X^{(1)}, X^{(2)}, Q, Z^{(1)}, Z^{(2)}, Y) \quad \text{a.s.}
\end{align*}
$$

Let $X^{(3), m} = Y^m + \alpha^{(1)} Z^{(1), m} - \alpha^{(2)} Z^{(2), m}$ and $X^{(3)} = Y + \alpha^{(1)} \bar{Z}^{(1)} - \alpha^{(2)} \bar{Z}^{(2)}$. Consequently, we have $\mathbb{P}^{m, \ast} = Q \circ (X^{(1)}, X^{(2)}, X^{(3), m}, Q^m, Z^{(1)}, Z^{(2), m})^{-1}$.

Define the candidate of the equilibrium as

$$
\mathbb{P}^* = Q \circ (\bar{X}, \bar{Q}, \bar{Z})^{-1} \quad \text{and} \quad \mu^{(i), \ast} = \mathbb{P}^* \circ (Z^{(i)})^{-1}, \quad i = 1, 2, \quad \mu^{(3), \ast} = \mathbb{P}^* \circ (X^{(3)})^{-1}.
$$

Then it can be checked by the same arguments as in Proposition 4.4 and Lemma 4.8 that $\mathbb{P}^* \in \mathcal{R}(\mu^*)$. For each constant $K$ define $J_K(\mathbb{P}; \mu)$ the same as $J(\mathbb{P}; \mu)$ in Lemma 4.10 but with $h, \alpha h^{(i)}, f$ and $g$ replaced by $h \land K, \alpha h^{(i)} \land K, f \land K$ and $g \land K$. Then from Lemma 4.10 and (5.6) we have

$$
\lim_{m \to \infty} J(\mathbb{P}^{m, \ast}; \mu^{m, \ast}) \geq \lim_{m \to \infty} J_K(\mathbb{P}^{m, \ast}; \mu^{m, \ast}) = J_K(\mathbb{P}^*; \mu^*).
$$

Letting $K$ go to infinity, monotone convergence implies

$$
\lim_{m \to \infty} J(\mathbb{P}^{m, \ast}; \mu^{m, \ast}) \geq J(\mathbb{P}^*; \mu^*). \quad (5.8)
$$

The next theorem concludes this section.

**Theorem 5.2.** The probability measures defined in (5.7) is a relaxed solution to MFG (1.1) with general singular controls, i.e., $J(\mathbb{P}^*; \mu^*) = \sup_{\mathbb{P} \in \mathcal{R}(\mu^*)} J(\mathbb{P}; \mu^*)$.

**Proof.** First of all, we prove for each $\mathbb{P} \in \mathcal{R}(\mu^*)$ with $J(\mathbb{P}; \mu^*) < \infty$, there exists $\mathbb{P}^m \in \mathcal{R}(\mu^{m, \ast})$ such that

$$
\lim_{m \to \infty} J(\mathbb{P}^{m, \ast}; \mu^{m, \ast}) = J(\mathbb{P}; \mu^*). \quad (5.9)
$$

Note that $\mathbb{P} \in \mathcal{R}(\mu^*)$ implies a tuple of stochastic processes $(\bar{X}, \bar{Q}, \bar{Z}, \bar{W}, \bar{\nu})$ defined on a probability space $(\Omega, \mathbb{F}, \mathbb{P})$ such that

$$
\begin{align*}
\bar{X}_t^{(i)} &= \int_0^t b^{(i)}(s, \bar{X}_s^{(i)}) ds + \kappa^{(i)}\mathbb{F}_s + \eta^{(i)}\mathbb{Z}_s^{(i)} + \int_0^t \sigma^{(i)}(s) d\mathbb{W}_s^{(i)}, \quad i = 1, 2, \\
\bar{X}_t^{(3)} &= \int_0^t \int_U h^{(3)}(s, \bar{X}_s^{(3)}, u) \bar{Q}_s(u) du ds + \int_0^t \int_U l(s, u) \bar{\nu}(ds, du) + \alpha^{(1)} \mathbb{Z}_t^{(1)} - \alpha^{(2)} \mathbb{Z}_t^{(2)}, \\
\mathbb{P} &= \mathbb{P} \circ (\bar{X}, \bar{Q}, \bar{Z})^{-1}.
\end{align*}
$$

Define

$$
\mathbb{Z}_t^{(i), m} = \begin{cases} 
\mathbb{Z}_t^{(i)}, & \mathbb{Z}_t^{(i)} \leq m, \\
m, & \mathbb{Z}_t^{(i)} > m, \quad i = 1, 2,
\end{cases}
$$

24
and

\[ \mathbb{P}^m = \hat{\mathbb{P}} \circ (\hat{X}^m, \hat{Q}, \hat{Z}^m)^{-1}, \]

where \( \hat{X}^m \) is defined as follows

\[
\begin{align*}
\hat{X}^{(i),m}_t &= \int_0^t b^{(i)}(s, \hat{X}^{(i),m}_s) \, ds + \kappa^{(i)} \hat{\mu}^{m,*} + \eta^{(i)} \hat{Z}^{(i),m}_s + \int_0^t \sigma^{(i)}(s) \, d\hat{W}_s, \quad i = 1, 2, \\
\hat{X}^{(3)}_t &= \int_0^t \int_U b^{(3)}(s, \hat{X}^{(3),m}_s, u) \hat{Q}_s(du) \, ds + \int_0^t \int_U l(s, u) \hat{N}(ds, du) + \alpha^{(1)} \hat{Z}^{(1),m}_t - \alpha^{(2)} \hat{Z}^{(2),m}_t.
\end{align*}
\]

Obviously, \( \mathbb{P}^m \in \mathcal{R}^m(\mu^{m,*}) \). Next we verify the convergence \((5.9)\). By definitions of \( \hat{X}^{(i),m} \) and \( \hat{X}^{(i)} \), we have for each continuous time \( t \in [0, T] \) of \( \hat{\mathbb{P}}^* \), including \( T \)

\[
|\hat{X}^{(i),m}_t - \hat{X}^{(i)}_t| \leq C |\hat{X}^{(i),m}_t - \hat{X}^{(i)}_t| + C |\hat{Z}^{(i),m}_t - \hat{Z}^{(i)}_t| + C \int_0^t |\hat{\mu}^{m,*} - \hat{\mu}_t| + |\hat{Z}^{(i),m}_t - \hat{Z}^{(i)}_t| \, ds
\]

\[
\leq C |\hat{\mu}^{m,*} - \hat{\mu}_t| + C |\hat{Z}^{(i),m}_t - \hat{Z}^{(i)}_t| \, 1_{\{\hat{Z}^{(i)}_t > m\}} + C \int_0^t |\hat{\mu}^{m,*} - \hat{\mu}_t| + 2 |\hat{Z}^{(1)}_t| \, 1_{\{\hat{Z}^{(1)}_t > m\}} \, ds
\]

\[
\rightarrow 0, \text{ as } m \to \infty.
\]

Similarly, for any \( t \in [0, T] \),

\[
|\hat{X}^{(3),m}_t - \hat{X}^{(3)}_t| \rightarrow 0.
\]

Note that by the definition \( \hat{Z}^m \leq \hat{Z}_t \). Assumption \( A7 \) implies for \( i = 1, 2 \)

\[
\left| h(\hat{X}^{(i),m}_t, \hat{X}^{(i),m}_t) - h(\hat{X}^{(i)}_t, \hat{X}^{(i)}_t) \right| \leq C(1 + |\hat{X}^{(i),m}|^{p+1} + |\hat{X}^{(i)}|^{p+1})
\]

\[
\leq C \left( 1 + |\hat{\mu}^{m,*}|^{p+1} + |\hat{Z}^{(i),m}|^{p+1} + |\hat{\mu}^{m,*}|^{p+1} + |\hat{Z}^{(i)}|^{p+1} + \int_0^t \sigma^{(i)}(s) \, d\hat{W}^{(i)}_s \right)^{p+1}
\]

\[
\leq C \left( \sup_m \mathbb{E}^{\mu^{m,*}} [|Z^{(i)}_T|^{p+1}] + \mathbb{E}^{\mu^*} [|Z^{(i)}_T|^{p+1}] + |\hat{Z}^{(i)}|^{p+1} + \int_0^t \sigma^{(i)}(s) \, d\hat{W}^{(i)}_s \right)^{p+1},
\]

which is integrable. Indeed, the finiteness of \( \sup_m \mathbb{E}^{\mu^{m,*}} [|Z^{(i)}_T|^{p+1}] \) is given by Lemma \( 5.1 \) Fatou’s lemma implies \( \mathbb{E}^{\mu^*} [|Z^{(i)}_T|^{p+1}] < \infty \). The same argument as in Lemma \( 5.1 \) implies \( \mathbb{E}^{\mu^*} [|Z^{(i)}_T|^{p+1}] < \infty \). Thus, dominated convergence yields

\[
\mathbb{E}^{\mu^*} \left[ \int_0^T \left| h(\hat{X}^{(i),m}_t, \hat{X}^{(i),m}_t) - h(\hat{X}^{(i)}_t, \hat{X}^{(i)}_t) \right| \, dt \right] \rightarrow 0.
\]

Similarly, we have

\[
\mathbb{E}^{\mu^*} \left[ \int_0^T h(x) \, dx + \int_0^T h(x) \, dx + \int_0^T f(t, \hat{X}_t^m, \mu^{m,*}, u) \hat{Q}_t(du) \, dt + g(\hat{X}_T^m) \right]
\]

\[
\rightarrow \mathbb{E}^{\mu^*} \left[ \int_0^T h(x) \, dx + \int_0^T h(x) \, dx + \int_0^T f(t, \hat{X}_t, \mu^{*}, u) \hat{Q}_t(du) \, dt + g(\hat{X}_T) \right].
\]

Finally, by (5.8) and the optimality of \( \mathbb{P}^{\mu^{m,*}} \) w.r.t. \( \mu^{m,*} \) we have

\[
J(\mathbb{P}; \mu^*) \leq \lim_{m \to \infty} J(\mathbb{P}^{\mu^{m,*}}; \mu^{m,*}) \leq \lim_{m \to \infty} J(\mathbb{P}^{\mu^{m,*}}; \mu^{m,*}) = J(\mathbb{P}; \mu^*).
\]
6 Conclusion

Motivated by optimal portfolio liquidation and optimal exploitation of exhaustible resource, we consider an extended MFG with singular controls by the probabilistic compactification mothod. We smooth the singular controls to circumvent the tightness issue. Our main result is the existence of equilibria. It is also interesting to characterize the equilibria, especially of the two examples in Section 2 so that one has better knowledge of how the representative player optimally chooses her strategy in response to the competitors. We leave the characterization as an independent work.

A $\mathcal{D}([0, T]; \mathbb{R}^d)$ is Polish under Weak $M_1$ Topology

This section proves that $\mathcal{D}([0, T]; \mathbb{R}^d)$ is a Polish space under weak $M_1$ topology. Denote by $SM_1$ and $WM_1$ strong and weak $M_1$ topologies, respectively. Since $SM_1$ and $WM_1$ coincide in $\mathcal{D}([0, T]; \mathbb{R})$, we denote $SM_1$ and $WM_1$ by $M_1$ in $\mathcal{D}([0, T]; \mathbb{R})$.

Firstly, it is well known that $\mathcal{D}([0, T]; \mathbb{R}^d)$ is separable under $J_1$ topology; see e.g. [34, Section 11.5]. Thus, $\mathcal{D}([0, T]; \mathbb{R}^d)$ is separable under (S- and W-) $M_1$ topology since $J_1$ is stronger than (S- and W-) $M_1$ topology. It remains to prove the topological completeness of $WM_1$. By [34 Theorem 12.8.1], $\mathcal{D}([0, T]; \mathbb{R}^d)$ is topologically complete under $SM_1$. In particular, this is true when $d = 1$. Therefore, there is a homeomorphic mapping $f : (\mathcal{D}([0, T]; \mathbb{R}), d_{SM_1}(= d_{WM_1} = d_{M_1})) \rightarrow (\mathcal{D}([0, T]; \mathbb{R}), \hat{d}_s)$, where $\hat{d}_s$ is the complete metric of $\mathcal{D}([0, T]; \mathbb{R})$. For any Cauchy sequence $\{x_n\} \subseteq (\mathcal{D}([0, T]; \mathbb{R}^d), d_{WM_1})$, i.e., $\|x_n - x_m\|_{d_{WM_1}} \rightarrow 0$, [34 Theorem 12.5.2] implies that $d_{M_1}(x_n^i, x_m^i) \rightarrow 0$, for any $i = 1, \cdots, d$, which implies by the continuity of $f$ that $\hat{d}_s(f(x_n^i), f(x_m^i)) \rightarrow 0$, for any $i = 1, \cdots, d$. By the completeness of $\hat{d}_s$ there exists $x^i \in \mathcal{D}([0, T]; \mathbb{R})$ such that $\hat{d}_s(f(x_n^i), f(x^i)) \rightarrow 0$ for each $i = 1, \cdots, d$, which implies by the continuity of $f^{-1}$ that $d_{M_1}(x_n^i, x^i) \rightarrow 0$. By [34 Theorem 12.5.2] again we have $d_{WM_1}(x_n, x) \rightarrow 0$, where $x = (x^1, \cdots, x^d) \in \mathcal{D}([0, T]; \mathbb{R}^d)$.
