Abstract

An \(r\)-dynamic \(k\)-coloring of a graph \(G\) is a proper \(k\)-coloring such that for any vertex \(v\), there are at least \(\min\{r, \deg_G(v)\}\) distinct colors in \(N_G(v)\). The \(r\)-dynamic chromatic number \(\chi_{dr}(G)\) of a graph \(G\) is the least \(k\) such that there exists an \(r\)-dynamic \(k\)-coloring of \(G\). The list \(r\)-dynamic chromatic number of a graph \(G\) is denoted by \(ch_{dr}(G)\). Loeb et al. \cite{11} showed that \(ch_{d3}(G)\) \(\leq 10\) for every planar graph \(G\), and there is a planar graph \(G\) with \(\chi_{d3}(G) = 7\).

In this paper, we study a special class of planar graphs which have better upper bounds of \(ch_{d3}(G)\). We prove that \(ch_{d3}(G) \leq 6\) if \(G\) is a planar graph which is near-triangulation, where a near-triangulation is a planar graph whose bounded faces are all 3-cycles.

Keywords: list \(r\)-dynamic coloring, planar graphs, triangulation, near-triangulation

1. Introduction

Let \(k\) be a positive integer. A proper \(k\)-coloring \(\phi : V(G) \to \{1, 2, \ldots, k\}\) of a graph \(G\) is an assignment of colors to the vertices of \(G\) so that any two adjacent vertices receive distinct colors. The chromatic number \(\chi(G)\) of a graph \(G\) is the least \(k\) such that there exists a proper \(k\)-coloring of \(G\). An \(r\)-dynamic \(k\)-coloring of a graph \(G\) is a proper \(k\)-coloring \(\phi\) such that for each vertex \(v \in V(G)\), either the number of distinct colors in its neighborhood is at least \(r\) or the colors in its neighborhood are all distinct, that is, \(|\phi(N_G(v))| = \min\{r, \deg_G(v)\}\). The \(r\)-dynamic chromatic number \(\chi_{d}(G)\) of a graph \(G\) is the least \(k\) such that there exists an \(r\)-dynamic \(k\)-coloring of \(G\).

A list assignment on a graph \(G\) is a function \(L\) that assigns each vertex \(v\) a set \(L(v)\) which is a list of available colors at \(v\). For a list assignment \(L\) of a graph \(G\), we say \(G\) is \(L\)-colorable if there exists a proper coloring \(\phi\) such that \(\phi(v) \in L(v)\) for every \(v \in V(G)\). A graph \(G\) is said to be \(k\)-choosable if for any list assignment \(L\) such that \(|L(v)| \geq k\) for every vertex \(v\), \(G\) is \(L\)-colorable.

For a list assignment $L$ of $G$, we say that $G$ is $r$-dynamically $L$-colorable if there exists an $r$-dynamic coloring $\phi$ such that $\phi(v) \in L(v)$ for every $v \in V(G)$. A graph $G$ is $r$-dynamically $k$-choosable if for any list assignment $L$ with $|L(v)| \geq k$ for every vertex $v$, $G$ is $r$-dynamically $L$-colorable. The list $r$-dynamic chromatic number $\text{ch}^d_r(G)$ of a graph $G$ is the least $k$ such that $G$ is $r$-dynamically $k$-choosable.

An interesting property of dynamic coloring is as follows.

$$\chi(G) \leq \chi^d_2(G) \leq \cdots \leq \chi^d_\Delta(G) = \chi(G^2),$$

where $G^2$ is the square of the graph $G$.

The dynamic coloring was first introduced in [9, 12]. On the other hand, Wegner [15] conjectured that if $G$ is a planar graph, then

$$\chi^d_\Delta(G) \leq \begin{cases} 
7, & \text{if } \Delta(G) = 3; \\
\Delta(G) + 5, & \text{if } 4 \leq \Delta(G) \leq 7; \\
\lfloor \frac{3\Delta(G)}{2} \rfloor + 1, & \text{if } \Delta(G) \geq 8.
\end{cases}$$

Lai et al. [13] posed a similar conjecture about dynamic coloring of planar graphs as follows.

**Conjecture 1.1** Let $G$ be planar graph. Then

$$\chi^d_r(G) \leq \begin{cases} 
r + 3, & \text{if } 1 \leq r \leq 2; \\
r + 5, & \text{if } 3 \leq r \leq 7; \\
\left\lfloor \frac{3r}{2} \right\rfloor + 1, & \text{if } r \geq 8.
\end{cases}$$

Lai et al. [14] showed the conjecture is true for planar graphs with girth at least 6. Several results about $r$-dynamic coloring were published in [1, 2, 5, 6, 7, 11]. In term of maximum average degree, there is a result published in [8]. And some special classes of graphs are also investigated, such as $K_{4,4}$-minor free graphs [13], $K_{1,3}$-free graphs [10] and bipartite graphs [3].

Loeb et al. [11] showed $\text{ch}^d_3(G) \leq 10$ if $G$ is a planar graph. On the other hand, there is a planar graph $F$ such that $\chi^d_3(F) = 7$. Thus the following is an interesting problem to study.

**Problem 1** What is $\chi^d_3(G)$ if $G$ is a planar graph? And what is $\text{ch}^d_3(G)$ if $G$ is a planar graph?

Currently, we have the following bounds.

$$7 \leq \max \left\{ \chi^d_3(G) : G \text{ is a planar graph} \right\} \leq 10. \quad (1)$$

It is natural to consider a special class of planar graphs for Problem 1. Recently, Asayama et al. [1] showed that $\chi^d_3(G) \leq 5$ if $G$ is a triangulated planar graph, and the upper bound is sharp. But, we do not know yet whether $\text{ch}^d_3(G) \leq 5$ or not, if $G$ is a triangulated planar graph.
Since there is a gap for general case of planar graphs, it would be interesting to study list 3-dynamic chromatic number $ch_3^d(G)$ for a special class of planar graphs. In this paper, we consider a near-triangulation where a near-triangulation is a planar graph whose bounded faces are all 3-cycles. Note that a triangulated planar graph is a special case of a near-triangulation. First, we show the following theorem.

**Theorem 1.2** If $G$ is a near-triangulation, then $ch_3^d(G) \leq 6$.

And we obtain the following corollary.

**Corollary 1.3** If $G$ is a triangulated planar graph, then $ch_3^d(G) \leq 6$.

Let $W_n$ be the wheel with $n + 1$ vertices such that $W_n$ is obtained from an $n$-cycle by adding a new vertex $u$ and joining $u$ and every vertex on the $n$-cycle. The following can be easily checked.

**Proposition 1.4** $ch_3^d(W_n) \leq 6$ for every positive integer $n \geq 3$ and $ch_3^d(W_5) = 6$.

Note that Proposition 1.4 and Theorem 1.2 imply that the upper bound of list 3-dynamic chromatic number of near triangulations is tight. And Corollary 1.3 implies that

$$5 \leq \max \{ ch_3^d(G) : G \text{ is a triangulated planar graph} \} \leq 6.$$

Thus it would be interesting to answer the following question.

**Question 1** Is it true that $ch_3^d(G) \leq 5$ if $G$ is a triangulated planar graph?

2. **Proof of Theorem 1.2**

Suppose that Theorem 1.2 does not hold, and let $G$ be a minimal counterexample to Theorem 1.2. Let $C : v_1v_2 \cdots v_tv_1$ in counter-clockwise order be the boundary of the outer face of a plane graph $G$. If $|V(G)| \leq 6$, then it is easy to obtain $ch_3^d(G) \leq 6$, a contradiction. Hence we have $|V(G)| \geq 7$.

First, we prove the following Claim.

**Claim 1** For any $v \in V(C)$, we have that $d_G(v) \geq 4$. 
Proof. Suppose that there is a vertex $v_k \in V(C)$ with $d_G(v_k) \leq 3$. Let $u_1, u_2, \ldots, u_s$ denote the neighbors of $v_k$ in counter-clockwise order. And let $u_1 = v_{k+1}$ ($k + 1$ are computed by module $t$).

If $d_G(v_k) = 2$ or $d_G(v_k) = 3$ with $u_1u_3 \in E(G)$, then we remove $v_k$ from $G$ and call the resulting graph by $G'$. If $d_G(v_k) = 3$ and $u_1u_3 \notin E(G)$, then we remove $v_k$ from $G$ and add the edge $u_1u_3$ in the outer face, and call the resulting graph by $G'$.

Let $L'(v) = L(v)$ for every $v \in V(G')$. Since $G$ is a minimal counterexample, $G'$ has a 3-dynamically $L'$-coloring $\phi$. 

If $d_G(v_k) = 2$, then there exists a vertex $u_0$ such that $u_0 \in (N_G(u_1) \cap N_G(u_2)) \setminus \{v_k\}$ since $|V(G)| \geq 7$. Then we color $v_k$ by a color $c \in L(v_k) \setminus \{\phi(u_0)\}$, and we obtain that $G$ has a 3-dynamic coloring from the list assignment $L$, a contradiction.

If $d_G(v_k) = 3$, then the vertices $u_1, u_2$ receive distinct colors under the coloring $\phi$. Suppose $u_1u_3 \in E(G)$. Then we color $v_k$ by a color $c \in L(v_k) \setminus \{\phi(u_1), \phi(u_2)\}$, and we obtain that $G$ has a 3-dynamic coloring from the list assignment $L$. This is a contradiction. Hence suppose that $u_1u_3 \notin E(G)$. If there is a vertex $u_i$ for $i \in \{1, 3\}$ such that $\phi(N_G(u_i))$ has at most two different colors, then we must color $v_k$ by a color $c \in L(v_k) \setminus \phi(N_G(v_k) \cup \phi(N_G(u_i)))$ so that vertex $u_i$ satisfies the conditions of 3-dynamic coloring. Then one can easily check that the number of forbidden colors at $v_k$ is at most 5 as follows.

Let $S$ be the set consisting of the forbidden colors at $v_k$. If $|\phi(N_G(u_1))| \geq 3$ and $|\phi(N_G(u_3))| \geq 3$, then $S = \{\phi(u_1), \phi(u_2), \phi(u_3)\}$. If $|\phi(N_G(u_i))| \leq 2$ and $|\phi(N_G(u_j))| \geq 3$ for $\{i, j\} = \{1, 3\}$, then $S = \{\phi(u_1), \phi(u_2), \phi(u_3)\} \cup \phi(N_G(u_i))$. If $|\phi(N_G(u_1))| \leq 2$ and $|\phi(N_G(u_3))| \leq 2$, then $S = \{\phi(u_1), \phi(u_2), \phi(u_3)\} \cup \phi(N_G(u_1)) \cup \phi(N_G(u_3))$. Since $u_2 \notin N_G(u_1) \cap N_G(u_3)$, we can easily obtain $|S| \leq 5$ for all cases above.

Thus we can color $v_k$ by a color $c \in L(v_k)$ so that $G$ has a 3-dynamic coloring from the list assignment $L$, and it implies that $G$ is 3-dynamically $L'$-colorable. This is a contradiction, which completes the proof of Claim \(\square\)

Next, we prove the following Claim.

Claim 2 For any $w \in V(G) \setminus V(C)$, we have that $d_G(w) \geq 6$.

Proof. Suppose that there is a vertex $w$ with $d_G(w) \leq 5$. Let $w_1, w_2, \ldots, w_s$ denote the neighbors of $w$ in counter-clockwise order.

Suppose $d_G(w) = 3$. We remove $w$ from $G$ and call the resulting graph by $G'$. Let $L'(v) = L(v)$ for every $v \in V(G')$. Since $G$ is a minimal counterexample, $G'$ has a 3-dynamically $L'$-
coloring \( \phi \). So, we can color \( w \) by a color \( c \in L(w) \setminus \phi(N_G(w)) \) so that \( G \) has a 3-dynamic coloring from the list assignment \( L \) since \( |L(v)| \geq 6 \) for each \( v \in V(G) \), a contradiction.

Now we suppose \( 4 \leq d_G(w) \leq 5 \). With Claim 1, we suppose \( d_G(v) \geq 4 \) for each \( v \in V(G) \). Then we remove \( w \) from \( G \) and add edges in the face formed by \( \{w_1, w_2, \ldots, w_s\} \) so that the resulting graph, denoted by \( G' \), is a near-triangulation. Let \( L'(v) = L(v) \) for every \( v \in V(G') \). Since \( G \) is a minimal counterexample, \( G' \) has a 3-dynamically \( L' \)-coloring \( \phi \). If \( N_G(w) = \{w_1, w_2, \ldots, w_s\} \) has all different colors in the coloring \( \phi \), then we color \( w \) by a color \( c \in L(w) \setminus \{\phi(w_i) : 1 \leq i \leq s\} \). Then this gives a 3-dynamic coloring from its list assignment \( L \).

Next, we consider the case when \( N_G(w) = \{w_1, w_2, \ldots, w_s\} \) have a common color. If \( w_{i-1} \) and \( w_{i+1} \) have a common color in the coloring \( \phi \) for some \( i \in [s] \) (\( i-1 \) and \( i+1 \) are computed by module \( s \)), then we color \( w \) by a color \( c \in L(w) \setminus \{\phi(w_i)\} \) for some \( w_i' \in N_G(w_i) \setminus \{w, w_{i-1}, w_{i+1}\} \) so that vertex \( w_i \) satisfies the condition of 3-dynamic coloring. It means that we select a neighbor \( w_i' \) of \( w_i \) and forbid \( \phi(w_i') \) at \( w \).

Since \( d_G(w) = 4 \) or \( d_G(w) = 5 \), then there are at most two vertices \( w_i \) such that \( \phi(w_{i-1}) = \phi(w_{i+1}) \) (\( i-1 \) and \( i+1 \) are computed by module \( s \)). Then the number of forbidden colors at \( w \) is at most 5.

So, we can color \( w \) by a color \( c \in L(w) \) so that \( G \) has a 3-dynamic coloring from the list assignment \( L \) since \( |L(v)| \geq 6 \) for each \( v \in V(G) \). Thus \( G \) is 3-dynamically \( L \)-colorable, which is a contradiction since \( G \) is a counterexample. This completes the proof of Claim 2. \( \square \)

Let \( k \) be the number of vertices in \( V(G) \setminus V(C) \). Then \( n(G) = t + k \) since \( |V(C)| = t \). Now from Claim 1 and Claim 2, we have

\[
2e(G) = \sum_{v \in V(G)} d_G(v) = \sum_{v \in V(C)} d_G(v) + \sum_{v \in V(G) \setminus V(C)} d_G(v) \geq 4t + 6k. \tag{2}
\]

And since \( G \) is a near-triangulation, we have

\[
e(G) = 3n(G) - 6 - (|V(C)| - 3) = 3n(G) - t - 3 = 2t + 3k - 3. \tag{3}
\]

So, by (2) and (3)

\[
4t + 6k - 6 = 2e(G) \geq 4t + 6k \implies -6 \geq 0,
\]

which is a contradiction. This completes the proof of Theorem 1. \( \square \)
