# ON THE PRESERVERS OF MAXIMALLY ENTANGLED STATES 

BEN GROSSMANN AND HUGO J. WOERDEMAN

#### Abstract

We characterize the linear maps that preserve maximally entangled states in $L(\mathcal{X} \otimes \mathcal{Y})$ in the case where $\operatorname{dim}(X)$ divides $\operatorname{dim}(Y)$.

## 1. Introduction

Entanglement is considered a valuable resource in quantum information theory; it is responsible for the power of quantum computing and for applications such as superdense coding and quantum teleportation. In the interest of "conserving" the resource of entanglement, we might ask the following question: which linear maps produce a maximally entangled output for any maximally entangled input?

More concretely: a quantum system with $m$ mutually exclusive configurations can be represented by an $m$-dimensional inner product space, which we will call $\mathcal{X}$. The configuration of such a system is represented with a unit vector $u \in \mathcal{X}$. If $\mathcal{X}, \mathcal{Y}$ are the spaces corresponding to two such systems, then a configuration of the joint system can be represented with a unit vector $u \in \mathcal{X} \otimes \mathcal{Y}$, where $\mathcal{X} \otimes \mathcal{Y}$ is the tensor product of the Hilbert spaces associated with each system. We could also represent this system with the associated "pure state" density operator $A=$ $u u^{*}$. We can measure the "entropy of entanglement" of $A$ by $S\left(\operatorname{tr}_{\mathcal{Y}}(A)\right)$, where $\operatorname{tr}_{\mathcal{Y}}$ denotes a partial trace over the space $\mathcal{Y}$ and $S(\rho)=-\operatorname{tr}\left(\rho \log _{2} \rho\right)$ is the Von Neumann entropy. We refer to the set of pure state density operators that maximize this measure of entanglement "maximally entangled states," and denote the set as $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$. This set can be succinctly described as

$$
\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}=\left\{\left.\frac{1}{m} \operatorname{vec}(A) \operatorname{vec}(A)^{*} \right\rvert\, A: \mathcal{Y} \rightarrow \mathcal{X} \text { is a coisometry }\right\}
$$

where vec stacks the rows of a matrix $A$ (see Section 2 for details). Quantum information is generally transmitted via a "quantum channel". Mathematically, this channel is a linear map that takes density matrices over a first system to density matrices over a second system (with an additional "complete positivity" condition). With this in mind, we hope to classify the linear maps $\Phi: \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \rightarrow$ $\operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$ that preserve the property of maximal entanglement, which is to say that they satisfy $\Phi\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \subset \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$.

The problem of classifying the linear maps that "preserve" the subset $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$ is an example of a "linear preserver problem". Linear preserver problems like this one have a long history (see, for instance, [3] and [1, Chapter 7]). Recently, there has been work done on linear preservers within the context of quantum information

[^0]theory. Two relevant papers to this endeavor are [2] and the more recent paper [5], whose results we generalize here.

In this paper, we prove the following result.
Theorem 1.1. Let $\mathcal{Y}=\mathcal{X}^{k}:=\mathcal{X} \oplus \cdots \oplus \mathcal{X}, k>1$. If $\Phi: \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \rightarrow$ $\operatorname{span}(\operatorname{MES} \mathcal{X}, \mathcal{Y})$ is an invertible linear map that preserves $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$, then $\Phi$ is of the form

$$
\Phi: X \mapsto(U \otimes V) X^{\sigma}(U \otimes V)^{*}
$$

where $U \in L(\mathcal{X}), V \in L(\mathcal{Y})$ are unitary if $A \mapsto A^{\sigma}$ denotes either the identity or transpose map.

This generalizes (the invertible case of) Poon's result from [5] which can be stated within our framework as follows:

Theorem 1.2. 5] A linear map $\Phi: \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{X}}\right) \rightarrow \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{X}}\right)$ preserves $\operatorname{MES}_{\mathcal{X}, \mathcal{X}}$ if and only if it has one of the following forms:
(1) $\Phi(A \otimes B)=(U \otimes V)(A \otimes B)^{\sigma}(U \otimes V)^{*}$
(2) $\Phi(A \otimes B)=(U \otimes V)(B \otimes A)^{\sigma}(U \otimes V)^{*}$
(3) $\Phi(X)=(\operatorname{tr} X) \rho$ for some $\rho \in \mathrm{MES}$
where $A \mapsto A^{\sigma}$ denotes either the identity or transpose map.
Notice that (2) does not appear in Theorem 1.1. Indeed, for (2) to make sense one needs $\mathcal{X}=\mathcal{Y}$. In addition, Poon was able to describe the non-invertible preservers, which take the form (3).

The proof can be summarized as follows. First, we show that an MES-preserving map $\Phi$ induces a continuous map $\zeta$ over the projective space $P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$ (to be introduced in Section 4). Moreover, we show that for mutually orthogonal coisometries $A, B$, there exist mutually orthogonal coisometries $C, D$ such that we have either

$$
\zeta([\alpha A+\beta B])=[\alpha C+\beta D] \quad \text { or } \quad \zeta([\alpha A+\beta B])=[\bar{\alpha} C+\bar{\beta} D]
$$

By considering the degree of $\zeta$ restricted to the span of $[A]$ and $[B]$, we deduce whether the $A \mapsto A^{\sigma}$ of our MES-preserving $\Phi$ is the identity or the transpose.

Having classified the possible maps $\zeta$, we then construct an MES-preserving extension $\tilde{\Phi}: \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}} \rightarrow \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$ and apply Theorem 1.2 to this extension $\tilde{\Phi}$. By considering the restriction of this map $\tilde{\Phi}$ to a subspace identified with $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$, we conclude that the restriction $\Phi$ must be of the form described in Theorem 1.1 .

The paper is organized as follows. In Section 2, we introduce definitions, particularly the definition of MES (the set of maximally entangled states) and the definition of our vectorization operator. In Section 3, we discuss some characterizations of $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$, and how it relates to the set of coisometries $\operatorname{coisom}(\mathcal{Y}, \mathcal{X})$. In Section 4, we define the continuous maps on MES that we will rely on in order to define the extension $\tilde{\Phi}$. In Section 5 , we consider how $\zeta$ behaves on pairwise-orthogonal coisometries. In Section 6, we use $\zeta$ to define the extension $\tilde{\Phi}: \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}} \rightarrow \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}$. Finally, in Section 7 we prove Theorem 1.1, our main result.

## 2. Definitions

Let $\mathcal{X}, \mathcal{Y}$ denote (finite dimensional, complex) Hilbert spaces with $\operatorname{dim}(\mathcal{X})=m$, $\operatorname{dim}(\mathcal{Y})=n$. Let $\mathcal{X} \otimes \mathcal{Y}$ denote the tensor product of these spaces, which is itself a Hilbert space of dimension $m n$. Let $L(\mathcal{X}, \mathcal{Y})$ denote the space of linear
transformations between $\mathcal{X}$ and $\mathcal{Y}$. We will also use the shorthand $L(\mathcal{X})=L(\mathcal{X}, \mathcal{X})$. We will use $\mathbb{1}_{\mathcal{X}}$ to denote the identity operator over the Hilbert space $\mathcal{X}$.

We say that an operator $A: \mathcal{X} \rightarrow \mathcal{Y}$ is an isometry if it satisfies $A^{*} A=\mathbb{1}_{\mathcal{X}}$. We will say that $A$ is a coisometry if its adjoint operator $A^{*}: \mathcal{Y} \rightarrow \mathcal{X}$ is an isometry.

A unit vector $u \in \mathcal{X} \otimes \mathcal{Y}$ is said to be maximally entangled if it can be written in the form

$$
\begin{equation*}
u=\sum_{j=1}^{r} \frac{1}{\sqrt{r}} x_{j} \otimes y_{j} \tag{2.1}
\end{equation*}
$$

for orthonormal sets of vectors $\left\{x_{1}, \ldots, x_{r}\right\} \subset \mathcal{X},\left\{y_{1}, \ldots, y_{r}\right\} \subset \mathcal{Y}$ and $r=\min \{m, n\}$.
The pure state (rank-1, trace-1, positive semidefinite operator) associated with $u$ is the projection operator $u u^{*} \in L(\mathcal{X} \otimes \mathcal{Y})$. Such an operator is called a maximally entangled state. That is, we define the set $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$ of maximally entangled states over $\mathcal{X}$ and $\mathcal{Y}$ to be

$$
\begin{equation*}
\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}=\left\{u u^{*}: u \text { is maximally entangled }\right\} \subset L(\mathcal{X} \otimes \mathcal{Y}) \tag{2.2}
\end{equation*}
$$

We will sometimes denote $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$ as MES (without its subscripts) when the context is clear.

We define the vectorization operator vec : $L(\mathcal{Y}, \mathcal{X}) \rightarrow \mathcal{X} \otimes \mathcal{Y}$ to be the linear map satisfying

$$
\begin{equation*}
\operatorname{vec}\left(x y^{T}\right)=x \otimes y \quad \text { for all } x \in \mathcal{X}, y \in \mathcal{Y} \tag{2.3}
\end{equation*}
$$

Notably, vec is an isomorphism of Hilbert spaces. It may be helpful to note that, in terms of matrices, vec can be written as vec : $\mathbb{C}^{m \times n} \rightarrow \mathbb{C}^{m n}$,

$$
\begin{equation*}
\operatorname{vec}\left(\left[a_{i j}\right]_{i=1}^{m} n=1\right)=\left(a_{11}, \ldots, a_{1 n}, a_{21}, \ldots, a_{2 n}, \ldots, a_{m 1}, \ldots, a_{m n}\right)^{T} \tag{2.4}
\end{equation*}
$$

which is to say that our vectorization operator "stacks the rows" of a matrix (in contrast to the other common convention of "stacking the columns"). We adopted this convention from [6].

Throughout the paper $e_{1}, \ldots, e_{n}$ will denote the canonical basis for $\mathbb{C}^{n}$ (for instance, $\left.e_{1}=(1,0, \ldots, 0)^{T}\right)$. We will also take $E_{i j} \in \mathbb{C}^{m \times n}$ to be the matrix $E_{i j}=e_{i} e_{j}^{T}$, i.e. the matrix that has a 1 as its $i, j$ entry and zeros elsewhere.

Remark 2.1. In the remainder of the paper, we will take $\operatorname{dim}(\mathcal{X})=m<\infty$ and $\operatorname{dim}(\mathcal{Y})=n<\infty$, with $m \leq n$.

## 3. Characterizing MES

Proposition 3.1. If $n \geq m, u$ is maximally entangled in $\mathcal{X} \otimes \mathcal{Y}$ iff there exists $a$ coisometry $A: \mathcal{Y} \rightarrow \mathcal{X}$ such that $u=\frac{1}{\sqrt{m}} \operatorname{vec}(A)$.

Proof: Suppose that $u$ is a maximally entangled unit vector. Let $\left\{x_{1}, \ldots, x_{m}\right\}$ and $\left\{y_{1}, \ldots, y_{n}\right\}$ be orthonormal bases of $\mathcal{X}$ and $\mathcal{Y}$ such that $u=\frac{1}{\sqrt{m}} \sum_{j=1}^{m} x_{j} \otimes y_{j}$. It follows that

$$
\begin{equation*}
\operatorname{vec}^{-1}(u)=\frac{1}{\sqrt{m}} \sum_{j=1}^{m} \operatorname{vec}^{-1}\left(x_{j} \otimes y_{j}\right)=\frac{1}{\sqrt{m}}\left(\sum_{j=1}^{m} x_{j} y_{j}^{T}\right) \tag{3.1}
\end{equation*}
$$

and we recognize that $A=\sum_{j=1}^{m} x_{j} y_{j}^{T}$ is a singular value decomposition of a coisometry.

Conversely, suppose $u=\frac{1}{\sqrt{m}} \operatorname{vec}(A)$. Then $A$ has a singular value decomposition $A=\sum_{j=1}^{m} x_{j} y_{j}^{T}$ so that

$$
\begin{equation*}
u=\frac{1}{\sqrt{m}} \operatorname{vec}\left(\sum_{j=1}^{m} x_{j} y_{j}^{T}\right)=\frac{1}{\sqrt{m}} \sum_{j=1}^{m} x_{j} \otimes y_{j} \tag{3.2}
\end{equation*}
$$

is maximally entangled.

Let $\operatorname{tr}_{\mathcal{Y}}: L(\mathcal{X} \otimes \mathcal{Y}) \rightarrow L(\mathcal{X})$ denote the "partial trace" over the space $\mathcal{Y}$. That is, we define $\operatorname{tr}_{\mathcal{Y}}$ to be the unique linear operator satisfying

$$
\begin{equation*}
\operatorname{tr}_{\mathcal{Y}}(A \otimes B)=\operatorname{tr}(B) A \quad \text { for all } A \in L(\mathcal{X}), \quad B \in L(\mathcal{Y}) \tag{3.3}
\end{equation*}
$$

The following lemma is stated, for instance, in Equation 1.133 of [6].
Lemma 3.2. For any operators $A, B: \mathcal{Y} \rightarrow \mathcal{X}$, we have

$$
\begin{equation*}
\operatorname{tr}_{\mathcal{Y}}\left(\operatorname{vec}(A) \operatorname{vec}(B)^{*}\right)=A B^{*} \tag{3.4}
\end{equation*}
$$

Proof: Suppose first that $A$ and $B$ are rank-1. We can then write $A=u v^{T}$ and $B=x y^{T}$ for $u, x \in \mathcal{X}$ and $v, y \in \mathcal{Y}$. We find that

$$
\begin{aligned}
\operatorname{tr}_{\mathcal{Y}}\left(\operatorname{vec}(A) \operatorname{vec}(B)^{*}\right) & =\operatorname{tr}_{\mathcal{Y}}\left((u \otimes v)(x \otimes y)^{*}\right) \\
& =\operatorname{tr}_{\mathcal{Y}}\left(\left(u x^{*}\right) \otimes\left(v y^{*}\right)\right) \\
& =\left(y^{*} v\right) u x^{*}=u v^{*} y x^{*}=\left(u v^{T}\right)\left(x y^{T}\right)^{*}=A B^{*}
\end{aligned}
$$

Now, if $A=\sum_{j} A_{j}$ and $B=\sum_{k} B_{k}$ where $A_{j}, B_{k} \in L(\mathcal{Y}, \mathcal{X})$ have rank 1 , then

$$
\begin{aligned}
\operatorname{tr} \mathcal{Y}\left(\operatorname{vec}(A) \operatorname{vec}(B)^{*}\right) & =\operatorname{tr} \mathcal{Y}\left(\operatorname{vec}\left(\sum_{j} A_{j}\right) \operatorname{vec}\left(\sum_{k} B_{k}\right)^{*}\right) \\
& =\sum_{j, k} \operatorname{tr}_{\mathcal{Y}}\left(\operatorname{vec}\left(A_{j}\right) \operatorname{vec}\left(B_{k}\right)^{*}\right)=\sum_{j, k} A_{j} B_{k}^{*} \\
& =\left(\sum_{j} A_{j}\right)\left(\sum_{k} B_{k}\right)^{*}=A B^{*}
\end{aligned}
$$

Since any operator can be written as a sum of rank-1 operators, the desired conclusion holds.

Lemma 3.3. For all $M \in \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$, we have $\operatorname{tr}_{\mathcal{Y}}(M)=\frac{1}{m} \mathbb{1}_{\mathcal{X}}$. Moreover, for $M \in \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$, we have $\operatorname{tr}_{\mathcal{Y}}(M)=\frac{\operatorname{tr}(M)}{m} \mathbb{1}_{\mathcal{X}}$.

Proof: By Proposition [3.1, there exists a coisometry $A: \mathcal{Y} \rightarrow \mathcal{X}$ such that $M=\frac{1}{m} \operatorname{vec}(A) \operatorname{vec}(A)^{*}$. By Lemma 3.2, we find that

$$
\begin{equation*}
\operatorname{tr}_{\mathcal{Y}}(M)=\frac{1}{m} \operatorname{tr}_{\mathcal{Y}}\left(\operatorname{vec}(A) \operatorname{vec}(A)^{*}\right)=\frac{1}{m} A A^{*}=\frac{1}{m} \mathbb{1}_{\mathcal{X}} . \tag{3.5}
\end{equation*}
$$

By the linearity of the partial trace, it follows that $\operatorname{tr} \mathcal{Y}(M)=\frac{\operatorname{tr}(M)}{m} \mathbb{1}_{\mathcal{X}}$ for all $M \in \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$.

The following proposition generalizes Remark 2.3 in [5].
Proposition 3.4. The set of pure states in the real linear span of MES is precisely MES. That is: if $M$ is a rank-1, trace-1, positive operator, then $M \in \operatorname{span}(\mathrm{MES})$ implies that $M \in$ MES.

Proof: Let $M$ be a rank-1, trace-1, positive operator in span(MES). Let $u$ be a unit-vector such that $M=u u^{*}$. Let $A: \mathcal{Y} \rightarrow \mathcal{X}$ be an operator such that $u=\frac{1}{\sqrt{m}} \operatorname{vec}(A)$. By Lemma 3.3, $M \in \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$ implies that

$$
\begin{equation*}
\operatorname{tr}_{\mathcal{Y}}(M)=\frac{\operatorname{tr} M}{m} \mathbb{1}_{\mathcal{X}}=\frac{1}{m} \mathbb{1}_{\mathcal{X}} . \tag{3.6}
\end{equation*}
$$

By Lemma 3.2, this implies that

$$
\begin{equation*}
\mathbb{1}_{\mathcal{X}}=m \operatorname{tr}_{\mathcal{Y}}(M)=\operatorname{tr}_{\mathcal{Y}}\left(\operatorname{vec}(A) \operatorname{vec}\left(A^{*}\right)\right)=A A^{*} \tag{3.7}
\end{equation*}
$$

That is, $A$ is a coisometry. By Proposition 3.1, we may conclude that $u=$ $\frac{1}{\sqrt{m}} \operatorname{vec}(A)$ is maximally entangled, and that $M=u u^{*}$ is an element of MES.

## 4. Continuous Maps on MES

Remark 4.1. In the remainder of the paper, $\Phi$ will denote an invertible linear map $\Phi: \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \rightarrow \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$ such that $\Phi\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \subset \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$.

For a (finite-dimensional) vector space $V$ and a subset $S \subset V$, let $P(S)$ denote complex projective space over $S$, the topological space of one-dimensional $\mathbb{C}$-subspaces of $V$ that contain a non-zero element of $S$. For an element $A \in S$, we use $[A]=\{z A: z \in \mathbb{C}\}$ to denote the element of $P(S)$ containing $A$.

For $A \in L(\mathcal{Y}, \mathcal{X})$, let $\pi_{A} \in L(\mathcal{X} \otimes Y)$ be given by

$$
\pi_{A}=\frac{1}{\operatorname{tr}\left(A A^{*}\right)} \operatorname{vec}(A) \operatorname{vec}(A)^{*}
$$

We see that $\pi_{A} \in \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$ if and only if $A: \mathcal{Y} \rightarrow \mathcal{X}$ is a (complex) multiple of a coisometry (that is, if $A A^{*}=k \mathbb{1}_{\mathcal{X}}$ for some $k>0$ ).

Remark 4.2. Let $K$ be a compact subset of the finite-dimensional normed vector space $L(\mathcal{Y}, \mathcal{X})$. The map $\pi$ is constant over any equivalence class in $P(K)$, so the induced map from $P(K)$ to $L(\mathcal{X} \otimes \mathcal{Y})$ given by $[A] \mapsto \pi_{A}$ is well-defined. Moreover, this induced map is a homeomorphism between $P(K)$ and the map's image.

With $K=\operatorname{coisom}(\mathcal{Y}, \mathcal{X})$ in particular, we see that the image of the map $[A] \mapsto \pi_{A}$ is precisely $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$.

Proof: To see that the map $[A] \mapsto \pi_{A}$ is well defined and continuous over the quotient space $P(K)$, it suffices to note that if $A_{1}, A_{2} \in K$ satisfy $A_{1} \sim A_{2}$ (i.e. if
$A_{1}=k A_{2}$ for some non-zero $k \in \mathbb{C}$ ), then $\pi_{A_{1}}=\pi_{A_{2}}$. We see moreover that this induced map is injective: that is, we observe that if $\pi\left(A_{1}\right)=\pi\left(A_{2}\right)$, then $A_{1} \sim A_{2}$. Because $K$ is compact, the quotient space $P(K)=K / \sim$ is also compact.

So, we have found that the induced map $[A] \mapsto \pi_{A}$ is a continuous, injective map from the compact quotient space $K / \sim$ to the Hausdorff space $L(\mathcal{X} \otimes \mathcal{Y})$. Because our map is an injective, continuous map with compact domain and Hausdorff codomain, it is a homeomorphism between the map's domain and the map's image (by Theorem 26.6 of [4), as desired.

With the above in mind, we note that the $\operatorname{set} \operatorname{coisom}(\mathcal{Y}, \mathcal{X})$ is compact in $L(\mathcal{Y}, \mathcal{X})$. We define $\zeta: P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X})) \rightarrow P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$ to be the unique linear map such that for all $A \in \operatorname{coisom}(\mathcal{Y}, \mathcal{X})$, we have $\pi_{\zeta[A]}=\Phi\left(\pi_{A}\right)$.

That is, we define $\zeta$ so that the following diagram (of continuous maps) commutes:

Since $\Phi$ is a continuous, invertible map on $\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$ and $\pi$ is a homeomorphism, we see that $\zeta$ must also be a continuous, invertible map on $P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$.

This map $\zeta$ will be particularly important to the construction of $\tilde{\Phi}$ in Section 6. To begin, we show that $\zeta$ satisfies the following "preservation of subspaces" property.

Proposition 4.3. For $A_{1}, A_{2}, A_{3} \in \operatorname{coisom}(\mathcal{Y}, \mathcal{X}):$ if $\left[A_{3}\right] \subset\left[A_{1}\right]+\left[A_{2}\right]$, then $\zeta\left[A_{3}\right]$ must be a subspace of $\zeta\left[A_{1}\right]+\zeta\left[A_{2}\right]$.

Proof: Equivalently, we wish to show that
$\exists \alpha>0$ such that $\pi_{A_{1}}+\pi_{A_{2}}-\alpha \pi_{A_{3}}$ is positive semidefinite $\Longrightarrow$
$\exists \beta>0$ such that $\pi_{\zeta\left[A_{1}\right]}+\pi_{\zeta\left[A_{2}\right]}-\beta \pi_{\zeta\left[A_{3}\right]}$ is positive semidefinite.
That is, we wish to show that

$$
\begin{aligned}
& \exists \alpha>0 \text { such that } \pi_{A_{1}}+\pi_{A_{2}}-\alpha \pi_{A_{3}} \text { is positive semidefinite } \Longrightarrow \\
& \exists \beta>0 \text { such that } \Phi\left(\pi_{A_{1}}+\pi_{A_{2}}-\beta \pi_{A_{3}}\right) \text { is positive semidefinite. }
\end{aligned}
$$

So, suppose that there exists an $\alpha>0$ such that $\pi_{A_{1}}+\pi_{A_{2}}-\alpha \pi_{A_{3}}$ is positive semidefinite. It follows that there exists an $\gamma \geq \alpha$ such that $\pi_{A_{1}}+\pi_{A_{2}}-\gamma \pi_{A_{3}}$ is rank 1 and positive semidefinite. Since $\pi_{A_{1}}+\pi_{A_{2}}-\gamma \pi_{A_{3}}$ is a rank-1 positive semidefinite element of span(MES), we may apply Proposition 3.4 to state that there exists a $k>0$ and coisometry $B: \mathcal{Y} \rightarrow \mathcal{X}$ such that

$$
\pi_{A_{1}}+\pi_{A_{2}}-\gamma \pi_{A_{3}}=k \pi_{B}
$$

Thus, we conclude that

$$
\Phi\left(\pi_{A_{1}}+\pi_{A_{2}}-\alpha \pi_{A_{3}}\right)=\Phi\left(\pi_{A_{1}}+\pi_{A_{2}}-\gamma \pi_{A_{3}}+(\gamma-\alpha) \pi_{A_{3}}\right)
$$

$$
\begin{aligned}
& =\Phi\left(k \pi_{B}+(\gamma-\alpha) \pi_{A_{3}}\right) \\
& =k \Phi\left(\pi_{B}\right)+(\gamma-\alpha) \Phi\left(\pi_{A_{3}}\right)
\end{aligned}
$$

Thus, the desired condition holds with $\beta=\alpha$.

## 5. Pairwise Orthogonal Coisometries

We will say that two coisometries $A_{1}, A_{2}: \mathcal{Y} \rightarrow \mathcal{X}$ are orthogonal if $A_{1} A_{2}^{*}=0$.
Lemma 5.1. For coisometries $A_{1}, A_{2}: \mathcal{Y} \rightarrow \mathcal{X}$, the following are equivalent:
(1) $A_{1} A_{2}^{*}=0$.
(2) $A_{2} A_{1}^{*}=0$.
(3) The map $\left[\begin{array}{c}A_{1} \\ A_{2}\end{array}\right]: \mathcal{Y} \rightarrow \mathcal{X} \oplus \mathcal{X}$ is a coisometry.
(4) $\alpha A_{1}+\beta A_{2}$ is a coisometry for $\alpha, \beta \in \mathbb{C}$ whenever $|\alpha|^{2}+|\beta|^{2}=1$.
(5) The images of $A_{1}^{*}, A_{2}^{*}$ are orthogonal subspaces of $\mathcal{Y}$.

Proof: $1 \Longleftrightarrow 2$ : It suffices to note that $\left(A_{1} A_{2}^{*}\right)^{*}=A_{2} A_{1}^{*}$.
$1 \Longrightarrow 3$ : Suppose that $A_{2} A_{1}^{*}=A_{1} A_{2}^{*}=0$. We then compute

$$
\left[\begin{array}{l}
A_{1}  \tag{5.1}\\
A_{2}
\end{array}\right]\left[\begin{array}{l}
A_{1} \\
A_{2}
\end{array}\right]^{*}=\left[\begin{array}{ll}
A_{1} A_{1}^{*} & A_{1} A_{2}^{*} \\
A_{2} A_{1}^{*} & A_{2} A_{2}^{*}
\end{array}\right]=\left[\begin{array}{cc}
\mathbb{1}_{\mathcal{X}} & 0 \\
0 & \mathbb{1}_{\mathcal{X}}
\end{array}\right]=\mathbb{1}_{\mathcal{X} \oplus \mathcal{X}}
$$

$3 \Longrightarrow 1$ : Suppose that $\left[\begin{array}{c}A_{1} \\ A_{2}\end{array}\right]$ is a coisometry. Then

$$
\mathbb{1}_{\mathcal{X} \oplus \mathcal{X}}=\left[\begin{array}{cc}
\mathbb{1}_{\mathcal{X}} & 0  \tag{5.2}\\
0 & \mathbb{1}_{\mathcal{X}}
\end{array}\right]=\left[\begin{array}{l}
A_{1} \\
A_{2}
\end{array}\right]\left[\begin{array}{l}
A_{1} \\
A_{2}
\end{array}\right]^{*}=\left[\begin{array}{ll}
A_{1} A_{1}^{*} & A_{1} A_{2}^{*} \\
A_{2} A_{1}^{*} & A_{2} A_{2}^{*}
\end{array}\right],
$$

from which we may conclude that $A_{j} A_{j}^{*}=\mathbb{1}_{\mathcal{X}}$ (that is, $A_{1}, A_{2}$ are coisometries) and $A_{1} A_{2}^{*}=0$ (that is, $A_{1}$ and $A_{2}$ are orthogonal).
$1 \Longleftrightarrow 4$ : We compute

$$
\begin{align*}
\left(\alpha A_{1}+\beta A_{2}\right)\left(\alpha A_{1}+\beta A_{2}\right)^{*}= & |\alpha|^{2} A_{1} A_{1}^{*}+|\beta|^{2} A_{2} A_{2}^{*}  \tag{5.3}\\
& \quad+\alpha \bar{\beta} A_{1} A_{2}^{*}+\bar{\alpha} \beta A_{2} A_{1}^{*}  \tag{5.4}\\
= & \left(|\alpha|^{2}+|\beta|^{2}\right) \mathbb{1}_{\mathcal{X}}+\left(\alpha \bar{\beta} A_{1} A_{2}^{*}\right)+\left(\alpha \bar{\beta} A_{1} A_{2}^{*}\right)^{*} \tag{5.5}
\end{align*}
$$

If $A_{1} A_{2}^{*}=0$, then we have $\left(\alpha A_{1}+\beta A_{2}\right)\left(\alpha A_{1}+\beta A_{2}\right)^{*}=\left(|\alpha|^{2}+|\beta|^{2}\right) \mathbb{1}_{\mathcal{X}}$, which is to say that $\alpha A_{1}+\beta A_{2}$ is a coisometry whenever $|\alpha|^{2}+|\beta|^{2}=1$. That is, $1 \Longrightarrow 4$.

Conversely, if 4 holds, then it must be that $\left(\alpha \bar{\beta} A_{1} A_{2}^{*}\right)+\left(\alpha \bar{\beta} A_{1} A_{2}^{*}\right)^{*}=0$ for all choices of $\alpha, \beta$ with $|\alpha|^{2}+|\beta|^{2}=1$. Let $\gamma=\alpha \bar{\beta}$, and choose self-adjoint $H, K$ such that $A_{1} A_{2}^{*}=H+i K$. We then compute

$$
\begin{equation*}
(\gamma(H+i K))+(\gamma(H+i K))^{*}=(\gamma+\bar{\gamma}) H+i(\gamma-\bar{\gamma}) K \tag{5.6}
\end{equation*}
$$

and, by 4 , we know that the above expression is zero for all $\gamma=\alpha \bar{\beta}$ with $\alpha, \beta \in \mathbb{C}$ satisfying $|\alpha|^{2}+|\beta|^{2}=1$.

Setting $\alpha=\beta=\frac{1}{\sqrt{2}}$, we find $\gamma=\frac{1}{2}$ and we see that we must have $H=0$. Setting $\alpha=\frac{i}{\sqrt{2}}$ and $\beta=\frac{1}{\sqrt{2}}$, we find $\gamma=\frac{i}{2}$ and we see that we must have $K=0$. Since $H=0$ and $K=0$, we conclude that $A_{1} A_{2}^{*}=0$.

The proof that $5 \Longleftrightarrow 1$ is straightforward and therefore omitted.

Lemma 5.2. For any two orthogonal coisometries $A_{1}, A_{2}: \mathcal{Y} \rightarrow \mathcal{X}$ : there exist orthogonal coisometries $B_{1}, B_{2}: \mathcal{Y} \rightarrow \mathcal{X}$ with $B_{i} \in \zeta\left(A_{i}\right)$ such that we have either

$$
\begin{align*}
& \Phi\left(\sum_{i, j=1}^{2} a_{i j} \operatorname{vec}\left(A_{i}\right) \operatorname{vec}\left(A_{j}\right)^{*}\right)=\sum_{i, j=1}^{2} a_{i j} \operatorname{vec}\left(B_{i}\right) \operatorname{vec}\left(B_{j}\right)^{*} \text { or }  \tag{5.7}\\
& \Phi\left(\sum_{i, j=1}^{2} a_{i j} \operatorname{vec}\left(A_{i}\right) \operatorname{vec}\left(A_{j}\right)^{*}\right)=\sum_{i, j=1}^{2} a_{i j} \operatorname{vec}\left(B_{j}\right) \operatorname{vec}\left(B_{i}\right)^{*}
\end{align*}
$$

Proof: To begin, select coisometries $\tilde{B}_{1} \in \zeta\left(A_{1}\right), \tilde{B}_{2} \in \zeta\left(A_{2}\right)$. Because $\Phi$ is invertible, $\tilde{B}_{1}$ and $\tilde{B}_{2}$ must be linearly independent. Let $V_{1}$ and $V_{2}$ denote the subspaces

$$
\begin{aligned}
& V_{1}=\operatorname{span}\left\{\operatorname{vec}\left(A_{i}\right) \operatorname{vec}\left(A_{j}\right)^{*}: i, j=1,2\right\} \\
& V_{2}=\operatorname{span}\left\{\operatorname{vec}\left(\tilde{B}_{i}\right) \operatorname{vec}\left(\tilde{B}_{j}\right)^{*}: i, j=1,2\right\}
\end{aligned}
$$

We observe that the elements of the form $\pi_{\alpha A_{1}+\beta A_{2}}$ span $V_{1}$ (for instance: we see that $\left\{\pi_{A_{1}}, \pi_{A_{2}}, \pi_{\left(A_{1}+A_{2}\right) / 2}, \pi_{\left(A_{1}+i A_{2}\right) / 2}\right\}$ forms a spanning set), and by Proposition 4.3 we see that the image of these elements must lie in $V_{2}$. Thus, $\Phi$ takes the subspace $V_{1}$ to $V_{2}$.

We define the map $G: \mathbb{C}^{2 \times 2} \rightarrow \mathbb{C}^{2 \times 2}$ so that

$$
\begin{aligned}
G\left(\left[\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right]\right) & =\left[\begin{array}{ll}
b_{11} & b_{12} \\
b_{21} & b_{22}
\end{array}\right] \Longleftrightarrow \\
\Phi\left(\sum_{i, j=1}^{2} a_{i j} \operatorname{vec}\left(A_{i}\right) \operatorname{vec}\left(A_{j}\right)^{*}\right) & =\sum_{i, j=1}^{2} b_{i j} \operatorname{vec}\left(\tilde{B}_{i}\right) \operatorname{vec}\left(\tilde{B}_{j}\right)^{*} \Longleftrightarrow \\
\Phi\left(\left[\operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{2}\right)\right]\left[\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right]\left[\begin{array}{c}
\operatorname{vec}\left(A_{1}\right)^{*} \\
\operatorname{vec}\left(A_{2}\right)^{*}
\end{array}\right]\right) & =\left[\operatorname{vec}\left(\tilde{B}_{1}\right) \operatorname{vec}\left(\tilde{B}_{2}\right)\right]\left[\begin{array}{ll}
b_{11} & b_{12} \\
b_{21} & b_{22}
\end{array}\right]\left[\begin{array}{l}
\operatorname{vec}\left(\tilde{B}_{1}\right)^{*} \\
\operatorname{vec}\left(\tilde{B}_{2}\right)^{*}
\end{array}\right]
\end{aligned}
$$

By our definition of $\tilde{B}_{1}, \tilde{B}_{2}$, we have $G\left(E_{11}\right)=E_{11}, G\left(E_{22}\right)=E_{22}$.
We note that

$$
\pi_{\alpha A_{1}+\beta A_{2}}=\frac{1}{m}\left[\operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{2}\right)\right]\left(\left[\begin{array}{l}
\alpha  \tag{5.9}\\
\beta
\end{array}\right]\left[\begin{array}{l}
\alpha \\
\beta
\end{array}\right]^{*}\right)\left[\begin{array}{c}
\operatorname{vec}\left(A_{1}\right)^{*} \\
\operatorname{vec}\left(A_{2}\right)^{*}
\end{array}\right]
$$

so that because $\Phi$ preserves MES, $G$ maps the rank-1 positive semidefinite matrices in $\mathbb{C}^{2 \times 2}$ to the rank-1 positive semidefinite matrices in $\mathbb{C}^{2 \times 2}$. Thus, $G: \mathbb{C}^{2 \times 2} \rightarrow$ $\mathbb{C}^{2 \times 2}$ is a positive map. That is: if $A \in \mathbb{C}^{2 \times 2}$ is positive semidefinite, then $G(A)$ is also positive semidefinite.

By [7, $G$ must be decomposable. That is, $\Phi$ must have the form $G=G_{1}+G_{2}$, where $G_{1}$ and $\tau \circ G_{2}$ are completely positive and $\tau$ denotes the transpose map $A \mapsto A^{T}$.

Let $J(G)$ denote the Choi matrix of $G$. That is,

$$
\left.J(G)=\sum_{i, j=1}^{2} E_{i j} \otimes G\left(E_{i j}\right)=\left(\mathbb{1}_{\mathbb{C}^{2 \times 2}} \otimes G\right)\left(\operatorname{vec}\left(\mathbb{1}_{\mathbb{C}^{2}}\right) \operatorname{vec}\left(\mathbb{1}_{\mathbb{C}^{2}}\right)^{*}\right)\right)
$$

So far, we may deduce that

$$
J(G)=J\left(G_{1}\right)+J\left(G_{2}\right)=\left[\begin{array}{cc}
G\left(E_{11}\right) & G\left(E_{12}\right) \\
G\left(E_{21}\right) & G\left(E_{22}\right)
\end{array}\right]=\left[\begin{array}{cc|cc}
1 & 0 & g_{11} & g_{12} \\
0 & 0 & g_{21} & g_{22} \\
\hline \bar{g}_{11} & \bar{g}_{21} & 0 & 0 \\
\bar{g}_{12} & \bar{g}_{22} & 0 & 1
\end{array}\right]
$$

Let $P_{i}, Q_{i}, R_{i}$ be defined so that

$$
J\left(G_{1}\right)=\left[\begin{array}{ll}
P_{1} & Q_{1} \\
Q_{1}^{*} & R_{1}
\end{array}\right], \quad J\left(G_{2}\right)=\left[\begin{array}{ll}
P_{2} & Q_{2} \\
Q_{2}^{*} & R_{2}
\end{array}\right]
$$

Because $G_{1}, \tau \circ G_{2}$ are completely positive, their Choi matrices $J\left(G_{1}\right)$ and $J\left(\tau \circ G_{2}\right)$ must be positive semidefinite. Thus, $P_{1}, P_{2}, R_{1}, R_{2} \succeq 0$ and

$$
\left[\begin{array}{ll}
P_{1} & Q_{1}  \tag{5.10}\\
Q_{1}^{*} & R_{1}
\end{array}\right] \succeq 0, \quad\left[\begin{array}{ll}
P_{2}^{T} & Q_{2}^{T} \\
\bar{Q}_{2} & R_{2}^{T}
\end{array}\right] \succeq 0
$$

Because $P_{1}, P_{2}$ are positive definite matrices satisfying $P_{1}+P_{2}=E_{11}$, we must have $P_{i}=p_{i} E_{11}$ with $p_{1}+p_{2}=1$ and $p_{i} \geq 0$. Similarly, $R_{i}=r_{i} E_{22}$ with $r_{1}+r_{2}=1$ and $r_{i} \geq 0$.

By (5.10), we must have $Q_{1}=q_{1} E_{12}$ and $Q_{2}=q_{2} E_{21}$, where $\left|q_{i}\right| \leq \sqrt{p_{i} r_{i}}$ for $i=1,2$.

Now, since $G$ maps rank-1 positive semidefinite matrices to rank-1 positive semidefinite matrices (as stated below (5.9)), it must be that the matrix

$$
G\left(\left[\begin{array}{l}
\alpha \\
\beta
\end{array}\right]\left[\begin{array}{l}
\alpha \\
\beta
\end{array}\right]^{*}\right)=\left[\begin{array}{cc}
|\alpha|^{2} & \alpha \bar{\beta} q_{1}+\bar{\alpha} \beta \bar{q}_{2} \\
\bar{\alpha} \beta \bar{q}_{1}+\alpha \bar{\beta} q_{2} & |\beta|^{2}
\end{array}\right]
$$

is positive semidefinite with rank 1 . Thus, its determinant must be zero for all $\alpha, \beta$. That is, we must have

$$
|\alpha|^{2}|\beta|^{2}=\left|\alpha \bar{\beta} q_{1}+\bar{\alpha} \beta \bar{q}_{2}\right|^{2}
$$

for all choices $\alpha, \beta \in \mathbb{C}$. Taking $\alpha=e^{i \theta}$ and $\beta=1$, we see that this implies

$$
1=\left|e^{i \theta} q_{1}+e^{-i \theta} q_{2}\right|^{2}, \quad \theta \in \mathbb{R}
$$

Thus, for all values of $\theta$,

$$
\left|e^{i \theta} q_{1}+e^{-i \theta} q_{2}\right|^{2}=\left|q_{1}\right|^{2}+\left|q_{2}\right|^{2}+2 \operatorname{Re}\left[q_{1} \bar{q}_{2} e^{i \theta}\right]
$$

is constant. This only occurs if $q_{1} \bar{q}_{2}=0$, which is to say that $q_{1}=0$ or $q_{2}=0$. That is, we must have

$$
J(G)=\left[\begin{array}{cc|cc}
1 & 0 & 0 & e^{-i \alpha} \\
0 & 0 & 0 & 0 \\
\hline 0 & 0 & 0 & 0 \\
e^{i \alpha} & 0 & 0 & 1
\end{array}\right] \quad \text { or } \quad J(G)=\left[\begin{array}{cc|cc}
1 & 0 & 0 & 0 \\
0 & 0 & e^{i \alpha} & 0 \\
\hline 0 & e^{-i \alpha} & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

If $J(G)$ has the first form, then we have

$$
\begin{aligned}
\Phi\left(\sum_{p, q=1}^{2} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right) & =\sum_{p, q=1}^{2} a_{p q} e^{i \alpha(p-q)} \operatorname{vec}\left(\tilde{B}_{p}\right) \operatorname{vec}\left(\tilde{B}_{q}\right)^{*} \\
& =\sum_{p, q=1}^{2} a_{p q} \operatorname{vec}\left(B_{p}\right) \operatorname{vec}\left(B_{q}\right)^{*}
\end{aligned}
$$

where we have taken $B_{1}:=\tilde{B}_{1}$ and $B_{2}:=e^{i \alpha} \tilde{B}_{2}$. That is, (5.7) applies, as desired.

If $J(G)$ has the second form, then we have

$$
\begin{aligned}
\Phi\left(\sum_{p, q=1}^{2} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right) & =\sum_{p, q=1}^{2} a_{p q} e^{i \alpha(q-p)} \operatorname{vec}\left(\tilde{B}_{q}\right) \operatorname{vec}\left(\tilde{B}_{p}\right)^{*} \\
& =\sum_{p, q=1}^{2} a_{p q} \operatorname{vec}\left(B_{q}\right) \operatorname{vec}\left(B_{p}\right)^{*}
\end{aligned}
$$

where again, we have taken $B_{1}:=\tilde{B}_{1}$ and $B_{2}:=e^{i \alpha} \tilde{B}_{2}$. That is, (5.8) applies, as desired.

If (5.7) applies, then since $\Phi$ preserves MES, we can state by Lemmas 3.2, 3.3, and 5.1 that for all $\alpha, \beta$ with $|\alpha|^{2}+|\beta|^{2}=1$, we have

$$
\begin{aligned}
\mathbb{1}_{\mathcal{X}}= & \operatorname{tr}_{\mathcal{Y}}\left(\Phi\left[\left(\operatorname{vec}\left(\alpha A_{1}+\beta A_{2}\right) \operatorname{vec}\left(\alpha A_{1}+\beta A_{2}\right)^{*}\right)\right]\right) \\
= & \operatorname{tr}_{\mathcal{Y}}\left[|\alpha|^{2} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right. \\
& \left.\quad+\alpha \bar{\beta} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{2}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{1}\right)^{*}\right] \\
= & |\alpha|^{2} B_{1} B_{1}^{*}+|\beta|^{2} B_{2} B_{2}^{*}+\alpha \bar{\beta} B_{1} B_{2}^{*}+\bar{\alpha} \beta B_{2} B_{1}^{*} \\
= & \left(|\alpha|^{2}+|\beta|^{2}\right) \mathbb{1}_{\mathcal{X}}+2 \operatorname{Re}\left[\alpha \bar{\beta} B_{1} B_{2}^{*}\right]=\mathbb{1}_{\mathcal{X}}+2 \operatorname{Re}\left[\alpha \bar{\beta} B_{1} B_{2}^{*}\right] .
\end{aligned}
$$

Thus, we have $\operatorname{Re}\left[\alpha \bar{\beta} B_{1} B_{2}^{*}\right]=0$ for all $\alpha, \beta \in \mathbb{C}$ with $|\alpha|^{2}+|\beta|^{2}=1$, so that $B_{1} B_{2}^{*}=0$. Thus, $B_{1}$ and $B_{2}$ are orthogonal coisometries.

Similarly: if (5.8) applies, then for all $\alpha, \beta$ with $|\alpha|^{2}+|\beta|^{2}=1$, we have

$$
\begin{aligned}
\mathbb{1}_{\mathcal{X}}= & \operatorname{tr} \mathcal{Y}\left(\Phi\left[\left(\operatorname{vec}\left(\alpha A_{1}+\beta A_{2}\right) \operatorname{vec}\left(\alpha A_{1}+\beta A_{2}\right)^{*}\right)\right]\right) \\
= & \operatorname{tr}_{\mathcal{Y}}\left[|\alpha|^{2} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right. \\
& \left.\quad+\alpha \bar{\beta} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{1}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right] \\
= & \mathbb{1}_{\mathcal{X}}+2 \operatorname{Re}\left[\alpha \bar{\beta} B_{2} B_{1}^{*}\right] .
\end{aligned}
$$

We again deduce that $B_{1}$ and $B_{2}$ are orthogonal coisometries. In either case, we have found that $B_{1}$ and $B_{2}$ are orthogonal coisometries, as desired.

We now consider maps over $P\left(\mathbb{C}^{2}\right)$ (which would more commonly be notated as $P \mathbb{C}^{1}$ in topological contexts). We will denote by $[\alpha, \beta]$ the equivalence class of $(\alpha, \beta) \in \mathbb{C}^{2}$. That is,

$$
[\alpha, \beta]=\{k(\alpha, \beta): k \in \mathbb{C}\} \in P\left(\mathbb{C}^{2}\right)
$$

For coisometries $A, B$ satisfying $A B^{*}=0$, we can select coisometries $C \in \zeta([A])$ and $D \in \zeta([B])$. For such an $A, B, C, D$, we then define $f: P\left(\mathbb{C}^{2}\right) \rightarrow P\left(\mathbb{C}^{2}\right)$ so that for $(\gamma, \delta) \in f([\alpha, \beta])$, we have

$$
\zeta([\alpha A+\beta B])=[\gamma C+\delta D]
$$

That is, if $\iota_{A, B}$ denotes the homeomorphism $[\alpha, \beta] \in P\left(\mathbb{C}^{2}\right) \mapsto[\alpha A+\beta B] \in$ $P(\operatorname{span}\{A, B\})$, then

$$
f_{A, B, C, D}=\iota_{C, D}^{-1} \circ \zeta \circ \iota_{A, B}
$$

so that $f$ is a well-defined, continuous map.

Lemma 5.3. For any coisometries $A, B$ satisfying $A B^{*}=0$ and coisometries $C \in \zeta([A])$ and $D \in \zeta([B])$, the map $f: P\left(\mathbb{C}^{2}\right) \rightarrow P\left(\mathbb{C}^{2}\right)$ described above is continuous.

Proof: Let $\iota_{A, B}$ denote the homeomorphism $[\alpha, \beta] \in P\left(\mathbb{C}^{2}\right) \rightarrow[\alpha A+\beta B] \in$ $P(\operatorname{span}(A, B))$, and similarly define $\iota_{C, D}$. We note that $\pi$ induces a homeomorphism between $P(\operatorname{span}(A, B))$ and the image of $P(\operatorname{span}(A, B))$ in $\mathrm{MES}_{\mathcal{X}, \mathcal{Y}}$, and a similar observation applies to $\operatorname{span}(C, D)$. Thus, we see that $f$ can be written as

$$
f=\left.\left.\iota_{C, D}^{-1} \circ \pi\right|_{P(\operatorname{span}(C, D))} ^{-1} \circ \Phi \circ \pi\right|_{P(\operatorname{span}(A, B))} \circ \iota_{A, B}
$$

and is thus the composition of continuous functions.

Since $P\left(\mathbb{C}^{2}\right)$ is homeomorphic to $S^{2}$ (the two-dimensional sphere), we can consider the degree of the map $f_{A, B}: P\left(\mathbb{C}^{2}\right) \rightarrow P\left(\mathbb{C}^{2}\right)$. Since $f$ is a homeomorphism, we must have $\operatorname{deg}(f) \in\{1,-1\}$.

Lemma 5.4. For a fixed MES-preserving $\Phi$, there exists an $\epsilon \in\{1,-1\}$ such that for all choices of $A, B, C, D \in \operatorname{coisom}(\mathcal{Y}, \mathcal{X})$ with $A B^{*}=0, C \in \zeta([A])$, and $D \in \zeta([B])$, we have $\operatorname{deg}\left(f_{A, B}\right)=\epsilon$.

Proof: Let $f_{0}$ be the map $f$ corresponding to the coisometries $A_{0}, B_{0}, C_{0}, D_{0}$, and let $f_{1}$ be the map corresponding to the coisometries $A_{1}, B_{1}, C_{1}, D_{1}$. In order to show that $f_{0}$ and $f_{1}$ have the same degree, it suffices to show that these maps are homotopic.

By Lemma 5.1 the set of pairs $(A, B)$ of coisometries such that $A B^{*}=0$ is path connected. Thus, there exist paths $A, B:[0,1] \rightarrow \operatorname{coisom}(\mathcal{Y}, \mathcal{X})$ such that $A(0)=A_{0}, A(1)=A_{1}, B(0)=B_{0}, B(1)=B_{1}$, and for all $t \in[0,1]$ we have $A(t) B^{*}(t)=0$.

Let $\Gamma(t)=\zeta([A(t)])$ and $\Delta(t)=\zeta([B(t)]) . \Gamma, \Delta$ are paths in $P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$ connecting $\zeta\left(\left[A_{0}\right]\right)$ to $\zeta\left(\left[A_{1}\right]\right)$ and $\zeta\left(\left[B_{0}\right]\right)$ to $\zeta\left(\left[B_{1}\right]\right)$.

If we consider the tautological vector bundle over $P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$, it suffices to find a non-vanishing (constant magnitude) vector-field over the image $\Gamma$ connecting $\left(C_{0}, \zeta\left(\left[A_{0}\right]\right)\right)$ to $\left(C(1), \zeta\left(\left[A_{1}\right]\right)\right)$ and a non-vanishing vector-field over the image of $\Delta$ connecting $\left(D_{0}, \zeta\left(\left[B_{0}\right]\right)\right)$ to $\left(D_{1}, \zeta\left(\left[B_{1}\right]\right)\right)$. These vector fields give us paths $C(t), D(t)$ in $\operatorname{coisom}(\mathcal{Y}, \mathcal{X})$.

We can construct such a vector field as follows. To begin, select a continuous $v, w:[0,1] \rightarrow \mathcal{X} \otimes \mathcal{Y}$ such that for all $t \in[0,1], \pi_{\zeta\left(\left[A_{t}\right]\right)} v(t) \neq 0$ and $\pi_{\zeta\left(\left[B_{t}\right]\right)} w(t) \neq 0$. With that, take $c(t)=\operatorname{vec}^{-1}\left(\pi_{\zeta\left(\left[A_{t}\right]\right)} v(t)\right)$. Finally, define $C(t)=e^{i(p+q t)} \frac{c(t)}{\|c(t)\|}$, where $p, q \in \mathbb{R}$ are chosen so that $C(0)=C_{0}$ and $C(1)=C_{1}$. Similarly, take $d(t)=\operatorname{vec}^{-1}\left(\pi_{\zeta\left(\left[B_{t}\right]\right)} w(t)\right)$. Define $D(t)=e^{i(r+s t)} \frac{d(t)}{\|d(t)\|}$, where $r, s \in \mathbb{R}$ are chosen so that $D(0)=D_{0}$ and $D(1)=D_{1}$.

With that, we see that $f_{t}$ for $t \in[0,1]$ is a homotopy of the maps $f_{0}$ and $f_{1}$.

Combining Lemmas 5.2 and 5.4 lets us deduce the following.

Proposition 5.5. Let $A_{1}, A_{2}$ be coisometries such that $A_{1} A_{2}^{*}=0$. Then there exist coisometries $B_{1} \in \zeta\left(\left[A_{1}\right]\right), B_{2} \in \zeta\left(\left[A_{2}\right]\right)$ such that for any $\alpha, \beta \in \mathbb{C}$ with $|\alpha|^{2}+|\beta|^{2}=1$, we have

$$
\zeta\left(\left[\alpha A_{1}+\beta A_{2}\right]\right)=\left[\alpha B_{1}+\beta B_{2}\right]
$$

in the case that $\epsilon=+1$, or

$$
\zeta\left(\left[\alpha A_{1}+\beta A_{2}\right]\right)=\left[\bar{\alpha} B_{1}+\bar{\beta} B_{2}\right]
$$

in the case that $\epsilon=-1$.
Proof: In the case that (5.7) holds for some coisometries $A_{1}, A_{2}, B_{1}, B_{2}$, we find that $\operatorname{deg}\left(f_{A_{1}, A_{2}, B_{1}, B_{2}}\right)=+1$, so that we have $\epsilon=+1$ globally. Applying (5.7), we find that

$$
\begin{aligned}
& \Phi\left(\pi_{\alpha A_{1}+\beta A_{2}}\right)= \Phi\left[\frac { 1 } { m } \left(|\alpha|^{2} \operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(A_{2}\right) \operatorname{vec}\left(A_{2}\right)^{*}\right.\right. \\
&\left.\left.\quad+\alpha \bar{\beta} \operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{2}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(A_{2}\right) \operatorname{vec}\left(A_{1}\right)^{*}\right)\right] \\
&=\frac{1}{m}\left(|\alpha|^{2} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right. \\
&\left.\quad+\alpha \bar{\beta} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{2}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{1}\right)^{*}\right) \\
&= \pi_{\alpha B_{1}+\beta B_{2}}
\end{aligned}
$$

so that we indeed have $\zeta\left(\left[\alpha A_{1}+\beta A_{2}\right]\right)=\left[\alpha B_{1}+\beta B_{2}\right]$.
Similarly: in the case that (5.8) holds for some coisometries $A_{1}, A_{2}, B_{1}, B_{2}$, we find that $\operatorname{deg}\left(f_{A_{1}, A_{2}, B_{1}, B_{2}}\right)=-1$, so that we have $\epsilon=-1$ globally. Applying (5.8), we find that

$$
\begin{aligned}
& \Phi\left(\pi_{\alpha A_{1}+\beta A_{2}}\right)= \Phi\left[\frac { 1 } { m } \left(|\alpha|^{2} \operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(A_{2}\right) \operatorname{vec}\left(A_{2}\right)^{*}\right.\right. \\
&\left.\left.\quad+\alpha \bar{\beta} \operatorname{vec}\left(A_{1}\right) \operatorname{vec}\left(A_{2}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(A_{2}\right) \operatorname{vec}\left(A_{1}\right)^{*}\right)\right] \\
&=\frac{1}{m}\left(|\alpha|^{2} \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{1}\right)^{*}+|\beta|^{2} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right. \\
&\left.\quad \alpha \bar{\beta} \operatorname{vec}\left(B_{2}\right) \operatorname{vec}\left(B_{1}\right)^{*}+\bar{\alpha} \beta \operatorname{vec}\left(B_{1}\right) \operatorname{vec}\left(B_{2}\right)^{*}\right) \\
&= \pi_{\bar{\alpha} B_{1}+\bar{\beta} B_{2}}
\end{aligned}
$$

so that we indeed have $\zeta\left(\left[\alpha A_{1}+\beta A_{2}\right]\right)=\left[\bar{\alpha} B_{1}+\bar{\beta} B_{2}\right]$.

Remark 5.6. Rather than using the degree of the maps $f_{A, B}$ to discriminate between the possible forms of $\zeta$, we could also use the $\operatorname{det} J(G)$, where $J(G)$ denotes the Choi matrix used in the proof of Lemma 5.2. In particular: in the $\epsilon=+1$ case we would compute $\operatorname{det} J(G)=0$, and in the $\epsilon=-1$ case we would compute $\operatorname{det} J(G)=-1$. By the continuity of the determinant, one may argue that given an invertible MES-preserving map $\Phi$, we must either have $\operatorname{det} J(G)=0$ for all constructions of $G$, or $\operatorname{det} J(G)=-1$ for all constructions of $G$.

## 6. Constructing an Extension

To begin, we generalize Proposition 5.5,
Proposition 6.1. Let $A_{1}, \ldots, A_{k}: \mathcal{Y} \rightarrow \mathcal{X}$ be a collection of mutually orthogonal coisometries. Then there exist mutually orthogonal coisometries $B_{1}, \ldots, B_{k}$ such that for any $\alpha_{1}, \ldots, \alpha_{k} \in \mathbb{C}$ with $\left|\alpha_{1}\right|^{2}+\cdots+\left|\alpha_{k}\right|^{2}=1$, we have

$$
\zeta\left(\left[\alpha_{1} A_{1}+\cdots+\alpha_{k} A_{k}\right]\right)=\left[\alpha_{1} B_{1}+\cdots+\alpha_{k} B_{k}\right]
$$

in the case that $\epsilon=+1$, or

$$
\zeta\left(\left[\alpha_{1} A_{1}+\cdots+\alpha_{k} A_{k}\right]\right)=\left[\bar{\alpha}_{1} B_{1}+\cdots+\bar{\alpha}_{k} B_{k}\right]
$$

in the case that $\epsilon=-1$.
Proof: In the $\epsilon=1$ case, we can apply Lemma 5.2 to show that there exist coisometries $B_{1}, \ldots, B_{k}$ and $\theta_{p q} \in \mathbb{R}$ for $p, q=1, \ldots, k$ such that $\theta_{1, q}=0$ for all $q$, $\theta_{q p}=-\theta_{p q}$, and we have

$$
\Phi\left(\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right)=\sum_{p, q=1}^{k} a_{p q} e^{i \theta_{p q}} \operatorname{vec}\left(B_{p}\right) \operatorname{vec}\left(B_{q}\right)^{*}
$$

Because $\Phi$ is MES-preserving, the matrix $\left[e^{i \theta_{p q}} a_{p q}\right]_{p, q=1}^{k}$ must be rank-one and positive semidefinite whenever $\left[a_{p q}\right]_{p, q=1}^{n}$ is rank-one and positive semidefinite. By considering the case where $a_{p q}=1$ for all $p, q$, we see that this can only occur if $M=\left[e^{i \theta_{p q}}\right]_{p, q}$ has rank one. If $M$ is a rank-one matrix whose first row and column are all $1 \mathrm{~s}, M$ must be the matrix whose entries are all 1s. Thus, we have $e^{i \theta_{p q}}=1$ for all $p, q$. That is, we have

$$
\Phi\left(\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right)=\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(B_{p}\right) \operatorname{vec}\left(B_{q}\right)^{*}
$$

which is equivalent to the desired statement,

$$
\zeta\left(\left[\alpha_{1} A_{1}+\cdots+\alpha_{k} A_{k}\right]\right)=\left[\alpha_{1} B_{1}+\cdots+\alpha_{k} B_{k}\right]
$$

Similarly, in the $\epsilon=-1$ case, we can apply Lemma 5.2 to show that there exist coisometries $B_{1}, \ldots, B_{k}$ and $\theta_{p q} \in \mathbb{R}$ for $p, q=1, \ldots, k$ such that $\theta_{1, q}=0$ for all $q$, $\theta_{q p}=-\theta_{p q}$, and we have

$$
\Phi\left(\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right)=\sum_{p, q=1}^{k} a_{p q} e^{i \theta_{p q}} \operatorname{vec}\left(B_{q}\right) \operatorname{vec}\left(B_{p}\right)^{*}
$$

Because $\Phi$ is MES-preserving, the matrix $\left[e^{i \theta_{p q}} a_{p q}\right]_{p, q=1}^{k}$ must be rank-one and positive semidefinite whenever $\left[a_{p q}\right]_{p, q=1}^{n}$ is rank-one and positive semidefinite. Applying the same analysis as above, we conclude $e^{i \theta_{p q}}=1$ for all $p, q$. That is, we have

$$
\Phi\left(\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(A_{p}\right) \operatorname{vec}\left(A_{q}\right)^{*}\right)=\sum_{p, q=1}^{k} a_{p q} \operatorname{vec}\left(B_{q}\right) \operatorname{vec}\left(B_{p}\right)^{*}
$$

which is equivalent to the desired statement,

$$
\zeta\left(\left[\alpha_{1} A_{1}+\cdots+\alpha_{k} A_{k}\right]\right)=\left[\bar{\alpha}_{1} B_{1}+\cdots+\bar{\alpha}_{k} B_{k}\right]
$$

We will also need the following lemma, which is the polarization identity in one of its forms.

Lemma 6.2. Given matrices $A, B \in \mathbb{C}^{p \times q}$, we have

$$
A B^{*}=\frac{1}{4} \sum_{k=0}^{3} i^{k}\left(A+i^{k} B\right)\left(A+i^{k} B\right)^{*}
$$

Proof:
We compute

$$
\begin{aligned}
\sum_{k=0}^{3} i^{k}\left(A+i^{k} B\right)\left(A+i^{k} B\right)^{*} & =\sum_{k=0}^{3} i^{k}\left(A A^{*}+i^{-k} A B^{*}+i^{k} B A^{*}+B B^{*}\right) \\
& =\sum_{k=0}^{3}\left(i^{k} A A^{*}+A B^{*}+i^{2 k} B A^{*}+i^{k} B B^{*}\right) \\
& =0+4 A B^{*}+0+0
\end{aligned}
$$

Thus, we have $A B^{*}=\frac{1}{4} \sum_{k=0}^{3} i^{k}\left(A+i^{k} B\right)\left(A+i^{k} B\right)^{*}$ as desired.

Proposition 6.3. Suppose that $\mathcal{Y}=\mathcal{X}^{k}:=\mathcal{X} \oplus \cdots \oplus \mathcal{X}$. Let $\Phi: \operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \rightarrow$ $\operatorname{span}\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right)$ denote an invertible linear map such that $\Phi\left(\operatorname{MES}_{\mathcal{X}, \mathcal{Y}}\right) \subset \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$. Then $\Phi$ can be extended to a map $\tilde{\Phi}: \operatorname{span}\left(\operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}\right) \rightarrow \operatorname{span}\left(\operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}\right)$ which satisfies $\tilde{\Phi}\left(\mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}\right) \subset \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$.

Proof: Let $\zeta: P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X})) \rightarrow P(\operatorname{coisom}(\mathcal{Y}, \mathcal{X}))$ be the map induced by $\Phi$, as defined in Section 4. Let $U: \mathcal{Y} \rightarrow \mathcal{Y}$ be a unitary transformation given by $U=\left[U_{j}\right]_{j=1}^{k}$ (where $\left.U_{j}: \mathcal{Y} \rightarrow \mathcal{X}\right)$. Note that $U_{p}, U_{q}$ are coisometries satisfying $U_{p} U_{q}^{*}=0$ for $1 \leq p, q \leq k$.

Define $\tilde{\Phi}: \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}} \rightarrow \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}$ as follows: For $j=1, \ldots, k$ let $V_{j} \in \zeta\left(\left[U_{j}\right]\right)$ be such that $\zeta\left(\left[\alpha U_{p}+\beta U_{q}\right]\right)=\left[\alpha V_{p}+\beta V_{q}\right]$ or $\zeta\left(\left[\alpha U_{p}+\beta U_{q}\right]\right)=\left[\bar{\alpha} V_{p}+\bar{\beta} V_{q}\right]$ for $1 \leq p, q \leq k$, as guaranteed by Proposition 6.1. Then, we take

$$
\begin{aligned}
& \tilde{\Phi}\left(\pi_{\left[U_{j}\right]_{j}}\right)=\tilde{\Phi}\left(\frac{1}{k m}\left[\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right]_{p, q=1}^{k}\right) \\
& \quad=\frac{1}{k m}\left[\operatorname{vec}\left(V_{p}\right) \operatorname{vec}\left(V_{q}\right)^{*}\right]_{p, q=1}^{k}
\end{aligned}
$$

Equivalently, we have defined $\tilde{\Phi}$ so that

$$
\tilde{\Phi}\left(\pi_{\left[U_{j}\right]_{j}}\right)=\pi_{\left[V_{j}\right]_{j}}
$$

By Proposition 6.1 $\left[V_{j}\right]_{j=1}^{k}$ is a coisometry, so that $\pi_{\left[V_{j}\right]_{j}} \in \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}$. Thus, we see from the above that $\tilde{\Phi}$ preserves $\operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$. It remains to be shown, however, that $\tilde{\Phi}$ as defined above is a linear map.

In the case of $\epsilon=1$, Lemma 6.2 yields

$$
\begin{aligned}
\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*} & =\frac{1}{4} \sum_{k=0}^{3} i^{k} \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right) \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right)^{*} \\
\Phi\left[\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right] & =\frac{1}{4} \sum_{k=0}^{3} i^{k} \Phi\left[\operatorname{vec}\left(U_{p}+i^{k} U_{q}\right) \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right)^{*}\right] \\
& =\frac{1}{4} \sum_{k=0}^{3} i^{k} \operatorname{vec}\left(V_{p}+i^{k} V_{q}\right) \operatorname{vec}\left(V_{p}+i^{k} V_{q}\right)^{*} \\
& =\operatorname{vec}\left(V_{p}\right) \operatorname{vec}\left(V_{q}\right)^{*}
\end{aligned}
$$

which means that our extension can be written as

$$
\begin{aligned}
\tilde{\Phi}\left(\pi_{\left[U_{j}\right]_{j}}\right) & =\tilde{\Phi}\left(\frac{1}{k m}\left[\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right]_{p, q=1}^{k}\right) \\
& =\frac{1}{k m}\left[\Phi\left(\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right)\right]_{p, q=1}^{k}
\end{aligned}
$$

So, for every $M \in \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}} \subset L(\mathcal{Y} \otimes \mathcal{Y})=L\left(\mathbb{C}^{k}\right) \otimes L(\mathcal{X} \otimes Y)$, we have $\tilde{\Phi}(M)=$ $\left(\mathbb{1}_{\mathbb{C}^{k \times k}} \otimes \Phi(M)\right)$. That is, $\left.\tilde{\Phi}\right|_{\mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}}$ is the restriction of a linear map, and is therefore linear.

In the case of $\epsilon=-1$, Lemma 6.2 yields

$$
\begin{aligned}
\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*} & =\frac{1}{4} \sum_{k=0}^{3} i^{k} \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right) \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right)^{*} \\
\Phi\left[\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right] & =\frac{1}{4} \sum_{k=0}^{3} i^{k} \Phi\left[\operatorname{vec}\left(U_{p}+i^{k} U_{q}\right) \operatorname{vec}\left(U_{p}+i^{k} U_{q}\right)^{*}\right] \\
& \left.=\frac{1}{4} \sum_{k=0}^{3} i^{k} \operatorname{vec}\left(V_{p}+i^{-k} V_{q}\right) \operatorname{vec}\left(V_{p}+i^{-k} V_{q}\right)^{*}\right] \\
& \left.=\frac{1}{4} \sum_{k=0}^{3} i^{k}\left(i^{-k} \operatorname{vec}\left(i^{k} V_{p}+V_{q}\right)\right)\left(i^{-k} \operatorname{vec}\left(i^{k} V_{p}+V_{q}\right)^{*}\right)\right] \\
& \left.=\frac{1}{4} \sum_{k=0}^{3} i^{k} \operatorname{vec}\left(V_{q}+i^{k} V_{p}\right) \operatorname{vec}\left(V_{q}+i^{k} V_{p}\right)^{*}\right] \\
& =\operatorname{vec}\left(V_{q}\right) \operatorname{vec}\left(V_{p}\right)^{*}
\end{aligned}
$$

which means that our extension can be written as

$$
\begin{aligned}
\tilde{\Phi}\left(\pi_{\left[U_{j}\right]_{j}}\right) & =\tilde{\Phi}\left(\frac{1}{k m}\left[\operatorname{vec}\left(U_{p}\right) \operatorname{vec}\left(U_{q}\right)^{*}\right]_{p, q=1}^{k}\right) \\
& =\frac{1}{k m}\left[\Phi\left(\operatorname{vec}\left(U_{q}\right) \operatorname{vec}\left(U_{p}\right)^{*}\right)\right]_{p, q=1}^{k}
\end{aligned}
$$

So, for every $M \in \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}} \subset L(\mathcal{Y} \otimes \mathcal{Y})=L\left(\mathbb{C}^{k}\right) \otimes L(\mathcal{X} \otimes \mathcal{Y})$, we have $\tilde{\Phi}(M)=$ $\left(\tau_{\mathbb{C}^{k \times k}} \otimes \Phi\right)(M)$. That is, $\left.\tilde{\Phi}\right|_{\mathrm{MES}_{\mathcal{Y}, \mathcal{V}}}$ is the restriction of a linear map, and is therefore linear.

## 7. The preservers of MES

We now consider the possible forms of this extension, using Theorem 1 from [5], which is to say Theorem 1.2 from the introduction. We note in particular that if $\Phi: \operatorname{span}\left(\mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}\right) \rightarrow \operatorname{span}\left(\mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}\right)$ is invertible, then it must be of the form (1) or (2).

Let $\operatorname{ad}_{U}$ denote the map $\operatorname{ad}_{U}: A \mapsto U A U^{-1}$. We make the following observation regarding these extended maps:
Lemma 7.1. If $B \in L(\mathcal{X} \otimes \mathcal{Y})$ satisfies $B M=M B$ for all $M \in \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}$, then $B=c \mathbb{1}_{\mathcal{X} \otimes \mathcal{Y}}$ for some $c \in \mathbb{C}$.

Proof: For every maximally entangled vector $u \in \mathcal{X} \otimes \mathcal{Y}$, we have

$$
B u u^{*}=u u^{*} B \Longrightarrow\left(B u u^{*}\right) u=\left(u u^{*} B\right) u \Longrightarrow B u=\left(u^{*} B u\right) u
$$

That is, every maximally entangled vector $u$ is an eigenvector of $B$ with associated eigenvalue $u^{*} B u$. Thus, for every maximally entangled vector $u, u^{*} B u$ is an eigenvalue of $B$. Because the set of maximally entangled vectors is connected and the map $u \mapsto u^{*} B u$ is continuous, the set

$$
\Omega=\left\{u^{*} B u: u \in \mathcal{X} \otimes \mathcal{Y} \text { is maximally entangled }\right\}
$$

is connected. Also, $\Omega$ is a subset of the spectrum of $B$, which is a finite set. Since $\Omega$ is connected and finite, it must be a singleton; thus there is a $c \in \mathbb{C}$ such that $\Omega=\{c\}$. Consequently, $B u=c u$ for all maximally entangled vectors $u$. Since the maximally entangled vectors span $\mathcal{X} \otimes \mathcal{Y}$, we may conclude that $B=c \mathbb{1}_{\mathcal{X} \otimes \mathcal{Y}}$ as desired.

Lemma 7.2. If $U_{1}, U_{2} \in L(\mathcal{X})$ and $V_{1}, V_{2} \in L(\mathcal{Y})$ are unitary operators such that

$$
\operatorname{ad}_{U_{1} \otimes V_{1}}(M)=\operatorname{ad}_{U_{2} \otimes V_{2}}(M) \quad \text { for all } M \in \operatorname{MES}_{\mathcal{X}, \mathcal{Y}}
$$

then we must have $U_{1} \otimes V_{1}=c U_{2} \otimes V_{2}$ for some $c \in \mathbb{C}$.
Proof: We may rewrite the above condition as

$$
\left(U_{2} \otimes V_{2}\right)^{*}\left(U_{1} \otimes V_{1}\right) M=M\left(U_{2} \otimes V_{2}\right)^{*}\left(U_{1} \otimes V_{1}\right) \quad \text { for all } M \in \operatorname{MES}_{\mathcal{X}, \mathcal{Y}} .
$$

Lemma 7.1 now gives $\left(U_{2} \otimes V_{2}\right)^{*}\left(U_{1} \otimes V_{1}\right)=c \mathbb{1}_{\mathcal{X}} \otimes \mathcal{Y}$ for some $c \in \mathbb{C}$.

Remark 7.3. From here on, we suppose that $\mathcal{Y}=\mathcal{X}^{k}$, for some integer $k \geq 2$. We also identify $\mathcal{Y}=\mathcal{X}^{k}$ with $\mathbb{C}^{k} \otimes \mathcal{X}$, where it is convenient to do so.

We now observe that $\tilde{\Phi}$ has the following properties:
Lemma 7.4. Define

$$
\begin{aligned}
P_{j} & =\left[\mathbb{1}_{\mathbb{C}^{k}}-2 E_{j j}\right] \otimes \mathbb{1}_{\mathcal{X}} \in L\left(\mathbb{C}^{k} \otimes \mathcal{X}\right)=L(\mathcal{Y}), \\
Q_{p q} & =\left(T_{p q} \otimes \mathbb{1}_{\mathcal{X}}\right) \otimes \mathbb{1}_{\mathcal{Y}} \in L\left(\left(\mathbb{C}^{k} \otimes \mathcal{X}\right) \otimes \mathcal{Y}\right)=L(\mathcal{Y} \otimes \mathcal{Y}),
\end{aligned}
$$

where $T_{p q}$ is the permutation matrix corresponding to the transposition of the $p, q$ entries of a vector in $\mathbb{C}^{k}$.

Then $\tilde{\Phi} \circ \operatorname{ad}_{P_{j} \otimes \mathbb{I}_{\mathcal{Y}}}=\operatorname{ad}_{P_{j} \otimes \mathbb{1} \mathcal{Y}} \circ \tilde{\Phi}$, and $\tilde{\Phi} \circ \operatorname{ad}_{Q_{p q}}=\operatorname{ad}_{Q_{p q}} \circ \tilde{\Phi}$.

Proof: In order to avoid cumbersome notation, we prove the result for $P_{j}$ with $j=1$ and for $Q_{p q}$ with $p=1, q=2$. However, the same proof can be applied for arbitrary indices.

Let $M$ be an element of $\operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$, with

$$
M=\left[M_{p, q}\right]_{p, q=1}^{k}, \quad M_{p q} \in L(\mathcal{X} \otimes \mathcal{Y})
$$

We compute

$$
\begin{aligned}
& \operatorname{ad}_{P_{1} \otimes \mathbb{1}_{\mathcal{Y}}}(\tilde{\Phi}(M))= \tilde{\Phi}\left(\operatorname{ad}_{P_{1} \otimes \mathbb{1}_{\mathcal{Y}}}(M)\right) \\
&=\left\{\begin{array}{cccc}
{\left[\left(M_{11}\right)\right.} & -\Phi\left(M_{12}\right) & -\Phi\left(M_{13}\right) & \cdots \\
-\Phi\left(M_{21}\right) & \Phi\left(M_{22}\right) & \Phi\left(M_{23}\right) & \cdots \\
-\Phi\left(M_{31}\right) & \Phi\left(M_{32}\right) & \Phi\left(M_{33}\right) & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \epsilon=1 \\
& {\left[\begin{array}{cccc}
\Phi\left(M_{11}\right) & -\Phi\left(M_{21}\right) & -\Phi\left(M_{31}\right) & \cdots \\
-\Phi\left(M_{12}\right) & \Phi\left(M_{22}\right) & \Phi\left(M_{32}\right) & \cdots \\
-\Phi\left(M_{13}\right) & \Phi\left(M_{23}\right) & \Phi\left(M_{33}\right) & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \epsilon=-1 }
\end{aligned} .
$$

And similarly,

$$
\begin{aligned}
\operatorname{ad}_{Q_{12}}(\tilde{\Phi}(M)) & =\tilde{\Phi}\left(\operatorname{ad}_{Q_{12}}(M)\right) \\
& =\left\{\begin{array}{cccc}
{\left[\begin{array}{cccc}
\Phi\left(M_{22}\right) & \Phi\left(M_{21}\right) & \Phi\left(M_{23}\right) & \cdots \\
\Phi\left(M_{12}\right) & \Phi\left(M_{11}\right) & \Phi\left(M_{13}\right) & \cdots \\
\Phi\left(M_{32}\right) & \Phi\left(M_{31}\right) & \Phi\left(M_{33}\right) & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \quad \epsilon=1} \\
& & & \\
{\left[\begin{array}{cccc}
\Phi\left(M_{22}\right) & \Phi\left(M_{12}\right) & \Phi\left(M_{32}\right) & \cdots \\
\Phi\left(M_{21}\right) & \Phi\left(M_{11}\right) & \Phi\left(M_{31}\right) & \cdots \\
\Phi\left(M_{23}\right) & \Phi\left(M_{13}\right) & \Phi\left(M_{33}\right) & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \quad \epsilon=-1}
\end{array} .\right.
\end{aligned}
$$

Lemma 7.5. Fix any unitary $U, V \in L(\mathcal{Y})$, and let $\mathbf{S}: L(\mathcal{Y} \otimes \mathcal{Y}) \rightarrow L(\mathcal{Y} \otimes \mathcal{Y})$ be the switch-operator, defined by $A \otimes B \mapsto B \otimes A$. Then for unitary $A \in L(\mathcal{Y})$, we have

$$
\begin{aligned}
\mathbf{S}\left(\pi_{A}\right) & =\pi_{A^{T}}, \\
\left(\pi_{A}\right)^{T} & =\pi_{\bar{A}}, \\
\operatorname{ad}_{U \otimes V}\left(\pi_{A}\right) & =\pi_{U A V^{T}} .
\end{aligned}
$$

Lemma 7.6. We have $\mathcal{Y}=\mathcal{X}^{k}$, with $k \geq 2$. Suppose that $\Psi: \operatorname{span}\left(\mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}\right) \rightarrow$ $\operatorname{span}\left(\operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}\right)$ is a linear, invertible, MES-preserving map that commutes with $\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\nu}}$ for all $j$. Then we must have

$$
\Psi(M)=(U \otimes V) M^{\sigma}(U \otimes V)^{*},
$$

where $\sigma$ is either the transpose or identity map. Moreover, either $U$ must be block diagonal (in other words, each copy of $\mathcal{X} \subset \mathcal{Y}$ is an invariant subspace of $U$ ), or $k=2$ and $U=\left[\begin{array}{cc}0 & U_{12} \\ U_{21} & 0\end{array}\right]$ with $U_{12}, U_{21} \in L(\mathcal{X})$ unitary.

Proof: Suppose that $\Psi$ is a map of the form (1) from Theorem 1.2] with $\sigma$ the identity map. That is, $\Psi=\operatorname{ad}_{U \otimes V}$. Since $\Psi$ commutes with $\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}}$ for all $j$, we have $\operatorname{ad}_{\left(P_{j} \otimes \mathbb{1}_{\mathcal{V}}\right)(U \otimes V)}=\operatorname{ad}_{(U \otimes V)\left(P_{j} \otimes \mathbb{1}_{\mathcal{Y}}\right)}$. By Lemma 7.2 we have $\left(P_{j} U\right) \otimes V=$ $c\left(U P_{j}\right) \otimes V$ for some $c \in \mathbb{C}$. That is, if $U=\left[U_{p, q}\right]_{p, q=1}^{k}$, then we have in the case of $j=2$

$$
\left[\begin{array}{cccc}
U_{11} & U_{12} & U_{13} & \cdots \\
-U_{21} & -U_{22} & -U_{23} & \cdots \\
U_{31} & U_{32} & U_{33} & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \otimes V=c\left[\begin{array}{cccc}
U_{11} & -U_{12} & U_{13} & \cdots \\
U_{21} & -U_{22} & U_{23} & \cdots \\
U_{31} & -U_{32} & U_{33} & \cdots \\
\vdots & \vdots & \vdots & \ddots
\end{array}\right] \otimes V .
$$

When $k>2$, we conclude that $U_{p q}=U_{q p}=0$ whenever $p \neq q$, as desired. When $k=2$ we either have that $c=1$ and $U_{12}=U_{21}=0$, or that $c=-1$ and $U_{11}=$ $U_{22}=0$.

Similarly, suppose that $\Psi$ is a map of the form (1) with $\sigma$ the transpose map, which is to say that $\Psi=\operatorname{ad}_{U \otimes V} \circ \tau$. Since $\Psi$ commutes with $\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}}$, we have

$$
\begin{aligned}
\operatorname{ad}_{P_{j} \otimes 1_{\mathcal{V}}} \circ \operatorname{ad}_{U \otimes V} \circ \tau & =\operatorname{ad}_{U \otimes V} \circ \tau \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}} \Longrightarrow \\
\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}} \circ \operatorname{ad}_{U \otimes V} \circ \tau}=\operatorname{ad}_{U \otimes V} \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}} \circ \tau} \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}} \circ \operatorname{ad}_{U \otimes V} & =\operatorname{ad}_{U \otimes V} \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}} .
\end{aligned}
$$

By Lemma 7.2] we have $\left(P_{j} U\right) \otimes V=c\left(U P_{j}\right) \otimes V$ for some $c \in \mathbb{C}$, which again allows us to conclude that $U$ is block-diagonal, or $k=2$ and $U=\left[\begin{array}{cc}0 & U_{12} \\ U_{21} & 0\end{array}\right]$.

Now, suppose that $\Psi$ is of the form (2) from Theorem [1.2, with $\sigma$ the identity map. That is, suppose that $\Psi=\operatorname{ad}_{U \otimes V} \circ \mathbf{S}$; we wish to show that $\Psi$ must fail to commute with $\operatorname{ad}_{P_{j} \otimes 1 y}$ for some $j$. By Lemma 7.5 we find that for unitary $A \in L(\mathcal{Y})$, we have

$$
\begin{aligned}
\left(\operatorname{ad}_{P_{j} \otimes \mathbb{1}} \circ \Psi\right)\left(\pi_{A}\right) & =\pi_{P_{j} U A^{T} V^{T}} \\
\left(\Psi \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}}\right)\left(\pi_{A}\right) & =\pi_{U A^{T} P_{j} V^{T}} .
\end{aligned}
$$

Thus, it suffices to find unitary $A \in L(\mathcal{Y})$ such that for some $j, P_{j} U A^{T} \neq c U A^{T} P_{j}$ for all $c \in \mathbb{C}$. Thus, we see that one $M \in \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$ for which $\left(\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}} \circ \Psi\right)(M) \neq$ $\left(\Psi \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}}\right)(M)$ is given by $M=\pi_{A}$, where $A$ is chosen so that $P_{j} U A^{T}$ and $U A^{T} P_{j}$ are not multiples. For instance, for $j=1$, we can take

$$
U A^{T}=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
\mathbb{1}_{\mathcal{X}} & \mathbb{1}_{\mathcal{X}} \\
\mathbb{1}_{\mathcal{X}} & -\mathbb{1}_{\mathcal{X}}
\end{array}\right] \oplus \mathbb{1}_{\mathcal{X}^{k-2}} .
$$

Similarly, suppose that $\Psi$ is of the form (2) from Theorem 1.2, with $\sigma$ the transpose map. That is, suppose that $\Psi=\operatorname{ad}_{U \otimes V} \circ \tau \circ \mathbf{S}$. By Lemma 7.5 we find
that for unitary $A \in L(\mathcal{Y})$, we have

$$
\begin{aligned}
\left(\operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{Y}}} \circ \Psi\right)\left(\pi_{A}\right) & =\pi_{P_{j} U A^{*} V^{T}} \\
\left(\Psi \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{Y}}}\right)\left(\pi_{A}\right) & =\pi_{U A^{*} P_{j} V^{T}}
\end{aligned}
$$

Thus, it suffices to find unitary $A \in L(\mathcal{Y})$ such that for some $j, P_{j} U A^{*} \neq c U A^{*} P_{j}$ for all $c \in \mathbb{C}$. Thus, we see that one $M \in \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}$ for which $\left(\operatorname{ad}_{P_{j} \otimes \mathbb{1}} \mathcal{Y}^{\circ} \circ \Psi\right)(M) \neq$ $\left(\Psi \circ \operatorname{ad}_{P_{j} \otimes \mathbb{1}_{\mathcal{V}}}\right)(M)$ is given by $M=\pi_{A}$, where $A$ is chosen so that $P_{j} U A^{*}$ and $U A^{*} P_{j}$ are not multiples. For instance, we can take

$$
U A^{*}=\frac{1}{\sqrt{2}}\left[\begin{array}{cc}
\mathbb{1}_{\mathcal{X}} & \mathbb{1}_{\mathcal{X}} \\
\mathbb{1}_{\mathcal{X}} & -\mathbb{1}_{\mathcal{X}}
\end{array}\right] \oplus \mathbb{1}_{\mathcal{X}^{k-2}}
$$

Lemma 7.7. Let $U, V \in L(\mathcal{Y})$ be unitary with $U \in L(\mathcal{Y})=L\left(\mathbb{C}^{k} \otimes \mathcal{X}\right)$ block diagonal. If $\Psi$ defined by

$$
\Psi(M)=(U \otimes V) M^{\sigma}(U \otimes V)^{*}, M \in \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}
$$

commutes with $\operatorname{ad}_{Q_{p q}}$ for $1 \leq p, q \leq k$, then $U$ either has the form

$$
U=\mathbb{1}_{\mathbb{C}^{k}} \otimes W
$$

for some unitary $W: \mathcal{X} \rightarrow \mathcal{X}$, or $k=2$ and $U=\left[\begin{array}{cc}1 & 0 \\ 0 & -1\end{array}\right] \otimes W$ for some unitary $W: \mathcal{X} \rightarrow \mathcal{X}$.

Proof: As in the last proof (invoking Lemma 7.1), we see that if $\Psi$ commutes with $\operatorname{ad}_{Q_{p q}}$, then we must have $Q_{p q}(U \otimes V)=c_{p q}(U \otimes V) Q_{p q}$ for some $c_{p q} \in \mathbb{C}$. Let $\operatorname{diag}\left[U_{j}\right]_{j=1}^{k}$ denote the block-diagonal matrix with $U_{j}$ on the $j$ th diagonal. Then the above tells us that $U_{p}=c_{p q} U_{q}, U_{q}=c_{p q} U_{p}$ and $U_{j}=c_{p q} U_{j}$ for $j \neq p, q$.

When $k>2$, this implies that $c_{p q}=1$ and $U_{p}=U_{q}$. As this holds for all pairs $p, q$, we may conclude that $U_{j}=U_{\ell}$ for all $1 \leq j, \ell \leq k$.

When $k=2$, we get from $U_{1}=c_{12} U_{2}=c_{12}^{2} U_{1}$, that $c_{12}= \pm 1$. Thus either $U_{1}=U_{2}$ or $U_{1}=-U_{2}$.

We can now finally prove our main result.
Proof of Theorem 1.1; By Proposition 6.3, $\Phi$ has an extension $\tilde{\Phi}: L(\mathcal{Y} \otimes \mathcal{Y}) \rightarrow$ $L(\mathcal{Y} \otimes \mathcal{Y})$, as stated there. By Lemma 7.4 this extension commutes with $\operatorname{ad}_{P_{j} \otimes \mathbb{1}}$ and $\operatorname{ad}_{Q_{p q}}$ for all $1 \leq j, p, q \leq k$. By Lemma 7.6, it follows that $\tilde{\Phi}$ is a map of the form $\tilde{\Phi}(M)=(\tilde{U} \otimes V) M^{\sigma}(\tilde{U} \otimes V)^{*}$, where $\sigma$ is either the transpose or identity map and with $\tilde{U}$ either block diagonal or, when $k=2$, of the form $\tilde{U}=\left[\begin{array}{cc}0 & U_{12} \\ U_{21} & 0\end{array}\right]$.

We first show that we can discard the last possibility. Indeed, from the proof of Proposition 6.3 we obtain that
$\tilde{\Phi}\left(\left[\begin{array}{ll}M_{11} & M_{12} \\ M_{21} & M_{22}\end{array}\right]\right)=\left[\begin{array}{ll}\Phi\left(M_{11}\right) & \Phi\left(M_{12}\right) \\ \Phi\left(M_{21}\right) & \Phi\left(M_{22}\right)\end{array}\right]$ or $\tilde{\Phi}\left(\left[\begin{array}{ll}M_{11} & M_{12} \\ M_{21} & M_{22}\end{array}\right]\right)=\left[\begin{array}{ll}\Phi\left(M_{11}\right) & \Phi\left(M_{21}\right) \\ \Phi\left(M_{12}\right) & \Phi\left(M_{22}\right)\end{array}\right]$.

If $\tilde{U}=\left[\begin{array}{cc}0 & U_{12} \\ U_{21} & 0\end{array}\right]$, then we obtain that for all $M=\left[M_{p q}\right]_{p, q=1}^{2} \in \mathrm{MES}_{\mathcal{Y}, \mathcal{Y}}$ either

$$
\Phi\left(M_{11}\right)=\left(U_{12} \otimes V\right) M_{22}\left(U_{12} \otimes V\right)^{*} \text { or } \Phi\left(M_{11}\right)=\left(U_{12} \otimes V\right) M_{22}^{T}\left(U_{12} \otimes V\right)^{*}
$$

When $\operatorname{dim} X>1$ (and thus $\operatorname{dim} Y>2$ ) this leads to a contradiction as one can vary $M_{22}$ without changing $M_{11}$.

If $k=2$ and $\operatorname{dim} \mathcal{X}=1$, we have $\mathcal{X} \otimes \mathcal{Y} \cong \mathcal{Y}=\mathbb{C}^{2}$, and $\Phi: L(\mathcal{X} \otimes Y) \rightarrow L(\mathcal{X} \otimes \mathcal{Y})$ defines a map on $2 \times 2$ matrices that preserves all rank-one orthogonal projections. This gives that $\Phi(X)=V X^{\sigma} V^{*}$, where $\sigma$ is either the transpose or the identity map and $V$ is unitary. Thus $\Phi$ is of the desired form.

Going back to the general case of $k \geq 2$, we can conclude that $\tilde{U}$ is block diagonal. Next, by Lemma 7.7, we find that

$$
\tilde{U}=\mathbb{1}_{\mathbb{C}^{k}} \otimes U, \text { or } k=2 \text { and } \tilde{U}=\left[\begin{array}{cc}
1 & 0 \\
0 & -1
\end{array}\right] \otimes U
$$

for some unitary $U: \mathcal{X} \rightarrow \mathcal{X}$. We now compute for $M=\left[M_{p q}\right]_{p, q=1}^{k} \in \operatorname{MES}_{\mathcal{Y}, \mathcal{Y}}$ that

$$
\begin{aligned}
\Phi\left(M_{11}\right) & =\left[e_{1}^{T} \otimes \mathbb{1}_{\mathcal{X}} \otimes \mathbb{1}_{\mathcal{Y}}\right] \tilde{\Phi}(M)\left[e_{1}^{T} \otimes \mathbb{1}_{\mathcal{X}} \otimes \mathbb{1}_{\mathcal{Y}}\right]^{*} \\
& =\left[e_{1}^{T} \otimes \mathbb{1}_{\mathcal{X}} \otimes \mathbb{1}_{\mathcal{Y}}\right](\tilde{U} \otimes V) M^{\sigma}(\tilde{U} \otimes V)^{*}\left[e_{1} \otimes \mathbb{1}_{\mathcal{X}} \otimes \mathbb{1}_{\mathcal{Y}}\right] \\
& =(U \otimes V) M_{11}^{\sigma}(U \otimes V)^{*}
\end{aligned}
$$

as desired.
