MULTIPLECTY IN ROOT COMPONENTS VIA GEOMETRIC SATAKE

MARC BESSON, SAM JERALDS, AND JOSHUA KIERS

ABSTRACT. In this note we explicitly construct top-dimensional components of the cyclic convolution varieties. These components correspond (via the geometric Satake equivalence) to irreducible summands \( V(\lambda + \mu - N\beta) \subset V(\lambda) \otimes V(\mu) \) for \( G = SL_{n+1} \), where \( N \geq 1 \) and \( \beta \) is a positive root. Furthermore, we deduce from these constructions a nontrivial lower bound on the multiplicity of these subrepresentations when \( \beta \) is not a simple root. In an appendix, we contrast this approach with a combinatorial proof of the same results using Littelmann paths.

1. Introduction

Let \( G = SL_{n+1}, n \geq 1 \), and let \( T, B \) be maximal toral and Borel subgroups of \( G \), respectively. Let \( \Phi \) denote the set of roots w.r.t. \( T \) and \( \{ \alpha_i \} \) the simple roots determined by \( B \). Given weights \( \lambda, \mu \) of \( T \), dominant w.r.t. \( B \), a standard question in representation theory is: what are the dominant weights \( \nu \) and positive integers \( m_{\lambda, \mu}^\nu \) such that

\[
V(\lambda) \otimes V(\mu) \simeq \bigoplus V(\nu)^{\otimes m_{\lambda, \mu}^\nu}
\]
as \( G \)-modules?

1.1. Root Components. Among the answers to the above questions–given by a myriad of formulas, combinatorial rules, and special cases–are the root components, which were constructed by Kumar [Kum92]:

**Theorem 1.** Suppose that \( \beta \) is a positive root and \( \lambda, \mu \) are dominant weights satisfying

1. \( \lambda + \mu - \beta \) is dominant;
2. \( \lambda(\alpha_i^\vee) = 0 \Rightarrow \beta - \alpha_i \notin \Phi \cup \{0\} \) (and the same replacing \( \lambda \) with \( \mu \)).

Then

\[
V(\lambda + \mu - \beta) \subset V(\lambda) \otimes V(\mu).
\]

Irreducible components of this form were originally conjectured by Wahl [Wah91] as representation-theoretic consequences of a geometric conjecture. The statement holds for any semisimple complex connected \( G \), but in this paper we will restrict our attention to type \( A \). Before we state our main result, we remark that Theorem 1 has an immediate corollary (cf. [Wah91, Theorem 6.5]):

**Corollary 1.** Suppose \( G \) has no component of type \( G_2 \). Let \( N \geq 1 \). Suppose that \( \beta \) is a positive root and \( \lambda, \mu \) are dominant weights satisfying

1. \( \lambda + \mu - N\beta \) is dominant;
2. \( \lambda(\alpha_i^\vee) < N \Rightarrow \beta - \alpha_i \notin \Phi \cup \{0\} \) (and the same replacing \( \lambda \) with \( \mu \)).
Then
\[ V(\lambda + \mu - N\beta) \subset V(\lambda) \otimes V(\mu). \]

**Proof.** Let \( \rho_\beta \) be the dominant weight \( \sum_{\beta - \alpha_i \in \Phi \cup \{0\}} \omega_i \). That is, \( N\rho_\beta \) is the minimal dominant weight satisfying condition (2). By assumption (2), \( \lambda = N\rho_\beta + \lambda' \) and \( \mu = N\rho_\beta + \mu' \) for suitable dominant weights \( \lambda', \mu' \). Since \( G \) is at most doubly-laced, \( 2\rho_\beta - \beta \) is dominant. By Theorem 1,
\[ V(2\rho_\beta - \beta) \subset V(\rho_\beta) \otimes V(\rho_\beta); \]
therefore by scaling, \( V(2N\rho_\beta - N\beta) \subset V(N\rho_\beta) \otimes V(N\rho_\beta) \). Finally, we always have \( V(\lambda' + \mu') \subset V(\lambda') \otimes V(\mu') \). By additivity of tensor product decompositions,
\[ V(2N\rho - N\beta + \lambda' + \mu') \subset V(\lambda' + N\rho_\beta) \otimes V(\mu' + N\rho_\beta), \]
as desired. \( \square \)

Our main result is a strengthening of Corollary 1 for \( SL_{n+1} \):

**Theorem 2.** Let \( N \geq 1 \). Suppose that \( G = SL_{n+1} \) and that \( \beta \) is a positive, non-simple root. Suppose there exist \( \lambda, \mu \) dominant weights satisfying

1. \( \lambda + \mu - N\beta \) is dominant;
2. \( \lambda(\alpha_i^\vee) < N \Rightarrow \beta - \alpha_i \notin \Phi \cup \{0\} \) (and the same replacing \( \lambda \) with \( \mu \)).

Then \( V(\lambda + \mu - N\beta) \) appears in \( V(\lambda) \otimes V(\mu) \) with multiplicity at least 2.

In fact, from the \( N = 1 \) statement, we can already obtain a better estimate:

**Corollary 2.** With hypotheses as in the previous theorem, the multiplicity of \( V(\lambda + \mu - N\beta) \) inside \( V(\lambda) \otimes V(\mu) \) is at least \( N + 1 \).

**Proof.** Let \( \rho_\beta, \mu', \lambda' \) be as in the proof of Corollary 1. Then by Theorem 2, \( V(2\rho_\beta - \beta) \) appears inside \( V(\rho_\beta) \otimes V(\rho_\beta) \) with multiplicity at least 2. By a standard argument, \( V(2N\rho_\beta - N\beta) \) appears inside \( V(N\rho_\beta) \otimes V(N\rho_\beta) \) with multiplicity at least \( N + 1 \); by Borel-Weil, we identify \( (V(\rho_\beta) \otimes V(\rho_\beta) \otimes V(2\rho_\beta - \beta)) \) with \( H^0((G/B)^3, \mathcal{L})^G \) for a suitable line bundle \( \mathcal{L} \); if \( \sigma, \tau \in H^0((G/B)^3, \mathcal{L})^G \) are linearly independent, then \( \sigma^N, \sigma^{-1}, \ldots, \tau^N \) are linearly independent elements of \( H^0((G/B)^3, \mathcal{L}^N)^G \) by irreducibility of \( (G/B)^3 \) and factorizability of homogeneous polynomials in 2 variables into linear factors.
Therefore \( V(2N\rho_\beta - N\beta + \lambda' + \mu') \) appears in \( V(N\rho_\beta + \lambda') \otimes V(N\rho_\beta + \mu') \) with multiplicity at least \( N + 1 \). \( \square \)

1.2. **Geometry.** We deduce Theorem 2 as an immediate consequence of a more geometric result, which we now explain. Let \( G \) be the Langlands dual group to \( G \) with dual torus \( T \) and Borel subgroup \( B \). By construction, there is a bijection between the set of dominant weights for \( G \) w.r.t. \( B \) and the dominant coweights of \( G \) w.r.t. \( B \). Let \( \lambda_i, i = 1, \ldots, s \) be a collection of such weights/coweights. Let \( W \) denote the Weyl group associated to \( \Phi_G \), with generators \( s_i \) associated to simple roots \( \alpha_i \) determined by \( B \). Note that \( W \) is canonically the Weyl group associated to \( \Phi^\vee = \Phi_G \).

Set \( \mathcal{K} = \mathbb{C}(t) \) and \( \mathcal{O} = \mathbb{C}[[t]] \). For every coweight \( \lambda : \mathbb{C}^s \to T \), there is an induced element \( t^\lambda \in G(\mathcal{K}) \). Inside the affine Grassmannian \( G(\mathcal{K})/G(\mathcal{O}) \), the cosets \( [\lambda] = t^\lambda G(\mathcal{O}) \) for \( \lambda \) dominant give a complete set of representatives for the
left-$G(O)$ orbits. For $(L_1, L_2) \in G(K)/G(O) \times G(K)/G(O)$, we define their distance $d(L_1, L_2)$ to be the unique dominant $\lambda$ satisfying

$$G(K)(L_1, L_2) = G(K)([0], [\lambda]).$$

Following [Hai03, §2], [Kam07, §1], we define the cyclic convolution variety $Gr_{G,c(\lambda)}$ as

$$Gr_{G,c(\lambda)} := \{(L_1, \ldots, L_s) \in (G(K)/G(O))^s \mid L_s = [0], d(L_{i-1}, L_i) = [\lambda_i] \forall i\};$$

here $L_0 := L_s$. It is a finite-dimensional complex algebraic variety whose dimension is always at most $\langle \rho, \sum \lambda_i \rangle$. Via the geometric Satake equivalence ([Lus83, Gin, BD, MV07]), the number of irreducible components of $Gr_{G,c(\lambda)}$ which attain the maximal dimension $\langle \rho, \sum \lambda_i \rangle$ equals

$$\dim(V(\lambda_1) \otimes \cdots \otimes V(\lambda_s))^G;$$

in fact, these irreducible components give a canonical basis of the latter vector space.

Therefore the representation theory of $G$ can be accessed from the geometry of $G(K)/G(O)$. Now let $\{\alpha_i\}$ be the set of simple roots for $G$; thus $\alpha_i^\vee$ are the simple roots for $G$. We prove

**Theorem 3.** Let $N \geq 1$. Let $G = PGL_{n+1}$ and $\beta$ a positive root for $G$. Suppose $\lambda, \mu$ are dominant coweights such that

1. $\lambda + \mu - N\beta^\vee$ is dominant;
2. $\alpha_i(\lambda) < N \implies \beta^\vee - \alpha_i^\vee \notin \Phi_G \cup \{0\}$ (and the same replacing $\lambda$ with $\mu$).

Then, with $\nu := -w_0(\lambda + \mu - N\beta^\vee)$, $Gr_{G,c(\lambda, \mu, \nu)}$ possesses a $G(O)$-orbit of dimension $\langle \rho, 2\lambda + 2\mu - N\beta^\vee \rangle$.

Furthermore, if $\beta$ is not simple, there exist at least two such (disjoint) $G(O)$-orbits.

Therefore Theorem 2 follows from Theorem 3 and the observations that (a) $G(O)$-orbits are always irreducible since $G(O)$ is connected and (b) $\langle \rho, 2\lambda + 2\mu - N\beta^\vee \rangle = \langle \rho, \lambda + \mu \rangle + \langle -w_0(\lambda, \mu, \nu) \rangle = \langle \rho, \lambda + \mu + \nu \rangle$.

**Example 1.** At this point we will pick up a running example, which will hopefully add some concreteness to what follows. On the representation-theoretic side, we work with $G = SL_3(\mathbb{C})$. Using the notation of $\Lambda_i$ for the $i$th fundamental weight of $G$ (and thus the $i$th fundamental coweight of $G$), we take $\beta = \alpha_2 + \alpha_3$ a positive root of $G$, and take $\lambda = \Lambda_2 + \Lambda_3$ and $\mu = \Lambda_1 + \Lambda_2 + \Lambda_3 + \Lambda_4 = \rho$. Lastly let us take $N = 1$. Then $\lambda + \mu - \beta^\vee = 2\Lambda_1 + \Lambda_2 + \Lambda_3 + 2\Lambda_4$ is dominant. Moreover, $\alpha_1(\lambda) = \alpha_4(\lambda) = 0$, and we see that neither $\beta^\vee - \alpha_i^\vee$ nor $\beta^\vee - \alpha_i^\vee$ is a root of $\Phi_G$, satisfying condition (2) of Theorem 3. One checks condition (2) also holds for $\mu$.

1.3. **Remarks.** Our proof of Theorem 3 is constructive; that is, we explicitly name points in $Gr_{G,c(\lambda, \mu, \nu)}$ whose $G(O)$-orbits have the desired dimension.

It is not known in general when top-dimensional components of cyclic convolution varieties (when they exist) are closures of $G(O)$-orbits. If $\lambda, \mu, \nu$ form a PRV-triple, then there exist such components that are $G(O)$-orbit closures (see [Kie19]), and we now have exhibited certain components for Wahl triples which are $G(O)$-orbit closures.

Different, though related, forms of the cyclic convolution variety appeared first in the works of Beilinson and Drinfeld, Anderson, Haines, and Kamniztner. Here we
use the construction which appears in [Hai03]; the top dimensional components of this variety are in bijection with the top dimensional components of the convolution fibers considered by Anderson [And03]. In an appendix, we give an alternate proof of Theorem 2 using Littelmann’s path model. Just as there is an alternate description of our work using Littelmann paths, there might be a useful description in terms of Anderson and Kammitzer’s MV polytopes.

1.4. Acknowledgements. We thank Prakash Belkale for providing feedback on an earlier version of this manuscript.

2. A Good Point inside \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \)

Let \( \lambda, \mu, \beta, \) and \( \nu = -w_0(\lambda + \mu - N\beta^\vee) \) be as in the hypothesis of Theorem 3. In this section we consider a point of \( G(\mathcal{K})/G(\mathcal{O}) \) and prove that it is contained in the variety \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \).

By way of motivation, recall the well-known identity
\[
\tag{1}
t^{-N\beta^\vee} = x_\beta(-t^{-N}) x_{-\beta}(t^N)s_\beta^{-1} x_{-\beta}(t^{-N})
\]
valid for \( G \) of any type with a pinning \( x_\gamma \). So for \( G \) of any type, one has some hope that
\[
([\lambda], g[\lambda + \mu - N\beta^\vee], [0])
\]
belongs to \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \) for some choice of \( g \in G(\mathcal{O}) \): of course \( d([0], [\lambda]) = \lambda \) and \( d(g[\lambda + \mu - N\beta^\vee], [0]) = \nu \), so the hope is that \( g t^{\lambda} t^{-N\beta^\vee}[\mu] \) might give the same coset as \( t^\lambda g' [\mu] \) for some \( g' \in G(\mathcal{O}) \) by inserting the expression \( \tag{1} \) for \( t^{-N\beta^\vee} \). The hope becomes a reality with \( g = x_\beta(t^{(\beta, \lambda)-N}) \) and \( g' = x_{-\beta}(t^N)s_\beta^{-1} \).

So the point \( \xi_0 = ([\lambda], x_\beta(t^{(\beta, \lambda)-N})[\lambda + \mu - N\beta^\vee], [0]) \) is always in \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \). However, even in type \( A \), if \( \beta \) is not simple, then the \( G(\mathcal{O}) \)-orbit of this point is not sufficient to produce a cycle of the correct (top) dimension in \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \). Therefore we must modify our point.

**Remark 1.** In fact, one can show the following: fix \( G \) of type \( A \) and \( \beta \) not simple. Then the two orbits \( O_1 \) and \( O_2 \) of our Theorem 3 satisfy
\[
\overline{O_1} \cap \overline{O_2} \supset G(\mathcal{O})\xi_0.
\]

We proceed now to name a “good” (i.e., its orbit dimension will be maximal) point in \( \text{Gr}_{G,c}(\lambda, \mu, \nu) \).

Let \( \{\alpha_1, \ldots, \alpha_n\} \) denote the standard choice of simple roots for \( G = \text{PGL}_{n+1} \). Then \( \beta = \alpha_p + \alpha_{p+1} + \ldots + \alpha_q \) for some integers \( 1 \leq p \leq q \leq n \). For each \( \gamma \in \Phi_G \), let \( x_\gamma(a) \) be the unipotent \( (n+1) \times (n+1) \) matrix with 1s on the diagonal and \( a \) in the off-diagonal entry associated with the root \( \gamma \) (0s elsewhere). For ease of notation, take \( \gamma_i \) to be the positive root \( \alpha_p + \ldots + \alpha_i \) for \( i \geq p \); therefore \( \gamma_q = \beta \).

Set
\[
\tag{2}
x = \prod_{i=p}^q x_{\gamma_i}(t^{(\gamma_i, \lambda)-N});
\]
note that this product is independent of order of multiplication. Then \( x \in G(\mathcal{O}) \) is the unipotent matrix with 1s on the diagonal and \( t^{(\gamma_i, \lambda)-N} \) in the \( (p, i+1) \) entry for each \( p \leq i \leq q \) (0s elsewhere). (Note that \( (\gamma_i, \lambda) - N \geq (\alpha_p, \lambda) - N \geq 0 \) by condition \( \tag{2} \) of Theorem 3.)
Proposition 1. The point $\xi = ([\lambda], x[\lambda + \mu - N\beta^\vee], [0])$ belongs to $\text{Gr}_{G,c(\lambda,\mu,\nu)}$.

Proof. It is clear that $d([0], [\lambda]) = \lambda$ and $d(x[\lambda + \mu - N\beta^\vee], [0]) = \nu$, so it suffices to establish that $d([\lambda], x[\lambda + \mu - N\beta^\vee]) = \mu$.

First of all, $xt\lambda = t^\lambda x'$, where

$$x' = \prod_{i=p}^q x_{\gamma_i}(t^{-N});$$

therefore we must show $d([0], x'[\mu - N\beta^\vee]) = \mu$. Essentially, we will argue that $x't^{-N}\beta^\vee \in G(\mathcal{O})$ up to right multiplication by $t^\mu G(\mathcal{O})t^{-\mu}$.

By identity (1),

$$x't^{-N}\beta^\vee[\mu] = \left(\prod_{i=p}^{q-1} x_{\gamma_i}(t^{-N})\right) x_\beta(t^N) s_\beta^{-1} x_\beta(t^{-N})[\mu].$$

Observe that $x_{\gamma_i}(t^{-N})x_{-\beta}(t^{-N}) = x_\beta(t^N)x_{-\delta_i}(-1)x_{\gamma_i}(t^{-N})$, where $\delta_i := \beta - \gamma_i = \alpha_{i+1} + \ldots + \alpha_q$. Furthermore, the root subgroups $x_{-\delta_i}()$ commute with $x_{\gamma_i}()$ for any $i, j \leq q - 1$ since $-\delta_i + \gamma_j$ is never a root. So

$$x't^{-N}\beta^\vee[\mu] = x_\beta(t^N) \prod_{i=p}^{q-1} x_{-\delta_i}(-1) \prod_{i=p}^{q-1} x_{\gamma_i}(t^{-N}) s_\beta^{-1} x_\beta(t^{-N})[\mu],$$

and we are reduced to showing $d([0], y[\mu]) = \mu$, with $y$ as indicated. One verifies that $s_\beta \gamma_i = \gamma_i - \beta = -\delta_i$, so

$$y[\mu] = s_\beta^{-1} \prod_{i=p}^q x_{-\delta_i}(t^{-N})[\mu].$$

Now, $x_{-\delta_i}(t^{-N})\mu = t^\mu x_{-\delta_i}(t^{(\mu\delta_i)}-N)$, and each $\langle \mu, \delta_i \rangle \geq \langle \mu, \alpha_q \rangle \geq N$, so

$$\langle [0], y[\mu] \rangle = \langle [0], s_\beta^{-1}[\mu] \rangle = s_\beta^{-1}([0], [\mu]),$$

and we are done.

Example 2. In our running example, since $\beta = \alpha_2 + \alpha_3$, we have $\gamma_2 = \alpha_2$, $\gamma_3 = \alpha_2 + \alpha_3$, $x = x_{\alpha_2}(t^{l_1-1})x_{\alpha_2+\alpha_3}(t^{l_2-1})$. As a matrix, the representative of our point is

$$\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & t^0 & t^1 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}$$

3. The dimension of $G(\mathcal{O})\xi$

In this section we wish to verify that the orbit $G(\mathcal{O})\xi \subseteq G_{G,c(\lambda,\mu,\nu)}$ has dimension equal to $\langle \rho, 2\lambda + 2\mu - N\beta^\vee \rangle$. We observe that $G(\mathcal{O})\xi \simeq G(\mathcal{O})/\text{Stab}(\xi)$ as varieties and that the latter is smooth with tangent space at $[0]$ isomorphic to

$$\mathcal{T} = \frac{\mathfrak{g}(\mathcal{O})}{\mathfrak{g}(\mathcal{O}) \cap \text{Ad}_{\lambda} \mathfrak{g}(\mathcal{O}) \cap \text{Ad}_{xt\lambda + \mu - N\beta^\vee} \mathfrak{g}(\mathcal{O})}.$$
therefore we set ourselves to the task of calculating $\dim T$.

Set $V := \mathfrak{g}(O) \cap \text{Ad}_\lambda \mathfrak{g}(O)$ and $W := \mathfrak{g}(O) \cap \text{Ad}_\lambda \mathfrak{g}(O) \cap \text{Ad}_{\mathfrak{g}(O)} g(O)$. It is well-known that $\dim \mathfrak{g}(O)/V = \langle 2\rho, \lambda \rangle$, so from the short exact sequence

$$0 \to V/W \to T \to \mathfrak{g}(O)/V \to 0$$

of vector spaces, we see it is sufficient to verify that $\dim V/W = \langle \rho, 2\mu - N\beta^\vee \rangle$.

The remainder of this section is devoted to this proof and is fairly technical.

**Proposition 2.** $\dim V/W = \langle 2\rho, \mu \rangle - N\langle \rho, \beta^\vee \rangle$.

Here is our plan for the proof: we will describe the subspace $W \subseteq V$ explicitly by the vanishing of certain linear equations; this will afford us with a description of the quotient $V/W$, whose dimension we will then calculate.

Let $v \in V$ be arbitrary. Since $v \in \mathfrak{g}(O)$ we may express $v$ as a matrix:

$$v = \begin{bmatrix} v_{1,1} & \cdots & v_{1,n+1} \\ \vdots & \ddots & \vdots \\ v_{n+1,1} & \cdots & v_{n+1,n+1} \end{bmatrix},$$

with each $v_{i,j} \in \mathcal{O}$ and $v_{n+1,n+1} = -\sum_{i=1}^n v_{i,i}$. For ease of notation, let $\varepsilon_{i,j}$ be the positive root $\alpha_i + \cdots + \alpha_{j-1}$ whenever $i < j$. Therefore $\varepsilon_{i,j} + \varepsilon_{j,k} = \varepsilon_{i,k}$ for any $i < j < k$. The stipulation $v \in t^\lambda \mathfrak{g}(O)t^{-\lambda}$ means, for all $1 \leq i < j \leq n + 1$,

$$t^{\langle \varepsilon_{i,j}, \lambda \rangle} v_{i,j}.$$

These conditions completely characterize elements of $V$.

Now, $v \in W$ if and only if $v \in V$ and $x^{-1}vx \in t^\varphi \mathfrak{g}(O)t^{-\varphi}$, where $\varphi = \lambda + \mu - N\beta^\vee$. The crux of what follows is to explicitly write $u = x^{-1}vx = (u_{i,j})$ in matrix coordinates; then we can check containment in $t^\varphi \mathfrak{g}(O)t^{-\varphi}$ coordinate-wise. In type $A$, where $x$ is a product of commuting unipotent elements as in 2, then we observe that

$$u_{i,j} = \begin{cases} 
  v_{i,j}, & j \leq p \text{ or } j > q + 1, i \neq p \\
  v_{i,j} - \sum_{k=p}^q a_{k+1}v_{k+1,j}, & j \leq p \text{ or } j > q + 1, i = p \\
  v_{i,j} + a_jv_{i,p}, & p < j \leq q + 1, i \neq p \\
  v_{i,j} - \sum_{k=p}^q a_{k+1}v_{k+1,j} - a_j \left( v_{p,p} - \sum_{k=p}^q a_{k+1}v_{k+1,p} \right), & p < j \leq q + 1, i = p 
\end{cases}$$

where $a_j = t^{\langle \varepsilon_{p,j}, \lambda \rangle} - N$ for $p < j \leq q + 1$. In terms of roots, the first case corresponds to a root $\alpha$ such that $\alpha - \gamma_i \notin \Phi \cup 0$ for all $\gamma_i$. Case 2 corresponds to roots $\alpha$ such that $\alpha - \gamma_i \notin \Phi \cup 0$ for some $i$’s. Case 3 corresponds to $\alpha - \gamma_i \in \Phi$ for exactly one $\gamma_i$. Case 4 corresponds to $\alpha$ being one of the $\gamma_i$. This particular breakdown into 4 cases is a pleasant feature of working in type $A$; in the other types there would be more cases to consider.

**Example 3.** In our running example of $A_4$ with $\beta = \alpha_2 + \alpha_3 \in \Phi_G$ we provide some explicit examples of the different cases. The root spaces $\alpha_1$ and $\alpha_4$ belong to Case 1, $-\alpha_1$ and $\alpha_2 + \alpha_3 + \alpha_4$ belong to Case 2, $\alpha_1 + \alpha_2$ and $\alpha_1 + \alpha_2 + \alpha_3$ belong to Case 3, and obviously $\alpha_2$ and $\alpha_2 + \alpha_3$ are the only roots in Case 4.

The conjugated matrix is
We are now ready to prove Proposition 2.

Proof of Proposition 2. We know that \( u \in t^\varphi \mathfrak{g}(O)t^{-\varphi} \) if and only if

\[
(3) \quad t^{(\varepsilon_{i,j}, \bar{\nu})}|u_{i,j}
\]

for every \( 1 \leq i < j \leq n + 1 \). We also want to measure the minimal power of \( t \) dividing each \( u_{i,j} \) solely based on the assumption that \( v \in V \); this enables us to measure the difference between \( W \) and \( V \). We examine our four cases.

(A) **Case** \( j \leq p \) or \( j > q + 1 \), \( i \neq p \)

In this case (3) holds if and only if \( t^{(\varepsilon_{i,j}, \bar{\nu})}|v_{i,j} \), since \( u_{i,j} = v_{i,j} \). Note that \( v_{i,j} \) is already divisible by \( t^{(\varepsilon_{i,j}, \bar{\nu})} \).

(B) **Case** \( i = p \), \( j > q + 1 \)

Here \( u_{i,j} = v_{i,j} - \sum_{k=p}^{q} a_{k+1} v_{k+1,j} \). We know that \( v_{i,j} \) is divisible by \( t^{(\varepsilon_{i,j}, \bar{\nu})} \). Assuming (3) holds in case (A), each \( v_{k+1,j} \) is divisible by \( t^{(\varepsilon_{k+1,j}, \lambda + \mu - N \beta^\vee)} \). If \( k < q \), then

\[
\langle \alpha_{k+1} + \ldots + \alpha_{j-1}, \mu \rangle \geq \langle \alpha_q, \mu \rangle \geq N
\]

and

\[
\langle \alpha_{k+1} + \ldots + \alpha_{j-1}, -N \beta^\vee \rangle = -N\langle \alpha_{k+1} + \ldots + \alpha_{j-1}, \alpha_p^\vee + \ldots + \alpha_q^\vee \rangle
\]

is 0, since necessarily \( p < k + 1 \). Otherwise, \( k = q \) and

\[
\langle \alpha_{q+1} + \ldots + \alpha_{j-1}, \mu \rangle \geq 0;
\]

\[
\langle \alpha_{q+1} + \ldots + \alpha_{j-1}, -N \beta^\vee \rangle = -N\langle \alpha_{q+1} + \ldots + \alpha_{j-1}, \alpha_p^\vee + \ldots + \alpha_q^\vee \rangle = N.
\]

Therefore in any case

\[
\langle \varepsilon_{k+1,j}, \lambda + \mu - N \beta^\vee \rangle \geq \langle \varepsilon_{k+1,j}, \lambda \rangle + N
\]

and each term \( a_{k+1} v_{k+1,j} \) is divisible by \( t^{(\varepsilon_{p,k+1}, \lambda + \mu - N \beta^\vee)} \)

\[
\frac{t^{(\varepsilon_{p,k+1}, \lambda + \mu - N \beta^\vee)}}{t^{(\varepsilon_{p,k+1}, \lambda)}} \cdot t^{(\varepsilon_{p,k+1}, \lambda)} + N = t^{(\varepsilon_{p,k+1}, \lambda)},
\]

so the entire \( u_{i,j} \) is divisible by \( t^{(\varepsilon_{p,j}, \lambda)} \).

(C) **Case** \( p < j \leq q + 1 \), \( i \neq p \)

In this case \( u_{i,j} = v_{i,j} + a_j v_{i,p} \). As before \( v_{i,j} \) is divisible by \( t^{(\varepsilon_{i,j}, \bar{\nu})} \). If \( i > p \), \( a_j v_{i,p} \) is divisible by \( t^{(\varepsilon_{p,j}, \lambda)} - N ; \)

note that

\[
\langle \alpha_p + \ldots + \alpha_{j-1}, \lambda \rangle - N \geq \langle \alpha_{p+1} + \ldots + \alpha_{j-1}, \lambda \rangle \geq \langle \alpha_i + \ldots + \alpha_{j-1}, \lambda \rangle,
\]

so if \( i > p \) then \( t^{(\varepsilon_{i,j}, \lambda)}|u_{i,j} \).

On the other hand, if \( i < p \), then

\[
\langle \alpha_i + \ldots + \alpha_{p-1}, \lambda - N \beta^\vee \rangle \geq \langle \alpha_i + \ldots + \alpha_{p-1}, -N \beta^\vee \rangle = N,
\]

\[
\begin{bmatrix}
  v_{11} & v_{12} & v_{13} + v_{12} & v_{14} + v_{12}t & v_{15} \\
  v_{21} - v_{31} - v_{41}t & v_{22} - v_{32} - v_{42}t & v_{23} - v_{33} - v_{43}t & v_{24} - v_{34} - v_{44}t & v_{25} - v_{35} - v_{45}t \\
  v_{31} & v_{32} & v_{33} + v_{32} & v_{34} + v_{32}t & v_{35} \\
  v_{41} & v_{42} & v_{43} + v_{42} & v_{44} + v_{42}t & v_{45} \\
  v_{51} & v_{52} & v_{53} + v_{52} & v_{54} + v_{52}t & v_{55}
\end{bmatrix}.
\]
so assuming (3) holds for case (A), \( a_j v_{i,p} \) is divisible by
\[
t^{(\varepsilon_{i,j}, \lambda)-N} \cdot t^{(\varepsilon_{i,p}, \lambda)+N} = t^{(\varepsilon_{i,j}, \lambda)}
\]
if \( i < p \).

We conclude that \( u_{i,j} \) is divisible by \( t^{(\varepsilon_{i,j}, \lambda)} \) in either case.

(D) **Case** \( p = i < j \leq q + 1 \)

Here \( u_{i,j} \) is divisible by \( t^{(\alpha_p + \ldots + \alpha_{j-1}, \lambda)} \), as we explain: the labels indicate minimal powers of \( t \) dividing each term below.

\[
\begin{align*}
u_{p,j} &= v_{p,j} - \sum_{k=p}^{j-2} a_{k+1} v_{k+1,j} - \sum_{k=j-1}^{q} a_{k+1} v_{k+1,j} + a_j \left( v_{p,p} - \sum_{k=p}^{q} a_{k+1} v_{k+1,p} \right) ; \\
\text{note that if } k \geq j - 1 \text{ then } \langle \varepsilon_{p,k+1}, \lambda \rangle \geq \langle \varepsilon_{p,j}, \lambda \rangle.
\end{align*}
\]

**Lemma 1.** Define a map
\[
V \xrightarrow{\phi_1} \bigoplus_{\text{case (A)}} t^{(\varepsilon_{i,j}, \lambda)} O \left( t^{(\varepsilon_{i,j}, \bar{\nu})} \right).
\]
\[
v \longmapsto (u_{i,j}).
\]
Then \( \phi_1 \) is surjective.

**Proof of Lemma 1.** For a given \( i,j \) of case (A), set \( v_{i,j} = t^{(\varepsilon_{i,j}, \lambda)} \) and all other \( v_{i',j'} = 0 \). Then \( v \in V \) and \( \phi_1(v) \) generates the range as an \( O \)-module. As \( \phi_1 \) is an \( O \)-linear morphism of \( O \)-modules, this establishes surjectivity.

Set \( W' := \ker \phi_1 \). Note that \( W \subseteq W' \), but in general they are not equal. Note also that \( W' \) is an \( O \)-submodule of \( V \).

**Lemma 2.** Define a map
\[
W' \xrightarrow{\phi_2} \bigoplus_{\text{case (B)}} t^{(\varepsilon_{p,j}, \lambda)} O \left( t^{(\varepsilon_{p,j}, \bar{\nu})} \right) \bigoplus_{\text{case (C)}} t^{(\varepsilon_{i,j}, \lambda)} O \left( t^{(\varepsilon_{i,j}, \bar{\nu})} \right) \bigoplus_{\text{case (D)}} t^{(\varepsilon_{p,j}, \lambda)} - N O \left( t^{(\varepsilon_{p,j}, \bar{\nu})} \right)
\]
\[
v \longmapsto (u_{p,j}, u_{i,j}, u_{p,j}),
\]
notation as above. Then \( \phi_2 \) is well-defined and surjective, and \( \ker \phi_2 \simeq W' \).

**Proof of Lemma 2.** By construction, \( \ker \phi_2 \simeq W \). The map is well-defined by the divisibility considerations of cases (B) and (C), assuming (3) holds in case (A) (this is why we have created the space \( W' \) and restricted our attention there).

Let \( p,j \) be as in case (B). Set \( v_{p,j} = t^{(\varepsilon_{p,j}, \lambda)} \) and all other \( v_{i',j'} = 0 \). Then \( v \in W' \) (the relevant \( v_{i',j'} \)'s are 0) and \( \phi_2(v) = \left( t^{(\varepsilon_{p,j})}, 0, 0 \right) \).
Let $i, j$ be as in case (C). Set $v_{i,j} = t^{(\varepsilon_{i,j}, \lambda)}$ and $v_{i,p} = 0$. If $i > p$, then set $v_{j,j} = 1$. Set all other $v_{i',j'} = 0$. Therefore $v \in W'$ and $\phi_2(v) = (0, t^{(\varepsilon_{i,j}, \lambda)}0)$ (a cancellation occurs at position $i, j$ in the latter 0 if $i > p$).

Let $p, j$ be as in case (D). Set $v_{j,j} = 1$ and all other $v_{i',j'} = 0$. Then $v \in W'$ and $\phi_2(v) = (0, 0, t^{(\varepsilon_{p,j}, \lambda)} - N)$. We see that the standard $O$-module generators of the range of $\phi_2$ are indeed hit by $\phi_2$. Since $\phi_2$ is an $O$-morphism, surjectivity follows.

We are finally in a position to attain the dimension calculation. The exact sequence

$$0 \to W'/W \to V/W \to V/W' \to 0$$

tells us that $\dim(V/W) = \dim(V/W') + \dim(W'/W)$. By construction,

$$\dim(V/W') = \dim(\text{Im}(\phi_1)) = \sum_{\text{case (A)}} \langle \varepsilon_{i,j}, \bar{\nu} - \lambda \rangle = \sum_{\text{case (A)}} \langle \varepsilon_{i,j}, \mu - N\beta' \rangle$$

and similarly

$$\dim(W'/W) = \dim(\text{Im}(\phi_2)) = \sum_{\text{case (B)}} \langle \varepsilon_{p,j}, \mu - N\beta' \rangle + \sum_{\text{case (C)}} \langle \varepsilon_{i,j}, \mu - N\beta' \rangle + \sum_{\text{case (D)}} \langle \varepsilon_{p,j}, \mu - N\beta' \rangle + N \rangle.$$

Note that, in case (D), the summation runs over $j$ such that $p < j \leq q + 1$, which is $\text{ht}(\beta')$-many terms. As each positive root of $G$ appears as a $\varepsilon_{i,j}$ in exactly one of our four cases, we have in total that

$$\dim(V/W) = \langle 2\rho, \mu - N\beta' \rangle + N\text{ht}(\beta') = \langle 2\rho, \mu - N\beta' \rangle + \langle \rho, N\beta' \rangle = \langle \rho, 2\mu - N\beta' \rangle.$$

\[ \square \]

4. A SECOND POINT IF $\beta$ IS NOT SIMPLE

So far, the combination of Propositions 1 and 2 proves the first statement of Theorem 3. In this section we prove the second statement, assuming $\beta$ is not simple. Toward that end, let

$$\tilde{x} = \prod_{i=p}^q x_{\gamma_i} (t^{(\gamma_i, \lambda)} - N),$$

where now $\gamma_i = \alpha_i + \ldots + \alpha_q$. Set

$$\tilde{\xi} = ([\lambda], \tilde{x}[\lambda + \mu - N\beta'], [0]).$$

\textbf{Example 4.} In our running example, $\tilde{x}$ is the matrix

$$\begin{pmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & t^1 & 0 \\
0 & 0 & 1 & t^0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix}.$$
Notice that it is the mirror image of the original matrix $x$ across the anti-diagonal. That is somewhat special to this example, but in general the minimal square submatrices of $\tilde{x}$ and $x$ containing all the powers of $t$ are mirror images of each other.

Since $p \neq q$, $\tilde{x} \neq x$, so we have some hope that $G(O)\xi \cap G(O)\tilde{\xi} = \emptyset$; we will prove this below. First, however, we record

**Proposition 3.** The point $\tilde{\xi}$ belongs to $\text{Gr}_{G,c(\lambda,\mu,\nu)}$, and $G(O)\tilde{\xi}$ has dimension $\langle \rho, 2\lambda + 2\mu - N\beta' \rangle$.

**Proof.** We argue by symmetry. There is a Dynkin diagram automorphism $\sigma$ of $G$ switching every index $i$ with $(n + 1) - i$ (on roots, coroots, root spaces, pinnings). Pairings are preserved under this automorphism. It naturally extends to an automorphism of $G(K)$ which fixes $G(O)$; in fact, it is explicitly given (at the matrix level) by

$$A \mapsto (A^{-1})^\tilde{t},$$

where $\tilde{t}$ denotes the anti-transpose of a matrix; that is, reflection of its entries across the antidiagonal. It is not in general true that $\tilde{x} = \sigma(x)$, but rather $\tilde{x} = \sigma(x')$ for some $x'$ which behaves like $x$. We make this more precise.

We have

$$\sigma(\tilde{x}) = \prod_{i=p}^q x_{\sigma(\gamma_i)}(-t^{\langle \sigma(\gamma_i), \sigma(\lambda) \rangle} - N),$$

and we note that $\sigma(\gamma_i) = \alpha_{n+1-q} + \ldots + \alpha_{n+1-i}$. Therefore, if $\eta$ is a coweight of $G$ pairing with each $\alpha_{n+1-q}, \ldots, \alpha_{n+1-p}$ to $1$, $(-1)^n\sigma(\tilde{x})(-1)^{-n}$ is the $x'$ as in (2), for the positive root $\beta' = \sigma(\beta)$ (that is, with $p' = n + 1 - q$ and $q' = n + 1 - p$).

By Proposition 1, $\xi' = ([\sigma(\lambda)], x'[\sigma(\lambda + \mu - N\beta')], [0]) \in \text{Gr}_{G,c(\sigma(\lambda), \sigma(\mu), \sigma(\nu))}$. Naturally $\sigma$ induces an isomorphism

$$\text{Gr}_{G,c(\lambda,\mu,\nu)} \to \text{Gr}_{G,c(\sigma(\lambda), \sigma(\mu), \sigma(\nu))},$$

and $\xi'$ is a $G(O)$-translate of $([\sigma(\lambda)], \sigma(\tilde{x})[\sigma(\lambda + \mu - N\beta')], [0]) = \sigma(\tilde{\xi})$ (just act on the left by $(-1)^{\eta}$), therefore $\tilde{\xi} \in \text{Gr}_{G,c(\lambda,\mu,\nu)}$.

Furthermore, the $G(O)$-orbit of $\xi'$ has dimension $\langle \rho, 2\sigma(\lambda) + 2\sigma(\mu) - N\sigma(\beta') \rangle$ by Proposition 2, but since $\sigma(\rho) = \rho$, this dimension equals $\langle \rho, 2\lambda + 2\mu - N\beta' \rangle$.

Therefore the $G(O)$-orbit of $\tilde{\xi}$ has this same dimension, as desired. \hfill \Box

Finally we prove that $\xi$ and $\tilde{\xi}$ really give distinct $G(O)$-orbits inside $\text{Gr}_{G,c(\lambda,\mu,\nu)}$.

**Proposition 4.** With all notation as above, $G(O)\xi \cap G(O)\tilde{\xi} = \emptyset$.

**Proof.** Assume for the sake of contradiction that $\tilde{\xi} = g \xi$ for some $g \in G(O)$. Immediately we recognize that $g$ also belongs to $t^\lambda G(O)t^{-\lambda}$ since $g \in \text{Stab}([\lambda])$.

Write

$$g = \begin{bmatrix} g_{1,1} & \cdots & g_{1,n+1} \\ \vdots & \ddots & \vdots \\ g_{n+1,1} & \cdots & g_{n+1, n+1} \end{bmatrix}$$

as an invertible matrix (representing the element in $\text{PGL}_{n+1}(O)$) with entries in $O$; so far we know $t^{\langle \varepsilon_i, \lambda \rangle} |g_{i,j}$ whenever $i < j$ (once again $\varepsilon_i := \alpha_i + \ldots + \alpha_{i-1}$).
By assumption, \( \tilde{x}^{-1}gx \) belongs to \( t^\nu G(O)t^{-\nu} \). Let \( h = \tilde{x}^{-1}gx \), and let \( \{h_{i,j}\} \) be the matrix coordinates of \( h \). Then

\[
h_{i,j} = \begin{cases} 
g_{i,j}, & i \notin [p, q], j \notin [p + 1, q + 1] 
g_{i,j} - g_{q+1,j}c_i, & i \in [p, q], j \notin [p + 1, q + 1] 
g_{i,j} + g_{i,p}b_j, & i \notin [p, q], j \in [p + 1, q + 1] 
g_{i,j} + g_{i,p}b_j - g_{q+1,j}c_i - g_{q+1,p}c_i b_j, & i \in [p, q], j \in [p + 1, q + 1];
\end{cases}
\]

here \( b_j = t^{(e_i,\lambda)}N^{-N} \) and \( c_i = t^{(e_i,\lambda)}N^{-N} \).

**Lemma 3.** For \( q + 1 \leq j \leq n \), \( g_{q+1,j} \) is divisible by \( t \).

**Proof of the lemma.** Let \( j \) be strictly bigger than \( q + 1 \) and \( \leq n \) (if possible). From above, \( h_{q,j} = g_{q,j} - g_{q+1,j}t^{(e_q,\lambda)}N^{-N} \).

From the assumption \( t^{(e_q,\lambda)\mu - N\beta^\vee} h_{q,j} \), from the observation that \( \langle e_q,\lambda + \mu - N\beta^\vee, \lambda \rangle \geq \langle e_q,\lambda \rangle \), and from the knowledge that \( t^{(e_q,\lambda)\mu} g_{q,j} \), we see that \( t^{(e_q,\lambda)\mu} \) should divide \( g_{q+1,j}t^{(e_q,\lambda)}N^{-N} \). This of course boils down to \( t^{(e_q,\lambda)\mu + N} g_{q+1,j} \), so at least \( t \mid g_{q+1,j} \).

For \( j = q + 1 \), we have

\[
h_{q,q+1} = g_{q,q+1} + t^{(e_{q+1,\lambda})N}(g_{q,p} - g_{q+1,p}t^{(e_{q+1,\lambda})N}) - g_{q+1,q+1}t^{(e_{q+1,\lambda})N}.
\]

Observe that \( t^{(e_{q+1,\lambda})\mu} g_{q,q+1} \) and \( t^{(e_{q+1,\lambda})\mu + N} g_{q+1,q+1} \). Furthermore, our assumption implies \( t^{(e_{q+1,\lambda})\mu} h_{q,q+1} \). So \( t^{(e_{q+1,\lambda})\mu} g_{q+1,q+1} \). Therefore \( t \) divides \( g_{q+1,q+1} \).

We now arrive at a contradiction: the matrix \( g \) is not invertible. Indeed, the entries \( g_{i,j} \) where \( i \leq q \) and \( j \geq q + 1 \) are divisible by \( t^{(e_i,\lambda)} \), which is a nonzero power of \( t \). By the preceding lemma, the entries \( g_{q+1,j} \) for \( j \geq q + 1 \) are also divisible by \( t \). This forces the lower-right \( (n - q - 1) \times (n - q) \) submatrix to contain the pivot points for the last \( n - q \) columns (assuming \( g \) is invertible), which cannot happen.

\[ \square \]

5. Appendix: A Combinatorial Approach to Theorem 2 Via Littelmann Paths

In this short appendix, we give a second proof Theorem 2 with a more combinatorial flavor, using the language of Littelmann paths. While the geometry of \( \text{Gr}_{G,c(\lambda,\mu,\nu)} \) and \( G(O) \)-orbits therein are of particular interest independent of Lie type, many of the methods used in the proof of Theorem 3 are specific to the case when \( G \) is of type \( A \). While we restrict ourselves again to this setting, the techniques of Littelmann paths can be readily adapted to more general settings.

We adopt notations and conventions from [Lit95], and assume that the reader has some familiarity with the path model in representation theory.

5.1. Paths and Tensor Product Decompositions. Let \( \pi_1(t), \pi_2(t), \ t \in [0,1] \) be two paths in the dominant chamber with \( \pi_1(1) = \lambda \), \( \pi_2(1) = \mu \). Then the tensor product of \( G \)-modules \( V(\lambda) \otimes V(\mu) \) decomposes as

\[
V(\lambda) \otimes V(\mu) \cong \bigoplus_{\pi} V(\pi(1)),
\]
Lemma 4. Let \( \chi \) be a dominant weight such that \( \chi(\alpha'_i) = 1 \). Then \( f_i(\pi_\chi) = \pi_{\chi - \alpha_i} \).

5.2. Construction of Paths for Wahl’s Conjecture. Let \( \lambda, \mu, \) and \( \beta \) satisfy the conditions of Theorem 2. We pass directly to the case where \( \lambda = \mu = N\rho_\beta \), where \( \rho_\beta \) is as defined in the proof of Corollary 1. We begin with the case \( N = 1 \).

Proposition 5. Let \( \beta = \alpha_p + \alpha_{p+1} + \cdots + \alpha_q \) be a root, where \( 1 \leq p < q \leq n \). Then \( \pi^{(1)} := f_{p}\pi f_{p+1}\cdots f_{q}\pi \rho_\beta \) and \( \pi^{(2)} := f_{q}\pi f_{q-1}\cdots f_{p}\pi \rho_\beta \) are distinct paths in the dominant chamber.

Proof. By definition, we have that \( \rho_\beta = \omega_p + \omega_q \). By repeated application of Lemma 4, we have that

\[
f_{p}\pi f_{p+1}\cdots f_{q}\pi \rho_\beta = f_{p}\pi \rho_\beta - \alpha_q - \cdots - \alpha_{p+1} =: f_{p}\pi \nu.
\]

As \( \nu(\alpha'_p) = 2 \), by direct application of the lowering operator we have

\[
f_{p}\pi \nu = \pi \nu - \alpha_p * \pi \nu.
\]

So, \( \pi^{(1)} = \pi \rho_\beta * \pi \nu - \alpha_p * \pi \nu \), which is a piecewise linear path with endpoints 0, \( \rho_\beta \), \( \rho_\beta + \frac{1}{2} \nu - \alpha_p \), and \( 2\rho_\beta - \beta \). The first, second, and fourth of these weights is dominant, so it suffices for \( \pi^{(1)} \) to be in the dominant chamber that \( \rho_\beta + \frac{1}{2} \nu - \alpha_p \) is dominant. This is easily verified.

Similarly, we find that \( \pi^{(2)} = \pi \rho_\beta * \pi \nu' - \alpha_q * \pi \nu' \), where \( \nu' = \beta - \alpha_p - \alpha_{p+1} - \cdots - \alpha_{q-1} \). As \( \rho_\beta + \frac{1}{2} \nu - \alpha_p \neq \rho_\beta + \frac{1}{2} \nu - \alpha_q \), we have that \( \pi^{(1)} \) and \( \pi^{(2)} \) are distinct paths.

Corollary 3. With \( \beta \) and \( \rho_\beta \) as in Proposition 5, we have \( \pi^{(1)}_N := \pi \rho_\beta * f_{p}\pi f_{p+1}\cdots f_{q}\pi \rho_\beta \) and \( \pi^{(2)}_N := \pi \rho_\beta * f_{q}\pi f_{q-1}\cdots f_{p}\pi \rho_\beta \) are two distinct paths in the dominant chamber.

Proof. By [Lit95, Lemma 2.3], we have that for any \( N \) and path \( \pi \) that \( N(f_i\pi) = f_i^N(N\pi) \), where \( N\pi \) is the stretched path \( (N\pi)(t) = N\pi(t) \). Then we have that

\[
N\pi^{(1)} = \pi \rho_\beta * N(f_{p}f_{p+1}\cdots f_{q}\pi \rho_\beta) = \pi \rho_\beta * f_{p}f_{p+1}\cdots f_{q}\pi \rho_\beta = \pi^{(1)}_N
\]

But by the computations in Proposition 5, \( \pi^{(1)}_N \) is a piecewise linear path with endpoints 0, \( N\rho_\beta \), \( N\rho_\beta + \frac{1}{2} \nu - N\alpha_p \), and \( 2N\rho_\beta - N\beta \), which are all dominant weights. So, \( \pi^{(1)}_N \) is in the dominant chamber.

A similar argument holds for \( \pi^{(2)}_N \).
Corollary 4. With $\lambda$, $\mu$, $\beta$, and $N$ as in Theorem 2, we have $V(\lambda + \mu - N\beta) \subset V(\lambda) \otimes V(\mu)$ with multiplicity at least 2.

Proof. As in the proof of Corollary 1, write $\lambda = N\rho_\beta + \lambda'$ and $\mu = N\rho_\beta + \mu'$ for some dominant weights $\lambda'$ and $\mu'$. By the tensor product decomposition given by the path model, $\pi_N^{(1)}$ and $\pi_N^{(2)}$ each contribute a unique copy of $V(\pi_N^{(1)}(1)) \cong V(\pi_N^{(2)}(1)) \cong V(2N\rho_\beta - N\beta)$ in the decomposition of $V(N\rho_\beta) \otimes V(N\rho_\beta)$. The result follows from additivity of tensor product decompositions as in the proof of Corollary 1.

We note in Proposition 5 and the following corollaries the necessity that $\beta$ being a non-simple root was vital to the multiplicity result; for a simple root $\alpha_i$, we would have $\pi_i^{(1)} = \pi_i^{(2)} = f_i\pi_{\omega_i}$, which would only give multiplicity at least one.

5.3. Remarks. Like the proof of Theorem 3, the proof of Proposition 5 is a constructive approach to Theorem 2 While we utilize the weight $\rho_\beta$ for computational ease in the path model, the lack of reliance on this in the constructions for points inside of $G_{c,c}(\lambda,\mu,\nu)$ is more satisfactory.

The lower bound on the multiplicity of the components in Theorem 2 is seemingly weak, particularly as $\lambda$ and $\mu$ move farther into the dominant chamber. Thus, one should be able to find many different sequences of lowering operators $f_{i_1} \cdots f_{i_k}$ such that $\pi_\lambda \cdot f_{i_1} \cdots f_{i_k}\pi_\mu$ corresponds to a copy of $V(\lambda + \mu - N\beta)$ inside of $V(\lambda) \otimes V(\mu)$; as remarked in §1.3, it is not clear if the geometric approach of constructing $G(O)$-orbits of appropriate points in $G_{c,c}(\lambda,\mu,\nu)$ would yield similar results. We note that the two distinct constructions in this paper—the points $x$ and $\bar{x}$ of §3 and §4 and the sequences of root operators in paths $\pi_N^{(1)}$ and $\pi_N^{(2)}$—both corresponded to an appropriate interpretation of “moving successively from one end of the root to the other” in their respective settings.
