PRESERVE ONE, PRESERVE ALL

MEERA MAINKAR AND BENJAMIN SCHMIDT

Abstract. Isometries of metric spaces \((X,d)\) preserve all level sets of \(d\). We formulate and prove cases of a conjecture asserting if \(X\) is a complete Riemannian manifold, then a function \(f : X \to X\) preserving at least one level set \(d^{-1}(r)\), with \(r > 0\) small enough, is an isometry.

1. Introduction

Given metric spaces \((X,d_X)\) and \((Y,d_Y)\) and a function \(f : X \to Y\), let

\[
P_f = \{ r > 0 \mid d_X^{-1}(r) \neq \emptyset \text{ and } d_X(x,y) = r \implies d_Y(f(x),f(y)) = r \} \]

\[
SP_f = \{ r > 0 \mid d_X^{-1}(r) \neq \emptyset \text{ and } d_X(x,y) = r \iff d_Y(f(x),f(y)) = r \}.
\]

The classical Beckman-Quarles theorem asserts if \(X = Y\) are Euclidean \(d\)-space \(\mathbb{E}^d\) and \(d \geq 2\), then \(P_f = \emptyset\) or \(f\) is an isometry [BeQu53]. The dimensional hypothesis is necessary.

**Example 1:** The bijection \(f\) of \(\mathbb{E}^1\) that fixes irrational numbers and adds one to rational numbers satisfies \(\mathbb{Q}_{>0} \subset SP_f\).

The Beckman-Quarles theorem does not generalize to Riemannian manifolds without additional assumptions.

**Example 2:** Given a subset \(A\) of the unit sphere \(S^n \subset \mathbb{E}^{n+1}\) with \(A = -A\), the bijection \(f\) of \(S^n\) that fixes the complement of \(A\) and is multiplication by \(-1\) on \(A\) satisfies \(\{ \frac{1}{2}\pi, \pi \} \subset SP_f\).

The convexity radius of \(S^n\) equals \(\frac{1}{2}\pi\), motivating the following conjectural generalization.

**Conjecture:** If \(X\) is a complete Riemannian manifold with positive convexity radius \(\text{conv}(X)\) and \(\dim(X) \geq 2\), then for each function \(f : X \to X\), either \((0,\text{conv}(X)) \cap P_f = \emptyset\) or \(f\) is an isometry.

The conjecture holds for real hyperbolic spaces [Ku79] and unit spheres [Ev95]. If \(f\) is a bijection of a locally compact geodesically complete \(\text{CAT}(0)\) space \(X\) with path connected metric spheres, then \(SP_f = \emptyset\) or \(f\) is an isometry [Be92, An06]; complete and simply connected Riemannian manifolds with nonpositive sectional curvatures are examples of such spaces. Theorems A-C below provide additional evidence for the validity of the conjecture.

---

1 The second author learned about the Beckman-Quarles Theorem after the \(d = 2\) case was given to him as a puzzle during the Lie Group Actions in Riemannian Geometry held at Dartmouth College in 2017. He thanks Dmytro Yeroshkin for the excellent puzzle and Carolyn Gordon and Michael Jablonski for organizing the excellent conference.

1 The \(d = 2\) case reappeared as Problem 6 in the 1997 Brazilian Mathematics Olympiad.
Theorem A: Let \( X \) be as in the conjecture. If a function \( f : X \to X \) is surjective or continuous, and if there exist \( \{ r, R \} \subset (0, \text{conv}(X)) \cap SP_f \) with \( r/R \) irrational, then \( f \) is an isometry.

A metric space \((X,d)\) is two-point homogenous if the isometry group acts transitively on each level \( d^{-1}(r)\); the connected two-point homogenous spaces consist of the Euclidean and rank one symmetric spaces \([Va72][Sz91]\). The noncompact connected two-point homogenous spaces have infinite convexity radii and the compact connected two-point homogenous spaces have convexity radii equal to half their diameter.

Theorem B: Let \( X \) be a connected two-point homogenous space with \( \dim(X) \geq 2 \) and \( f : X \to X \) be a surjective or continuous function. If \( (0, \frac{2}{3} \text{conv}(X)) \cap SP_f \neq \emptyset \), then \( f \) is an isometry.

The proof of Theorem B does not use the classification of connected two-point homogenous spaces. Instead, a unified approach is presented using the authors' Diameter Theorem \([MaSc19]\).

Theorem C: Let \( X \) be as in the conjecture and have a periodic geodesic flow of period 1. If \( f : X \to X \) is a surjective or continuous function, then \((0, \text{conv}(X)) \cap SP_f \subset \mathbb{Q}\) or \( f \) is an isometry.

Up to rescaling the metric, the positively curved (rank one) locally symmetric spaces satisfy the hypotheses of Theorem C. Smooth spheres in each dimension are known to admit metrics as in Theorem C in addition to the constant curvature spaces \([Be78]\).

The proofs of Theorems A-C construct sequences of preserved distances converging to zero and then apply the following generalization of the Myers-Steenrod Theorem \([MySt39]\) to conclude \( f \) is an isometry.

Immerison Theorem: Let \( X \) and \( Y \) be Riemannian manifolds with \( X \) complete and \( \dim(X) \geq 2 \). If \( f : X \to Y \) is a function and \( 0 \) is a limit point of \( P_f \), then \( f \) is a Riemannian immersion.

In the Immersion Theorem, the assumption that \( 0 \) is a limit point of \( P_f \) cannot be weakened to the assumption, as in the conjecture, that \((0, \text{conv}(X)) \cap P_f \neq \emptyset \).

Example 3: The chromatic number of the plane is at most seven since there exists a function \( c : \mathbb{E}^2 \to \{1, 2, 3, 4, 5, 6, 7\} \) with the property that for each \( x, y \in \mathbb{E}^2 \), if \( d(x, y) = 1 \), then \( c(x) \neq c(y) \) \([Ha61]\). Attributed to Iswell]. Given vertices \( \{v_1, v_2, v_3, v_4, v_5, v_6, v_7\} \) of a regular simplex in \( \mathbb{E}^6 \) with unit side lengths, define \( f : \mathbb{E}^2 \to \mathbb{E}^6 \) by \( f(x) = v_{c(x)} \). Then \( 1 \in (0, \text{conv}(\mathbb{E}^2)) \cap P_f \), but \( f \) is discontinuous.

Functions that are surjective or continuous and that strongly preserve a small distance are bijective (Lemmas \([4.2][4.3]\)). If a bijection preserves a distance then it also preserves the set of metric spheres having radii equal to that distance. Smaller preserved distances are constructed by intersecting such spheres. The convexity hypothesis ensures nonempty intersections.

For \( X \) as in the conjecture, \( x \in X \) and \( r > 0 \), let \( S^r_x = \{ y | d(x, y) = r \} \). Let \(|Y|\) denote the cardinality of a set \( Y \).

Sphere Intersections Theorem: Let \( x_1, x_2 \in X \) and \( r_1, r_2 \in (0, \text{conv}(X)) \).

(1) \( S^r_{x_1} \cap S^r_{x_2} \neq \emptyset \iff |r_1 - r_2| \leq d(x_1, x_2) \leq r_1 + r_2 \),
Lemma 2.2. Let \( r_1, r_2 \) with \( r_1, r_2 \geq 0 \), \( \{x \in X \mid d(x, y) < r_1 \} \) and \( \{x \in X \mid d(x, y) < r_2 \} \) are minimizing. The injectivity radius of a point in \( X \) lies entirely in \( \text{conv}(X) \). Sufficiently small metric balls are strongly convex \([Wh32]\). The convexity radius is reviewed in section 2, where also, the various implications in the Sphere Intersections Theorem are proved as independent lemmas. Each one is proved assuming weaker hypotheses on the radii except for the implication

\[
S_{r_1}^x \cap S_{r_2}^x \neq \emptyset \iff |r_1 - r_2| \leq d(x_1, x_2) \leq r_1 + r_2.
\]

The importance of convexity in this implication is illustrated by the following example.

Example 4: Let \( x_1, x_2 \in S^2 \) be a pair of antipodal points. Then \( d(x_1, x_2) = \pi = 2\text{conv}(S^2) \). Given \( r_1 \in (\frac{1}{2}\pi, \pi) \) and \( r_2 \in (\pi - r_1, r_1) \) the intersection \( S_{r_1}^{x_1} \cap S_{r_2}^{x_2} \) is empty while the inequalities \( |r_1 - r_2| < d(x_1, x_2) < r_1 + r_2 \) are valid.

The Immersion Theorem is proved in section 3. Preliminary results about the structure of preserved distances are proved in section 4 and Theorems A-C are proved in section 5.

2. Sphere Intersections Theorem

In this section, \( X \) denotes a complete Riemannian manifold. The Riemannian structure induces a complete geodesic metric

\[
d : X \times X \to \mathbb{R}.
\]

Given \( x \in X \) and \( r > 0 \), let

\[
S_r^x = \{ y \mid d(x, y) = r \}, \quad B_r^x = \{ y \mid d(x, y) < r \}, \quad D_r^x = \{ y \mid d(x, y) \leq r \}.
\]

A subset \( Y \subseteq X \) is strongly convex if for each \( y_1, y_2 \in Y \), there is a unique minimizing geodesic in \( X \) with endpoints \( y_1 \) and \( y_2 \), and moreover, this geodesic lies entirely in \( Y \). Sufficiently small metric balls are strongly convex \([Wh32]\). The convexity radius of \( X \), denoted \( \text{conv}(X) \), is the supremum of positive numbers \( r \) having the property that for each \( x \in X \) and \( 0 < s < r \), the open ball \( B_r^x \) is strongly convex, provided such a positive number exists, and is zero otherwise.

The injectivity radius of a point \( x \in X \), denoted \( \text{inj}(x) \), is the supremum of positive real numbers \( r \) such that all geodesic segments of length \( r \) issuing from \( x \) are minimizing. The injectivity radius of a point in \( X \) depends continuously on the point. The injectivity radius of \( X \), denoted \( \text{inj}(X) \), equals the infimum of the injectivity radii of its points.

Lemma 2.1. The inequality \( \text{conv}(X) \leq \frac{1}{2} \text{inj}(X) \) holds.

Proof. The inequality follows easily from \([Kl59, Di17]\), see e.g. \([MaSc19]\) Lemma 3.3. \( \square \)

The next lemma is well known; the proof is omitted.

Lemma 2.2. Let \( a, b, x \in X \). If equality holds in the triangle inequality

\[
d(a, b) \leq d(a, x) + d(x, b),
\]

then there is an arclength parameterized minimizing geodesic \( \tau : [0, d(a, b)] \to X \) with \( a = \tau(0) \), \( x = \tau(d(a, x)) \), and \( b = \tau(d(a, b)) \).

Lemma 2.3. If \( S_{r_1}^{x_1} \cap S_{r_2}^{x_2} \neq \emptyset \), then \( |r_1 - r_2| \leq d(x_1, x_2) \leq r_1 + r_2 \).
Lemma 2.4. If \( \dim(X) \geq 2 \), \(|r_1 - r_2| \leq d(x_1, x_2) \leq r_1 + r_2 \), and either

1. \( r_1, r_2 \in (0, \text{conv}(X)) \), or
2. \( 0 < r_2 \leq \min\{r_1, \text{inj}(x_2)\} \) and \( r_1 + 2r_2 \leq \text{inj}(x_1) \),

then

\[ S_{r_1}^x \cap S_{r_2}^x \neq \emptyset. \]

Proof. By Lemma 2.1, the hypotheses imply \( r_i \leq \text{inj}(x_i) \) for \( i = 1, 2 \). In particular, the spheres \( S_{r_i}^x \neq \emptyset \) for \( i = 1, 2 \). If \( d(x_1, x_2) = 0 \), then \( r_1 = r_2 \), and \( S_{r_1}^x = S_{r_2}^x \), concluding the proof in this case. Now assume \( d(x_1, x_2) > 0 \). Without loss of generality, \( r_2 \leq r_1 \). Set

\[ T_- = d(x_1, x_2) - r_2 \quad \text{and} \quad T_+ = d(x_1, x_2) + r_2. \]

The hypotheses imply the inequalities

\[ |T_-| \leq r_1 \quad \text{and} \quad r_1 \leq T_+ \leq r_1 + 2r_2. \]

Let \( \gamma : \mathbb{R} \to X \) be an arclength parameterized geodesic with \( x_1 = \gamma(0) \) and \( x_2 = \gamma(d(x_1, x_2)) \). Set

\[ a = \gamma(T_-) \quad \text{and} \quad b = \gamma(T_+). \]

As \( r_2 \leq \text{inj}(x_2) \), the restrictions of the geodesic \( \gamma \) to the length \( r_2 \) intervals \([T_-, d(x_1, x_2)]\) and \([d(x_1, x_2), T_+]\) are minimizing. Therefore

\[ a, b \in S_{r_2}^x. \]

If \( d(x_1, a) = r_1 \) or \( d(x_1, b) = r_1 \), then \( S_{r_1}^x \cap S_{r_2}^x \neq \emptyset \), concluding the proof in these cases. Now assume

\[ d(x_1, a) \neq r_1 \quad \text{and} \quad d(x_1, b) \neq r_1. \]

We now claim

\[ T_- \leq |T_-| = d(x_1, a) < r_1 < T_+. \]

To verify this claim, note that by (2.1), \(|T_-| \leq r_1 \leq \text{inj}(x_1)\), implying

\[ d(x_1, a) = d(\gamma(0), \gamma(T_-)) = |T_-| \leq r_1, \]

and by (2.2), \( T_- \leq |T_-| = d(x_1, a) < r_1 \). Similarly, if the inequality \( r_1 \leq T_+ \) in (2.2) is an equality, then

\[ d(x_1, b) = d(\gamma(0), \gamma(T_+)) = d(\gamma(0), \gamma(r_1)) = r_1, \]

contradicting (2.4), and concluding the verification of (2.5).

We next claim

\[ d(x_1, b) > r_1. \]

To verify (2.6), first consider the case when hypothesis (2) holds. In this case, \( T_+ = d(x_1, x_2) + r_2 \leq r_1 + 2r_2 \leq \text{inj}(x_1) \), whence

\[ d(x_1, b) = d(\gamma(0), \gamma(T_+)) = T_+ = d(x_1, x_2) + r_2 \geq (r_1 - r_2) + r_2 = r_1. \]

By (2.4), the inequality is strict, concluding the verification of (2.6) in this case.
To complete the verification of (2.6), now consider the case when hypothesis (1) holds. If (2.6) fails, then \( d(x_1, b) \leq r \), and by (2.5), \( d(x_1, b) < r \). This inequality and (2.5) imply that \( a, b \in B_{r_1}^2 \), a strongly convex ball since \( r_1 < \text{conv}(X) \). As \( r_2 < \text{conv}(X) \), Lemma 2.1 implies that the restriction of \( \gamma \) to the length 2\( r_2 \) interval \([T_-, T_+]\) is a minimizing geodesic joining \( a \) to \( b \). As \( B_{r_1}^2 \) is strongly convex, this minimizing geodesic is contained in \( B_{r_1}^2 \), or equivalently,

\[
(2.7) \quad t \in [T_-, T_+] \implies d(x_1, \gamma(t)) < r_1.
\]

On the other hand, by (2.5) there exists \( \epsilon > 0 \) with

\[
\epsilon < \min\{T_+ - r_1, \text{conv}(X) - r_1, \frac{1}{2} \text{inj}(X)\}.
\]

As

\[
1 + \epsilon < \text{conv}(X) + \epsilon \leq \frac{1}{2} \text{inj}(X) + \epsilon < \text{inj}(X),
\]

the restriction of \( \gamma \) to \([0, r_1 + \epsilon]\) is a minimizing geodesic. Therefore, \( d(x_1, \gamma(r_1 + \epsilon)) = d(\gamma(0), \gamma(r_1 + \epsilon)) = r_1 + \epsilon \), contrary to (2.7), concluding the verification of (2.6).

The inequalities (2.5) and (2.6) imply that \( S_{r_1}^x \cap S_{r_2}^x \neq 0 \) as will now be demonstrated. As \( \text{dim}(X) \geq 2 \) and \( r_2 < \text{inj}(x_2) \), the metric sphere \( S_{r_2}^x \) is path connected. Let \( \phi : [0, 1] \rightarrow S_{r_2}^x \) be a continuous path with \( \phi(0) = a \) and \( \phi(1) = b \) and define \( f : [0, 1] \rightarrow \mathbb{R} \) by \( f(t) = d(x_1, \phi(t)) \). Then \( f(0) < r_1 \) and \( f(1) > r_1 \) by (2.5) and (2.6). By the intermediate value theorem, there exists \( t_0 \in (0, 1) \) with \( f(t_0) = r_1 \).

It follows

\[
\phi(t_0) \in S_{r_1}^x \cap S_{r_2}^x,
\]

concluding the proof. \[\square\]

**Lemma 2.5.** If \( \text{dim}(X) \geq 2 \), \( r_2 < \text{inj}(x_2) \), \( r_1 + r_2 < \text{inj}(x_1) \), \( r_2 \leq r_1 \), and \( |S_{r_1}^x \cap S_{r_2}^x| = 1 \), then \( d(x_1, x_2) = r_1 - r_2 > 0 \) or \( d(x_1, x_2) = r_1 + r_2 \).

**Proof.** As \( r_i < \text{inj}(x_i) \), the metric spheres \( S_{r_i}^x \) are embedded codimension one submanifolds of \( X \).

If \( x_1 = x_2 \) and \( r_2 < r_1 \), then \( S_{r_1}^x \) and \( S_{r_2}^x \) have empty intersection. If \( x_1 = x_2 \) and \( r_1 = r_2 \), then \( S_{r_1}^x \cap S_{r_2}^x = S_{r_1}^x \) has dimension \( \text{dim}(X) - 1 > 0 \). Therefore \( d(x_1, x_2) > 0 \).

Let \( z \) be the unique point in \( S_{r_1}^x \cap S_{r_2}^x \). As \( z \) is the unique point and \( \text{dim}(X) \geq 2 \), the codimension one submanifolds \( S_{r_1}^x \) and \( S_{r_2}^x \) do not intersect transversally at \( z \). Therefore \( T_z S_{r_1}^x = T_z S_{r_2}^x \) as subspaces of \( T_z X \).

For \( i = 1, 2 \), let \( \gamma_i : [0, r_i] \rightarrow X \) be an arclength parameterized minimizing geodesic joining \( x_i = \gamma_i(0) \) to \( z = \gamma_i(r_i) \). By Gauss’ Lemma, \( \gamma_i(r_i) \) is perpendicular to the subspace \( T_z S_{r_i}^x \) of \( T_z X \). Conclude \( \dot{\gamma}_1(r_1) = \pm \dot{\gamma}_2(r_2) \).

If \( \dot{\gamma}_1(r_1) = \dot{\gamma}_2(r_2) : = : v \) let \( \gamma : \mathbb{R} \rightarrow X \) denote the complete geodesic in \( X \) with \( \dot{\gamma}(0) = -v \). Then \( \gamma(r_2) = x_2 \) and \( \gamma(r_1) = x_1 \). As \( r_1 < \text{inj}(x_1) \) the geodesic \( \tau : [0, r_1] \rightarrow X \) defined by \( \tau(s) = \gamma(r_1 - s) \) is unit speed and minimizing. Therefore

\[
d(x_1, x_2) = d(\tau(0), \tau(r_1 - r_2)) = d(\gamma(0), \gamma(r_1 + r_2)) = r_1 + r_2.
\]

If \( \dot{\gamma}_1(r_1) = -\dot{\gamma}_2(r_2) : = : v \), then let \( \gamma : \mathbb{R} \rightarrow X \) denote the complete geodesic with \( \dot{\gamma}(0) = \dot{\gamma}_1(0) \). Then \( x_1 = \gamma(0) \) and \( x_2 = \gamma(r_1 + r_2) \), and since \( r_1 + r_2 < \text{inj}(x_1) \), \( d(x_1, x_2) = d(\gamma(0), \gamma(r_1 + r_2)) = r_1 + r_2 \). \[\square\]

**Lemma 2.6.** If \( 0 < r_2 < r_1 < \text{inj}(x_1) \) and \( d(x_1, x_2) = r_1 - r_2 \), then \( |S_{r_1}^x \cap S_{r_2}^x| = 1 \).
Proof. As \( r_1 - r_2 < r_1 < \text{inj}(x_1) \) there is a unique arclength parameterized minimizing geodesic \( \bar{\gamma} : [0, r_1 - r_2] \to X \) joining \( x_1 = \bar{\gamma}(0) \) to \( x_2 = \bar{\gamma}(r_1 - r_2) \). Let \( \gamma : \mathbb{R} \to X \) denote its complete extension. Then \( x_1 = \gamma(0) \) and \( x_2 = \gamma(r_1 - r_2) \). Set \( p = \gamma(r_1) \). As \( r_1 < \text{inj}(x_1) \), the restriction of \( \gamma \) to \( [0, r_1] \) is minimizing. Therefore

\[
d(x_1, p) = d(\gamma(0), \gamma(r_1)) = r_1 \quad \text{and} \quad d(x_2, p) = d(\gamma(r_1 - r_2), \gamma(r_1)) = r_2
\]

and \( p \in S^x_{r_1} \cap S^x_{r_2} \). If \( q \in S^x_{r_1} \cap S^x_{r_2} \), then

\[
r_1 = d(x_1, q) \leq d(x_1, x_2) + d(x_2, q) = (r_1 - r_2) + r_2 = r_1.
\]

By Lemma 2.2 there is an arclength parameterized minimizing geodesic \( \tau : [0, r_1] \to X \) joining \( x_1 = \tau(0) \) to \( q = \tau(r_1) \) with \( x_2 = \tau(r_1 - r_2) \). By uniqueness, the restriction of \( \tau \) to \( [0, r_1 - r_2] \) equals \( \bar{\gamma} \), and consequently, the restriction of \( \gamma \) to \( [0, r_1] \) equals \( \tau \). Therefore \( q = \tau(r_1) = \gamma(r_1) = p \).

\[ \square \]

Lemma 2.7. If \( r_1 + r_2 < \text{inj}(x_1) \) and \( d(x_1, x_2) = r_1 + r_2 \), then \( |D^x_{r_1} \cap D^x_{r_2}| = 1 \) and \( D^x_{r_1} \cap D^x_{r_2} = S^x_{r_1} \cap S^x_{r_2} \).

Proof. As \( r_1 + r_2 < \text{inj}(x_1) \) there exists a unique arclength parameterized minimizing geodesic \( \gamma : [0, r_1 + r_2] \to X \) joining \( x_1 = \gamma(0) \) to \( x_2 = \gamma(r_1 + r_2) \). Let \( p = \gamma(r_1) \). As \( \gamma \) is arclength parameterized and minimizing,

\[
d(x_1, p) = d(\gamma(0), \gamma(r_1)) = r_1 \quad \text{and} \quad d(p, x_2) = d(\gamma(r_1), \gamma(r_1 + r_2)) = r_2
\]

and \( p \in S^x_{r_1} \cap S^x_{r_2} \). If \( q \in D^x_{r_1} \cap D^x_{r_2} \), then

\[
r_1 + r_2 = d(x_1, x_2) \leq d(x_1, q) + d(q, x_2) \leq r_1 + r_2.
\]

By Lemma 2.2 there is a minimizing unit speed geodesic \( \tau : [0, r_1 + r_2] \to X \) joining \( x_1 = \tau(0) \) to \( x_2 = \tau(r_1 + r_2) \) with \( q = \tau(r_1) \). As \( \gamma \) is unique, \( \gamma \) equals \( \tau \) and \( p = \gamma(r_1) = \tau(r_1) = q \).

\[ \square \]

Proof of Sphere Intersections Theorem.

Lemmas 2.3, 2.4 together imply statement (1) in the Theorem. Lemma 2.1 and Lemmas 2.5, 2.7 together imply statement (2) in the Theorem.

\[ \square \]

3. Immersion Theorem

Let \((X, g)\) be a complete Riemannian manifold with \( \dim(X) \geq 2 \) and let \((Y, h)\) be a Riemannian manifold. Let \( d_X \) and \( d_Y \) denote the complete geodesic metrics on \( X \) and \( Y \) induced by the Riemannian metrics \( g \) and \( h \). Let \( f : X \to Y \) be a function and assume that \( 0 \) is a limit point of \( P_f \).

The Myers-Steenrod Theorem [MySt39] asserts that a surjective distance preserving function between Riemannian manifolds is a smooth Riemannian isometry. The Immersion Theorem – that \( f \) is a Riemannian immersion – is a generalization of the Myers-Steenrod Theorem. The proof here adapts Palais’ proof [Pa67] of the Myers-Steenrod Theorem as presented in [KoNo].

A preliminary well-known lemma concerns functions between inner product spaces of possibly unequal dimensions.

Lemma 3.1. Let \( V_1 \) and \( V_2 \) be real inner product spaces. If a function \( F : V_1 \to V_2 \) satisfies \( \langle u, w \rangle = \langle F(u), F(w) \rangle \) for all \( u, w \in V_1 \), then \( F \) is a linear isometric map.
Proof. It suffices to prove that $F$ is linear. Let $u, w \in V_1$ and $\alpha \in \mathbb{R}$. Use the hypothesis and bilinearity of the inner products to determine
\[
\langle F(\alpha u + w) - \alpha F(u) - F(w), F(\alpha u + w) - \alpha F(u) - F(w) \rangle = \langle (\alpha u + w) - \alpha u - w, (\alpha u + w) - \alpha u - w \rangle = 0.
\]
\[\square\]

Lemma 3.2. The function $f$ is 1-Lipschitz.

Proof. Let $x, y \in X$ and $\epsilon > 0$. As $X$ is complete, there exists a minimizing geodesic
\[\gamma : [0, d_X(x, y)] \rightarrow X\]
joining $x$ to $y$. Set $\delta = \min \{ \text{inj}(\gamma(t)) \mid t \in [0, d_X(x, y)] \}$ and choose $l \in P_f$ with $l < \min \{ d_X(x, y), \delta/3, \epsilon/2 \}$. As $l < d_X(x, y)$, there exists $k \in \mathbb{N}$ such that
\[k \cdot l < d_X(x, y) \leq (k + 1) \cdot l.
\]
For each integer $i$ with $0 \leq i \leq k$ set $x_i = \gamma(il)$. The above inequalities imply that $d_X(x_k, y) < l$. As $l < \delta/3$, Lemma 2.4-(2) implies there exists $z \in S^x \cap S^y$. As $\gamma$ is minimizing, $d_X(x_i, x_{i+1}) = l$ for each integer $0 \leq i \leq k - 1$.

As $l \in P_f$ and $l < \epsilon/2$, the triangle inequality implies that
\[dy(f(x), f(y)) \leq \sum_{i=0}^{k-1} dy(f(x_i), f(x_{i+1})) + dy(f(x_k), f(z)) + dy(f(z), f(y)) = k \cdot l + 2 \cdot l < d_X(x, y) + \epsilon.
\]
\[\square\]

Lemma 3.3. For each $l \in P_f$ and arclength parameterized minimizing geodesic $\gamma : [0, l] \rightarrow X$, the curve $f \circ \gamma : [0, l] \rightarrow Y$ is an arclength parameterized minimizing geodesic.

Proof. By Proposition 3.8, it suffices to prove that $f \circ \gamma$ is an isometric map of the interval $[0, l]$ into $Y$. If $0 \leq s_1 < s_2 \leq l$, then by Lemma 3.2
\[dy(f(\gamma(s_1)), f(\gamma(s_2))) \leq s_2 - s_1.
\]
The assumptions imply that $dy(f(\gamma(0)), f(\gamma(l))) = l$. Therefore, if $0 \leq t_1 < t_2 \leq l$, the triangle inequality implies
\[l = dy(f(\gamma(0)), f(\gamma(l))) \leq dy(f(\gamma(0)), f(\gamma(t_1))) + dy(f(\gamma(t_1)), f(\gamma(t_2))) + dy(f(\gamma(t_2)), f(\gamma(l))) \leq (t_2 - t_1) + (l - t_2) = l.
\]
Conclude $dy(f(\gamma(t_1)), f(\gamma(t_2))) = t_2 - t_1$.
\[\square\]

Proof of Immersion Theorem.

Fix $x \in X$. Let $S_x X$ and $T_x X$ denote the unit tangent sphere and tangent space of $X$ at $x$, respectively. Let $S_{f(x)} Y$ and $T_{f(x)} Y$ denote the unit tangent sphere and tangent space of $Y$ at $f(x)$, respectively.

Choose $l \in P_f$ with $l < \min \{ \text{inj}(x), \text{inj}(f(x)) \}$. Given $u \in S_x X$, denote by $\gamma_u : [0, l] \rightarrow X$ the arclength parameterized minimizing geodesic with $\gamma_u(0) = u$ and let $\gamma_u = f \circ \gamma_u$. By Lemma 3.3 $\gamma_u : [0, l] \rightarrow Y$ is an arclength parameterized minimizing geodesic in $Y$. Define
\[F : S_x X \rightarrow S_{f(x)} Y
\]
by $F(u) = \tilde{\gamma}_u(0)$ for each $u \in S_\gamma X$. This function extends to a function
\[ L : T_x X \to T_{f(x)} Y \]
defined by $L(\alpha u) = \alpha F(u)$ for each $\alpha \in \mathbb{R}$ and $u \in S_x X$.

Let $\exp_x$ and $\exp_{f(x)}$ denote the restrictions of the exponential maps of $X$ at $x$ and of $Y$ at $f(x)$ to the open balls $B^X_1 \subset T_x X$ and $B^Y_1 \subset T_{f(x)} Y$, respectively. By the choice of $l$, $\exp_x$ and $\exp_{f(x)}$ are diffeomorphisms onto the open balls $B^X_1 \subset X$ and $B^Y_1 \subset Y$. Moreover, the restriction of $f$ to $B^X_1$ is given by
\[ (3.1) \]
\[ f = \exp_{f(x)} \circ L \circ \exp_x^{-1}. \]
It suffices to prove that for each $u, w \in T_x X$,
\[ (3.2) \]
\[ g(u, w) = h(L(u), L(w)), \]
as will now be explained. If $(3.2)$ holds, then by Lemma 3.1 $L$ is linear and isometric, and by $(3.1)$, $f$ is smooth with derivative map at $x$ equal to $L$.

It remains to establish the validity of $(3.2)$. As $L$ satisfies $L(\alpha u) = \alpha L(v)$ for each $\alpha \in \mathbb{R}$ and $v \in V$ and carries unit vectors to unit vectors, it suffices to demonstrate $(3.2)$ for distinct unit vectors $u$ and $w$. By Cauchy-Schwartz, there exist $\theta$ and $\bar{\theta}$ such that $\cos(\theta) = g(u, w)$ and $\cos(\bar{\theta}) = h(F(u), F(w))$.

Let $\gamma_u$, $\gamma_w$, $\bar{\gamma}_u$, and $\bar{\gamma}_w$ be geodesic segments as defined above. By the law of cosines (see e.g. [KoNo, Lemma, Page 170]),
\[ \cos(\theta) = \lim_{s \to 0} \frac{2s^2 - d^2_X(\gamma_u(s), \gamma_w(s))}{2s^2} \quad \text{and} \quad \cos(\bar{\theta}) = \lim_{s \to 0} \frac{2s^2 - d^2_Y(\bar{\gamma}_u(s), \bar{\gamma}_w(s))}{2s^2}. \]
Therefore, it suffices to find a sequence $\{s_i\}$ of positive real numbers that converge to zero and satisfy $d_X(\gamma_u(s_i), \gamma_w(s_i)) = d_Y(\bar{\gamma}_u(s_i), \bar{\gamma}_w(s_i))$.

Define $h : [0, \epsilon] \to X$ by $h(s) = d(\gamma_u(s), \gamma_w(s))$. Then $h$ is continuous and $h(0) = 0$. As $u$ and $w$ are distinct, there exists $\epsilon > 0$ such that the restriction of $h$ to $[0, \epsilon]$ is a homeomorphism onto its image $[0, h(\epsilon)]$. As 0 is a limit point of $P_f$, the set $P_f \cap [0, h(\epsilon)]$ contains a sequence $\{t_i\}$ converging to zero. Letting $s_i = h^{-1}(t_i)$, the sequence $\{s_i\}$ has the desired properties above. \qed

4. Preserved Distances

In this section, $X$ denotes a complete Riemannian manifold with $\text{conv}(X) > 0$ and $\dim(X) \geq 2$. Let $f : X \to X$ be a function.

**Lemma 4.1.** If $0 < r < \text{conv}(X)$ and $x, y \in X$ satisfy $S^r_x = S^y_y$, then $x = y$.

**Proof.** Let $\gamma : [-r, r] \to X$ be an arclength parameterized geodesic with $\gamma(0) = x$. By Lemma 2.1 $2r \in \text{inj}(X)$ so that $\gamma$ is the unique minimizing geodesic segment with endpoints $\gamma(-r)$ and $\gamma(r)$. Therefore, $d(\gamma(\pm r), x) = r$ and $d(\gamma(-r), \gamma(r)) = 2r$. The triangle inequality and the hypothesis $S^r_x = S^y_y$ imply
\[ 2r = d(\gamma(-r), \gamma(r)) \leq d(\gamma(-r), y) + d(y, \gamma(r)) = r + r = 2r. \]
By Lemma 2.2 there is a minimizing geodesic with endpoints $\gamma(-r)$ and $\gamma(r)$ and midpoint $y$. As the segment $\gamma$ is unique, $x = y$. \qed

**Remark 4.1.** The convexity hypothesis in Lemma 4.1 is necessary as illustrated by metric spheres in $S^2$ with antipodal centers and radii $\frac{1}{2}\pi$.

**Lemma 4.2.** If $\{0, \text{conv}(X)\} \cap SP_f \neq \emptyset$, then $f$ is injective.
Lemma 4.4. If \( f \) is continuous and \( (0, \text{conv}(X)) \cap SP_f \neq \emptyset \), then \( f \) is surjective.

Proof. Let \( r \in (0, \text{conv}(X)) \cap SP_f \) and assume that \( f(x) = f(y) \). If \( a \in S^x_r \), then since \( r \in SP_f \),

\[
r = d(a, x) = d(f(a), f(x)) = d(f(a), f(y)) = d(a, y).
\]

Conclude \( S^x_r = S^y_r \) and by Lemma 4.3, \( x = y \). □

Lemma 4.3. If \( f \) is continuous and \( (0, \text{conv}(X)) \cap SP_f \neq \emptyset \), then \( f \) is surjective.

Proof. Let \( r \in (0, \text{conv}(X)) \cap SP_f \). As \( X \) is connected, it suffices to prove that the image of \( f \) is both open and closed. To achieve this, we demonstrate that if \( p \) is in the image of \( f \), then so too is the closed ball \( D^p_{2r} \).

As a preliminary observation, note that if \( x \in X \), then by Lemma 4.2 and invariance of domain, the restriction of \( f \) to \( S^x_r \) is a homeomorphism onto \( S^f(x) \).

Now assume \( p = f(a) \) and \( d(p, q) \leq 2r \). By Lemma 2.4(1), there exists \( z \in S^p_r \cap S^q_r \). As the restriction of \( f \) to \( S^p_r \) is a homeomorphism onto \( S^f_p \) and \( z \in S^p_r \), there exists \( b \in S^p_r \) with \( f(b) = z \). As the restriction of \( f \) to \( S^f_p \) is a homeomorphism onto \( S^x_r \) and \( q \in S^x_r \), there exists \( e \in S^p_r \) with \( f(e) = q \), completing the proof. □

Lemma 4.4. If \( f \) is surjective, \( x_1, x_2 \in X \), and \( r_1, r_2 \in SP_f \), then

\[
\begin{align*}
&f(S^x_{r_1} \cap S^x_{r_2}) = S^f(x_1) \cap S^f(x_2) .
\end{align*}
\]

Proof. If \( x \in S^x_{r_1} \cap S^x_{r_2} \), then \( d(x, x_1) = r_1 \) and \( d(x, x_2) = r_2 \). As \( r_1, r_2 \in P_f \), \( d(f(x), f(x_1)) = r_1 \) and \( d(f(x), f(x_2)) = r_2 \). Therefore

\[
\begin{align*}
f(S^x_{r_1} \cap S^x_{r_2}) &\subseteq S^f(x_1) \cap S^f(x_2) .
\end{align*}
\]

If \( y \in S^y_{r_1} \cap S^y_{r_2} \), then \( d(y, f(x_1)) = r_1 \) and \( d(y, f(x_2)) = r_2 \). There exists \( x \) such that \( f(x) = y \). As \( r_1, r_2 \in SP_f \), \( d(x, x_1) = r_1 \) and \( d(x, x_2) = r_2 \). Therefore

\[
\begin{align*}
x \in S^x_{r_1} \cap S^x_{r_2} \text{ and } \quad f(S^x_{r_1} \cap S^x_{r_2}) &\subseteq S^f(x_1) \cap S^f(x_2) .
\end{align*}
\]

Lemma 4.5. Let \( f \) be surjective and \( r_1, r_2 \in SP_f \). If \( r_1 > r_2 \), \( r_1 + r_2 < \inf\{X\} \), and \( d(x_1, x_2) \in \{r_1 - r_2, r_1 + r_2\} \), then \( d(f(x_1), f(x_2)) \in \{r_1 - r_2, r_1 + r_2\} \).

Proof. By Lemmas 2.6 and 2.7, \( |S^x_{r_1} \cap S^x_{r_2}| = 1 \). Therefore, \( |f(S^x_{r_1} \cap S^x_{r_2})| = 1 \). By Lemma 4.4, \( |S^f(x_1) \cap S^f(x_2)| = 1 \). By Lemma 2.5,

\[
d(f(x_1), f(x_2)) \in \{r_1 - r_2, r_1 + r_2\} .
\]

Lemma 4.6. If \( f \) is surjective and \( r \in (0, \text{conv}(X)) \cap SP_f \), then \( 2r \in SP_f \).

Proof. Assume \( d(x_1, x_2) = 2r \). By the Sphere Intersections Theorem-(2), \( |S^x_{r_1} \cap S^x_{r_2}| = 1 \). Therefore \( |f(S^x_{r_1} \cap S^x_{r_2})| = 1 \). By Lemma 4.4, \( |S^f(x_1) \cap S^f(x_2)| = 1 \). By the Sphere Intersection Theorem-(2), \( d(f(x_1), f(x_2)) = 2r \). Conclude \( 2r \in P_f \).

By Lemma 4.2, \( f \) is bijective; repeating the argument with \( f^{-1} \) demonstrates \( 2r \in SP_f \).

Lemma 4.7. Let \( f \) be surjective and \( r \in (0, \text{conv}(X)) \cap SP_f \). Let \( k \) be the largest integer with the property that for each positive integer \( j \leq k \), \( jr \in SP_f \), provided a largest such integer exists, and let \( k = \infty \) otherwise. Then \( kr \geq \text{conv}(X) \).
Proof. Note that by Lemma 4.6, \( k \geq 2 \). We argue by contradiction. Without loss of generality, \( k < \infty \). If \( kr < \text{conv}(X) \), then applying Lemma 4.5 to \( f \) and \( f^{-1} \) with \( r_1 = kr \) and \( r_2 = r \) implies that a pair of points \( x_1, x_2 \in X \) satisfies \( d(x_1, x_2) \in \{(k-1)r, (k+1)r\} \) if and only if \( d(f(x_1), f(x_2)) \in \{(k-1)r, (k+1)r\} \). By the definition of \( k \), \( (k-1)r \in SP_f \). It then follows \( (k+1)r \in SP_f \), the desired contradiction. \( \square \)

Lemma 4.8. Let \( a, b \in X \) and \( r \in (0, \text{conv}(X)) \).

1. If \( d(a, b) < r \), then \( S^a_r \cap S^b_r \neq \emptyset \) and \( S^a_{2r} \cap S^b_{2r} = \emptyset \).
2. If \( S^a_r \cap S^b_r \neq \emptyset \), \( S^a_{2r} \cap S^b_{2r} = \emptyset \), and \( r \in (0, \frac{2}{3} \text{conv}(X)) \), then \( d(a, b) < r \).

Proof. If \( d(a, b) < r \), then since \( r < \text{conv}(X) \), Lemma 2.3 implies \( S^a_r \cap S^b_r \neq \emptyset \). By Lemma 2.3, \( S^a_{2r} \cap S^b_{2r} = \emptyset \).

Next assume that \( r < \frac{2}{3} \text{conv}(X) \), \( S^a_r \cap S^b_r \neq \emptyset \), and \( S^a_{2r} \cap S^b_{2r} = \emptyset \). Since \( S^a_r \cap S^b_r \neq \emptyset \), Lemma 2.3 implies \( d(a, b) \leq 2r \). By Lemma 2.3, \( 3r < \text{inj}(X) \). Therefore, since \( S^a_{2r} \cap S^b_{2r} = \emptyset \), Lemma 2.4 implies \( d(a, b) > 3r \) or \( d(a, b) < r \). Therefore \( d(a, b) < r \). \( \square \)

Remark 4.2. The hypothesis in Lemma 4.8(2) is likely not optimal. If \( X \) is the unit two sphere, then this statement is valid for \( r \leq \frac{1}{5} \text{conv}(X) \).

Lemma 4.9. If either

1. \( f \) is surjective and \( r \in (0, \frac{2}{3} \text{conv}(X)) \) \( \cap SP_f \), or
2. \( f \) is continuous and \( r \in (0, \text{conv}(X)) \) \( \cap SP_f \),

then \( d(x_1, x_2) < r \) if and only if \( d(f(x_1), f(x_2)) < r \). In particular,

1. For each \( x \in X \), \( f(D^r_x) = D^r_{f(x)} \), and
2. If \( Y \subseteq X \) satisfies \( \text{Diam}(Y) = r \), then \( \text{Diam}(f(Y)) = \text{Diam}(f(Y)) \).

Proof. Assertions (1) and (2) in the Lemma follow immediately from the main assertion of the Lemma.

We first prove the main assertion assuming hypothesis (1). By Lemma 4.6, \( 2r \in SP_f \). By Lemma 4.3, \( f(S^a_{2r} \cap S^b_{2r}) = S^{f(x_1)}_{r} \cap S^{f(x_2)}_{r} \) and \( f(S^a_{2r} \cap S^b_{2r}) = S^{f(x_1)}_{2r} \cap S^{f(x_2)}_{2r} \). The main assertion of the Lemma is now a consequence of Lemma 4.3.

We conclude with the proof of the main assertion assuming hypothesis (2). By invariance of domain and Lemmas 4.2 and 4.3, \( f \) is a homeomorphism. It follows that if \( x \in X \), then the function \( h : B^r \rightarrow \mathbb{R} \) defined by \( h(y) = d(f(x), f(y)) \) is an interval in \( [0, r) \cup (r, \infty) \). The conclusion follows since \( h(x) = 0 \). \( \square \)

Lemma 4.10. If \( r \in (0, \text{conv}(X)) \) \( \cap P_f \) and \( d(x_1, x_2) \leq 2r \), then \( d(f(x_1), f(x_2)) \leq 2r \).

Proof. By the Sphere Intersection Theorem-(1), there exists \( z \in S^a_{r_1} \cap S^b_{r_2} \). As \( r \in P_f \), \( d(f(x_1), f(x_2)) \leq d(f(x_1), f(z)) + d(f(z), f(x_2)) = 2r. \) \( \square \)

Lemma 4.11. If \( f \) is surjective, \( r_1, r_2 \in (0, \text{conv}(X)) \) \( \cap SP_f \), and \( r_1 - r_2 \leq 2r_2 < r_1 + r_2 \), then \( r_1 - r_2 \in SP_f \).

Proof. Assume that \( d(a, b) = r_1 - r_2 \). By Lemma 4.5, \( d(f(a), f(b)) = r_1 - r_2 \) or \( d(f(a), f(b)) = r_1 + r_2 \). As \( r_1 - r_2 \leq 2r_2 \), Lemma 4.10 implies \( d(f(a), f(b)) \leq 2r_2 < r_1 + r_2 \), whence \( d(f(a), f(b)) = r_1 - r_2 \). By Lemma 4.2, \( f \) is bijective; repeating the argument with \( f^{-1} \) demonstrates \( r_1 - r_2 \in SP_f \). \( \square \)
Given $x \in \mathbb{R}$, let $\lfloor x \rfloor \in \mathbb{Z}$ denote the largest integer less than or equal to $x$.

**Proposition 4.12.** If $f$ is surjective, $r_1, r_2 \in (0, \text{conv}(X)) \cap SP_f$, and $r_1 > r_2$, then $r_1 - \lfloor r_1/r_2 \rfloor r_2 \in SP_f$.

**Proof.** Note that $|r_1/r_2|r_2 \leq r_1 < (1 + |r_1/r_2|)r_2$. The conclusion holds trivially when the first inequality is an equality. Now consider the case when $|r_1/r_2|r_2 < r_1 < (1 + |r_1/r_2|)r_2$. If $|r_1/r_2| = 1$, then $r_1 - r_2 < r_1 < 2r_2$, and by Lemma 4.11, $r_1 - r_2 \in SP_f$.

Now assume that $|r_1/r_2| \geq 2$. Then

$$r_1 - |r_1/r_2|r_2 < r_2 \leq r_1/2 < \text{conv}(X)/2.$$  
If $d(a, b) = r_1 - |r_1/r_2|r_2$, then applying Lemma 11.9 with $r = r_2$ implies

$$d(f(a), f(b)) < r_2.$$  
As $|r_1/r_2|r_2 < r_1 < \text{conv}(X)$, Lemma 11.7 implies $|r_1/r_2|r_2 \in SP_f$. It then follows from Lemma 4.5 applied to the radii $r_1$ and $|r_1/r_2|r_2$, that $d(f(a), f(b)) = r_1 - |r_1/r_2|r_2$. By Lemma 4.7, $f$ is bijective; repeating the argument with $f^{-1}$ demonstrates $r_1 - |r_1/r_2|r_2 \in SP_f$. □

5. Theorems A-C

Theorem A is based on the following lemma.

**Lemma 5.1.** Let $S$ be a subset of $(0, \infty)$ satisfying:

1. If $a, b \in S$ and $a > b$, then $a - [a/b]b \in S \cup \{0\}$.
2. There exist $a, b \in S$ with $a/b$ irrational.

Then 0 is a limit point of $S$.

**Proof.** Let $\epsilon > 0$. We will show $S \cap (0, \epsilon) \neq \emptyset$. To this end, consider a strictly decreasing sequence $\{s_i\}$ in $S$ constructed as follows: Let $a, b \in S$ be as in (2) with $a > b$. Set $s_1 = a$, $s_2 = b$. Define $s_3 = s_1 - [s_1/s_2]s_2$. Verify $s_2 > s_3 > 0$ and $s_2/s_3$ is irrational. Defining $s_i = s_{i-2} - [s_{i-2}/s_{i-1}]s_{i-1}$ iteratively produces the desired sequence. As $S$ is bounded below, the strictly decreasing sequence $\{s_i\}$ is Cauchy. Therefore, for $n$ sufficiently large

$$s_{n+1} = s_{n-1} - [s_{n-1}/s_n]s_n \leq s_{n-1} - s_n < \epsilon.$$ □

**Proof of Theorem A.**

By Lemmas 4.2 and 4.3, $f$ is a bijection. Let $S = (0, \text{conv}(X)) \cap SP_f$. The set $S$ satisfies Lemma 5.1(1) by Proposition 4.12 and Lemma 5.1(2) by hypothesis. Therefore, zero is a limit point of $S$. The Immersion Theorem implies that $f$ is a Riemannian immersion. Bijective Riemannian immersions are isometries, concluding the proof. □

Theorem B is based on the following specialization of the main theorem in [MaSc19].

**Diameter Theorem:** If $0 < r < \text{conv}(X)$ and if $\gamma : [0, 2r] \to X$ is an arclength parameterized geodesic, then the function

$$g(t) = \text{Diam}(D^{\gamma(0)}_r \cap D^{\gamma(t)}_r)$$
Lemma 5.4. If □ immersion, hence an isometry.

is continuous, monotonically decreasing, and satisfies \( g(t) > 2r - t \) for \( t \in (0, 2r) \).

Given a pair of points \( x \) and \( y \) in the Euclidean plane and \( r > 0 \), the intersection \( D^x_r \cap D^y_r \) has diameter \( r \) if and only if \( d(x, y) = \sqrt{3}r \). The next Corollary is a generalization of this fact for connected two-point homogeneous spaces.

**Corollary 5.2.** If \( X \) is a connected two point homogenous space and \( 0 < r < \text{conv}(X) \), then there is a unique \( \tilde{r} \in (0, 2r) \) with the property that for all \( x, y \in X \) satisfying \( d(x, y) \leq 2r \),

\[
\text{Diam}(D^x_r \cap D^y_r) = r \iff d(x, y) = \tilde{r}.
\]

Moreover, \( \tilde{r} \in (r, 2r) \).

**Proof.** Fix a geodesic as in the Diameter Theorem and let \( g : [0, 2r] \to \mathbb{R} \) be the associated diameter function. As \( X \) is two-point homogeneous, it suffices to prove that there is a unique \( \tilde{r} \in (0, 2r) \) such that \( g(\tilde{r}) = r \), and moreover, \( \tilde{r} \in (r, 2r) \). By the Diameter Theorem, \( g(t) \) is continuous, monotonically decreasing, and satisfies \( g(r) > 2r - r = r \). By Lemma 2.1, \( g(2r) = 0 \). The conclusion follows. \( \square \)

**Lemma 5.3.** If \( X \) is a connected two-point homogenous space, \( f : X \to X \) is a bijection, \( r \in (0, 2r) \cap \text{SP}_f \), and \( \tilde{r} \in (r, 2r) \) is as in Corollary 5.2 then \( \tilde{r} \in \text{SP}_f \).

**Proof.** By Corollary 5.2 if \( d(x, y) = \tilde{r} \), then \( \text{Diam}(D^x_r \cap D^y_r) = r \). By Lemma 4.9 \( \text{Diam}(D^r_x \cap D^r_y) = \text{Diam}(f(D^r_x \cap D^r_y)) = r \). In particular, \( D^r_x \cap D^r_y \) is nonempty. If \( z \in D^r_x \cap D^r_y \), then \( d(f(x), f(y)) \leq d(f(x), z) + d(z, f(y)) \leq 2r \). By Corollary 5.2, \( d(f(x), f(y)) = \bar{r} \) and \( \tilde{r} \in P_f \). Repeating this argument after replacing \( f \) with \( f^{-1} \) demonstrates \( \tilde{r} \in \text{SP}_f \). \( \square \)

**Proof of Theorem B.**

By Lemmas 1.2 and 1.3 \( f \) is a bijection. Define \( l_0 := r \) and let \( l_0 = \tilde{r} \in (l_0, 2l_0) \) is dense in \( [0, 1] \).

By Lemma 2.1 \( l_0 + l_0 < 2r < 2 \text{conv}(X) \leq \text{inj}(X) \). Apply Lemma 3.11 with \( r_1 = l_0 \) and \( r_2 = l_0 \) to conclude \( l_1 \in \text{SP}_f \).

For \( i \geq 2 \), define \( l_i \) inductively by \( l_i := l_{i-1} - l_{i-1} \). Repeating the above argument, the sequence \( \{l_i\} \) is strictly decreasing and satisfies \( l_i \in \text{SP}_f \). As the sequence \( \{l_i\} \) is bounded below by \( 0 \), it is Cauchy. Therefore, given \( \epsilon > 0 \), for \( i \) sufficiently large, \( l_i - |l_i/l_{i+1}|l_{i+1} < \epsilon \). By Proposition 1.12 \( l_i - |l_i/l_{i+1}|l_{i+1} \in \text{SP}_f \). Therefore \( l_i \) is a limit point of \( \text{SP}_f \). By the Immersion Theorem, \( f \) is a bijective Riemannian immersion, hence an isometry. \( \square \)

Theorem C is based on the following well known density lemma.

**Lemma 5.4.** If \( r \in (0, \infty) \) is irrational, then the set \( \{nr - \lfloor nr \rfloor \mid n \in \mathbb{N} \} \) is dense in \( [0, 1] \).

**Proof of Theorem C.**

By Lemmas 1.2 and 1.3 \( f \) is a bijection. Assume that \( r \in (0, \text{conv}(X)) \cap \text{SP}_f \) is irrational. Let \( \epsilon > 0 \). By the Immersion Theorem, it suffices to prove \( (0, \epsilon) \cap \text{SP}_f \neq \emptyset \). By Lemma 5.4 there exists \( n \in \mathbb{N} \) such that \( 0 < nr - \lfloor nr \rfloor < \epsilon \) and \( nr - \lfloor nr \rfloor < \text{inj}(X) \). We claim that \( nr - \lfloor nr \rfloor \in \text{SP}_f \).
Given \( x, y \in X \) with \( d(x, y) = nr - \lfloor nr \rfloor \), let \( \gamma : \mathbb{R} \to X \) be the arclength parameterized geodesic with \( \gamma(0) = x \) and \( \gamma(nr - \lfloor nr \rfloor) = y \). As \( \gamma \) is periodic with period one, \( \gamma(nr) = \gamma(nr - \lfloor nr \rfloor) = y \).

Let \( \tilde{\gamma} : \mathbb{R} \to X \) be the arclength parameterized geodesic with \( \tilde{\gamma}(0) = f(\gamma(0)) \) and \( \tilde{\gamma}(r) = f(\gamma(r)) \). We claim that for all \( i \in \mathbb{N} \),

\[
(5.1) \quad f(\gamma(ir)) = \tilde{\gamma}(ir) .
\]

The case \( i = 1 \) in (5.1) holds by construction; the remaining cases \( i > 1 \) will be established using strong induction. If (5.1) holds for all \( 0 \leq k < i \), then since

\[
d(\gamma((i-2)r), \gamma((i-1)r)) = r = d(\gamma((i-1)r), \gamma(ir))
\]

and

\[
d(\gamma((i-2)r), \gamma(ir)) = 2r,
\]

Lemmas 2.2 and 4.6 imply that \( f(\gamma((i-2)r)) \), \( f(\gamma((i-1)r)) \), and \( f(\gamma(ir)) \) lie in a common minimizing geodesic segment of length \( 2r \). Since \( f(\gamma(kr)) = \tilde{\gamma}(kr) \) when \( k = (i-2) \) and \( k = (i-1) \), this minimizing geodesic segment is the restriction of \( \tilde{\gamma} \) to the interval \([0,kr] \), verifying (5.1) when \( k = i \).

As \( \tilde{\gamma} \) is periodic with period one, \( f(y) = f(\gamma(nr)) = \tilde{\gamma}(nr) = \tilde{\gamma}(nr - \lfloor nr \rfloor) \). Therefore, the restriction of \( \tilde{\gamma} \) to the interval \([0, nr - \lfloor nr \rfloor] \) is a geodesic segment of length \( nr - \lfloor nr \rfloor \) joining \( f(x) \) to \( f(y) \). As \( nr - \lfloor nr \rfloor < \text{inj}(X) \), \( d(f(x), f(y)) = nr - \lfloor nr \rfloor \) and \( nr - \lfloor nr \rfloor \in P_f \). Repeating the argument with \( f^{-1} \) demonstrates \( nr - \lfloor nr \rfloor \in SP_f \), concluding the proof. \( \square \)
