Abstract

We consider sequential change point detection in multiple data streams, where each stream has its own change point. Once a change point is detected for a data stream, this stream is deactivated permanently. The goal is to maximize the normal operation of the pre-change streams, while controlling the proportion of post-change streams among the active streams at all time points. This problem has wide applications in science, social science, and engineering. Taking a Bayesian formulation, we develop a compound sequential decision theory framework for this problem. Under this framework, an oracle procedure is proposed that is optimal among all sequential procedures which control the expected proportion of post-change streams at each time point. We also investigate the asymptotic behavior of the proposed method when the number of data streams grows large. Several non-standard technical tools involving partially ordered spaces and monotone coupling of stochastic processes are developed for proving the optimality result. Numerical examples are provided to illustrate the use and performance of the proposed method.

Keywords: sequential analysis, change point detection, compound sequential decision
1 Introduction

Sequential change detection studies the detection of time point after which there is a distributional change in sequentially observed data. Methods for sequential change detection have many applications in various fields, including engineering, education, medical diagnostics, finance, among others, where a change point typically corresponds to a deviation of a data stream from its 'normal' state. While early works on this topic (Page 1954; Roberts 1966; Shewhart 1931; Shiryaev 1963) study the change in a single data stream, many recent developments focus on change detection in multiple data streams (Chan 2017; Chen 2019; Chen and Zhang 2015; Mei 2010; Tartakovsky and Veeravalli 2008; Xie and Siegmund 2013).

In this paper, we consider a multi-stream sequential change detection problem, where each stream has its own change point. Once a change point is detected for a data stream, this stream is deactivated permanently and thus its data are no longer collected. The goal is to maximize the normal operation of the pre-change streams, while controlling the proportion of post-change streams among the active ones at all time points.

This multi-stream sequential change detection problem is commonly encountered in the real world. One such example is monitoring the item pool for a standardized high-stake educational test (e.g., admission, licensing, and certification tests), which is one of the most important problems in educational testing that has received much attention in recent years (Choe et al. 2018; Cizek and Wollack 2016; van der Linden and Lewis 2015; Veerkamp and Glas 2000). Almost every standardized test has an item pool, where items in the pool are administrated repeatedly. As a consequence, an item faces the risk of being leaked once exposed to the test takers in one administration. In this application, each data stream corresponds to an item, and a change point corresponds to the time point after which the item is leaked to a large number of future test takers. Once a change point is detected for an item, the test administrator would like to remove it from the item pool to ensure test fairness. On the other hand, due to the high cost of
developing a new item, the test administrator has the incentive to maximize the usage of an item before it is leaked. Besides educational testing, similar problems are also widely seen in many other fields, including engineering (e.g., Basseville and Nikiforov 1993, Li et al. 2014) and public health (e.g., Farrington et al. 1996).

We provide a compound sequential decision framework for this multi-stream change point detection problem. First, a Bayesian formulation is provided for this problem that imposes a distributional assumption on the stream-specific change points. This formulation is an extension of the classical Bayesian setting for change point in a single data stream; see e.g., Polunchenko and Tartakovsky (2012) and references therein.

Second, we propose performance metrics and optimality criteria under this formulation. Specifically, we propose a compound decision risk measure, named the Local Post-change Non-detection Rate (LPNR) which is defined as the conditional expectation of the Post-change Non-detection Proportion (PNP) given the up-to-date information, where PNP is the proportion of post-change streams among the active streams at a time point. Note that once a stream has been detected and deactivated, its data are no longer collected and thus the stream is excluded from the evaluation of LPNR. As a trade-off of the LPNR, we also define a stream utilization measure as the total number of data points collected from the beginning to each time point. By making more detections, we tend to reduce the LPNR, but, in the meantime, the expected stream utilization measure is reduced as well. Our compound sequential decision objective is to maximize the expected stream utilization, while controlling the LPNR to be below a pre-specified threshold at any time point.

Third, we propose a sequential decision procedure which controls LPNR under any pre-specified threshold. Theoretical properties are established for the proposed procedure. In particular, we show that the proposed procedure is optimal under suitable conditions. That is, among all sequential procedures which control the same level of LPNR, the proposed procedure leads to the highest stream utilization at each time point. Furthermore, asymptotic theory is developed for characterizing the performance of the proposed method as the number of data streams grows large, which supports its
use in large-scale applications.

Our theoretical developments for the proposed procedure, especially its uniform optimality, are non-trivial. Part of the challenge lies in the complexity of both the information filtration and the decision space. That is, to make an appropriate sequential decision, one has to take into account all the historical information from all the data streams. In addition, a compound sequential decision at one time point is a mapping from all historical information to the decision space, where the complexity of the decision space is exponential in the number of active data streams at time $t$. Moreover, the uniform optimality result cannot be derived directly from standard stochastic control theory such as backward induction for solving Bellman optimality equations (Bellman, 1966). This is because a uniformly optimal sequential procedure simultaneously maximizes infinitely many stochastic optimization problems, while standard methods, such as backward induction, focus on one stochastic optimization problem. Our theoretical results provide mathematical characterizations for this highly complex optimization problem and show that the proposed procedure gives the global optimal solution under suitable conditions. To characterize this optimization problem, we develop new mathematical tools, including a special partial order relationship defined over unions of finite-dimensional cubes and a construction of monotone coupling for several stochastic processes. These tools are of independent value for solving stochastic control problems.

It is worth noting that our setting is different from most of the existing works on multi-stream change point detection, including Tartakovsky and Veeravalli (2008), Mei (2010), Xie and Siegmund (2013), Chen and Zhang (2015), Chan (2017), and Chen (2019). Specifically, these works consider the detection of a single change point, after which all (or part) of the data streams deviate from their initial states. They develop sequential procedures for detecting this single change point by aggregating information from multiple streams, and establish optimal properties for the proposed procedures. In contrast, under the current setting, each stream has its own change point and a compound decision is needed at each time point that consists of detection
decisions for all active streams. Our theoretical developments share a similar flavor as those in the sequential change detection literature on the optimality of sequential procedures (e.g., Lorden 1971, Moustakides 1986, Pollak 1985, 1987, Shiryaev 1963), though the classical optimality results are based on non-compound measures such as false alarm rate and detection delay. In addition, the current one is essentially a multi-stream stochastic control problem, due to the deactivation interventions on individual streams, while the existing methods essentially solve a sequential estimation problem without a control step. The stochastic control step leads to a much more complicated information filtration compared with the existing works, bringing further challenge to our theoretical development.

Finally, we provide a connection between the current work and compound decision theory (see e.g., Zhang 2003) which dates back to the seminal works of Robbins 1951, 1956. In particular, the LPNR metric in our framework is closely related to the local false discovery and non-discovery rates developed in Efron et al. (2001) and Efron 2004, 2008, 2012 for the compound decision of multiple testing. Similar to the local false discovery and non-discovery rates for multiple testing, the proposed LPNR metric is also scalable in that the same level of LPNR remains sensible, even when having a very large number of data streams. In the sequential analysis literature, the idea of compound decision is rarely explored, except in Song and Fellouris (2019) and Bartroff 2018 who develop compound decision theory for sequential multiple testing. In terms of multi-stream sequential change point detection, to our best knowledge, the proposed one is the first compound decision theory framework.

The rest of the paper is organized as follows. In Section 2 we provide a Bayesian setting for multi-stream change detection and propose a compound sequential decision theory framework which includes the definition of the local post-change non-detection rate and the stream utilization measure, and optimality criteria based on these two metrics. In Section 3 a sequential procedure is proposed for solving the problem. Its theoretical properties, including optimality and asymptotic results, are provided in Section 4 followed by a proof sketch and several new mathematical tools. Fi-
nally, numerical experiments are presented in Section 5 and discussions are provided in Section 6. The proofs of all the technical results are provided in the supplementary material.

2 Compound Sequential Change Detection

2.1 Change Point Models

Consider in total $K$ data streams. For each $k = 1, \ldots, K$, the observations from the $k$th stream are $X_{k,t}$, $t = 1, 2, \ldots$. Each stream $k$ is associated with a change point, denoted by $\tau_k$, which takes value in $\{0\} \cup \mathbb{Z}_+$. The random vector $(\tau_1, \cdots, \tau_K)$ is assumed to follow a known prior distribution. Given the change points, the data points $X_{k,t}$ from the $k$th stream at time $t$ are independent for different $t$ and $k$. It is further assumed that the pre-change and post-change distributions of $X_{k,t}$ have the density functions $p_{k,t}(\cdot)$ and $q_{k,t}(\cdot)$ with respect to some baseline measure $\mu$. That is, $X_{k,t}$ has the following conditional density functions

$$X_{k,t} \mid \tau_1, \cdots, \tau_K, \{X_{l,s}; 1 \leq l \leq K, 1 \leq s \leq t - 1\} \sim \begin{cases} p_{k,t} & \text{if } t \leq \tau_k, \\ q_{k,t} & \text{if } t > \tau_k. \end{cases} \quad (1)$$

Throughout the paper, we assume that $p_{k,t}$ and $q_{k,t}$ have the same support.

Equation (2.1) provides a general model for change points in multiple data streams. It contains some commonly used models as special cases. We provide two examples below.

**Example 1** (A partially dependent model). *Let $\tau_0$ be a non-negative random variable and $\tau_1, \cdots, \tau_K$ are independent and identically distributed (i.i.d.) conditional on $\tau_0$, with conditional distribution*

$$P(\tau_k = m | \tau_0 = m) = \eta \text{ and } P(\tau_k = \infty | \tau_0 = m) = 1 - \eta$$
for \( m = 0, 1, \cdots \) and some parameter \( \eta \in [0, 1] \).

The above model describes the situation where there is a single change point for all of the data streams. After the change point, all or part the the data streams have a distributional change. If we further let \( p_{k,t} \) be the density function of standard normal distribution \( N(0, 1) \), and \( q_{k,t} \) be the density function of \( N(\mu, 1) \) for some \( \mu > 0 \). Then this model becomes a Bayesian formulation of the change point models studied in Chan (2017); Mei (2010); Xie and Siegmund (2013). An interesting boundary case is \( \eta = 1 \), where all the change points \( \tau_1 = \cdots = \tau_K \) are the same. This case can be viewed as a single change point affecting all the data streams.

**Example 2** (An i.i.d. change point model). Assume that \( \tau_1, \cdots, \tau_K \) are i.i.d. geometrically distributed random variables with \( \mathbb{P}(\tau_k = m) = \theta(1 - \theta)^m \) for \( m = 0, 1, \cdots \) and \( \theta \in (0, 1) \). In addition, assume that all the \( p_{k,t} \)'s are the same and all the \( q_{k,t} \)'s are the same. That is, there are density functions \( p \) and \( q \) such that and \( p_{k,t}(x) = p(x) \) and \( q_{k,t}(x) = q(x) \) for all \( k, t, x \). This model is referred to as model \( \mathcal{M}_s \) in the rest of the paper.

The geometric distribution assumption in the above example is a standard assumption in the literature of Bayesian sequential change detection; see Polunchenko and Tartakovsky (2012) for a review. With the geometric distribution assumption, the posterior distribution of each change point has a nice form that is convenient to analyze. More discussions on this model will be provided in the sequel.

### 2.2 Compound Sequential Change Detection

We now describe the setting for compound sequential change detection. A compound sequential change detection procedure is defined through an index set process, \( S_t \subset \{1, \ldots, K\} \), where \( S_t \) indicates the set of active streams at time \( t \). Specifically, if \( k \in S_t \), then stream \( k \) is active at time \( t \); otherwise, it is deactivated. We require the process to satisfy that \( S_{t+1} \subset S_t \) for all \( t = 1, 2, \cdots \), meaning that a stream is not allowed to be re-activated once turned off. At the beginning of data collection (i.e., \( t = 1 \)), all
the data streams are active, and thus \( S_1 = \{1,\ldots,K\} \). A compound sequential change detection procedure \( S_t \) is then defined together with an information filtration, where the definition is inductive. We first let \( \mathcal{F}_1 = \sigma(X_{k,1}, k = 1,\ldots,K) \). Then for any \( t > 1 \), we let \( \mathcal{F}_t = \sigma(\mathcal{F}_{t-1}, S_t, X_{k,t}, k \in S_t) \), where \( S_t \subset \{1,\ldots,K\} \) is \( \mathcal{F}_{t-1} \) measurable. We say \( \{\mathcal{F}_t\}_{t=1,2,\ldots} \) is the information filtration for compound sequential change detection, and the index set process \( \{S_t\}_{t \geq 1} \) describes a compound sequential change detection procedure. Note that it is equivalently to represent the compound sequential change detection procedure by a random vector \( T = (T_1,\cdots,T_K) \), where \( T_k \in \mathbb{Z}_+ \) is defined as

\[
T_k = \sup\{t : k \in S_t\}.
\]

It is easy to check that \( \{T_k = t\} \in \mathcal{F}_t \) for all \( t \), and thus \( T_k \) is a stopping time under the filtration \( \{\mathcal{F}_t\}_{t=1,2,\ldots} \).

An illustrative example is given in Figure 1 with three data streams (i.e., \( K = 3 \)). A circle represents a data point following the pre-change distribution and a square represents a data point from the post-change distribution. For example, a change point occurs to the first data stream at time \( t = 3 \) (i.e. \( \tau_1 = 3 \)). As a result, data collected after this change point, \( X_{1,4} \) and \( X_{1,5} \) are from the post-change distribution as indicated by the squares. This change point is detected at time \( t = 5 \), denoted by \( T_1 = 5 \). Once this change point is detected, stream 1 is deactivated permanently and thus no data is collected at \( t \geq 6 \).

We provide a few remarks. First, the stopping time \( T_k \) indicates the time up to which we collect data from the \( k \)th stream. In other words, starting from time \( T_k + 1 \), the \( k \)th stream is deactivated and its data are no longer collected. The index set at time \( t \) is given by \( S_t = \{k : T_k \geq t\} \). Second, the sigma field \( \sigma(X_{k,s \wedge T_k}, s \leq t, k = 1,\ldots,K) \) is in \( \mathcal{F}_t \), meaning that our information filtration at time \( t \) contains all the information from the streams when they are active. Third, in addition to the information from observable data \( X_{k,t} \), the filtration \( \mathcal{F}_t \) also contains information about the sequential decision history, as \( S_s \) is measurable with respective to \( \mathcal{F}_t \), for all \( s \leq t \).
Figure 1: An illustration of the process of multi-stream change detection with three streams (i.e., $K = 3$). The pre- and post-change distributions are represented by circles and squares, respectively. The change time $\tau_1 = 3$, $\tau_2 = 2$, and $\tau_3 > 6$, and the detection time $T_1 = 5$, $T_2 = 3$, and $T_3 > 6$. The index set and the corresponding post-change non-detection proportion at each time point are also given.

2.3 Post-change False Non-detection Rate

The primary goal of this paper is to make a compound decision at each time point to control the proportion of post-change streams among the active ones. More precisely, we define the post-change non-detection proportion,

$$
PNP_{t+1}(T) = \frac{\sum_{k \in S_{t+1}} 1(\tau_k < t)}{|S_{t+1}| \lor 1} = \frac{\sum_{k=1}^K 1(T_k > t, \tau_k < t)}{\sum_{k=1}^K 1(T_k > t) \lor 1},$$

where $t = 1, 2, ... a \lor b = \max(a, b)$ and $|S|$ indicates the size of a set $S$. In this definition, $|S_{t+1}|$ represents the total number of streams being used at time $t + 1$, and $\sum_{k \in S_{t+1}} 1(\tau_k < t)$ represents the total number of the post-change streams being used at time $t + 1$. By having the ‘$\lor 1$’, the denominator is guaranteed to be non-zero and thus $PNP_{t+1}(T)$ is always well-defined. Finally, we let $PNP_1 = 0$, as $\tau_k \geq 0$ for $k = 1, 2, ..., K$. In the example in Figure 1, $S_5 = \{1, 3\}$ and thus

$$
PNP_5(T) = \frac{1(\tau_1 < 4) + 1(\tau_3 < 4)}{|\{1, 3\}|} = \frac{1}{2}.$$
Controlling the PNP is practically meaningful. For example, in detecting compromised items in educational testing, PNP represents the proportion of leaked items in the item pool. To ensure test fairness, ideally, we would like to control the PNP to be below an acceptable level at each time point. However, PNP\(_t(T)\) cannot be directly controlled, as the change points \(\tau_k\) are not directly observable. As an alternative, we control the local post-change non-detection rate (LPNR) which serves as an estimate of PNP\(_t(T)\). The LPNR is defined as

\[
\text{LPNR}_{t+1}(T) = \mathbb{E}(\text{PNP}_{t+1}(T)|\mathcal{F}_t), \ t = 1, 2, ...
\]

Since PNP\(_1 = 0\), LPNR\(_1(T)\) is set to 0. In what follows, we will focus on sequential change detection procedures which control the LPNR to be below a pre-specified level \(\alpha\) (e.g., \(\alpha = 1\%\)) all the time. More precisely, for a given \(\alpha \in [0, 1]\), we consider the following class of compound sequential change detection procedures which controls the LPNR to be below \(\alpha\) level at each time point \(t\),

\[
\mathcal{T}_\alpha = \{T = (T_1, \cdots, T_K) \in \mathcal{T} : \text{LPNR}_t(T) \leq \alpha \text{ a.s.}, \text{ for all } t = 1, 2, \cdots \},
\]

where \(\mathcal{T}\) denotes the entire set of compound sequential change detection procedures.

We make two remarks. First, \(\text{LPNR}_{t+1}(T)\) is a random variable measurable with respect to \(\mathcal{F}_t\). It depends on both the change point model and the change detection rule \(T\). The calculation of this conditional expectation under specific models is discussed in the sequel. Second, it is easy to observe that \(\mathbb{E}(\text{PNP}_t(T)) \leq \alpha\) for every \(t\), for any \(T \in \mathcal{T}_\alpha\). That is, the unconditional expectation of PNP is also controlled at the same \(\alpha\) level.

### 2.4 Stream Utilization and Optimality Criteria

Given a level \(\alpha\), the class \(\mathcal{T}_\alpha\) has many elements. We compare them based on their utilization of data streams. More precisely, we consider the following measure of stream
utilization

\[ U_t(T) = \sum_{s=1}^{t} |S_s| = \sum_{s=1}^{t} \sum_{k=1}^{K} \mathbb{1}(T_k \geq s), \]

where \( T = (T_1, \cdots, T_K) \) is a compound sequential change detection procedure and \( U_t(T) \) is the total number of data points collected from the beginning to time \( t \). For two sequential procedures \( T \) and \( T' \) in \( T_\alpha \), we say \( T \) is more efficient than \( T' \) at time \( t \) if \( \mathbb{E}(U_t(T)) \geq \mathbb{E}(U_t(T')) \); that is, \( T \) utilizes the data streams more efficiently during the period from time 1 to \( t \). In addition, we say \( T \) is uniformly more efficient than \( T' \) if \( \mathbb{E}(U_t(T)) \geq \mathbb{E}(U_t(T')) \) for all \( t = 1, 2, \ldots \).

Following the previous discussion, our goal becomes to develop a sequential procedure which is not only efficient in data utilization, but also controls the LPNR to be below a pre-specified \( \alpha \) level all the time. In particular, we consider the following two optimality criteria. These criteria will guide our development of compound sequential change detection procedures to be discussed in Section 3.

**Definition 1** (Uniform optimality). We say a sequential procedure \( T^* \in T_\alpha \) is uniformly optimal in \( T_\alpha \), if \( T^* \) is uniformly more efficient than \( T \), for any \( T \in T_\alpha \). That is,

\[ \mathbb{E}(U_t(T^*)) = \max_{T \in T_\alpha} \mathbb{E}(U_t(T)), \]

for all \( t = 1, 2, \ldots \).

Ideally, we would like to find this uniformly optimal \( T^* \). However, such a procedure does not necessarily exist. Thus, we also consider a weaker version of optimality, which is referred to as the local optimality at a given time point.

**Definition 2** (Local optimality). Given \( F_t \) at time \( t \), we say the choice of \( S_{t+1} \subset S_t \) is locally optimal at time \( t + 1 \), if \( S_{t+1} \) is \( F_t \) measurable,

\[ \mathbb{E} \left( \frac{\sum_{k \in S_{t+1}} \mathbb{1}(\tau_k < t)}{|S_{t+1}| \vee 1} \bigg| F_t \right) \leq \alpha, \]
Note that the local optimality criterion only looks at one step forward. It maximizes the stream utilization in the subsequent step. Achieving local optimality in each step does not necessarily lead to uniform optimality.

### 2.5 Connection with Existing Works

We now provide the connection between the proposed compound sequential change detection framework and existing works on single-data-stream change detection and on compound decision for non-sequential multiple testing.

A single-stream change detection procedure (see, e.g., [Poor and Hadjiliadis, 2008](#) for a review) typically keeps a balance between the expected detection delay and false alarm, where a false alarm is an event for which the change is declared by the decision maker before the change actually occurs. A commonly used metric for false alarm is the average run length - the expected stopping time until the first false alarm. Based on these two metrics, a commonly adopted Bayesian optimality criterion is to minimize the expected detection delay, while in the meantime to control the average run length to false alarm above a pre-specified threshold.

The LPNR and stream utilization metrics proposed above share similar flavors of the expected detection delay and average run length metrics, respectively. More precisely, the LPNR, which is defined through \( \text{PNP}_t(T) \), can be viewed as a detection delay measure aggregated over multiple streams and adaptive to the filtration \( \mathcal{F}_t \). In fact, taking a limit of \( t \) in the numerator of \( \text{PNP}_t(T) \), we obtain

\[
\sum_{t=0}^{\infty} \sum_{k=1}^{K} \mathbb{1}(T_k > t, \tau_k < t) = \sum_{k=1}^{K} (T_k - \tau_k - 1)_+,
\]

which is an aggregated version of the detection delays of multiple streams. Our ex-
Expected stream utilization measure has a similar flavor as the average running length by its definition. We choose to maximize the stream utilization measure while controlling for the LPNR instead of the other way around, because controlling the LPNR is more sensible in most multi-stream change detection applications and a threshold is easier to specify for LPNR due to its definition as an expected proportion.

Our LPNR metric is also closely related to the local false non-discovery rate metric (Efron, 2004, 2008, 2012; Efron et al., 2001) which is developed for non-sequential multiple testing. The local false non-discovery rate can be viewed as the expected proportion of non-null hypotheses (i.e., false non-discoveries) among the non-rejected hypotheses (i.e., non-discoveries), where the expectation is with respect to the posterior probability measure under a Bayesian formulation of multiple testing. Under the current framework, at each time point, the remaining active streams play the same role as the non-discoveries, the undetected post-change streams serve as the false non-discoveries, and the conditional probability measure under the current information filtration corresponds to the posterior probability measure. In this sense, our LPNR can be viewed as an extension of the local non-discovery rate metric to the current sequential multi-stream change detection problem.

3 Proposed Method

3.1 One-step Update Rule

We first propose a one-step update rule for controlling the LPNR to be below a pre-specified level. Let a certain sequential procedure be implemented from time 1 to $t$, and $\mathcal{F}_t$ be the current information filtration. A one-step update rule decides the index set $S_{t+1} \subset S_t$ based on the up-to-date information $\mathcal{F}_t$, so that the LPNR at time $t + 1$
is controlled below the pre-specified level $\alpha$. In the meantime, this update rule tries to maximize the size of $S_{t+1}$ to optimize stream utilization. The proposed one-step update rule is described in Algorithm 1 below.

**Algorithm 1** One-step update rule.

**Input:** Threshold $\alpha$, the current index set $S_t$, and posterior probabilities $(W_{k,t})_{k \in S_t}$, where

$$W_{k,t} = \mathbb{P}(\tau_k < t | \mathcal{F}_t).$$

1: Arrange the posterior probabilities in an ascending order. That is,

$$W_{k_1,t} \leq W_{k_2,t} \leq \cdots \leq W_{k_{|S_t|},t},$$

where $S_t = \{k_1, \ldots, k_{|S_t|}\}$. To avoid additional randomness, when there exists a tie ($W_{k_i,t} = W_{k_{i+1},t}$), we require $k_i < k_{i+1}$.

2: For $n = 1, \ldots, |S_t|$, define

$$R_n = \frac{\sum_{i=1}^{n} W_{k_i,t}}{n}.$$ and define $R_0 = 0$.

3: Find the largest $n \in \{0, 1, \ldots, |S_t|\}$ such that $R_n \leq \alpha$.

**Output:** $S_{t+1} = \{k_1, \ldots, k_n\}$ if $n \geq 1$ and $S_{t+1} = \emptyset$ if $n = 0$.

The proposed one-step update rule strictly controls the LPNR, as formally described in Proposition 1.

**Proposition 1.** Suppose that we obtain the index set $S_{t+1}$ using Algorithm 1, given the index set $S_t$ and information filtration $\mathcal{F}_t$ at time $t$. Then the LPNR at time $t + 1$ satisfies

$$\mathbb{E} \left( \frac{\sum_{k \in S_{t+1}} I(\tau_k < t)}{|S_{t+1}| \vee 1} | \mathcal{F}_t \right) \leq \alpha.$$

### 3.2 Proposed Algorithm

The proposed compound sequential change detection procedure adaptively applies the above one-step update rule. This method is formally described in Algorithm 2 below. We will later refer to this procedure as $\mathbb{T}^P$, where the superscript ‘$P$’ stands for the ‘proposed’ method.
Algorithm 2 Proposed Procedure (T<sup>P</sup>).

**Input:** Threshold α.

1. Let \( S_1 = \{1, \cdots, K\} \) and \( W_{k,1} = \mathbb{P}(\tau_k < 1|\mathcal{F}_1) \) for \( k \in S_1 \).
2. For \( t = 1, 2, 3, \cdots \), input \( \alpha \), \( S_t \) and \((W_{k,t})_{k \in S_t}\) to Algorithm 1 and obtain \( S_{t+1} \) and \( W_{k,t+1} = \mathbb{P}(\tau_k < t + 1|\mathcal{F}_{t+1}) \) for \( k \in S_{t+1} \), where \( \mathcal{F}_{t+1} = \sigma(\mathcal{F}_t, S_{t+1}, X_{k,t+1}, k \in S_{t+1}) \).

**Output:** \( \{S_t\}_{t=1,2,\cdots} \), or equivalently, \( T^P = (T_1, \cdots, T_K) \), where \( T_k = \sup\{t : k \in S_t\} \).

Making use of Proposition 1, it is easy to show that the proposed procedure controls the LPNR at each step. This result is summarized in Proposition 2.

**Proposition 2.** Let \( T^P \) be defined in Algorithm 2. Then, \( T^P \in T_\alpha \).

### 3.3 Calculation of Posterior Probabilities

The proposed update rule relies heavily on the posterior probability

\[
W_{k,t} = \mathbb{P}(\tau_k < t|\mathcal{F}_t),
\]

which is the conditional probability of the change point has occurred to stream \( k \) before the current time point \( t \). In general, this posterior probability depends on data from all the streams and thus its evaluation may be computationally intensive when \( K \) is large and \((\tau_1, \cdots, \tau_K)\) has a complex dependence structure. In that case, a Markov chain Monte Carlo method may be needed for evaluating this posterior probability.

However, under the special case of model \( \mathcal{M}_s \), this posterior probability is easy to evaluate using an iterative update rule. This result is given in Lemma 1 below.

**Lemma 1.** Under model \( \mathcal{M}_s \), \( W_{k,0} = 0 \) for \( 1 \leq k \leq K \) and \( W_{k,t} \) can be computed using the following update rule for \( 1 \leq k \leq K \),

\[
W_{k,t+1} = \begin{cases} 
\frac{q(X_{k,t+1})p(X_{k,t+1})}{(1-\theta)(1-W_{k,t})/(\theta+(1-\theta)W_{k,t})+q(X_{k,t+1})/p(X_{k,t+1})} & \text{for } 1 \leq t \leq T_k - 1, \\
W_{k,T_k} & \text{for } t \geq T_k.
\end{cases}
\]
We point out that the iteration in the above lemma is a slight modification of a classical result for Bayesian sequential change detection (Shiryaev [1963]). Indeed, with a single data stream, the statistic $W_{k,t}$ is known to be the test statistic for the Shiryaev procedure, a sequential change point detection procedure that has been proved the Bayes rule for minimizing the average detection delay while controlling the probability of false alarm. A slight difference here is that $W_{k,t}$ stays the same after $T_k$ due to the control process.

4 Theoretical Results

In this section, we first show optimality results for the proposed one-step update rule and the proposed procedure $\mathcal{T}^P$, under the optimality criteria given in Section 2.4. Then, we present theoretical results regarding properties of the proposed method, when the number of streams $K$ grows large. Finally, we compare it with other sequential procedures and provide a proof sketch.

4.1 Optimality Results

We first point out that the proposed update rule is locally optimal, following the notion of local optimality given in Definition 2. We summarize this result in Proposition 3 below.

**Proposition 3.** Given LPNR level $\alpha$ and information filtration $\mathcal{F}_t$, the index set $S_{t+1}$ given by Algorithm 1 is locally optimal at time $t + 1$.

In general, having local optimality in each step does not necessarily lead to uniform optimality and a uniformly optimal procedure may not even exist. However, Theorem 1 below shows that a uniformly optimal procedure exists under change point model $\mathcal{M}_s$ and in particular, the proposed procedure is uniformly optimal. In other words, the uniformly optimal procedure is obtained by achieving local optimality in each step.

**Theorem 1.** Under model $\mathcal{M}_s$, the proposed method $\mathcal{T}^P$ is uniformly optimal in $\mathcal{T}_\alpha$. 

16
The proof of Theorem 1 is involved. Heuristically, for a given \( t \), a larger value of \( W_{k,t} = \mathbb{P}(\tau_k \leq t - 1|\mathcal{F}_t) \) suggests a higher chance that a change point has already taken place for the \( k \)th data stream. This is why the proposed procedure chooses to detect streams with the largest posterior probabilities \( W_{k,t} \). Indeed, according to Proposition 3, this update rule is locally optimal. However, the local optimality does not necessarily imply uniform optimality. To show uniform optimality, one needs to look into the future. More specifically, we need to deal with the situation where a large value of \( W_{k,t} \) is due to random noise and the posterior probability of the stream may become small at a future time point. In other words, supposing that \( W_{k_1,t} > W_{k_2,t} \), we need to show that it is more optimal to detect \( k_1 \) than \( k_2 \) at time \( t \) under our optimality criteria, even though \( W_{k_1,t+s} < W_{k_2,t+s} \) can happen with high probability for some \( s > 0 \). To establish the uniform optimality, we need the \( W_{k,t} \) process generated by the proposed procedure to have some stochastically monotone property to be discussed in the sequel. This property relies on the model \( \mathcal{M}_s \) and may not hold under a more general model. A proof sketch for Theorem 1 is provided in Section 4.3 and a detailed proof is given in the supplementary material.

For models not in \( \mathcal{M}_s \), there may not be a uniformly optimal sequential procedure. One such example is given below.

**Example 3** (Non-existence of uniformly optimal procedure). Let \( K = 4 \) and \( \tau_k \)s be independent, for \( k = 1, \ldots, 4 \). The change point distributions satisfy \( \mathbb{P}(\tau_k \geq 4) = 0 \) for \( k = 1, \ldots, 4 \). For \( m = 0, 1, 2, 3 \) and \( k = 1, 2, 3, 4 \), the probabilities \( \mathbb{P}(\tau_k = m) \) are given below.

<table>
<thead>
<tr>
<th>( k )</th>
<th>( m = 0 )</th>
<th>( m = 1 )</th>
<th>( m = 2 )</th>
<th>( m = 3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.1</td>
<td>0.9</td>
<td>0.9</td>
<td>0.9</td>
</tr>
<tr>
<td>2</td>
<td>0.4</td>
<td>0.6</td>
<td>0.6</td>
<td>0.6</td>
</tr>
<tr>
<td>3</td>
<td>0.43</td>
<td>0.57</td>
<td>0.57</td>
<td>0.57</td>
</tr>
<tr>
<td>4</td>
<td>0.55</td>
<td>0.45</td>
<td>0.45</td>
<td>0.45</td>
</tr>
</tbody>
</table>

In addition, let \( X_{k,t}\)|\( t \leq \tau_k \sim \text{Bernoulli}(0.5) \) and \( X_{k,t}|t > \tau_k \sim \text{Bernoulli}(0.51) \) for
k = 1, ⋯, 4. Finally, we set α = 0.34. This model is not in \( M_s \), as the change points are not identically distributed.

Enumerating all elements in \( \mathcal{T}_\alpha \), we have

\[
\sup_{T \in \mathcal{T}_\alpha} \mathbb{E}(U_2(T)) = 7 \text{ and } \sup_{T \in \mathcal{T}_\alpha} \mathbb{E}(U_4(T)) = 10.
\]

However, there is no such a sequential procedure maximizing stream utilization at both \( t = 2 \) and \( t = 4 \). Consequently, there does not exist a uniformly optimal procedure in this example. The calculation for this example is provided in the supplementary material.

### 4.2 Asymptotic Theory

In modern multi-stream change detection problems, the number of data streams is typically large. To improve our understanding of the proposed method in large-scale applications, we study the asymptotic properties of the proposed method when the number of streams \( K \) goes to infinity.

**i.i.d. data streams** We first study the structure of \( \mathbb{T}^P \) under model \( M_s \). We define the following process

\[
V_0 = 0 \text{ and } V_{t+1} = \frac{q(X_{1,t+1})/p(X_{1,t+1})}{(1 - \theta)(1 - V_t)/(\theta + (1 - \theta)V_t) + q(X_{1,t+1})/p(X_{1,t+1})},
\]

where parameter \( \theta \) and densities \( p(\cdot) \) and \( q(\cdot) \) are given by the model \( M_s \). We further define \( \lambda_0 = 1 \) and

\[
\lambda_t = \sup \left\{ \lambda : \lambda \in [0, 1] \text{ and } \mathbb{E} \left( V_t \mid V_t \leq \lambda, V_s \leq \lambda_s, 0 \leq s \leq t - 1 \right) \leq \alpha \right\}
\]

for \( t = 1, 2, \cdots \). Theorem 2 below shows that when \( K \) grows to infinity, the proposed sequential procedure \( \mathbb{T}^P \) converges to a limiting procedure \( \mathbb{T}^\dagger \), for which the choice of
index set $S_{t+1}^\dagger$ is given by

$$S_{t+1}^\dagger = \{ k \in S_t^\dagger : W_{k,t} \leq \lambda_t \}.$$  

It suggests that when $K$ is large, we can replace the proposed procedure $T^P$ by the limiting procedure $T^\dagger$. The latter is computationally faster, as the thresholds $\lambda_t$ can be computed offline and the updates for streams can be computed in parallel.

We make the following technical assumption.

A1. For $Z_1$ following density function $p(\cdot)$ and $Z_2$ following density function $q(\cdot)$, the likelihood ratios $\frac{q(Z_1)}{p(Z_1)}$ and $\frac{q(Z_2)}{p(Z_2)}$ have continuous and strictly positive density functions over $\mathbb{R}_+$ (with respect to the Lebesgue measure).

The above assumption is easily satisfied by continuous random variables. For example, it is satisfied when $p(\cdot)$ and $q(\cdot)$ are the density functions of two normal distributions with different means and/or variances.

**Theorem 2.** Assume that model $M_\theta$ holds and Assumption A1 is satisfied. To emphasize the dependence on $K$, we denote the proposed procedure by $T^P_K$, the corresponding information filtration at time $t$ by $\mathcal{F}^P_{K,t}$, and the index set at time $t$ by $S^P_{K,t}$. Then, the following results hold for each $t \geq 1$.

1. $\lim_{K \to \infty} \lambda_{K,t} = \lambda_t$ a.s., where $\lambda_{K,t} = \max \{ W_{k,t} : k \in S^P_{K,t+1} \}$ is the threshold used by $T^P_K$.

2. $\lim_{K \to \infty} LPNR_t(\mathbb{P}^P_K) = \mathbb{E} \left( V_t \mid V_s \leq \lambda_s, 0 \leq s \leq t \right)$ a.s. Moreover,

$$\mathbb{E} \left( V_t \mid V_s \leq \lambda_s, 0 \leq s \leq t \right) = \begin{cases} 1 - (1 - \theta)^t, & t < \frac{\log(1 - \alpha)}{\log(1 - \theta)}, \\ \alpha, & t \geq \frac{\log(1 - \alpha)}{\log(1 - \theta)}. \end{cases} \quad (2)$$

3. $\lim_{K \to \infty} K^{-1}\left| S^P_{K,t+1} \right| = \mathbb{P} (V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$ a.s.

We remark that according to the definition of $\lambda_t$ and the second statement of Theorem 2 when $t < \log(1 - \alpha)/\log(1 - \theta)$, $\lim_{K \to \infty} LPNR_t(\mathbb{P}^P_K) < \alpha$ a.s. and no
Figure 2: Properties of the limiting procedure T*.

Panels (a)-(c): Values of $\lambda_t$, $E(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$, and $P(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$, respectively, when $\alpha = 0.1$.

Panels (d)-(f): Values of $\lambda_t$, $E(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$, and $P(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$, respectively, when $\alpha = 0.05$.

Deactivation of streams is needed yet. Otherwise, $\lim_{K \to \infty} LPNR_{t+1}(T^*_K) = \alpha$ a.s., which is achieved by deactivating suspicious streams. In what follows, we provide a numerical example to illustrate the properties of the limiting procedure.

**Example 4.** In this example, we let the pre-change distribution be $N(0,1)$ and the post-change distribution be $N(1,1)$, and $\theta = 0.075$ for the geometric distribution in the change points model. Two thresholds $\alpha$ are considered, $\alpha = 0.1$ and 0.05. The values of $\lambda_t$, $E(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$, and $P(V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$ are shown in Figure 2.

**Completely dependent change points** Theorem 3 below provides theoretical results for the case when all the change points are completely dependent, i.e., $\tau_1 = \cdots = \tau_K = \tau_0$. We make the following assumption.

A2. For $Z_1$ following density $p(\cdot)$ and $Z_2$ following density $q(\cdot)$, the density functions
satisfy
\[ \mathbb{E} \left( \log \frac{p(Z_1)}{q(Z_1)} \right) > 0, \mathbb{E} \left( \log \frac{q(Z_2)}{p(Z_2)} \right) > 0, \]
\[ \mathbb{E} \left( \log \frac{p(Z_1)}{q(Z_1)} \right)^2 < \infty, \text{ and } \mathbb{E} \left( \log \frac{q(Z_2)}{p(Z_2)} \right)^2 < \infty. \]

Note that \( \mathbb{E} \left( \log\left(\frac{p(Z_1)}{q(Z_1)}\right) \right) \) and \( \mathbb{E} \left( \log\left(\frac{q(Z_2)}{p(Z_2)}\right) \right) \) are the Kullback-Leibler divergence between \( p(\cdot) \) and \( q(\cdot) \). Requiring them to be positive is the same as requiring \( p(\cdot) \) and \( q(\cdot) \) to be densities of two different distributions.

**Theorem 3.** Suppose that data follow a special case of the model given in Example \( 7 \) when \( \eta = 1 \) and \( \tau_0 \sim \text{Geom}(\theta) \), and Assumption A2 holds. Let
\[ W_t = \mathbb{P} \left( \tau_0 < t \mid X_{k,s}, 1 \leq k \leq K, 1 \leq s \leq t \right), \]
and
\[ T = \min \{ t : W_t > \alpha \}. \]

Then, \( T^P_K = (T, \cdots, T) \). Moreover, the following asymptotic results hold.

1. \( \lim_{K \to \infty} (T - \tau_0) = 1 \) a.s.,
2. \( \lim_{K \to \infty} \text{LPNR}_{t+1}(T^P_K) = 0 \) a.s.,
3. \( \lim_{K \to \infty} K^{-1} |S^P_{K,t+1}| = 1(\tau_0 \geq t) \) a.s.

According to the above theorem, the detection time in the proposed procedure is the same for all the data streams. This detection rule is the same as the classical Shiryaev procedure (Shiryaev, 1963) for a single data stream. It thus has all the optimality properties of the Shiryaev procedure. We further remark that the last limit in the above theorem is non-degenerate in the sense that it is a Bernoulli random variable, rather than a constant as in Theorem \( 2 \).
4.3 More Theoretical Properties and a Proof Sketch

We first extend Theorem 1 by investigating a comparison between an arbitrary sequential procedure in $\mathcal{T}_\alpha$ and a procedure which switches from this procedure to the proposed procedure after a certain time point. This result provides further insights into the proposed procedure. Specifically, we use $T^A \in \mathcal{T}_\alpha$ to denote an arbitrary sequential procedure which controls the LPNR. We further consider a sequential procedure $T^{AP_{t_0}}$, which takes the same procedure as $T^A$ for $t = 1, ..., t_0$. After time $t_0 + 1$ and onwards, each step of $T^{AP_{t_0}}$ follows the proposed update rule in Algorithm 1. Theorem 4 compares four sequential procedures, including $T^A$, $T^{AP_{t_0}}$, $T^{AP_{t_0+1}}$, and $T^P$.

**Theorem 4.** Let $T^A \in \mathcal{T}_\alpha$ be an arbitrary sequential procedure. Further let $T^{AP_{t_0}}$ and $T^{AP_{t_0+1}}$ be the switching procedures described above, with switching time $t_0$ and $t_0 + 1$, respectively, for some $t_0 \geq 0$. Then, $T^{AP_{t_0}}, T^{AP_{t_0+1}} \in \mathcal{T}_\alpha$ and under model $M_s$

\[
E\left(U_t(T^A)\right) \leq E\left(U_t(T^{AP_{t_0+1}})\right) \leq E\left(U_t(T^{AP_{t_0}})\right) \leq E\left(U_t(T^P)\right),
\]

for all $t = 1, 2, \cdots$.

The above theorem implies that, under model $M_s$, $T^{AP_{t_0}}$ is uniformly better than $T^A$. It also suggests to switch to the proposed procedure as soon as possible, if one cannot use the proposed procedure at the beginning due to practical constraints. Theorems 1 and 4 are implied by the following theorem.

**Theorem 5.** Suppose that model $M_s$ holds. For any $t_0, s \geq 0$ and any sequential detection procedure $T^A \in \mathcal{T}_\alpha$, let $\mathcal{F}^A_t$ be the information filtration and $S^A_t$ be the set of active streams at time $t$ given by $T^A$. Then,

\[
E\left[|S^A_{t_0+s}| \mid \mathcal{F}^A_{t_0}\right] \leq E\left[|S^{AP_{t_0}}_{t_0+s}| \mid \mathcal{F}^A_{t_0}\right] \text{ a.s.} \quad (3)
\]

Theorem 5 is proved through an induction argument. Its proof is involved, relying on some monotone coupling results on stochastic processes living in a special partially ordered space. In what follows, we give a sketch of the proof to provide more insights.
into the proposed procedure. When \( s = 0 \), it is trivial that (7) holds. The induction is to show that for any \( T^A \in \mathcal{T}_n \) and any \( t_0 \), (7) holds for \( s = s_0 + 1 \), assuming that it holds for \( s \leq s_0 \). The induction step is proved by the following three steps.

1. Show that \( T^{AP_{t_0+1}} \) is ‘better’ than \( T^A \) conditional on \( \mathcal{F}_{t_0}^A \).
2. Show that \( T^{AP_{t_0}} \) is ‘better’ than \( T^{AP_{t_0+1}} \) conditional on \( \mathcal{F}_{t_0}^A \).
3. Show that \( T^{AP_{t_0}} \) is ‘better’ than \( T^A \) conditional on \( \mathcal{F}_{t_0}^A \) by combining the first two steps.

Here, we say a procedure is ‘better than’ the other, if its conditional expectation of the size of index set at time \( t_0 + s + 1 \) is no less than that of the other, given the information filtration \( \mathcal{F}_{t_0}^A \). Roughly, we prove the first step by replacing \( t_0 \) with \( t_0 + 1 \) in the induction assumption and taking conditional expectation given \( \mathcal{F}_{t_0}^A \), and prove the third step by combining the first and second steps. The main technical challenge lies in the second step, for which we develop several technical tools. Among these tools, an important one is the following monotone coupling result regarding a special partial order relationship.

We define a partially ordered space \( (\mathcal{S}_0, \leq) \) as follows. Let

\[
\mathcal{S}_0 = \bigcup_{k=1}^{K} \left\{ v = (v_1, \ldots, v_k) \in [0, 1]^k : 0 \leq v_1 \leq \cdots v_k \leq 1 \right\} \cup \{\emptyset\},
\]

where \( \emptyset \) represents a vector with zero length. For \( u \in \mathcal{S}_0 \), let \( \dim(u) \) be the length of the vector \( u \).

**Definition 3.** For \( u, v \in \mathcal{S}_0 \), we say \( u \preceq v \) if \( \dim(u) \geq \dim(v) \) and \( u_i \leq v_i \) for \( i = 1, \ldots, \dim(v) \). In addition, we say \( u \preceq \emptyset \) for any \( u \in \mathcal{S}_0 \).

For any vector \( v = (v_1, \ldots, v_m) \), we use the notation \([v] = (v_{(1)}, \ldots, v_{(m)})\) for its order statistic. In addition, let \([\emptyset] = \emptyset\).

To emphasize the dependence on the sequential procedure, we use \( S^A_t \) and \( \mathcal{F}^A_t \) to denote the index set and the information filtration at time \( t \) given by the sequential
procedure $T^A$. We further define

$$W^A_{k,t} = P\left(\tau_k < t \mid F^A_t\right).$$

Similarly, we can define the index set $S^A_{t_0}$, information filtration $F^A_{t_0}$, and posterior probability $W^A_{k,t}$ given by the sequential procedure $T^A_{t_0}$.

**Proposition 4.** Let $\{x_t, s_t, 1 \leq t \leq t_0\}$ be any sequence in the support of the stochastic process $\{(X_{k,t})_{k \in S^A_t}, S^A_t, 1 \leq t \leq t_0\}$ following a sequential procedure $T^A \in T_\alpha$. Then, there exists a coupling of $\mathcal{S}_o$-valued random variables $(\hat{W}, \hat{W}')$ such that

$$\hat{W} \overset{d}{=} \left[\left(W^A_{k,t_0+1}\right)_{k \in S^A_{t_0+1}}\right] \left\{(X_{k,t})_{k \in S^A_t} = x_t, S^A_t = s_t, 1 \leq t \leq t_0\right\},$$

$$\hat{W}' \overset{d}{=} \left[\left(W^A_{k,t_0+1}\right)_{k \in S^A_{t_0+1}}\right] \left\{(X_{k,t})_{k \in S^A_t} = x_t, S^A_t = s_t, 1 \leq t \leq t_0\right\},$$

and $\hat{W} \leq \hat{W}'$ a.s., where $\overset{d}{=}$ denotes that random variables on both sides are identically distributed.

**Remark 1.** The support of the process $\{(X_{k,t})_{k \in S^A_t}, S^A_t, 1 \leq t \leq t_0\}$ depends on the sequential procedure $T^A$. Moreover, the coupling $(\hat{W}, \hat{W}')$ in the above proposition depends on the sequential procedure $T^A$ and the sequence $\{x_t, s_t, 1 \leq t \leq t_0\}$.

Let

$$Y_s = \left[\left(W^A_{k,t_0+s}\right)_{k \in S^A_{t_0+s}}\right] \in \mathcal{S}_o.$$ 

Under model $M_s$, the stochastic process $Y_s$ is stochastically monotone in that the following monotone coupling result holds.

**Proposition 5.** Suppose that model $M_s$ holds. Then for any $y, y' \in \mathcal{S}_o$ such that $y \leq y'$, there exists a coupling $(\hat{Y}_s, \hat{Y}'_s), s = 0, 1, ..., \text{satisfying}$

1. $\{\hat{Y}_s : s \geq 0\}$ has the same distribution as the conditional process $\{Y_s : s \geq 0\}$ given $Y_0 = y$, and $\{\hat{Y}'_s : s \geq 0\}$ has the same distribution as the conditional process $\{Y'_s : s \geq 0\}$ given $Y_0 = y'$. 

24
2. \( \hat{Y}_s \leq \hat{Y}_s', \text{ a.s. for all } s \geq 0. \)

Moreover, the process \((\hat{Y}_s, \hat{Y}_s')\) does not depend on \(T^A, t_0, \) or the information filtration \(\mathcal{F}^A_{t_0}.\)

Roughly, Proposition 4 shows that the sequential procedure \(T^A_{t_0} \) tends to have a stochastically smaller detection statistic, in terms of the partial order \(\leq\), than that of \(T^A_{t_0+1} \) at time \(t_0 + 1\), and thus tends to keep more active streams. Proposition 5 further shows that this trend will be carried over to any future time, including time \(t_0 + s + 1\). The second step of induction is proved by formalizing this heuristic.

5 Numerical Examples

5.1 Comparison with a Non-compound Decision Rule

We first compare the proposed method with a non-compound decision method. The latter classifies the streams at each time point by comparing their current posterior probabilities to a pre-specified threshold which is set to be a fixed constant across different time points.

We simulate data from model \(M_s.\) Three values of stream size \(K\) are considered, including \(K = 10, 50, \) and 100. For all the data streams, we let the pre- and post-change distributions be \(N(0, 1)\) and \(N(1, 1)\), respectively. We set \(\theta = 0.1, \) under which the mean change time is \(\frac{(1 - \theta)}{\theta} = 9.\)

We first compare the two approaches under the constraint of controlling LPNR to be below \(\alpha\) at each time point, where \(\alpha\) is set to be 0.05. For the non-compound decision method, to control LPNR, a conservative decision rule is taken that sets the threshold to be \(\alpha.\) For each value of \(K,\) we replicate the simulation 5,000 times and present the resulting mean stream utilization and mean PNP at each time point. The results are given in Figures 3. As we can see, both methods control the mean PNP level to be below \(\alpha, \) but the non-compound decision rule is more conservative. In addition, the proposed approach achieves a higher level of mean stream utilization in
Figure 3: Comparison of the proposed method and a non-compound decision method, both of which control LPNR under level $\alpha = 0.05$. Panels (a)-(c) show the mean stream utilization for $K = 10, 50, \text{and} 100$, respectively, and Panels $(d)-(f)$ show the mean PNP for $K = 10, 50, \text{and} 100$, respectively. The results are based on 5,000 independent simulations.

We then compare the two approaches across a wider range of $\alpha$ values. For each time point $t = 3, 4$, we draw a curve for each of these two approaches. A point on the curve indicates the mean PNP level ($x$-axis) and the mean stream utilization ($y$-axis) given by running the corresponding procedure at a certain level of $\alpha$. Each point is obtained by averaging over 5,000 independent simulations. Results are presented in Figure 3. As we can see, the curve produced by the proposed method is always above the one given by the non-compound decision method, suggesting the outperformance of the proposed one. Although not presented in this figure, similar patterns are observed for other time points.

5.2 A Simulated Example of Detecting Compromised Test Items

We now provide a simulated example mimicking a more realistic setting for the sequential detection of compromised items in educational testing. This setting is similar to that
Consider a standardized test with an initial item pool consisting of 500 items. Each item constitutes a data stream and each time point corresponds to one period of test administration (e.g., one day/one week). We assume that all the active items are used in each test period. The test is assumed to follow a Rasch model (Rasch, 1960), one of the most commonly used IRT models. Under the Rasch model, each item $k$ is assumed to have a parameter, known as the difficulty parameter, denoted by $\beta_k$. A larger value of $\beta_k$ indicates that the item is more difficult. Once an item is compromised, the estimate of $\beta_k$ tends to be lower, as it becomes ‘easier’ to the student population due to some students having preknowledge about the item. The value of $\beta_k$ is estimated after each period of test administration for the monitoring of item leakage.

Similar to the setting of Veerkamp and Glas (2000), we let data $X_{k,t}$ be the estimate of $\beta_k$ after $t$th test administration period. We assume $X_{k,t}$ to follow a normal distribution $N(\beta_k^*, 0.3^2)$ before the change point, and to follow a normal distribution
\( N(\beta_k^* - 0.5, 0.2^2) \) after the change point, where \( \beta_k^* \) is the true difficulty parameter for the item. In this example, \( \beta_k^* \)'s are generated i.i.d., following a standard normal distribution. In practice, the variances of the pre-change and post-change distributions, and the decrease in the difficulty parameter due to cheating, can be specified based on historical data, and \( \beta_k^* \) can be set based on pre-test data. We further assume that our data and change points follow the model \( \mathcal{M}_s \). We consider two possible values for parameter \( \theta \) in the geometric distribution, including \( \theta = 0.01 \) and \( 0.05 \). For these values of \( \theta \), the corresponding expected time to leakage is 99 and 19, respectively. Two values of \( \alpha \) are considered, including \( \alpha = 0.01 \) and \( 0.05 \).

For each combination of \( \alpha \) and \( \theta \), we replicate the simulation 1,000 times. Our results are shown in Figures 5 and 6, where the two figures correspond to the three change points models, \( \theta = 0.01 \) and \( 0.05 \), respectively. In each figure, Panels (a)-(c) give the results when \( \alpha = 0.01 \) for the PNP, stream utilization, and active item size, respectively, and Panels (d)-(f) give the results when \( \alpha = 0.05 \) for the same performance metrics, respectively. Each panel shows the boxplots of the corresponding metric at different time points. These results suggest that the proposed method sensibly controls the quality of the remaining item pool and also makes good use of the items.

### 6 Discussions

Motivated by multi-stream change detection applications in the real world, specifically the sequential detection of compromised items in educational testing, we provide a compound decision framework for sequential change detection in multiple data streams and propose a sequential procedure which is shown to be uniformly optimal under a Bayesian change points model. We establish theoretical properties for the proposed method and further show its superior performance through numerical examples.

The current work can be extended along several directions. First, different optimality criteria may be considered and the proposed procedure can be extended accordingly. For example, different streams may have different weights due to their diverse
Figure 5: A simulated example of detecting compromised test items, for $\theta = 0.01$ in the change points model. Panels (a)-(c) give the results when $\alpha = 0.01$ for the PNP, stream utilization, and active item size, respectively, and Panels (d)-(f) give the results when $\alpha = 0.05$ for the same performance metrics, respectively.

Figure 6: A simulated example of detecting compromised test items, for $\theta = 0.05$ in the change points model. Panels (a)-(c) give the results when $\alpha = 0.01$ for the PNP, stream utilization, and active item size, respectively, and Panels (d)-(f) give the results when $\alpha = 0.05$ for the same performance metrics, respectively.
importance in practice. In that case, more general definitions of local post-change non-detection rate and stream utilization measure can be given, for which a tailored sequential procedure can be derived.

Second, in some real applications, the distribution for change points and the distributions for pre- and post-change data may not be known in advance. Under suitable models, these distributions can be consistently estimated when the number of streams $K$ goes to infinity. It is thus sensible to proposed an empirical Bayesian approach which combines the proposed procedure together with sequential estimation of unknown distributions.

Third, optimal sequential procedures remain to be developed under reasonable models for dependent change points. In particular, in many multi-stream change detection problems, the change points may be driven by a low-dimensional latent process, which can be described by a factor-type model. Several questions remain to be answered under a factor-type model for change points, including the existence of a uniformly optimal procedure and the construction of the uniformly optimal procedure if it exists.

Finally, a more general setting is needed that allows new data streams to be added dynamically. For example, in educational testing, once an item is removed from the item pool, a new one needs to be developed to maintain the size of the pool. The inclusion of new data streams changes the information filtration. Under the new information filtration which contains information from both the original and new streams, a locally optimal procedure can be developed under similar optimality criteria. However, it is unclear whether this procedure is still uniformly optimal. This problem is worth future investigation.
Supplementary Material: Proof of Theoretical Results

A Notations

For the readers’ convenience, we provide a list of notations below.

- $X_{S,t}$ for some set $S \subset \{1, \cdots, K\}$: $X_{S,t} = (X_{k,t})_{k \in S}$.
- $X_{k,s,t}$: $X_{k,s,t} = (X_{k,r})_{s \leq r \leq t}$.
- $\mathcal{T}^A$: an arbitrary sequential procedure.
- $S^A_t$: The set of active streams at time $t$ given by procedure $\mathcal{T}^A$.
- $\mathcal{F}^A_t$: $\sigma$-field of information obtained up to time $t$ following $\mathcal{T}^A$.
- $W^A_{k,t}$: posterior probability $P(\tau_k < t | \mathcal{F}^A_t)$ at the $k$-th stream following $\mathcal{T}^A$ at time $t$.
- $W^A_{S,t}$ for some set $S \subset \{1, \cdots, K\}$: $W^A_{S,t} = (W^A_{k,t})_{k \in S}$.
- $\mathcal{T}^P$: the proposed sequential procedure.
- $S^P_t, \mathcal{F}^P_t, W^P_{k,t}, W^P_{S,t}$ are defined similarly for procedure $\mathcal{T}^P$.
- $\mathcal{T}^{AP}_{t_0}$: the sequential procedure that takes the same steps as $\mathcal{T}^A$ up to time $t_0$ (meaning $S^A_{t_0} = S^A_t$ for $1 \leq t \leq t_0$) and updates by Algorithm [1] from time $t_0 + 1$ and onward.
- $S^AP_{t_0}, \mathcal{F}^{AP}_{t_0}, W^{AP}_{k,t}, W^{AP}_{S,t}$ are defined similarly for procedure $\mathcal{T}^{AP}_{t_0}$.
- $\overset{d}{\equiv}$: equal in distribution.
- $\emptyset$: a vector with zero length.
- dim: length of a vector, where dim($\emptyset$) = 0.
- $Z \sim N(0,1)$: the notation ‘$\sim$’ means that the left side follows the distribution on the right side.
B Proof of Theorem 5

Theorem 5. Suppose that model $M_s$ holds. For any $t_0, s \geq 0$ and any sequential detection procedure $T^A \in \mathcal{T}_a$, let $\mathcal{F}_t^A$ be the information filtration and $S_t^A$ be the set of active streams at time $t$ given by $T^A$. Then,

$$
\mathbb{E} \left[ |S_{t_0+s}^A| \mid \mathcal{F}_{t_0}^A \right] \leq \mathbb{E} \left[ |S_{t_0+s}^{AP_{t_0}}| \mid \mathcal{F}_{t_0}^A \right] \text{ a.s.}
$$

(7)

Proof of Theorem 5. We will prove the theorem by inducting on $s$.

For the base case ($s = 0$) the theorem is obviously true for all $t_0$ and all $T^A \in \mathcal{T}_a$ as the both sides of (7) are exactly the same.

We will prove the induction step in the rest of the proof. Assume (7) is true for any strategy $T^A \in \mathcal{T}_a$ and any $t_0$, for some $s = s_0$. Our goal is to prove that it is also true for any $t_0$, for $s = s_0 + 1$, using the following steps.

Step 1: comparing $T^{AP_{t_0+1}}$ and $T^A$. For $s = s_0 + 1$, since we assume (7) is true for all $t_0$, we could replace $t_0$ by $t_0 + 1$ and $s$ by $s_0$ in (7) and arrive at

$$
\mathbb{E} \left[ |S_{t_0+s_0+1}^A| \mid \mathcal{F}_{t_0+1}^A \right] \leq \mathbb{E} \left[ |S_{t_0+s_0+1}^{AP_{t_0+1}}| \mid \mathcal{F}_{t_0+1}^A \right] \text{ a.s.}
$$

Taking conditional expectation $\mathbb{E} \left[ \cdot \mid \mathcal{F}_{t_0}^A \right]$ on both sides, we arrive at

$$
\mathbb{E} \left[ |S_{t_0+s_0+1}^A| \mid \mathcal{F}_{t_0}^A \right] \leq \mathbb{E} \left[ |S_{t_0+s_0+1}^{AP_{t_0+1}}| \mid \mathcal{F}_{t_0}^A \right] \text{ a.s.}
$$

(B.1)

Step 2: comparing $T^{AP_{t_0+1}}$ and $T^{AP_{t_0}}$. First, define a function $\phi_{t,s} : \mathcal{S}_0 \to \mathbb{R}$,

$$
\phi_{t,s}(u) = \mathbb{E} \left[ \dim \left( \left[ W_{t+s+\delta_t}^{AP_{t_0}} \right] \mid \left[ W_{t+s}^{AP_{t_0}} \right] = u \right) \right]
$$

(B.2)

for $t, s \geq 0$. From Proposition 5 we can see that $\phi_{t,s}(u)$ does not depend on the sequential procedure $T^A$ and the value of $t$. Thus, by replacing $T^A$ with $T^{AP_{t_0}}$, $t$ with
$t_0 + 1$, and $s$ with $s_0$ in [B], we obtain

$$
\phi_{t_0+1,s_0}(u) = E\left[ \dim \left( \left[ W_{S_{t_0+1}^{A_{t_0}}_{t_0+1}} \right] \left[ W_{S_{t_0+1}^{A_{t_0}}_{t_0+1}} \right] = u \right) \right]. \tag{B.3}
$$

Here, to see the superscript of the process in the above equation is $A_{t_0}$, we used the fact that if we follow the procedure $T^{A_{t_0}}$ and switch to the proposed procedure at time $t_0 + 1$, then the overall sequential procedure is still $T^{A_{t_0}}$.

Moreover, for any $u \leq u' \in S_0$, there exists a coupling $(\hat{Y}_s, \hat{Y}_s')$ such that $\hat{Y}_s$ has the same distribution as $[W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}]$, given $[W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] = u$, $\hat{Y}_s'$ has the same distribution as $[W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}]$, given $[W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] = u'$, and $\hat{Y}_s \leq \hat{Y}_s'$ a.s. Thus,

$$
\phi_{t,s}(u) = E\left( \dim(\hat{Y}_s) \right) \text{ and } \phi_{t,s}(u') = E\left( \dim(\hat{Y}_s') \right).
$$

According to the definition of the partial relationship ‘$\leq$’, $\hat{Y}_s \leq \hat{Y}_s'$ implies $\dim(\hat{Y}_s) \geq \dim(\hat{Y}_s')$. Combining this result with the above display, we conclude that $\phi_{t,s}(u) \geq \phi_{t,s}(u')$ for any $u \leq u' \in S_0$.

Next, we write $E\left[ |S_{t_0+1}^{A_{t_0}}| \left| F_{t_0}^A \right. \right]$ and $E\left[ |S_{t_0+1}^{A_{t_0}}| \left| F_{t_0}^A \right. \right]$ in terms of the conditional expectation involving the function $\phi_{t,s}$. We start with $E\left[ |S_{t_0+1}^{A_{t_0}}| \left| F_{t_0}^A \right. \right]$. By the iterative law of conditional expectation and [B], we obtain

$$
E\left[ |S_{t_0+1}^{A_{t_0}}| \left| F_{t_0}^A \right. \right] = E\left[ \dim \left( [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \left| [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \right) \left| F_{t_0}^A \right. \right]
$$

$$
= E\left[ \dim \left( [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \left| [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \right) \left| F_{t_0}^A \right. \right]
$$

$$
= E\left[ \phi_{t_0+1,s_0} \left( [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \right) \left| F_{t_0}^A \right. \right].
$$

According to the definition of the information filtration $F_{t_0}^A$, we further write the above conditional expectation as

$$
E\left[ |S_{t_0+1}^{A_{t_0}}| \left| F_{t_0}^A \right. \right] = E\left[ \phi_{t_0+1,s_0} \left( [W_{S_{t_0+1}^{A_{t_0}}}^{A_{t_0}}] \right) \left| \{ S_{t_0+1}^{A_{t_0}} \} \right| \{ S_{t_0+1}^{A_{t_0}} \} \right]. \tag{B.4}
$$

33
Similarly, we have

\[
E \left[ S_{t_0 + s_0 + 1} | F_{t_0} \right] = E \left[ \phi_{t_0 + 1, s_0} \left( \left[ W_{t_0 + 1}^{AP} \right]_{t_0 + 1} \right) \mid \{ S_r^A, X_{k,r}, k \in S_r^A, 1 \leq r \leq t_0 \} \right].
\]  
(B.5)

We proceed to a comparison between (B) and (B). According to Proposition 4, for each sequence \( \{ x_r, s_r, 1 \leq r \leq t_0 \} \) that is in the support of the process \( \{ X_{s_{\Phi},r}, S_r^A, 1 \leq r \leq t_0 \} \) there exists a coupling \( (\widehat{W}, \widehat{W}') \) such that

\[
\widehat{W} \overset{d}{=} \left[ W_{t_0}^{AP} \right]_{t_0 + 1} \mid \{ X_{s_r^A,r} = x_r, S_r^A = s_r, 1 \leq r \leq t_0 \},
\]

and

\[
\widehat{W}' \overset{d}{=} \left[ W_{t_0}^{AP} \right]_{t_0 + 1} \mid \{ X_{s_r^A,r} = x_r, S_r^A = s_r, 1 \leq r \leq t_0 \},
\]

and

\[
\widehat{W} \leq \widehat{W}' \text{ a.s.}
\]

Thus,

\[
E \left[ \phi_{t_0 + 1, s_0} \left( \left[ W_{t_0}^{AP} \right]_{t_0 + 1} \right) \mid X_{s_r^A,r} = x_r, S_r^A = s_r, 1 \leq r \leq t_0 \right] = E \phi_{t_0 + 1, s_0} \left( \widehat{W} \right) \quad (B.6)
\]

and

\[
E \left[ \phi_{t_0 + 1, s_0} \left( \left[ W_{t_0}^{AP} \right]_{t_0 + 1} \right) \mid X_{s_r^A,r} = x_r, S_r^A = s_r, 1 \leq r \leq t_0 \right] = E \phi_{t_0 + 1, s_0} \left( \widehat{W}' \right) \quad (B.7)
\]

On the other hand, note that we have shown \( \phi_{t_0 + 1, s_0} (u) \geq \phi_{t_0 + 1, s_0} (u') \) for any \( u \leq u' \in S_0 \) and \( \widehat{W} \leq \widehat{W}' \text{ a.s.} \) by the coupling. Thus,

\[
\phi_{t_0 + 1, s_0} \left( \widehat{W} \right) \geq \phi_{t_0 + 1, s_0} \left( \widehat{W}' \right) \text{ a.s.}
\]
Combining the above inequality with (B) and (B), we arrive at

\[
\mathbb{E}\left[\phi_{t_0+1,s_0}\left([W_{S_{t_0+1}}^{AP_{t_0}}]_{r}^{s} = x_r, S_r^A = s_r, 1 \leq r \leq t_0\right)\right]
\geq \mathbb{E}\left[\phi_{t_0+1,s_0}\left([W_{S_{t_0+1}+1}^{AP_{t_0+1}}]_{r}^{s} = x_r, S_r^A = s_r, 1 \leq r \leq t_0\right)\right]
\]

for each sequence \{x_r, s_r, 1 \leq r \leq t_0\} that is in the support of the process \{X_{S_r^A}, S^A_r, 1 \leq r \leq t_0\}. Comparing the above inequality with (B) and (B), we conclude that

\[
\mathbb{E}\left[|S_{t_0+s_0+1}^{AP_{t_0}}|\big|\mathcal{F}_{t_0}\right] \geq \mathbb{E}\left[|S_{t_0+s_0+1}^{AP_{t_0+1}}|\big|\mathcal{F}_{t_0}\right] \text{ a.s.} \quad (B.8)
\]

Step 3: combining results from Steps 1 and 2. Combining (B) and (B), we obtain

\[
\mathbb{E}\left[|S_{t_0+s_0+1}^{AP_{t_0}}|\big|\mathcal{F}_{t_0}\right] \leq \mathbb{E}\left[|S_{t_0+s_0+1}^{AP_{t_0+1}}|\big|\mathcal{F}_{t_0}\right] \text{ a.s.,}
\]

which implies that (7) holds for arbitrary \(T^A \in \mathcal{T}_\alpha, t_0, \) and \(s = s_0 + 1\). This completes the induction.

\[\square\]

C Proof of Theorems 1 and 4

It suffices to prove Theorem 4, as Theorem 1 is straightforwardly implied by Theorem 4.

**Theorem 4.** Let \(T^A \in \mathcal{T}_\alpha\) be an arbitrary sequential procedure. Further let \(T^{AP_{t_0}}\) and \(T^{AP_{t_0+1}}\) be the switching procedures described above, with switching time \(t_0\) and \(t_0 + 1\), respectively, for some \(t_0 \geq 0\). Then, \(T^{AP_{t_0}}, T^{AP_{t_0+1}} \in \mathcal{T}_\alpha\) and under model \(M_s\)

\[
\mathbb{E}\left(U_t(T^A)\right) \leq \mathbb{E}\left(U_t(T^{AP_{t_0+1}})\right) \leq \mathbb{E}\left(U_t(T^{AP_{t_0}})\right) \leq \mathbb{E}\left(U_t(T^P)\right),
\]

for all \(t = 1, 2, \ldots\)

**Proof of Theorem 4** Applying Theorem 5 but replacing \(t_0\) by \(t_0 + 1\), and taking ex-
pectation on both sizes of the inequality, we obtain

$$\mathbb{E}|S_{t_0+1+s}| \leq \mathbb{E}|S_{t_0+1+s}^{AP}|$$

for every $t_0 \geq 0$ and $s \geq 0$. That is, for every $t \geq t_0 + 1$,

$$\mathbb{E}|S_t| \leq \mathbb{E}|S_t^{AP_{t_0+1}}|.$$

For $t < t_0 + 1$, as $T^A$ and $T^{AP_{t_0+1}}$ share the same index set, we have

$$\mathbb{E}|S_t^A| = \mathbb{E}|S_t^{AP_{t_0+1}}|.$$

Combining the above inequalities, we obtain

$$\mathbb{E}|S_t^A| \leq \mathbb{E}|S_t^{AP_{t_0+1}}|$$

for all $t \geq 0$. This further implies

$$\mathbb{E}\{U_t(T^A)} = \sum_{s=1}^{t} \mathbb{E}|S_s^A| \leq \sum_{s=1}^{t} \mathbb{E}|S_s^{AP_{t_0+1}}| = \mathbb{E}\{U_t(T^{AP_{t_0+1}})}.$$

This proves the inequality for comparing procedures $T^A$ and $T^{AP_{t_0+1}}$. We then compare $T^{AP_{t_0+1}}$ and $T^{AP_{t_0}}$, based on the same arguments above except that we replace $T^A$ by $T^{AP_{t_0+1}}$, and replace $T^{AP_{t_0+1}}$ by $T^{AP_{t_0}}$. We obtain

$$\mathbb{E}\{U_t(T^{AP_{t_0+1}})} \leq \mathbb{E}\{U_t(T^{AP_{t_0}})}$$

for all $t \geq 0$.

Finally, we compare $T^{AP_{t_0}}$ and $T^P = T^{AP_0}$ using a similar argument, which gives

$$\mathbb{E}\{U_t(T^{AP_{t_0}})} \leq \mathbb{E}\{U_t(T^P)}.$$
D Proof of Propositions 4 and 5

The proof of Propositions 4 and 5 is involved. We will first introduce some concepts in stochastic ordering, followed by several useful lemmas, and then present the proof of the propositions.

D.1 Stochastic ordering

We first review a few important concepts and classic results on partially ordered spaces. More details about stochastic ordering and coupling can be found in Kamae et al. (1977); Lindvall (1999, 2002); Thorisson (2000).

Definition 4 (Partially Ordered Space (pospace)). A space \( (S, \preceq) \) is said to be a partially ordered space (or pospace) if \( \preceq \) is a partial order relation over the topological space \( S \) and the set \( \{(x,y) \in S^2 : x \preceq y\} \) is a closed subset of \( S^2 \).

Definition 5 (Increasing functions over a partially ordered space). Let \( (S_1, \preceq_{S_1}) \) and \( (S_2, \preceq_{S_2}) \) be partially ordered polish spaces. A map \( g : S_1 \to S_2 \) is said to be increasing if \( g(u) \preceq_{S_2} g(v) \) for all \( u \preceq_{S_1} v \) with \( u, v \in S_1 \).

Definition 6 (Stochastic ordering of real-valued random variables). Let \( X \) and \( Y \) be two random variables, we say \( X \) is stochastically less than or equal to \( Y \), if \( \mathbb{P}(X \geq x) \geq \mathbb{P}(Y \geq x) \) for all real number \( x \). In this case, we write \( X \leq_{st} Y \).

The following statements give some equivalent definitions for \( X \leq_{st} Y \)

Fact 1. The following statements are equivalent.

1. \( X \leq_{st} Y \).
2. For all increasing, bounded, and measurable functions \( g : \mathbb{R} \to \mathbb{R}, \mathbb{E}(g(X)) \leq \mathbb{E}(g(Y)) \).
3. There exists a coupling $(\hat{X}, \hat{Y})$ such that $\hat{X} \overset{d}{=} X$, $\hat{Y} \overset{d}{=} Y$, and

$$\hat{X} \leq \hat{Y} \text{ a.s.}$$

Here, $\overset{d}{=}$ denotes that the random variables on both sides have an identical distribution.

In particular, the equivalence between 1 and 3 is known as the Strassen’s Theorem (Strassen [1965]).

**Definition 7** (Stochastic ordering on a partially ordered polish space). Let $(S, \preceq)$ be a partially ordered polish space, and let $X$ and $Y$ be $S$-valued random variables. We say $Y$ stochastically dominates $X$, denoted by $X \preceq_{st} Y$ if for all bounded, increasing, and measurable function $g : S \to \mathbb{R}$, $\mathbb{E}(g(X)) \leq \mathbb{E}(g(Y))$.

**Fact 2** (Strassen’s theorem for polish pospace, Theorem 2.4 in Lindvall (2002)). Let $(S, \preceq)$ be a polish partially ordered space, and let $X$ and $Y$ be $S$-valued random variables. Then, $X \preceq_{st} Y$ if and only if there exists a coupling $(\hat{X}, \hat{Y})$ such that $\hat{X} \overset{d}{=} X$, $\hat{Y} \overset{d}{=} Y$ and $\hat{X} \leq \hat{Y}$ a.s.

**Definition 8** (Stochastic dominance for Markov kernels). Let $K$ and $\tilde{K}$ be transition kernels for Markov chains over a partially ordered polish space $(S, \preceq)$. The transition kernel $\tilde{K}$ is said to stochastically dominate $K$ if

$$x \preceq y \implies K(x, \cdot) \preceq_{st} \tilde{K}(y, \cdot).$$

In particular, if the above is satisfied for the same kernel $K = \tilde{K}$, then we say $K$ is stochastically monotone.

**Fact 3** (Strassen’s theorem for Markov chains over a polish pospace). Let $\{X_t\}$ and $\{Y_t\}$ be Markov chains over a partially ordered polish space, $(S, \preceq)$, with transition kernels $K$ and $\tilde{K}$ where $\tilde{K}$ stochastically dominates $K$. Then, for all initial points $x_0 \preceq y_0$, there is a coupling $\{(\tilde{X}_t, \tilde{Y}_t)\}$ of $\{X_t\}$ starting at $x_0$ and $\{Y_t\}$ starting at $y_0$.
such that

$$\widehat{X}_t \leqslant \widehat{Y}_t \quad \forall t \text{ a.s.}$$

Fact 3 is a special case of Theorem 5.8 in Lindvall (2002).

D.2 Stochastic ordering and Markov chains on $S_u$ and $S_o$

In this section, we provide some supporting lemmas regarding properties of the partial order relationship defined in Section 4.3 and show stochastic ordering of several Markov chains. The proof of these lemmas is given in Section D.4.

Recall that in Section 4.3 we define a space

$$S_o = \bigcup_{k=1}^{K} \left\{ \mathbf{v} = (v_1, \ldots, v_k) \in [0, 1]^k : 0 \leq v_1 \leq \cdots v_k \leq 1 \right\} \cup \{\emptyset\}.$$  

Here, we also define a space with unordered elements.

$$S_u = \bigcup_{k=1}^{K} [0, 1]^k \cup \{\emptyset\}.$$  

We first present a lemma showing that the space $(S_o, \leq)$ is a polish partial order space.

**Lemma D.1.** $(S_o, \leq)$ is a partially ordered space. In addition, $S_o$ is a polish space equipped with the metric

$$d(u, v) = \begin{cases} \max_{1 \leq m \leq \dim(u)} |u_m - v_m| & \text{if } \dim(u) = \dim(v) \geq 1 \\ 0 & \text{if } u = v = \emptyset \\ 2 & \text{if } \dim(u) \neq \dim(v) \end{cases}$$

for $u, v \in S_o$.

We define mappings $I_o : S_o \to \{0, \cdots, K\}$ and $H_o : S_o \to S_o$ as follows. For any
\( u \in S_\alpha \), define

\[
I_\alpha(u) = \begin{cases} 
\sup \{ n : \sum_{i=1}^{n} u_i \leq \alpha n, n \in \{0, \ldots, \dim(u)\} \} & \text{if } \dim(u) \geq 1, u = (u_1, \ldots, u_{\dim(u)}) \\
0 & \text{if } \dim(u) = 0,
\end{cases}
\]

and

\[
H_\alpha(u) = \begin{cases} 
(u_1, \ldots, u_{I_\alpha(u)}) & \text{if } I_\alpha(u) \geq 1, \\
\emptyset & \text{otherwise}.
\end{cases}
\]

The mapping \( H_\alpha \) is closely related to the one-step update rule in Algorithm 1 as summarized in the next lemma.

**Lemma D.2.** If we input \((W_{k,t})_{k \in S_t} = u\) and an index set \(S_t\) with \(|S_t| = \dim(u)\) in Algorithm 1 then the output \(S_{t+1}\) satisfies

\[
|S_{t+1}| = I_\alpha(u) \text{ and } [(W_{k,t})_{k \in S_{t+1}}] = H_\alpha([u]).
\]

Other compound sequential detection rules in \(T_\alpha\) are characterized through the next lemma.

**Lemma D.3.** \( \mathbb{T} = (T_1, \cdots, T_K) \in T_\alpha \) if and only if

\[
\mathbb{T} \in T \text{ and } \sum_{k=1}^{K} \mathbb{1}(T_k > t)W_{k,t} \leq \alpha \cdot \sum_{k=1}^{K} \mathbb{1}(T_k > t) \text{ for } t = 0, 1, 2, \cdots.
\]

The above expression is equivalent to

\[
S_{t+1} \text{ is } F_t \text{ measurable, } S_{t+1} \subseteq S_t, \sum_{k \in S_{t+1}} W_{k,t} \leq \alpha \cdot |S_{t+1}|
\]

for \( t = 0, 1, 2, \cdots \), and \( T_k = \sup \{t : k \in S_t\} \).

The next lemma compares the second statement in the above lemma with the output of the function \( H_\alpha \).
Lemma D.4. Let \( \mathbf{u} = (u_1, \ldots, u_m) \in S_u \) with \( \dim(\mathbf{u}) = m \geq 1 \). Let \( k_1, \ldots, k_l \in \{1, \ldots, m\} \) be distinct and satisfy

\[
\sum_{i=1}^{l} u_{k_i} \leq \alpha l.
\]

Then, \( H_0([\mathbf{u}]) \leq \delta [u_{k_1, \ldots, u_{k_l}}] \). Moreover, if \( H_0([\mathbf{u}]) = \emptyset \), then for any \( S \subset \{1, \ldots, m\} \) with \( |S| \geq 1 \), \( \sum_{i \in S} u_i > \alpha |S| \).

Lemma D.5. For any \( \mathbf{u} \preceq \mathbf{v} \in S_o \), \( H_o(\mathbf{u}) \preceq H_o(\mathbf{v}) \). That is, the mapping \( H_o(\mathbf{u}) \) is increasing in \( \mathbf{u} \).

Next, we present several lemmas on the stochastic ordering of random variables and Markov chains. We start with a simple but useful result regarding the stochastic monotonicity of a likelihood ratio under a mixture model.

Lemma D.6. Let \( p(x) \) and \( q(x) \) be two density functions with respect to some baseline measure \( \mu \) and assume that \( p(\cdot) \) and \( q(\cdot) \) have the same support. Let \( L(x) = \frac{q(x)}{p(x)} \) be the likelihood ratio. For \( \delta \in [0, 1] \), let \( Z_\delta \) be a random variable with the density function \( \delta q + (1 - \delta)p \) and \( L_\delta = L(Z_\delta) \). Then, for \( 0 \leq \delta_1 < \delta_2 \leq 1 \), we have

\[
L_{\delta_1} \leq_{st} L_{\delta_2}.
\]

This result is intuitive: if we have more weights in \( q \) for the mixture distribution, then the likelihood ratio will be larger, giving more evidence in favor of \( q \).

Lemma D.7. Assume model \( \mathcal{M}_s \) holds. Let \( V_{k,t} = \mathbb{P}(\tau_k < t | X_{k,1}, \ldots, X_{k,t}) \). Then,

\[
V_{k,0} = 0 \quad \text{and} \quad V_{k,t+1} = \frac{q(X_{k,t+1})/p(X_{k,t+1})}{(1 - \theta)(1 - V_{k,t})/\theta + (1 - \theta)V_{k,t}} + q(X_{k,t+1})/p(X_{k,t+1}).
\]

Moreover, \( \{V_{k,t}\}_{t=0,1} \ldots \) are independent and identically distributed processes for different \( k \).
Lemma D.8. Assume model $M_s$ holds. Let $\delta_{k,t} = \mathbb{P}(\tau_k \leq t | X_{k,1}, \ldots, X_{k,t})$, then

$$\delta_{k,t} = \theta + (1 - \theta)V_{k,t},$$

where $V_{k,t}$ is defined in (D.7).

Lemma D.9. Under model $M_s$, the process $\{V_{1,t}\}_{t \geq 0}$ defined in (D.7) is a homogeneous Markov chain. In addition, its transition kernel is stochastically monotone. We will later refer to this transition kernel as $K(\cdot, \cdot)$.

Lemma D.10. For any $t \geq 1$ and $\mathbb{T}^A$, $[W^A_{S_{t+1}, t+1}]$ is conditionally independent of $\mathcal{F}^A_t$ given $[W^A_{S_{t+1}, t}]$. Moreover, the conditional density of $[W^A_{S_{t+1}, t+1}]$ at $v$ given $[W^A_{S_{t+1}, t}] = u \in S_o$ is

$$K_a(u, v) := \begin{cases} \sum_{\pi \in P_{\text{dim}(u)}} \prod_{l=1}^{\text{dim}(u)} K(u_l, v_{\pi(l)}) & \text{if } \text{dim}(u) = \text{dim}(v) \geq 1, \\ 1 & \text{if } \text{dim}(u) = \text{dim}(v) = 0, \\ 0 & \text{otherwise}, \end{cases}$$

where $P_m$ denotes the set of all permutations over $\{1, \ldots, m\}$.

Lemma D.11. For each $u \in S_o$ with $\text{dim}(u) = m \geq 1$, generate an $S_o$-valued random variable $V$ as follows,

1. For each $k \in \{1, \ldots, m\}$, generate $Z_k \sim K(u_k, \cdot)$ independently for different $k$.
2. Let $V = [(Z_1, \ldots, Z_m)]$.

In addition, if $m = 0$, we let $V = \emptyset$. Then, $V \sim K_a(u, \cdot)$.

Lemma D.12. For $u, u' \in S_o$ with $u \leq u'$, we have $K_a(u, \cdot) \leq_{st} K_a(u', \cdot)$.

Lemma D.13. For any $t, s \geq 0$ and $\mathbb{T}^A$, $[W^A_{S_{t+s+1}, t+s+1}]$ is conditionally independent of $\mathcal{F}^A_{t+s}$ given $[W^A_{S_{t+s+1}, t+s}]$. Moreover, the conditional density of $[W^A_{S_{t+s+1}, t+s+1}]$ at $v$
given \([W_{S_{t+s+1},t+s}^{AP}] = u \in S_o\) is

\[
\mathbb{K}_o(u, v) := \mathbb{K}_o(H_o(u), v) = \begin{cases} 
\sum_{\pi \in P_{I_o(u)}} \prod_{l=1}^{I_o(u)} K(H_o(u)_l, v_{\pi(l)}) & \text{if } \dim(v) = I_o(u) \geq 1 \\
1 & \text{if } \dim(v) = I_o(u) = 0 \\
0 & \text{otherwise,}
\end{cases}
\]

where \(P_m\) denotes the set of all permutations over \(\{1, \cdots, m\}\).

**Remark D.1.** There is a key difference between Lemma \textbf{D.10} and Lemma \textbf{D.13} though they may look similar at a first glance. In Lemma \textbf{D.10}, we consider the conditional distribution of \([W_{S_{t+1},t+1}]^A\) given \([W_{S_{t+1},t+1}]^A\), where the index set \(S_{t+1}^A\) is the same for the two random vectors. In Lemma \textbf{D.13}, we consider the conditional distribution of \([W_{S_{t+s+1},t+s+1}]^{AP}\) given \([W_{S_{t+s+1},t+s+1}]^{AP}\), where the two random vectors are associated with two different index sets \(S_{t+s+1}^{AP}\) and \(S_{t+s}^{AP}\). This difference reflects a key difference between the proposed one-step update rule and an arbitrary procedure.

**Lemma D.14.** For each \(u \in S_o\) and \(m = I_o(u)\), generate an \(S_o\)-valued random variable \(V\) as follows,

1. For each \(k \in \{1, \cdots, m\}\), generate \(Z_k \sim K(H_o(u)_k, \cdot)\) independently for different \(k\).
2. Let \(V = [(Z_1, ..., Z_m)]\).

In addition, if \(m = 0\), we let \(V = \emptyset\). Then, \(V \sim \mathbb{K}_o(u, \cdot)\).

### D.3 Proof of Propositions \[4\] and \[5\]

**Proposition 4.** Let \(\{x_t, s_t, 1 \leq t \leq t_0\}\) be any sequence in the support of the stochastic process \(\{(X_{k,t})_{k \in S_t^A}, S_t^A, 1 \leq t \leq t_0\}\) following a sequential procedure \(T^A \in T_\alpha\). Then,
there exists a coupling of $S_0$-valued random variables $(\hat{W}, \hat{W}')$ such that

$$\hat{W} \overset{d}{=} \left[ \left( W^{AP}_{t_0+1} \right)_{k \in S_{t_0+1}} \right] \{ (X_{k,t})_{k \in S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \},$$

$$\hat{W}' \overset{d}{=} \left[ \left( W^{AP}_{t_0+1} \right)_{k \in S_{t_0+1}} \right] \{ (X_{k,t})_{k \in S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \},$$

and $\hat{W} \leq \hat{W}'$ a.s., where $\overset{d}{=}$ denotes that random variables on both sides are identically distributed.

**Proof of Proposition 4** First, given $\{ X_{S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \}$, $[W^A_{S_0, t_0}]$ is determined. To simplify the notation, we assume $W^A_{S_0, t_0} = w_{t_0} \in S_0$ given $\{ X_{S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \}$. According to Lemma D.10 (replacing $t$ by $t_0$), the conditional distribution of $[W^A_{S_{t_0+1}, t_0+1}]$ given $\{ X_{S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \}$ is the same as the conditional distribution given $[W^A_{S_{t_0+1}, t_0+1}] = w^*_{t_0+1}$.

We perform a similar analysis by replacing $T^A$ by $T^{AP}_{t_0}$ in the above analysis. We denote $[W^{AP}_{S_{t_0+1}, t_0}] = w_{t_0+1}$ and obtain that the conditional density of $[W^{AP}_{S_{t_0+1}, t_0}]$ given $\{ X_{S_t} = x_t, S_t^A = s_t, 1 \leq t \leq t_0 \}$ is $K_{a}(w^*_{t_0+1}, \cdot)$.

According to the above analysis and Strassen Theorem for pospace (Fact 2), to prove the proposition, it is sufficient to show $K_{a}(w_{t_0+1}, \cdot) \leq_{st} K_{a}(w^*_{t_0+1}, \cdot)$. By Lemma D.12 we have $K_{a}(u, \cdot) \leq_{st} K_{a}(u', \cdot)$ for any $u \leq u' \in S_0$. Thus, it is sufficient to show that $w_{t_0+1} \leq w^*_{t_0+1}$.

Now we compare $w_{t_0+1}$ and $w^*_{t_0+1}$. According to the definition of $T^{AP}_{t_0}$ and Lemma D.2, we know $w_{t_0+1} = H_0([w_{t_0}])$. There are two cases: 1) $w^*_{t_0+1} = \emptyset$, and 2) $w^*_{t_0+1} \neq \emptyset$. We analyze these cases separately. For the first case, $w_{t_0+1} \leq w^*_{t_0+1}$ by definition of the partial order. For the second case, according to Lemma D.3 and
Moreover, the process \( p_K \) to show that \( F_T \) which is independent of the sequential procedure we obtain that \( t \).

**Proof of Proposition 5.** Recall \( F_H \) a coupling \( p_u \). For the rest of the proof, according to Definition 8 and Fact 3, it is sufficient to show that \( \mathbb{E}[\mathcal{M}_s] \) holds. Then for any \( y, y' \in S_o \) such that \( y \preceq y' \), there exists a coupling \( (\hat{Y}_s, \hat{Y}'_s), s = 0, 1, \ldots \), satisfying

1. \( \{\hat{Y}_s : s \geq 0\} \) has the same distribution as the conditional process \( \{Y_s : s \geq 0\} \) given \( Y_0 = y \), and \( \{\hat{Y}'_s : s \geq 0\} \) has the same distribution as the conditional process \( \{Y'_s : s \geq 0\} \) given \( Y_0 = y' \).

2. \( \hat{Y}_s \leq \hat{Y}'_s \), a.s. for all \( s \geq 0 \).

Moreover, the process \( (\hat{Y}_s, \hat{Y}'_s) \) does not depend on \( T^A \), \( t_0 \), or the information filtration \( F_{t_0}^A \).

**Proof of Proposition 5**

Recall \( Y_s = \left( \begin{array}{c} W_{AP}^{t_0} \\ k \\ \end{array} \right) \). By letting \( t = t_0 \) in Lemma D.13 we obtain that \( \{Y_s\}_{s \geq 0} \) is a homogeneous Markov chain, whose transition kernel is \( \mathbb{K}_o \), which is independent of the sequential procedure \( T^A \), \( t_0 \), and the information filtration \( F_{t_0}^A \). For the rest of the proof, according to Definition 8 and Fact 3, it is sufficient to show that \( \mathbb{K}_o \) is stochastically monotone. That is, \( \mathbb{K}_o(u, \cdot) \leq_{st} \mathbb{K}_o(u', \cdot) \) for any \( u, u' \in S_o \) with \( u \preceq u' \). Thus, it is sufficient to show that for all \( u \preceq u' \) there exists a coupling \( (\hat{V}, \hat{V}') \) such that \( \hat{V} \sim \mathbb{K}_o(u, \cdot), \hat{V}' \sim \mathbb{K}_o(u', \cdot) \) and \( \hat{V} \preceq \hat{V}' \) a.s. In what follows, we construct such a coupling.

For \( u \preceq u' \) with \( u, u' \in S_o \), we know that \( H_u(u) \preceq H_u(u') \) by Lemma D.5. By the definition of the partial order, this implies that \( \dim(H_u(u')) \leq \dim(H_u(u)) \) and \( H_u(u)_k \leq H_u(u')_k \) for each \( 1 \leq k \leq \dim(H_u(u')) \). By Lemma D.9 this further implies

\[
K(H_u(u)_k, \cdot) \leq_{st} K(H_u(u')_k, \cdot)
\]
for \( k = 1, \ldots, \dim(H_u(u')) \). Thus, by Strassen’s Theorem for random variables (Fact 1),
this implies that there exists a coupling \((\hat{Z}_k, \hat{Z}'_k)\) such that
\[
\hat{Z}_k \sim K(H_u(u)_k, \cdot), \hat{Z}'_k \sim K(H_u(u')_k, \cdot), \text{ and } \hat{Z}_k \leq \hat{Z}'_k \text{ a.s.}
\]

for \( k = 1, \ldots, \dim(H_u(u')) \). In addition, we choose the coupling so that \((\hat{Z}_k, \hat{Z}'_k)\) are
independent for different \( k \). For \( \dim(H_u(u')) < k \leq \dim(H_u(u)) \), we construct \( \hat{Z}_k \sim K(H_u(u)_k, \cdot) \) so that \( \hat{Z}_k \)'s are independent for different \( k \). Let \( \hat{Z} = (\hat{Z}_1, \ldots, \hat{Z}_{\dim(H_u(u))}) \)
and \( \hat{Z}' = (\hat{Z}'_1, \ldots, \hat{Z}'_{\dim(H_u(u'))}) \).

For this coupling, it is easy to verify
\[
\dim(\hat{Z}) \geq \dim(\hat{Z}') \text{ and } \hat{Z}_k \leq \hat{Z}'_k \text{ for } 1 \leq k \leq \dim(\hat{Z}') \text{ a.s.}
\]
Thus, \([\hat{Z}] \leq [\hat{Z}']\) a.s. Let \( \hat{V} = [\hat{Z}] \) and \( \hat{V}' = [Z']\). Then, our coupling \((\hat{V}, \hat{V}')\) gives
\[
\hat{V} \leq \hat{V}' \text{ a.s.}
\]
On the other hand, by Lemma [D.14], we have
\[
\hat{V} \sim K_0(u, \cdot) \text{ and } \hat{V}' \sim K_0(u', \cdot).
\]
Therefore,
\[
K_0(u, \cdot) \leq_{st} K_0(u', \cdot).
\]
D.4 Proof of supporting lemmas in Section D.2

Lemma D.1. \((S_o, \preceq)\) is a partially ordered space. In addition, \(S_o\) is a polish space equipped with the metric

\[
d(u, v) = \begin{cases} 
\max_{1 \leq m \leq \dim(u)} |u_m - v_m| & \text{if } \dim(u) = \dim(v) \geq 1 \\
0 & \text{if } u = v = \emptyset \\
2 & \text{if } \dim(u) \neq \dim(v)
\end{cases}
\]

for \(u, v \in S_o\).

Proof of Lemma D.1. First, \(S_o\) is the union of polish spaces \(\{u = (u_1, \ldots, u_m) : 0 \leq u_1 \leq \cdots \leq u_m \leq 1\} \) and \(\{\emptyset\}\). Thus, it is also a polish space. Second, it is straightforward to verify that \(d(u, v)\) is a metric defined over \(S_o\).

Now, we verify that the partial order relationship \(\preceq\) is closed over \(S_o\). To see this, let \(u, v \in S_o\) satisfying \(u \preceq v\). There are two cases: 1) \(\dim(u) < \dim(v)\), or 2) \(\dim(u) \geq \dim(v)\) and there exists \(m \in \{1, \ldots, \dim(v)\}\) such that \(u_m > v_m\). Let \(B_d(u, \delta)\) and \(B_d(v, \delta)\) be \(d\)-balls centering at \(u\) and \(v\) with \(\delta\) chosen according to different cases: \(\delta = 1/2\) for the first case; and \(\delta = \frac{u_m - v_m}{4}\) for the second case. Then, it is easy to verify that for all \(u' \in B_d(u, \delta)\) and \(v' \in B_d(v, \delta)\), we have \(u' \preceq v'\). That is, the partial order relationship \(\preceq\) is closed over \(S_o\). 

Lemma D.2. If we input \((W_{k,t})_{k \in S_t} = u\) and an index set \(S_t\) with \(|S_t| = \dim(u)\) in Algorithm 1, then the output \(S_{t+1}\) satisfies

\[
|S_{t+1}| = I_o(u) \text{ and } [(W_{k,t})_{k \in S_{t+1}}] = H_o([u]).
\]

Proof of Lemma D.2. If \(u = \emptyset\), then \([u] = \emptyset\) and \(|S_t| = 0\). This implies \(I_o([u]) = 0\) and \(H_o([u]) = \emptyset\). In the rest of the proof we assume that \(u \neq \emptyset\). By Step 1 of Algorithm 1 we obtain that \([u] = (W_{k_1,t}, \ldots, W_{k|S_t|,t})\) where \(S_t = \{k_1, \ldots, k|S_t|\}\) and \(W_{k_1,t} \preceq \cdots \preceq W_{k|S_t|,t}\). According to Step 2 and 3 of the algorithm and the definition of
In (D.2), the largest $n$ making $R_n \leq \alpha$ is $I_o([u])$ and $H_o([u]) = [(W_{k,t})_{k \in S_{t+1}}]$. 

Lemma D.3. $\mathcal{T} = (T_1, \cdots, T_K) \in \mathcal{T}_\alpha$ if and only if

$$\mathcal{T} \in \mathcal{T} \text{ and } \sum_{k=1}^{K} 1(T_k > t)W_{k,t} \leq \alpha \cdot \sum_{k=1}^{K} 1(T_k > t) \text{ for } t = 0, 1, 2, \cdots$$

The above expression is equivalent to

$$S_{t+1} \text{ is } \mathcal{F}_t \text{ measurable, } S_{t+1} \subset S_t, \sum_{k \in S_{t+1}} W_{k,t} \leq \alpha \cdot |S_{t+1}|$$

for $t = 0, 1, 2, \cdots$, and $T_k = \sup\{t : k \in S_t\}$.

Proof of Lemma D.3. By definition and the $\mathcal{F}_t$ measurability of $S_{t+1}$,

$$\text{LPNR}_{t+1}(\mathcal{T}) = \mathbb{E}\left[\frac{\sum_{k \in S_{t+1}} 1(\tau_k < t) |S_{t+1}| \vee 1}{|S_{t+1}| \vee 1} \mid \mathcal{F}_t\right] = \frac{\sum_{k \in S_{t+1}} \mathbb{P}(\tau_k < t \mid \mathcal{F}_t)}{|S_{t+1}| \vee 1} = \sum_{k \in S_{t+1}} \frac{W_{k,t}}{|S_{t+1}| \vee 1}.$$ 

Thus, $\mathcal{T} \in \mathcal{T}_\alpha$ if and only if

$$\sum_{k \in S_{t+1}} W_{k,t} \leq \alpha \text{ a.s.},$$

which is equivalent to

$$\sum_{k \in S_{t+1}} W_{k,t} \leq \alpha |S_{t+1}| \text{ a.s.},$$

for every $t$. 

Lemma D.4. Let $u = (u_1, \cdots, u_m) \in \mathcal{S}_u$ with $\dim(u) = m \geq 1$. Let $k_1, \cdots, k_l \in \{1, \cdots, m\}$ be distinct and satisfy

$$\sum_{i=1}^{l} u_{k_i} \leq \alpha l.$$ 

Then, $H_o([u]) \leq [(u_{k_1}, \cdots, u_{k_l})]$. Moreover, if $H_o([u]) = \emptyset$, then for any $S \subset \{1, \cdots, m\}$ with $|S| \geq 1$, $\sum_{i \in S} u_i > \alpha |S|$. 

48
Proof of Lemma D.4. We first prove the ‘Moreover’ part of the lemma by contradiction. If on the contrary $H_o([\mathbf{u}]) = \emptyset$ and there exists a non-empty set $S \subset \{1, \ldots, m\}$ such that $\sum_{i \in S} u_i \leq \alpha |S|$, then there exists $i \in S$ such that $u_i \leq \alpha$. This further implies $[\mathbf{u}]_i \leq u_i \leq \alpha$ and $I_o([\mathbf{u}]) \geq 1$, which contracts with the assumption $H_o([\mathbf{u}]) = \emptyset$.

We proceed to the proof of the rest of the lemma. We first prove that $l$ in the lemma satisfies $l \leq I_o([\mathbf{u}])$. To see this, recall that $([\mathbf{u}]_1, \ldots, [\mathbf{u}]_m)$ is the order statistic of $(u_1, \ldots, u_m)$. Thus,

$$\sum_{i=1}^l [\mathbf{u}]_i \leq \sum_{i=1}^l u_{k_i} \leq \alpha l. \quad \text{(D.3)}$$

Recall $I_o([\mathbf{u}]) = \sup\{n : \sum_{i=1}^n [\mathbf{u}]_i \leq \alpha n, n \in \{0, \ldots, m\}\}$. Thus, (D.4) implies $l \leq I_o([\mathbf{u}])$.

Next, we prove that $H_o([\mathbf{u}]) \leq [(u_{k_1}, \ldots, u_{k_l})]$. Without loss of generality, assume $u_{k_1}, \ldots, u_{k_l}$ are ordered. That is, $u_{k_1} \leq \cdots \leq u_{k_l}$ and $[(u_{k_1}, \ldots, u_{k_l})] = (u_{k_1}, \ldots, u_{k_l})$. Then, according to the definition of the order statistic $[\mathbf{u}]$, we have $[\mathbf{u}]_i \leq u_{k_i}$ for $i = 1, \ldots, l$. Recall $H_o([\mathbf{u}]) = ([\mathbf{u}]_1, \ldots, [\mathbf{u}]_{I_o(\mathbf{u})})$. This implies $H_o([\mathbf{u}]) \leq [(u_{k_1}, \ldots, u_{k_l})]$.

Lemma D.5. For any $\mathbf{u} \preceq \mathbf{v} \in \mathcal{S}_o$, $H_o(\mathbf{u}) \preceq H_o(\mathbf{v})$. That is, the mapping $H_o(\mathbf{u})$ is increasing in $\mathbf{u}$.

Proof of Lemma D.5. If $\mathbf{v} = \emptyset$, then $H_o(\mathbf{v}) = \emptyset$ and $H_o(\mathbf{u}) \preceq \emptyset = H_o(\mathbf{v})$ by the definition of the partial order. In the rest of the proof we assume $\dim(\mathbf{v}) \geq 1$ and $\mathbf{v} = (v_1, \ldots, v_{\dim(\mathbf{v})})$. As we assumed $\mathbf{u} \preceq \mathbf{v}$, this implies $\dim(\mathbf{u}) \geq \dim(\mathbf{v}) \geq 1$. We further denote $\mathbf{u} = (u_1, \ldots, u_{\dim(\mathbf{u})})$

We first show that if $\sum_{i=1}^{L+1} v_i \leq \alpha(L + 1)$ for some $L$, then $\sum_{i=1}^{L} v_i \leq \alpha L$. That is, $(\sum_{i=1}^{L} v_i)/L$ is increasing in $L$. To see this, consider two cases. If $v_{L+1} \leq \alpha$, then $v_1 \leq \cdots \leq v_L \leq \alpha$ and thus $\sum_{i=1}^{L} v_i \leq \alpha L$. If $v_{L+1} > \alpha$, then $\sum_{i=1}^{L} v_i \leq \sum_{i=1}^{L+1} v_i - \alpha \leq \alpha L$. This result implies that $\sum_{i=1}^{L} v_i \leq \alpha L$ for all $1 \leq L \leq I_o(\mathbf{v})$.

Now we show that $I_o(\mathbf{u}) \geq I_o(\mathbf{v})$ by contradiction. If on the contrary $I_o(\mathbf{u}) < I_o(\mathbf{v})$,
then $I_o(u) + 1 \leq I_o(v) \leq \dim(v)$ and

$$\sum_{i=1}^{I_o(u)+1} u_i \leq \sum_{i=1}^{I_o(u)+1} v_i \leq \alpha(I_o(u) + 1).$$

This contradicts with the definition of $I_o(u)$. Therefore, $I_o(u) \geq I_o(v)$.

We proceed to showing $H_o(u) \leq H_o(v)$. By the definition of $H_o$, we have $H_o(u) = (u_1, \ldots, u_{I_o(u)})$ and $H_o(v) = (v_1, \ldots, v_{I_o(v)})$. Since we assume $u \leq v$, we have $u_i \leq v_i$ for all $i = 1, \ldots, I_o(v)$. This shows that $H_o(u) \leq H_o(v)$.

Lemma D.6. Let $p(x)$ and $q(x)$ be two density functions with respect to some baseline measure $\mu$ and assume that $p(\cdot)$ and $q(\cdot)$ have the same support. Let $L(x) = \frac{q(x)}{p(x)}$ be the likelihood ratio. For $\delta \in [0, 1]$, let $Z_\delta$ be a random variable with the density function $\delta q + (1 - \delta)p$ and $L_\delta = L(Z_\delta)$. Then, for $0 \leq \delta_1 < \delta_2 \leq 1$, we have

$$L_{\delta_1} \leq_{st} L_{\delta_2}.$$

Proof of Lemma D.6. Let $g$ be a bounded increasing function. Then,

$$\begin{align*}
\mathbb{E}g(L_{\delta_2}) - \mathbb{E}g(L_{\delta_1}) &= \mathbb{E}_{Z \sim \delta_2 q + (1 - \delta_2)p} g(L(Z)) - \mathbb{E}_{Z \sim \delta_1 q + (1 - \delta_1)p} g(L(Z)) \\
&= \delta_2 \mathbb{E}_{Z \sim q} g(L(Z)) + (1 - \delta_2) \mathbb{E}_{Z \sim p} g(L(Z)) \\
&\quad - \left\{ \delta_1 \mathbb{E}_{Z \sim q} g(L(Z)) + (1 - \delta_1) \mathbb{E}_{Z \sim p} g(L(Z)) \right\} \\
&= (\delta_2 - \delta_1) \left\{ \mathbb{E}_{Z \sim q} g(L(Z)) - \mathbb{E}_{Z \sim p} g(L(Z)) \right\}.
\end{align*}$$

Note that $L(Z) = q(Z)/p(Z)$ and $\mathbb{E}_{Z \sim q} g(L(Z)) = \mathbb{E}_{Z \sim p} \{ L(Z) g(L(Z)) \}$. Thus, the above display can be further written as

$$\mathbb{E}g(L_{\delta_2}) - \mathbb{E}g(L_{\delta_1}) = (\delta_2 - \delta_1) \mathbb{E}_{Z \sim p} \{ (L(Z) - 1) g(L(Z)) \}.$$

For notational simplicity, let $Y = L(Z)$ with $Z \sim p$. Then, $\mathbb{E}(Y) = 1$ and the above
display implies

\[ \mathbb{E}g(L_{\delta_2}) - \mathbb{E}g(L_{\delta_1}) = (\delta_2 - \delta_1)\mathbb{E}\{(Y - 1)g(Y)\} = (\delta_2 - \delta_1)\mathbb{E}\{(Y - 1)(g(Y) - g(1))\} \geq 0. \]

The last inequality in the above display is due to the fact that \((Y - 1)(g(Y) - g(1)) \geq 0\) for all increasing function \(g\). We remark that it is also a special case of Harris inequality (Harris, 1960).

\[ \square \]

**Lemma D.7.** Assume model \( \mathcal{M}_s \) holds. Let \( V_{k,t} = \mathbb{P}(\tau_k < t|X_1, \cdots, X_{k,t}) \). Then,

\[
V_{k,0} = 0 \text{ and } V_{k,t+1} = \frac{q(X_{k,t+1})/p(X_{k,t+1})}{(1 - \theta)(1 - V_{k,t})/(\theta + (1 - \theta)V_{k,t}) + q(X_{k,t+1})/p(X_{k,t+1})},
\]

(D.1)

Moreover, \( \{V_{k,t}\}_{t=0,1,\ldots} \) are independent and identically distributed processes for different \( k \).

**Proof of Lemma D.7.** First, it is easy to see that \( \{V_{k,s}\}_{s \geq 0} \) are independent and identically distributed processes for different \( k \). For the rest of the proof, it is sufficient to prove the lemma for \( k = 1 \). First, \( \mathbb{P}(\tau_1 < t|X_{1,0}) = \mathbb{P}(\tau_1 < 0) = 0 = V_0 \). Thus, it is sufficient to verify the update rule for \( V_{1,t} \). A direct calculation gives

\[
\mathbb{P}(\tau_1 \leq t - 1|X_{1,1:t}) = \frac{\sum_{s=0}^{t-1} \mathbb{P}(\tau_1 = s) \prod_{r=1}^{s} p(X_{1,r}) \prod_{r=s+1}^{t} q(X_{1,r})}{\sum_{s=0}^{t-1} \theta(1 - \theta)^s L_{1,(s+1):t}} = \frac{\sum_{s=0}^{t-1} \theta(1 - \theta)^s L_{1,(s+1):t} + (1 - \theta)^t}{Q_{1,t}}
\]

where we write \( L_{k,(s+1):t} := \prod_{r=s+1}^{t} \frac{q(X_{k,r})}{p(X_{k,r})} \), the likelihood ratio between \( p(\cdot) \) and \( q(\cdot) \) based on the data \( X_{1,(s+1):t} \), and \( Q_{1,t} = \sum_{s=0}^{t-1} \theta(1 - \theta)^s L_{1,(s+1):t} \). Then,

\[
Q_{1,t} = \frac{(1 - \theta)^t \mathbb{P}(\tau_1 \leq t - 1|X_{1,1:t})}{1 - \mathbb{P}(\tau_1 \leq t - 1|X_{1,1:t})}.
\]

51
Note that

\[ Q_{1,t+1} = \sum_{s=0}^{t} \theta(1-\theta)^s L_{1,(s+1):t+1} = q(X_{1,t+1})/p(X_{1,t+1}) \{ \theta(1-\theta)^t + Q_{1,t} \} . \]

Thus,

\[
P(\tau_1 \leq t|X_{1,1:t+1})
= \frac{Q_{1,t+1}}{Q_{1,t+1} + (1-\theta)^t+1}
= \frac{q(X_{1,t+1})/p(X_{1,t+1}) \{ \theta(1-\theta)^t + Q_{1,t} \}}{q(X_{1,t+1})/p(X_{1,t+1}) (\theta + (1-\theta)^{-t} Q_{1,t})}
= \frac{q(X_{1,t+1})/p(X_{1,t+1}) + (1-\theta)/ \{ \theta + (1-\theta)^{-t} Q_{1,t} \}}{q(X_{1,t+1})/p(X_{1,t+1}) + (1-\theta)/ \{ \theta + \frac{P(\tau_1 \leq t-1|X_{1,1:t})}{1-P(\tau_1 \leq t-1|X_{1,1:t})} \}}.
\]

We complete the proof by simplifying the above result.

**Lemma D.8.** Assume model $\mathcal{M}_s$ holds. Let $\delta_{k,t} = P(\tau_k \leq t|X_{k,1}, \cdots, X_{k,t})$, then

\[ \delta_{k,t} = \theta + (1-\theta) V_{k,t}, \]

where $V_{k,t}$ is defined in (D.7).

**Proof of Lemma D.8.** By symmetry, it is sufficient to prove the lemma for $k = 1$.

Recall $L_{k,(s+1):t} = \prod_{r=s+1}^{t} \frac{q(X_{k,r})}{p(X_{k,r})}$ and $Q_{k,t} = \sum_{s=0}^{t-1} \theta(1-\theta)^s L_{1,(s+1):t}$.

A direct calculation using Bayes formula gives

\[
\delta_{k,t} = \frac{\sum_{s=0}^{t-1} P(\tau_1 = s) \prod_{r=1}^{t} p(X_{1,r}) \prod_{r=s+1}^{t} q(X_{1,r}) + P(\tau_1 = t) \prod_{r=1}^{t} p(X_{1,r})}{\sum_{s=0}^{t-1} P(\tau_1 = s) \prod_{r=1}^{t} p(X_{1,r}) \prod_{r=s+1}^{t} q(X_{1,r}) + P(\tau_1 = t) \prod_{r=1}^{t} p(X_{1,r})}
= \frac{\sum_{s=0}^{t-1} \theta(1-\theta)^s L_{1,(s+1):t} + \theta(1-\theta)^t}{\sum_{s=0}^{t-1} \theta(1-\theta)^s L_{1,(s+1):t} + (1-\theta)^t}
= \frac{Q_{1,t} + \theta(1-\theta)^t}{Q_{1,t} + (1-\theta)^t}
= V_{1,t} + \theta(1 - V_{1,t})
= \theta + (1-\theta) V_{1,t}.
\]
**Lemma D.9.** Under model $\mathcal{M}_s$, the process $\{V_{1,t}\}_{t \geq 0}$ defined in [D.7] is a homogeneous Markov chain. In addition, its transition kernel is stochastically monotone. We will later refer to this transition kernel as $K(\cdot, \cdot)$.

**Proof of Lemma** D.9. We first study the conditional distribution of $X_{1,t+1}$ given $V_{1,0}, \cdots, V_{1,t}$. According to the change point model $\mathcal{M}_s$, we know that $X_{1,t+1}$ is conditionally independent of $V_{1,0}, \cdots, V_{1,t}$ given the event $\{\tau_1 \leq t\}$. That is, given $V_{1,0}, \cdots, V_{1,t}$, the conditional density function of $X_{1,t+1}$ is $\delta_{1,t} q(x) + (1 - \delta_{1,t}) p(x)$, which depends on $X_{1,1}, \cdots, X_{1,t}$ only through $V_{1,t}$.

Let the function $L(x) := q(x)/p(x)$ and let $L_{k,t+1} := q(X_{k,t+1})/(X_{k,t+1})$. Then, $L_{1,t+1} = L(X_{1,t+1})$, whose conditional distribution given $V_{1,0}, \cdots, V_{1,t}$ only depends on $V_{1,t}$. According to the iteration [D.7], this implies that the process $\{V_{1,t}\}_{t \geq 0}$ is a Markov process. Note that $\delta_{1,t}$ and the iteration [D.7] depend on $t$ only through $V_{1,t}$. Thus, this Markov chain is a homogeneous Markov chain. We now show that its transition kernel is stochastically monotone.

Let $\delta(x) = \theta + (1 - \theta) x$. For $x \in (0, 1)$, we consider the following steps of generating a random variable $V(x)$.

1. Generate $Z(x)$ with the density $\delta(x) q(\cdot) + (1 - \delta(x)) p(\cdot)$.
2. Let $$V(x) = \frac{L(Z(x))}{L(Z(x)) + (1 - \theta) (1 - x) / (\theta + (1 - \theta) x)}.$$ From the iteration [D.7] and $X_{1,t+1}|V_t = x \sim (1 - \delta(x)) q(\cdot) + \delta(x) p(\cdot)$, we can see that $V(x)$ has the same distribution as that of $V_{1,t+1}$ given $V_{1,t} = x$. In other words, $V(x)$ has the density function $K(x, \cdot)$.

Now we show that $K(x, \cdot) \leq_{st} K(x', \cdot)$ for any $0 < x \leq x' < 1$ by coupling. Specifically, since $\delta(x)$ is increasing in $x$, $\delta(x) \leq \delta(x')$. Then, by Lemma D.6 we know $L(Z(x)) \leq_{st} L(Z(x'))$. According to the Strassen Theorem for random variables (Fact 1), there exists a coupling $(\hat{L}, \hat{L'})$ such that $\hat{L} = L(Z(x))$, $\hat{L'} = L(Z(x'))$ and $\hat{L} \leq \hat{L'}$.
a.s. Then, let \( \hat{V} = \frac{\hat{L}}{L + (1 - \theta)(1 - x)/(\theta + (1 - \theta)x)} \) and \( \hat{V}' = \frac{\hat{L}'}{L' + (1 - \theta)(1 - x')/(\theta + (1 - \theta)x')} \). Because \( \hat{L} \leq \hat{L}' \) and \( x \leq x' \),

\[
\hat{V} = \frac{\hat{L}}{L + (1 - \theta)(1 - x)/(\theta + (1 - \theta)x)} \leq \frac{\hat{L}'}{L' + (1 - \theta)(1 - x')/(\theta + (1 - \theta)x')} \leq \frac{\hat{L}'}{L' + (1 - \theta)(1 - x')/(\theta + (1 - \theta)x')} = \hat{V}' \ a.s.
\]

That is, \( \hat{V} \leq \hat{V}' \) a.s., and \( (\hat{V}, \hat{V}') \) is a coupling of \( (V(x), V(x')) \). Thus, \( V(x) \leq_{st} V(x') \) and so is \( K(x, \cdot) \leq_{st} K(x', \cdot) \).

**Lemma D.10.** For any \( t \geq 1 \) and \( \mathbb{T}^A \), \( \left[ W^A_{S_{t+1}, t+1} \right] \) is conditionally independent of \( F_t^A \) given \( \left[ W^A_{S_{t+1}, t} \right] \). Moreover, the conditional density of \( \left[ W^A_{S_{t+1}, t+1} \right] \) at \( \mathbf{v} \) given \( \left[ W^A_{S_{t+1}, t} \right] = \mathbf{u} \in S_o \) is

\[
K_o(\mathbf{u}, \mathbf{v}) := \begin{cases} 
\sum_{\pi \in P_{\dim(\mathbf{u})}} \prod_{l=1}^{\dim(\mathbf{u})} K(u_l, v_{\pi(l)}) & \text{if } \dim(\mathbf{u}) = \dim(\mathbf{v}) \geq 1, \\
1 & \text{if } \dim(\mathbf{u}) = \dim(\mathbf{v}) = 0, \\
0 & \text{otherwise},
\end{cases}
\]

where \( P_m \) denotes the set of all permutations over \( \{1, \cdots, m\} \).

**Proof of Lemma D.10** First, if \( \dim(\mathbf{u}) = 0 \), then \( \mathbf{u} = \emptyset \), and \( \left[ W^A_{S_{t+1}, t+1} \right] = \mathbf{u} \) means that \( S_{t+1} = \emptyset \). Thus, the conditional distribution of \( \left[ W^A_{S_{t+1}, t+1} \right] \) given \( \left[ W^A_{S_{t+1}, t} \right] = \mathbf{u} \) is a point mass at \( \emptyset \), and \( K_o(\emptyset, \emptyset) = 1 \). In the rest of the proof, we focus on the case that \( \mathbf{u} \neq \emptyset \).

We start with deriving the conditional density of \( \left[ W^A_{S_{t+1}, t+1} \right] \) at \( \mathbf{v} \in S_u \) given \( X_{S_{t+1}, t} = x_1, S_1 = s_1, \cdots, X_{S_{t+1}, t} = x_t, S_t = s_t, S_{t+1} = s_{t+1} \) and \( W^A_{S_{t+1}, t} = \mathbf{u} \) for some \( x_1, \cdots, x_t \) and \( s_1, \cdots, s_{t+1} \), and \( \mathbf{u} \in S_u \). Clearly, the conditional density is 0 when \( \dim(\mathbf{u}) \neq \dim(\mathbf{v}) \), and is arbitrary when \( \dim(\mathbf{u}) \neq |s_{t+1}| \) (the density of the random variable being conditional on is zero). Thus, we will focus on the case where \( \dim(\mathbf{u}) = \dim(\mathbf{v}) = }
\(|s_{t+1}| = m\) for some \(m \in \{1, \cdots, K\}\), and we will write \(u = (u_1, \cdots, u_m)\) and \(v = (v_1, \cdots, v_m)\).

Note that given \(S_{t+1}^A = s_{t+1}, W_{s_{t+1}^A}^A = u, W_{k,t+1}^A\)'s are independent for different \(k \in s_{t+1}\). Moreover, given \(S_{t+1}^A = s_{t+1}, W_{s_{t+1}^A}^A = u, W_{k,t+1}^A\) is the same as \(V_{k,t+1}\) (defined in \([D.7]\)) for \(k \in s_{t+1}\), and is independent of \(X_{S_{A,t}^1} = x_1, S_{A,t}^A = s_1, \cdots, X_{S_{A,t}^1} = x_t\) and \(S_{t}^A = s_t\). Thus, \(W_{s_{t+1}^A}^A\) is conditionally independent of \(\mathcal{F}_{t}^A\) given \(S_{t+1}^A = s_{t+1}, W_{s_{t+1}^A}^A = u\), and its conditional density (by Lemma \([D.9]\)) is

\[
\prod_{l=1}^{m} K(u_l, v_l),
\]

Because \([W_{s_{t+1}^A}^A]\) is the order statistic of \(W_{s_{t+1}^A}^A\), we further obtain its conditional density at \(v \in S_o\) given \(S_{t+1}^A = s_{t+1}, W_{s_{t+1}^A}^A = u, W_{s_{t+1}^A}^A\),

\[
\sum_{\pi \in \mathcal{P}_m} \prod_{l=1}^{m} K(u_l, v_{\pi(l)}) = \sum_{\pi \in \mathcal{P}_m} \prod_{l=1}^{m} K([u]_l, v_{\pi(l)}) = \mathbb{K}_a([u], v),
\]

for \(v \in S_o\) with \(\dim(v) = m\). Observe that the above function is independent of \(s_{t+1}\) for \(|s_{t+1}| = m\) and depend on \(u\) only through its order statistic \([u]\). Thus, we further conclude that \([W_{s_{t+1}^A}^A]\) is conditionally independent of \(\mathcal{F}_{t}^A\) given \([W_{s_{t+1}^A}^A] = u \in S_o\) satisfying \(\dim(u) = m\), and its conditional density is \(\mathbb{K}_a(u, \cdot)\).

**Lemma D.11.** For each \(u \in S_o\) with \(\dim(u) = m \geq 1\), generate an \(S_o\)-valued random variable \(V\) as follows,

1. For each \(k \in \{1, \cdots, m\}\), generate \(Z_k \sim K(u_k, \cdot)\) independently for different \(k\).
2. Let \(V = [(Z_1, \cdots, Z_m)]\).

In addition, if \(m = 0\), we let \(V = \emptyset\). Then, \(V \sim \mathbb{K}_a(u, \cdot)\).

**Proof of Lemma D.11** The lemma is obviously true when \(m = 0\). When \(m \geq 1\), let \(z = (z_1, \cdots, z_m)\). By step 1, the joint density for \((Z_1, \cdots, Z_m)\) at \(z\) is

\[
\prod_{i=1}^{m} K(u_i, z_i).
\]
By step 2, $V$ is the order statistic of $(Z_1, \ldots, Z_m)$. Thus, its density is

$$\sum_{\pi \in \mathcal{P}_m} \prod_{i=1}^{m} K(u_i, z_{\pi(i)}) = \mathbb{K}_a(u, z).$$

\[\square\]

**Lemma D.12.** For $u, u' \in S_0$ with $u \leq u'$, we have $\mathbb{K}_a(u, \cdot, \cdot) \leq_{st} \mathbb{K}_a(u', \cdot, \cdot)$.

**Proof of Lemma D.12.** The lemma is obvious if $u' = \emptyset$. In what follows, we assume $\dim(u') = m' \geq 1$ and $\dim(u) = m$. Then, $u \leq u'$ means $m \geq m' \geq 1$ and $u_l \leq u'_l$ for $1 \leq l \leq m'$. Let $(Z_1, Z'_1), \ldots, (Z_m, Z'_m)$ be independent random vectors such that $Z_l \sim K(u_l, \cdot)$, $Z'_l \sim K(u'_l, \cdot)$ and $Z_l \leq Z'_l$ a.s. Such random vectors exist because of Strassen Theorem and Lemma D.9 that the kernel $K(\cdot, \cdot)$ is stochastically monotone.

In addition, for $m < l \leq m'$, let $Z'_l \sim K(u'_l, \cdot)$ be independent random variables.

Let $Z = (Z_1, \ldots, Z_m) \sim \mathbb{K}_a(u, \cdot)$, $Z' = (Z'_1, \ldots, Z'_m)$, $V = [Z]$ and $V' = [Z']$. Then, $V \leq V'$ a.s. On the other hand, by Lemma D.11, we have

$$V \sim \mathbb{K}_a(u, \cdot) \text{ and } V' \sim \mathbb{K}_a(u', \cdot),$$

and $V \leq V'$ a.s. By Fact 2, the existence of such a coupling implies $\mathbb{K}_a(u, \cdot) \leq_{st} \mathbb{K}_a(u', \cdot, \cdot)$.

\[\square\]

**Lemma D.13.** For any $t, s \geq 0$ and $\mathbb{T}^A$, $[W_{s,t+s+1}^{AP_t}]$ is conditionally independent of $\mathcal{F}_{t+s}$ given $[W_{s,t+s}^{AP_t}]$. Moreover, the conditional density of $[W_{s,t+s}^{AP_t}]$ at $v$ given $[W_{s,t+s}^{AP_t}] = u \in S_0$ is

$$\mathbb{K}_o(u, v) := \mathbb{K}_a(H_o(u), v) = \begin{cases} \sum_{\pi \in \mathcal{P}_m} \prod_{i=1}^{m} K(H_o(u)_i, v_{\pi(i)}) & \text{if } \dim(v) = I_0(u) \geq 1 \\ 1 & \text{if } \dim(v) = I_0(u) = 0 \\ 0 & \text{otherwise} \end{cases}$$

where $\mathcal{P}_m$ denotes the set of all permutations over $\{1, \ldots, m\}$. 

56
Proof of Lemma D.13. Apply Lemma D.10 by replacing $T$ by $T^{AP_t}$ and $t$ by $t+s$, we obtain that $[W_{AP_t, S_{t+s+1}, t+s+1}]$ is conditionally independent of $F_{t+s}$ given $[W_{AP_t, S_{t+s+1}, t+s}]$. On the other hand, according to the one-step update rule in Algorithm 1 and Lemma D.2, we can see that $[W_{AP_t, S_{t+s+1}, t+s}] = H_o([W_{AP_t, S_{t+s}}, t+s])$. Therefore, we further obtain that $[W_{AP_t, S_{t+s+1}, t+s+1}]$ is conditionally independent of $F_{t+s}$ given $[W_{AP_t, S_{t+s}}, t+s]$.

We proceed to derive its conditional density at $v$ given $[W_{AP_t, S_{t+s}}, t+s] = u$. We first notice that $\dim(v) = |S_{t+s+1}^{AP_t}| = I_o(u)$ (by Lemma D.2). Thus, the conditional density is zero when $\dim(v) \neq I_o(u)$. For $\dim(v) = I_o(u)$, by Lemma D.10 and the above analysis, the conditional density is

$$K_a(H_o(u), v) = \sum_{\pi \in P_{I_o(u)}} \prod_{l=1}^{I_o(u)} K(H_o(u)_l, v_{\pi(l)}) = K_o(u, v).$$

This completes the proof of the lemma.

Lemma D.14. For each $u \in S_o$ and $m = I_o(u)$, generate an $S_o$-valued random variable $V$ as follows,

1. For each $k \in \{1, \cdots, m\}$, generate $Z_k \sim K(H_o(u)_k, \cdot)$ independently for different $k$.
2. Let $V = [(Z_1, \ldots, Z_m)]$.

In addition, if $m = 0$, we let $V = \emptyset$. Then, $V \sim K_o(u, \cdot)$.

Proof of Lemma D.14 The lemma is a direct application of Lemma D.11 and $K_o(u, v) = K_a(H_o(u), v)$.\qed
E Proof of Lemma 1 and Propositions 1 - 3

Lemma 1. Under model $\mathcal{M}_s$, $W_{k,0} = 0$ for $1 \leq k \leq K$ and $W_{k,t}$ can be computed using the following update rule for $1 \leq k \leq K$,

$$W_{k,t+1} = \begin{cases} 
\frac{q(X_{k,t+1})/p(X_{k,t+1})}{(1-\theta)(1-W_{k,t})/(\theta + (1-\theta)W_{k,t}) + q(X_{k,t+1})/p(X_{k,t+1})} & \text{for } 1 \leq t \leq T_k - 1, \\
W_{k,T_k} & \text{for } t \geq T_k.
\end{cases}$$

Proof of Lemma 1. For each $k \in S_{t+1}$, according to the independence assumption for model $\mathcal{M}_s$,

$$W_{k,t+1} = \mathbb{P}(\tau_k < t + 1|\mathcal{F}_{t+1}) = \mathbb{P}(\tau_k < t + 1|X_{k,1:t+1}).$$

On the other hand, according to Lemma D.7, we have

$$\mathbb{P}(\tau_k < t + 1|X_{k,1:t+1}) = \frac{q(X_{k,t+1})/p(X_{k,t+1})}{(1-\theta)(1-W_{k,t})/(\theta + (1-\theta)W_{k,t}) + q(X_{k,t+1})/p(X_{k,t+1})}.$$

Thus, for $k \in S_{t+1}$,

$$W_{k,t+1} = \frac{q(X_{k,t+1})/p(X_{k,t+1})}{(1-\theta)(1-W_{k,t})/(\theta + (1-\theta)W_{k,t}) + q(X_{k,t+1})/p(X_{k,t+1})}. \quad (E.1)$$

Note that $k \in S_{t+1}$ is equivalent to $T_k \geq t + 1$. Thus, (E) holds for $1 \leq t \leq T_k - 1$. Moreover, for $t \geq T_k$,

$$W_{k,t+1} = \mathbb{P}(\tau_k < t + 1|\mathcal{F}_{t+1}) = \mathbb{P}(\tau_k < t|X_{1,1:T_k},T_k) = W_{k,T_k}.$$

This completes our proof.

We proceed to the proofs of propositions.

Proposition 1. Suppose that we obtain the index set $S_{t+1}$ using Algorithm 1, given the index set $S_t$ and information filtration $\mathcal{F}_t$ at time $t$. Then the LPNR at time $t + 1$ satisfies

$$\mathbb{E} \left( \frac{\sum_{k \in S_{t+1}} 1(\tau_k < t)}{|S_{t+1}|} \mid \mathcal{F}_t \right) \leq \alpha.$$
Proof of Proposition 1. First, it is easy to see that $S_{t+1}$ obtained from Algorithm 1 is $\mathcal{F}_t$ measurable. Thus,

$$\mathbb{E}\left(\frac{\sum_{k \in S_{t+1}} 1(\tau_k < t)}{|S_{t+1}| \lor 1} | \mathcal{F}_t \right) = \frac{\sum_{k \in S_{t+1}} W_{k,t}}{|S_{t+1}| \lor 1}.$$

On the other hand, according to the second and third steps of the algorithm,

$$\sum_{k \in S_{t+1}} W_{k,t} = R_n \leq \alpha.$$

Therefore,

$$\mathbb{E}\left(\frac{\sum_{k \in S_{t+1}} 1(\tau_k < t)}{|S_{t+1}| \lor 1} | \mathcal{F}_t \right) \leq \alpha. \quad \square$$

Proposition 2. Let $T_P$ be defined in Algorithm 2. Then, $T_P \in \mathcal{T}_\alpha$.

Proof of Proposition 2. This proposition is proved by combining the results of Proposition 1 and Lemma D.3.

Proposition 3. Given LPNR level $\alpha$ and information filtration $\mathcal{F}_t$, the index set $S_{t+1}$ given by Algorithm 1 is locally optimal at time $t + 1$.

Proof of Proposition 3. Let $S_{t+1}$ be the index set obtained by Algorithm 1. By Lemma D.2, $|S_{t+1}| = I_o([W_{S,t}])$ and $[W_{S_{t+1},t}] = H_o([W_{S,t}])$. There are two cases: 1) $|S_{t+1}| = 0$, and 2) $|S_{t+1}| = n \geq 1$. For the first case, $[W_{S_{t+1},t}] = \emptyset$. Note that

$$\mathbb{E}\left(\frac{\sum_{k \in S} 1(\tau_k < t)}{|S| \lor 1} | \mathcal{F}_t \right) = \frac{\sum_{k \in S} W_{k,t}}{|S| \lor 1}.$$ 

By the ‘Moreover’ part of Lemma D.4, we can see that the only set $S$ satisfying

$$\mathbb{E}\left(\frac{\sum_{k \in S} 1(\tau_k < t)}{|S| \lor 1} | \mathcal{F}_t \right) \leq \alpha$$

is $S = \emptyset$. That is $|S| = 0$. Thus, $|S_{t+1}| \geq |S|$.

For the second case where $|S_{t+1}| = n \geq 1$ and any set $|S|$ satisfying

$$\mathbb{E}\left(\frac{\sum_{k \in S} 1(\tau_k < t)}{|S| \lor 1} | \mathcal{F}_t \right) \leq \alpha,$$

we use Lemma D.4 again and obtain that $[W_{S_{t+1},t}] = H_o([W_{S,t}]) \leq [W_{S,t}]$. This implies $|S_{t+1}| = \dim([W_{S_{t+1},t}]) \geq \dim([W_{S,t}]) = |S|$. \quad \square
F Proof of Theorem 2 and Theorem 3

F.1 Proof of Theorem 2

Theorem 2. Assume that model $\mathcal{M}_s$ holds and Assumption A1 is satisfied. To emphasize the dependence on $K$, we denote the proposed procedure by $\mathcal{P}_K$, the corresponding information filtration at time $t$ by $\mathcal{F}_{K,t}$, and the index set at time $t$ by $\mathcal{S}_{K,t}$. Then, the following results hold for each $t \geq 1$.

1. $\lim_{K \to \infty} \lambda_{K,t} = \lambda_t$ a.s., where $\lambda_{K,t} = \max \{ W_{k,t} : k \in \mathcal{S}_{K,t+1} \}$ is the threshold used by $\mathcal{P}_K$.

2. $\lim_{K \to \infty} \text{LPNR}_{t+1}(\mathcal{P}_K) = \mathbb{E}\left( V_t \mid V_s \leq \lambda_s, 0 \leq s \leq t \right)$, a.s. Moreover,

$$
\mathbb{E}\left( V_t \mid V_s \leq \lambda_s, 0 \leq s \leq t \right) = \begin{cases} 1 - (1 - \theta)^t, & t < \frac{\log(1 - \alpha)}{\log(1 - \theta)}, \\ \alpha, & t \geq \frac{\log(1 - \alpha)}{\log(1 - \theta)}. \end{cases}
$$

3. $\lim_{K \to \infty} K^{-1}|\mathcal{S}_{K,t+1}| = \mathbb{P} (V_1 \leq \lambda_1, \ldots, V_t \leq \lambda_t)$ a.s.

We start with a lemma that is useful for the proof of Theorem 2. Its proof is provided in Section F.3.

Lemma F.1. Under model $\mathcal{M}_s$ and Assumption A1, we have the following results.

1. For each $t \geq 1$, $(V_1, \ldots, V_t)$ has a continuous and strictly positive joint density function over $(0,1)^t$ (with respect to the Lebesgue measure).

2. For any $(v_1, \ldots, v_t) \in (0,1)^t$, $\mathbb{P}(V_1 \leq v_1, \ldots, V_t \leq v_t) > 0$.

3. For any $(v_1, \ldots, v_t) \in (0,1)^t$, the conditional distribution of $V_{t+1}$ given $V_1 \leq v_1, \ldots, V_t \leq v_t$ has a continuous and positive density function over $(0,1)$.

Proof of Theorem 2. For a sufficiently large $t_0$ ($t_0 > t$), let $\mathbb{P}^*$ denote the probability measure for $(V_1, \ldots, V_{t_0})$, and let $\mathbb{Q}$ be an arbitrary probability measure for a $t_0$-dimensional random vector. We define several mappings iteratively as follows. We
initialize the mapping \( \Lambda_0(\mathbb{Q}) = 1 \) for every \( \mathbb{Q} \). Then, for \( t \geq 1 \), define

\[
D_t(\lambda, \mathbb{Q}) = \mathbb{Q}(V_t \leq \lambda, \mathbb{V}_{t-1} \leq \Lambda_{t-1}(\mathbb{Q})) ,
\]

\[
N_t(\lambda, \mathbb{Q}) = \mathbb{E}_{\mathbb{Q}}[\mathbb{I}[V_t \leq \lambda, \mathbb{V}_{t-1} \leq \Lambda_{t-1}(\mathbb{Q})]] ,
\]

\[
G_t(\lambda, \mathbb{Q}) = \frac{N_t(\lambda, \mathbb{Q})}{D_t(\lambda, \mathbb{Q})} = \mathbb{E}_{\mathbb{Q}}[V_t | V_t \leq \lambda, \mathbb{V}_{t-1} \leq \Lambda_{t-1}(\mathbb{Q})] ,
\]

and

\[
\Lambda_t(\mathbb{Q}) = \sup \{ \lambda : G_t(\lambda, \mathbb{Q}) \leq \alpha \text{ and } \lambda \in [0, 1] \} .
\]

In the above equations, we use notation \( \mathbb{V}_t = (V_1, \cdots, V_t) \) and \( \Lambda_t(\mathbb{Q}) = (\Lambda_1(\mathbb{Q}), \cdots, \Lambda_t(\mathbb{Q})) \).

In addition, \( \{ \mathbb{V}_t \leq \Lambda_t(\mathbb{Q}) \} \) denotes the event \( \{ V_1 \leq \Lambda_1(\mathbb{Q}), \cdots, V_t \leq \Lambda_t(\mathbb{Q}) \} \).

The next lemma, whose proof is given in Section [F.3], provides results about the above mappings. For two probability measures \( \mathbb{Q} \) and \( \mathbb{Q}' \) for a \( t_0 \)-dimensional random vector \( \mathbb{V}_t \), their sup-norm is defined as \( \| \mathbb{Q} - \mathbb{Q}' \|_\infty = \sup_{\mathbb{V} \in \mathbb{R}^{t_0}} | \mathbb{Q}(\mathbb{V}_t \leq \mathbb{V}) - \mathbb{Q}'(\mathbb{V}_t \leq \mathbb{V}) | \) . Then, we say a mapping \( f(\mathbb{Q}') \) is sup-norm continuous at \( \mathbb{Q}' = \mathbb{Q} \) if

\[
\lim_{\delta \to 0} \sup_{\| \mathbb{Q}' - \mathbb{Q} \|_\infty \leq \delta} | f(\mathbb{Q}') - f(\mathbb{Q}) | = 0 .
\]

**Lemma F.2.** For each \( 1 \leq t \leq t_0 \), we have the following results.

1. For any fixed \( \mathbb{Q} \), \( G_t(\lambda, \mathbb{Q}) \) is non-decreasing in \( \lambda \). Moreover, \( G_t(\lambda, \mathbb{P}^*) \) is strictly increasing in \( \lambda \in (0, 1] \) under Assumption A1.

2. For any fixed \( \lambda \in (0, 1] \), \( D_t(\lambda, \mathbb{Q}) \), \( N_t(\lambda, \mathbb{Q}) \), and \( G_t(\lambda, \mathbb{Q}) \) are sup-norm continuous in \( \mathbb{Q} \) at \( \mathbb{Q} = \mathbb{P}^* \) under Assumption A1.

3. \( \Lambda_t(\mathbb{Q}) \) is sup-norm continuous at \( \mathbb{Q} = \mathbb{P}^* \) under Assumption A1. In addition, \( \Lambda_t(\mathbb{P}^*) > 0 \).

By definition, \( \lambda_t = \Lambda_t(\mathbb{P}^*) \), where \( \mathbb{P}^* \) denotes the true probability measure of \( (V_1, \cdots, V_{t_0}) \). On the other hand, define the empirical measure (recall \( V_{k,t} = \mathbb{P}(\tau_k < t | X_{k,1}, \cdots, X_{k,t}) \))

\[
\mathbb{P}_K = \frac{1}{K} \sum_{k=1}^{K} \delta_{(V_{k,1}, \cdots, V_{k,t_0})} .
\]
It is not hard to verify that
\[ \hat{\lambda}_{K,t} = \Lambda_t(\mathbb{P}_K). \]

Now we are able to prove the first part of theorem. Let
\[ C = \{ (-\infty, x] : x \in \mathbb{R}^{t_0} \} \]
where \((-\infty, x]\) denotes the set \((-\infty, x_1] \times \cdots \times (-\infty, x_{t_0}]\). It is known that \( C \) is a Vapnik-\v{C}hervonenkis class and thus, \( \lim_{K \to \infty} \sup_{C \in C} |\mathbb{P}_K(V_{t_0} \in C) - \mathbb{P}^*(V_{t_0} \in C)| = 0 \) a.s. (see, e.g., Shorack and Wellner (2009)). In other words,
\[ \lim_{K \to \infty} \|\mathbb{P}_K - \mathbb{P}^*\|_\infty = 0 \text{ a.s.} \quad (F.1) \]

This result combined with the third statement of Lemma \( F.2 \) implies
\[ \lim_{K \to \infty} \Lambda_t(\mathbb{P}_K) = \Lambda_t(\mathbb{P}^*) \text{ a.s.} \]

That is, \( \lim_{K \to \infty} \hat{\lambda}_{K,t} = \lambda_t \) a.s. This completes our proof for the first statement of the theorem. We proceed to the second and third statements of the theorem. Let
\[ J_t(\mathbb{Q}) = \mathbb{E}_\mathbb{Q} \left( V_t 1 \{ V_t \leq \Lambda_t(\mathbb{Q}) \} \right) \text{ and } H_t(\mathbb{Q}) = \mathbb{Q} \left( V_t \leq \Lambda_t(\mathbb{Q}) \right). \]

We can see that the mapping \( H_t \) is the composition of \( D_t(\cdot, \mathbb{Q}) \) and \( \Lambda_t(\mathbb{Q}) \). According to Lemma \( F.1 \) and Lemma \( F.2 \) both mappings are sup-norm continuous at \( \mathbb{Q} = \mathbb{P}^* \), and as a result, their composition \( H_t(\mathbb{Q}) \) is also sup-norm continuous at \( \mathbb{Q} = \mathbb{P}^* \). Similarly, according to Lemma \( F.1 \) and Lemma \( F.2 \), we can also see that \( J_t(\mathbb{Q}) \) is sup-norm continuous at \( \mathbb{Q} = \mathbb{P}^* \).

These results, combined with \( \text{[F.1]} \), give
\[ \lim_{K \to \infty} H_t(\mathbb{P}_K) = H_t(\mathbb{P}^*) \text{ a.s.}, \quad (F.2) \]
and

$$\lim_{K \to \infty} J_t(\mathbb{P}_K) = J_t(\mathbb{P}^*) \text{ a.s.} \quad (F.3)$$

Note that

$$H_t(\mathbb{P}_K) = K^{-1}|S_{t+1}| \quad \text{and} \quad \frac{J_t(\mathbb{P}_K)}{H_t(\mathbb{P}_K)} = \mathbb{E}(\mathbb{P}N\mathbb{P}_{t+1}(T)|\mathcal{F}_t). \quad (F.4)$$

(F.1), (F.1), and (F.1) together complete the second and third statements of the theorem.

In the rest of the proof, we show that (2) holds.

We first show that for $$t \leq L$$:

$$\log \lambda \leq \alpha \log \lambda$$

We show this by induction. For $$t = 0$$, $$\lambda_0 = 1$$ by definition. Assume that for some $$t \geq 1$$, $$\lambda_0 = \cdots = \lambda_{t-1} = 1$$, then

$$G_t(\lambda, \mathbb{P}^*) = \mathbb{E}[V_t|V_t \leq \lambda, \mathbf{V}_{t-1} \leq \mathbf{\Lambda}_{t-1}(\mathbb{P}^*)] = \mathbb{E}[V_t|V_t \leq \lambda].$$

In addition, $$G_t(1, \mathbb{P}^*) = \mathbb{E}(V_t) = \mathbb{P}(\tau_1 < t) = 1 - (1 - \theta)^t \leq \alpha$$ for $$t \leq L$$. By Lemma F.2, we know that $$G_t(\lambda, \mathbb{P}^*)$$ is increasing in $$\lambda$$. Thus,

$$\lambda_t = \sup \{\lambda : G_t(\lambda, \mathbb{P}^*) \leq \alpha \text{ and } \lambda \in [0, 1]\} = 1.$$ 

This completes the induction. As a result, for $$1 \leq t \leq L$$, $$\mathbb{E}[V_t|V_t \leq \lambda_t, \mathbf{V}_{t-1} \leq \mathbf{\Lambda}_{t-1}] = G_t(1, \mathbb{P}^*) = 1 - (1 - \theta)^t$$.

We proceed to the proof of (2) for $$t \geq L$$. Note that $$N_t(\lambda, \mathbb{P}^*)$$ and $$D_t(\lambda, \mathbb{P}^*)$$ are continuous in $$\lambda \in (0, 1)$$ (note that $$\mathbf{V}_t$$ has a joint probability density function by Lemma F.1). Moreover, by Lemma F.2 and Lemma F.1, $$D_t(\lambda, \mathbb{P}^*) > 0$$ for $$\lambda > 0$$. Thus, for each $$t$$, $$G_t(\lambda_t, \mathbb{P}^*) = \alpha$$ is equivalent to

$$G_t(1, \mathbb{P}^*) \geq \alpha. \quad (F.5)$$

We will show (F.1) $$t > L$$ by induction. Let $$[L]$$ be the largest integer smaller or equal
to $L$. According to the definition of $L$, we can see that

$$G_{|L|+1}(1, \mathbb{P}^*) = \mathbb{E}(V_{|L|+1}) = 1 - (1 - \theta)|L| + 1 > \alpha.$$  

This proves the base case for the induction.

Assume that for $1 \leq s \leq t - 1$, $G_s(1, \mathbb{P}^*) > \alpha$. Then,

$$G_t(1, \mathbb{P}^*) = \mathbb{E}[V_t|V_{t-1} \leq \lambda_{t-1}] = \mathbb{E}[\mathbb{E}(V_t|X_{1,1:t-1})|V_{t-1} \leq \lambda_{t-1}], \quad (F.6)$$

where $\lambda_{t-1} = (\lambda_1, \cdots, \lambda_{t-1})$. On the other hand,

$$\mathbb{E}(V_t|X_{1,1:t-1})$$

$$= \mathbb{E}[\mathbb{P}(\tau_1 < t|X_{1,1:t})|X_{1,1:t-1}]$$

$$= \mathbb{P}(\tau_1 < t|X_{1,1:t-1})$$

$$= \mathbb{P}(\tau_1 \leq t - 1|X_{1,1:t-1})$$

$$= \delta_{1,t-1}$$

$$= \theta + (1 - \theta)V_{t-1},$$

where the last two equations are due to Lemma [D.8]. The above display and (F.1) give

$$G_t(1, \mathbb{P}^*) = \mathbb{E}[\theta + (1 - \theta)V_{t-1}|V_{t-1} \leq \lambda_{t-1}] = \theta + (1 - \theta)\mathbb{E}[V_{t-1}|V_{t-1} \leq \lambda_{t-1}].$$

By induction assumption, we have

$$\mathbb{E}[V_{t-1}|V_{t-1} \leq \lambda_{t-1}] = \alpha.$$  

The above two equations give

$$G_t(1, \mathbb{P}^*) = \theta + (1 - \theta)\alpha > \alpha.$$  

This completes our proof. \qed
F.2 Proof of Theorem 3

Theorem 3. Suppose that data follow a special case of the model given in Example 1 when \( \eta = 1 \) and \( \tau_0 \sim \text{Geom}(\theta) \), and Assumption A2 holds. Let

\[
W_t = \mathbb{P} \left( \tau_0 < t \mid X_{k,s}, 1 \leq k \leq K, 1 \leq s \leq t \right),
\]

and

\[
T = \min \{ t : W_t > \alpha \}.
\]

Then, \( \mathbb{P}_K^P = (T, \cdots, T) \). Moreover, the following asymptotic results hold.

1. \( \lim_{K \to \infty} (T - \tau_0) = 1 \) a.s.,
2. \( \lim_{K \to \infty} \text{LPNR}_{t+1}(\mathbb{P}_K^P) = 0 \) a.s.,
3. \( \lim_{K \to \infty} K^{-1} |S_{K,t+1}^P| = \mathbbm{1}(\tau_0 \geq t) \) a.s.

Proof of Theorem 3 We first note that under the model considered in this theorem, \( W_{1,t} = \cdots = W_{K,t} = \mathbb{P}(\tau_0 < t | \mathcal{F}_t) \). Thus, according to \( \mathbb{P}^P \), if \( W_{1,t} \leq \alpha \), then \( \sum_{k \in S_t} W_{t,k} \leq \alpha |S_t| \), and \( S_{t+1} = S_t \). Moreover, if for some \( t \) such that \( S_t = \{1, \cdots, K\} \) and \( W_{1,t+1} > \alpha \), then for any \( S \neq \emptyset \), \( \sum_{k \in |S|} W_{k,t+1} = W_{k,t+1} |S| > \alpha |S| \), and thus \( S_{t+1} = \emptyset \). Thus, \( \mathbb{P}^P = (T, \cdots, T) \). In other words, \( S_t = \{1, \cdots, K\} \) for \( t \leq T \) and \( S_t = \emptyset \) for \( t > T \).

Note that for \( t \leq T \), \( \mathcal{F}_t = \sigma(\{W_{k,s} \mid 1 \leq s \leq t, 1 \leq k \leq K\}) \). Let \( \hat{W}_{k,t} = \mathbb{P}(\tau_0 < t | X_{k,s}, 1 \leq k \leq K, 1 \leq s \leq t) \), which is the conditional probability without deactivating any stream. Then, \( W_{k,t} = \hat{W}_{k,t} \) for \( t \leq T \) where we recall \( T = \inf \{ t : \hat{W}_{1,t} > \alpha \} \). We have

\[
\hat{W}_{k,t} = \frac{\sum_{s=0}^{t-1} \theta \left( 1 - \theta \right)^s \prod_{r=s+1}^{t} \prod_{k=1}^{K} q(X_{k,r})/p(X_{k,r})}{\sum_{s=0}^{t-1} \theta \left( 1 - \theta \right)^s \prod_{r=s+1}^{t} \prod_{k=1}^{K} q(X_{k,r})/p(X_{k,r}) + (1 - \theta)^t}
\]

\[
= \frac{\sum_{s=0}^{t-1} \theta \left( 1 - \theta \right)^s \exp \left( \sum_{k=1}^{K} l_{k,s,t} \right)}{\sum_{s=0}^{t-1} \theta \left( 1 - \theta \right)^s \exp \left( \sum_{k=1}^{K} l_{k,s,t} \right) + (1 - \theta)^t} \tag{F.7}
\]

where we define \( l_{k,s,t} = \sum_{r=s+1}^{t} \log (q(X_{k,r})/p(X_{k,r})) \).
For each \( u \in \mathbb{Z}_+ \cup \{0\} \), let \( A_u = \{ \tau_0 = u \} \). By the strong law of large numbers, under Assumption A2,

\[
P \left( \lim_{K \to \infty} \frac{1}{K} \sum_{k=1}^{K} l_{k,s,t} = \mathbb{E}(l_{1,s,t} | \tau_0 = u) \bigg| A_u \right) = 1
\]  

(F.8)

for each \( s, t, u \in \mathbb{Z}_+ \cup \{0\} \) with \( s < t \). In particular,

\[
\mathbb{E}(l_{1,s,t} | \tau_0 = u) = \begin{cases} 
-(t-s)\mathbb{E}_{Z_1 \sim p} \log(p(Z_1)/q(Z_1)) < 0 & \text{if } t \leq u \\
\mathbb{E}_{Z_2 \sim q} \log(q(Z_2)/p(Z_2)) > 0 & \text{if } t = u + 1 \text{ and } s = u.
\end{cases}
\]

Thus, for each \( s < t \leq u \) we have

\[
P \left( \lim_{K \to \infty} \sum_{k=1}^{K} l_{k,s,t} = -\infty \bigg| A_u \right) = 1,
\]  

(F.9)

and for \( t = u + 1 = s + 1 \),

\[
P \left( \lim_{K \to \infty} \sum_{k=1}^{K} l_{k,s,t} = \infty \bigg| A_u \right) = 1.
\]

According to (F.2), (F.2) and (F.2), we have that for each \( t \leq u \)

\[
P \left( \lim_{K \to \infty} \widetilde{W}_{k,t} = 0 \bigg| A_u \right) = 1.
\]

Moreover, for \( t \geq u + 1 \),

\[
P \left( \lim_{K \to \infty} \widetilde{W}_{k,t} = 1 \bigg| A_u \right) = 1.
\]

Combining the above two equations for different \( u \in \mathbb{Z}_+ \cup \{0\} \), we arrive at

\[
P \left( \lim_{K \to \infty} \widetilde{W}_{k,t} = 1 \bigg( t \geq \tau_0 + 1 \right) = 1.
\]

In other words,

\[
\lim_{K \to \infty} \widetilde{W}_{1,t} = 1 \big( t \geq \tau_0 + 1 \) \ a.s.
\]
Now we turn to the analysis of $W_{k,t}$ and $S_t$ for the proposed procedure. Let $\omega$ be a sample path with $\lim_{K \to \infty} \tilde{W}_{k,t}(\omega) = 1(t \geq \tau_0(\omega) + 1)$ for all $t = 1, 2, \cdots$. Then, there exists $K_0(\omega)$ large enough such that $\tilde{W}_{1,t}(\omega) < \alpha$ for $t \leq \tau_0(\omega)$ and $\tilde{W}_{1,\tau_0(\omega)+1}(\omega) > \alpha$ for all $K \geq K_0(\omega)$. Then, we have $T(\omega) = \inf\{t : \tilde{W}_{1,t}(\omega) > \alpha\} = \tau_0(\omega) + 1$. Note that the set of such sample path $\omega$ has a probability of one. Thus,

$$\lim_{K \to \infty} (T - \tau_0) = 1$$

$$\lim_{K \to \infty} W_{k,t} = 0$$

for $t \leq \tau_0$ a.s.

This proves the first statement of the theorem. For the second statement, we have

$$\lim_{K \to \infty} \mathbb{E} \{P_{N^t+1}(\mathcal{T}^P)|\mathcal{F}_t\} = \lim_{K \to \infty} \frac{\sum_{k=1}^{K} 1(T > t)W_{k,t}}{\sum_{k=1}^{K} 1(T > t)} \lor 1 = \lim_{K \to \infty} W_{k,t} 1(T > t) = 0$$

a.s.

For the third statement, we have

$$\lim_{K \to \infty} K^{-1}|S_{t+1}| = \lim_{K \to \infty} 1(T > t) = 1(\tau_0 \geq t)$$

a.s.

F.3 Proof of supporting lemmas in Section F.1

Lemma F.1. Under model $\mathcal{M}_s$ and Assumption A1, we have the following results.

1. For each $t \geq 1$, $(V_1, \cdots, V_t)$ has a continuous and strictly positive joint density function over $(0,1)^t$ (with respect to the Lebesgue measure).

2. For any $(v_1, \cdots, v_t) \in (0,1)^t$, $\mathbb{P}(V_1 \leq v_1, \cdots, V_t \leq v_t) > 0$.

3. For any $(v_1, \cdots, v_t) \in (0,1)^t$, the conditional distribution of $V_{t+1}$ given $V_{1} \leq v_1, \cdots, V_t \leq v_t$ has a continuous and positive density function over $(0,1)$.

Proof of Lemma F.1. Note that the second statement of the lemma is obvious given the first statement, and the third statement is a straightforward application of a combination of the first and second statements. Thus, it suffices to show the first statement of the lemma. In what follows, we prove the first statement by induction.
For $Z_1$ follow the density function $p(\cdot)$, $Z_2$ follows the density function $q(\cdot)$, let $f_1(\cdot)$ and $f_2(\cdot)$ be the density functions of $q(Z_1)/p(Z_1)$ and $q(Z_2)/p(Z_2)$. By Assumption A1, $f_i(z) > 0$ for all $z > 0$ and $i = 1, 2$.

For $t = 1$, under the model $\mathcal{M}_t$, $X_{1,1}$ follows the mixture density $(1 - \theta)p(\cdot) + \theta q(\cdot)$. Thus, $q(X_{1,1})/p(X_{1,1})$ has the density function $(1 - \theta)f_1 + \theta f_2$, which is strictly positive and continuous over $\mathbb{R}_+$. Note that $V_1 = \frac{q(X_{1,1})/p(X_{1,1})}{(1 - \theta)p + \theta q}$. By standard calculation of density of random variable after transformation, we can see that the density of $V_1$ is

$$f_{V_1}(v) = \frac{c}{(1 - v)^2} \left\{ (1 - \theta)f_1 \left( \frac{cv}{1 - v} \right) + \theta f_2 \left( \frac{cv}{1 - v} \right) \right\}, \quad (F.10)$$

where $c = (1 - \theta)/\theta$. This density function is strictly positive and continuous for $v \in (0, 1)$.

Assume the induction assumption that the joint density for $(V_1, \cdots, V_t)$, denoted by $f_{V_1,\cdots,V_t}(v_1, \cdots, v_t)$, is strictly positive and continuous over $(0,1)^t$. We proceed to showing $f_{V_1,\cdots,V_{t+1}}(v_1, \cdots, v_{t+1})$ is strictly positive and continuous over $(0,1)^{t+1}$. Recall that $V_{t+1} = \frac{q(X_{t+1,1})/p(X_{t+1,1})}{(1 - \theta)p + \theta q}$. With a similar derivation as that for [F.3], we have the conditional density of $V_{t+1}$ given $V_1 = v_1, \cdots, V_t = v_t$ is

$$f_{V_{t+1}|V_1=v_1,\cdots,V_t=v_t}(v) = \frac{c_t}{(1 - v)^2} \left\{ (1 - \theta_t)f_1 \left( \frac{c_tv}{1 - v} \right) + \theta_t f_2 \left( \frac{c_tv}{1 - v} \right) \right\},$$

where we define $c_t = \frac{(1 - \theta)(1 - v_t)}{\theta + (1 - \theta)v_t} > 0$ and $\theta_t = \mathbb{P}(\tau_1 \leq t | V_1 = v_1, \cdots, V_t = v_t) = v_t(1 - \theta) + \theta \in (0, 1)$. It is easy to see that both $c_t$ and $\theta_t$ are continuous in $v_t$. As a result, $f_{V_{t+1}|V_1=v_1,\cdots,V_t=v_t}(v_{t+1})$ is strictly positive and is continuous in $v_1, \cdots, v_{t+1}$ for $v_1, \cdots, v_{t+1} \in (0,1)$ and so $f_{V_1,\cdots,V_{t+1}}(v_1, \cdots, v_{t+1}) = f_{V_1,\cdots,V_{t}}(v_1, \cdots, v_{t})f_{V_{t+1}|V_1=v_1,\cdots,V_t=v_t}(v_{t+1})$.

This completes our induction and the proof of the lemma.

Lemma F.2. For each $1 \leq t \leq t_0$, we have the following results.

1. For any fixed $Q$, $G_t(\lambda, Q)$ is non-decreasing in $\lambda$. Moreover, $G_t(\lambda, \mathbb{P}^*)$ is strictly increasing in $\lambda \in (0, 1]$ under Assumption A1.
2. For any fixed $\lambda \in (0, 1)$, $D_t(\lambda, Q)$, $N_t(\lambda, Q)$, and $G_t(\lambda, Q)$ are sup-norm continuous in $Q$ at $Q = P^*$ under Assumption A1.

3. $\Lambda_t(Q)$ is sup-norm continuous at $Q = P^*$ under Assumption A1. In addition, $\Lambda_t(P^*) > 0$.

Proof of Lemma F.2. For $t = 0, 1, \cdots$ and $\lambda < \lambda'$, let $\tilde{V}$ be a random variable following the same distribution as $V_t | V_{t-1} \leq \Lambda_{t-1}(Q)$. Then, by the definition of conditional expectation, we have

$$G_t(\lambda', Q) - G_t(\lambda, Q) = Z^{-1} \left[ E_Q \left( \tilde{V} 1 \{ \tilde{V} \leq \lambda' \} \right) Q \left( \tilde{V} \leq \lambda \right) - E_Q \left( \tilde{V} 1 \{ \tilde{V} \leq \lambda \} \right) Q \left( \tilde{V} \leq \lambda' \right) \right]$$

where $Z = Q \left( \tilde{V} \leq \lambda \right) Q \left( \tilde{V} \leq \lambda' \right)$. Let $\tilde{V}'$ be an independent copy of $\tilde{V}$, then the above display implies

$$G_t(\lambda', Q) - G_t(\lambda, Q) = Z^{-1} \left[ E_Q \left( \tilde{V}' 1 \{ \lambda < \tilde{V}' \leq \lambda', \tilde{V} \leq \lambda \} \right) - E_Q \left( \tilde{V} 1 \{ \lambda < \tilde{V} \leq \lambda' \} \right) \right] \leq 0,$$

because $\tilde{V}' - \tilde{V} 1 \{ \lambda < \tilde{V}' \leq \lambda', \tilde{V} \leq \lambda \} \geq 0$. From the above display we get

$$G_t(\lambda', Q) - G_t(\lambda, Q) \geq 0.$$

Because $\tilde{V}' - \tilde{V} 1 \{ \lambda < \tilde{V}' \leq \lambda', \tilde{V} \leq \lambda \} \geq 0$, $G_t(\lambda', Q) - G_t(\lambda, Q) \geq 0$ from the above display.

In what follows, we use induction to prove the rest of the lemma. Namely, for $\lambda \in (0, 1)$, we will prove the following statements for $t = 1, 2, \cdots, t_0$:

$$G_t(\lambda, P^*) \text{ is strictly increasing in } \lambda; \quad (F.12)$$

$$D_t(\lambda, Q), N_t(\lambda, Q), \text{ and } G_t(\lambda, Q) \text{ are sup-norm continuous at } Q = P^*; \quad (F.13)$$

$$\Lambda_t(Q) \text{ is sup-norm continuous at } Q = P^*. \quad (F.14)$$

We start with the base case that $t = 1$. In this case, the conditional distribution
$V_1 | V_0 \leq \mathbf{A}_0(Q)$ is the same as the unconditional distribution of $V_1$ for any $Q$. According to Lemma F.1, $V_1$ has a strictly positive and continuous density function over $(0,1)$ under $\mathbb{P}^*$. Thus, $\mathbb{P}^* \left( \left( \hat{V}' - \hat{V} \right) 1 \{ \lambda < \hat{V}' \leq \lambda', \hat{V} \leq \lambda \} \geq 0 \right) > 0$ for $\hat{V}$ and $\hat{V}'$ are identically distributed as $V_1$. According to (F.3), $G_1(\lambda', \mathbb{P}^*) - G_1(\lambda, \mathbb{P}^*) > 0$. That is, $G_1(\lambda, \mathbb{P}^*)$ is strictly increasing in $\lambda$. This proves the base case for (F.3). For (F.3) and (F.3) the proof of the base cases is similar to that of the induction given below. Thus, we omit the proof for their base cases here.

Now we assume that (F.3), (F.3), and (F.3) hold for $t = 1, 2, \cdots, s - 1$. We proceed to prove these equations for $t = s$. First, note that $V_t | V_{t-1} \leq \mathbf{A}_{t-1}(\mathbb{P}^*)$ has a continuous and strictly positive density function over $(0,1)$. Thus, (F.3) is proved by combining (F.3) with similar arguments as those for the base case where $t = 1$.

**Proof of (F.3) for $t = s$.** By the induction assumption, $\Lambda_1(Q), \cdots, \Lambda_{s-1}(Q)$ is sup-norm continuous in $Q$ at $Q = \mathbb{P}^*$. This implies that $(\lambda, \Lambda_{s-1}(Q))$, a vector-valued mapping, is also sup-norm continuous in $Q$ at $Q = \mathbb{P}^*$. On the other hand, $(\lambda, \Lambda_{s-1}(\mathbb{P}^*)) \in (0,1]^s$ by induction assumptions, and $V_t$ has a continuous joint probability cumulative function at $(\lambda, \Lambda_{s-1}(\mathbb{P}^*))$ (by Lemma F.1). Combining these results, we can see that $\mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q))$ is sup-norm continuous at $Q = \mathbb{P}^*$.

Now we analyze the mapping $D_s(\lambda, Q) = Q (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q))$.

$$
|D_s(\lambda, Q) - D_s(\lambda, \mathbb{P}^*)| \\
= |Q (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) - \mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(\mathbb{P}^*))| \\
\leq |Q (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) - \mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(\mathbb{P}^*))| \\
+ |\mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) - \mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(\mathbb{P}^*))| \\
\leq \|Q - \mathbb{P}^*\|_\infty \\
+ |\mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) - \mathbb{P}^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(\mathbb{P}^*))|.
$$
Therefore,

\[
\limsup_{\|Q - P^*\|_\infty \to 0} |D_s(\lambda, Q) - D_s(\lambda, P^*)| = \lim_{\|Q - P^*\|_\infty \to 0} \|Q - P^*\|_\infty \\
+ \lim_{\|Q - P^*\|_\infty \to 0} |P^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) - P^* (V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(P^*))|
\]

= 0.

That is, \(D_s(\lambda, Q)\) is sup-norm continuous at \(P^*\). Moreover, by Lemma F.1 and \((\lambda, \Lambda_{s-1}(P^*)) \in (0, 1]^s\), we have \(D_s(\lambda, P^*) > 0\). This further implies that \(D_s(\lambda, Q)^{-1}\) is also sup-norm continuous at \(P^*\).

We proceed to the analysis of \(N_s(\lambda, Q)\). We have

\[
N_s(\lambda, Q) = \mathbb{E}_Q \left[ V_s \mathbb{1} \{V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)\} \right] \\
= \mathbb{E}_Q \left[ \int_0^1 \mathbb{1}\{r < V_s\} dr \mathbb{1} \{V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)\} \right] \\
= \int_0^1 Q (r < V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) dr \\
= \int_0^\lambda \mathbb{Q}(V_s \leq \lambda, V_{s-1} \leq \Lambda_{s-1}(Q)) dr \\
- \int_0^\lambda \mathbb{Q}(V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q)) dr \\
= D_s(\lambda, Q) - \int_0^\lambda D_s(r, Q) dr
\]

We have already shown that the first term \(D_s(\lambda, Q)\) on the right-hand side of the above
display is sup-norm continuous at $P^*$. We take a closer look at the second term,

$$\left| \int_0^\lambda D_s(r, Q)dr - \int_0^\lambda D_s(r, P^*)dr \right|$$

$$\leq \int_0^\lambda |Q (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q)) - P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q))| dr$$

$$+ \int_0^\lambda |P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q)) - P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(P^*))| dr (F.16)$$

$$\leq \|Q - P^*\|_\infty$$

$$+ \int_0^\lambda |P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q)) - P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(P^*))| dr$$

Since $\Lambda_{s-1}(Q)$ is sup-norm continuous at $Q = P^*$, for any $\varepsilon > 0$, there exists $\delta > 0$ such that $\|Q - P^*\|_\infty \leq \delta$ implies $\|\Lambda_{s-1}(Q) - \Lambda_{s-1}(P^*)\| \leq \varepsilon$. Then, for each $r \in [0,1]$ and $\|Q - P^*\|_\infty \leq \delta$, $\|(r, \Lambda_{s-1}(Q)) - (r, \Lambda_{s-1}(P^*))\| \leq \varepsilon$, and

$$\sup_{\|Q - P^*\| \leq \delta} \|P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(Q)) - P^* (V_s \leq r, V_{s-1} \leq \Lambda_{s-1}(P^*))\|$$

$$\leq \sup_{\|v_s - v_s'\| \leq \varepsilon} \|P^* (V_s \leq v_s) - P^* (V_s \leq v_s')\|$$

$$\leq \varepsilon (0,1)$$

By Lemma [F.1], $V_s$ has a continuous density function. Thus, its cumulative distribution function, $P^* (V_s \leq v_s)$, is continuous over $[0,1]^s$. As $[0,1]^s$ is compact, this continuity implies that the cumulative distribution is also uniformly continuous over $[0,1]^s$. That is, for any $\varepsilon_1$ small enough, there is $\varepsilon > 0$, such that

$$\sup_{\|v_s - v_s'\| \leq \varepsilon, v_s, v_s' \in [0,1]^s} \|P^* (V_s \leq v_s) - P^* (V_s \leq v_s')\| \leq \varepsilon_1.$$  

Combine the above inequality with (F.3) and (F.3), we can see that for any $\varepsilon_1 > 0$, there is $0 < \delta < \varepsilon_1$ such that for $\|Q - P^*\|_\infty \leq \delta$,

$$\left| \int_0^\lambda D_s(r, Q)dr - \int_0^\lambda D_s(r, P^*)dr \right| \leq \delta + \varepsilon_1 \leq 2\varepsilon_1.$$  

Therefore, $\int_0^\lambda D_s(r, Q)dr$ is sup-norm continuous at $Q = P^*$. This result, combined with (F.3), shows that $N_s(\lambda, Q)$ is sup-norm continuous at $Q = P^*$. 

72
Finally, the sup-norm continuity of $G_s(\lambda, Q)$ is implied by that of $D_s(\lambda, Q)^{-1}$ and $N_s(\lambda, Q)$ for $\lambda \in (0, 1]$.

**Proof of (F.3) for $t = s$.** Recall $\Lambda_s(Q) = \sup \{ \lambda : G_s(\lambda, Q) \leq \alpha \text{ and } \lambda \in [0, 1] \}$.

We discuss two cases.

**Case 1:** $\Lambda_s(\mathbb{P}^*) = 1$. For any sufficiently small $\epsilon > 0$, by the strict increasing property of $G_s(\lambda, \mathbb{P}^*)$ there exists $\epsilon_1 > 0$ such that $G_s(\lambda', \mathbb{P}^*) < G_s(\Lambda_s(\mathbb{P}^*), \mathbb{P}^*) - 2\epsilon_1$ for all $\lambda' \leq \Lambda_s(\mathbb{P}^*) - \epsilon$. On the other hand, according to the sup-norm continuity of $G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, Q)$ at $Q = \mathbb{P}^*$, there exists $\delta > 0$ such that $|G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, Q) - G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, \mathbb{P}^*)| \leq \epsilon_1$ for all $\|Q - \mathbb{P}^*\|_{\infty} \leq \delta$. Then, for all $\|Q - \mathbb{P}^*\|_{\infty} \leq \delta$ and $\lambda' \leq \Lambda_s(\mathbb{P}^*) - \epsilon$, we have

$$
G_s(\lambda', Q) \\
\leq G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, Q) \\
\leq G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, \mathbb{P}^*) + |G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, Q) - G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, \mathbb{P}^*)| \\
\leq G_s(\Lambda_s(\mathbb{P}^*) - \epsilon, \mathbb{P}^*) + \epsilon_1 \\
\leq G_s(\Lambda_s(\mathbb{P}^*), \mathbb{P}^*) - \epsilon_1 \\
\leq \alpha - \epsilon_1.
$$

This implies $1 - \epsilon = \Lambda_s(\mathbb{P}^*) - \epsilon \leq \Lambda_s(Q) \leq 1$ for all $\|Q - \mathbb{P}^*\|_{\infty} \leq \delta$.

**Case 2:** $\Lambda_s(\mathbb{P}^*) < 1$. Using similar arguments as those for the Case 1, we arrive at that for any $\epsilon > 0$ there exists $\delta > 0$ such that $\Lambda_s(\mathbb{P}^*) - \epsilon \leq \Lambda_s(Q)$ for all $\|Q - \mathbb{P}^*\|_{\infty} \leq \delta$.

We proceed to an upper bound of $\Lambda_s(Q)$.

Note that in this case, $G_s(\Lambda_s(\mathbb{P}^*), \mathbb{P}^*) = \alpha$. According to the definition of $\Lambda_s(\mathbb{P}^*)$, for any $\epsilon > 0$, then there exists $\epsilon_1 > 0$ such that $G_s(\lambda', \mathbb{P}^*) > \alpha + 2\epsilon_1$ for all $\lambda' \geq \Lambda_s(\mathbb{P}^*) + \epsilon$. On the other hand, according to the sup-norm continuity of $G_s(\Lambda_s(\mathbb{P}^*) + \epsilon, Q)$ at $Q = \mathbb{P}^*$, there exists $\delta$ such that $|G_s(\Lambda_s(\mathbb{P}^*) + \epsilon, Q) - G_s(\Lambda_s(\mathbb{P}^*) + \epsilon, \mathbb{P}^*)| \leq \epsilon_1$.
for all \( \|Q - P^*\|_\infty \leq \delta \). Then, for all \( \|Q - P^*\|_\infty \leq \delta \) and \( \lambda' > \Lambda_s(P^*) + \varepsilon \), we have

\[
G_s(\lambda', Q) \\
\geq G_s(\Lambda_s(P^*) + \varepsilon, Q) \\
\geq \alpha + 2\varepsilon_1 - |G_s(\Lambda_s(P^*) + \varepsilon, Q) - G_s(\Lambda_s(P^*) + \varepsilon, P^*)| \\
\geq \alpha + \varepsilon_1.
\]

This implies that for \( \lambda' > \Lambda_s(P^*) + \varepsilon \) and \( \|Q - P^*\|_\infty \leq \delta \), \( G_s(\lambda', Q) > \alpha \). Thus, \( \Lambda_s(Q) \leq \Lambda_s(P^*) + \varepsilon \) for \( \|Q - P^*\|_\infty \leq \delta \). Combining the upper bound and lower bound of \( \Lambda_s(Q) \), we arrive at

\[
|\Lambda_s(Q) - \Lambda_s(P^*)| \leq \varepsilon
\]

for \( \|Q - P^*\|_\infty \leq \delta \).

This completes the proof of (F.3).

Finally, we show \( \Lambda_t(P^*) > 0 \). This is true because \( G_t(\lambda, P^*) \) is continuous and strictly increasing in \( \lambda \) and \( \lim_{\lambda \to 0^+} G_t(\lambda, P^*) = 0 < \alpha \).

\( \square \)

G  Calculations for Example 3

We start with calculating \( \mathbb{P}(\tau_k = 0|X_{k,1} = x_{k,1}, \ldots, X_{k,t} = x_{k,t}) \). Let \( t_1 = t_4 = 3 \) and \( t_2 = t_3 = 1 \). Under the model specified in the example, we have \( \tau_k = 0 \) or \( \tau_k = t_k \) a.s. for \( k = 1, \ldots, 4 \). As a result, we have

\[
\mathbb{P}(\tau_k \leq t - 1|X_{k,1} = x_{k,1}, \ldots, X_{k,t} = x_{k,t}) = 1
\]

for \( t \geq t_k + 1 \).

To simplify the calculation for the other cases, we first prove the following auxiliary result: under the model specified in this example, for any \( x_{k,1}, \ldots, x_{k,t} \in \{0, 1\} \) and
Indeed, direct calculation gives

\[ P(\tau_k \leq t-1|X_{k,1} = x_{k,1}, \ldots, X_{k,t} = x_{k,t}) = P(\tau_k = 0)(0.51)^{\sum_{s=1}^{t} x_{k,t}}(0.49)^{t-\sum_{s=1}^{t} x_{k,t}} + P(\tau_k = t_k)(0.5)^t. \]  

(G.1)

The above display is monotonically increasing in \( \sum_{s=1}^{t} x_{k,t} \). Thus, (G) is proved.

Let \( \tilde{W}_{k,t} = P(\tau_k \leq t-1|X_{k,1} = x_{k,1}, \ldots, X_{k,t} = x_{k,t}) \). Using (G) and (G), we obtain that for \( 0 \leq t \leq t_k \),

\[ \tilde{W}_{k,t} \in \left[ \frac{P(\tau_k = 0)(0.49)^{t}}{P(\tau_k = 0)(0.49)^{t} + P(\tau_k = t_k)(0.5)^{t}} \right] \cdot \left[ \frac{P(\tau_k = 0)(0.51)^{t}}{P(\tau_k = 0)(0.51)^{t} + P(\tau_k = t_k)(0.5)^{t}} \right]. \]

Plugging \( P(\tau_k = 0) \) and \( P(\tau_k = t_k) = 1 - P(\tau_k = 0) \) into the above equations, we obtain that \( \tilde{W}_{k,t} = 1 \) for \( t \geq 4 \), and for \( 0 \leq t \leq 3 \), the a.s. range of \( \tilde{W}_{k,t} \)'s are given below (numbers are rounded to the third decimal place).

<table>
<thead>
<tr>
<th>( \tilde{W}_{k,t} )</th>
<th>( t = 1 )</th>
<th>( t = 2 )</th>
<th>( t = 3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( k = 1 )</td>
<td>[0.098, 0.102]</td>
<td>[0.096, 0.104]</td>
<td>[0.095, 0.105]</td>
</tr>
<tr>
<td>( k = 2 )</td>
<td>[0.395, 0.405]</td>
<td>{1}</td>
<td>{1}</td>
</tr>
<tr>
<td>( k = 3 )</td>
<td>[0.425, 0.435]</td>
<td>{1}</td>
<td>{1}</td>
</tr>
<tr>
<td>( k = 4 )</td>
<td>[0.545, 0.555]</td>
<td>[0.540, 0.560]</td>
<td>[0.535, 0.565]</td>
</tr>
</tbody>
</table>
With these numbers, the following inequalities can be verified.

\[
\tilde{W}_{1,1} < \alpha < \tilde{W}_{2,1} < \tilde{W}_{3,1} < \tilde{W}_{4,1},
\]
\[
\frac{1}{3} (\tilde{W}_{1,1} + \tilde{W}_{2,1} + \tilde{W}_{3,1}) \leq 0.314 < \alpha = 0.34,
\]
\[
\frac{1}{3} (\tilde{W}_{1,1} + \tilde{W}_{2,1} + \tilde{W}_{4,1}) \geq 0.346 > \alpha
\]
\[
\frac{1}{2} (\tilde{W}_{1,1} + \tilde{W}_{4,1}) \leq 0.329 < \alpha.
\]

The above inequalities implies that \(E[\text{PNP}_2(T)\mid F_1] \leq \alpha\) is equivalent to

\[
S_2 \in \{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{1, 4\}, \{1\}, \emptyset\}. \]

Now we consider \(S_3\). We can verify the following inequalities.

\[
\tilde{W}_{1,2} < \alpha < \tilde{W}_{4,2} < \tilde{W}_{2,2} = \tilde{W}_{3,2},
\]
\[
\frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{2,2}) = \frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{3,2}) \geq 0.548 > \alpha
\]
\[
\frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{4,2}) \leq 0.332 < \alpha.
\]

The above inequalities implies that \(E[\text{PNP}_3(T)\mid F_2] \leq \alpha\) is equivalent to that \(S_3 \subset S_2\) and

\[
S_3 \in \{\{1, 4\}, \{1\}, \emptyset\}. \]

Similarly, for \(S_4\), we have

\[
\tilde{W}_{1,3} < \alpha < \tilde{W}_{4,3} < \tilde{W}_{2,3} = \tilde{W}_{3,3},
\]
\[
\frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{2,2}) = \frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{3,2}) \geq 0.547 > \alpha
\]
\[
\frac{1}{2} (\tilde{W}_{1,2} + \tilde{W}_{4,2}) \leq 0.336 < \alpha.
\]

This implies that \(E[\text{PNP}_4(T)\mid F_3] \leq \alpha\) is equivalent to that \(S_4 \subset S_3\) and

\[
S_4 \in \{\{1, 4\}, \{1\}, \emptyset\}. \]
Finally, since $\tilde{W}_{k,t} = 1$ for all $t \geq 4$ and $k = 1, \cdots, 4$, we obtain $S_t = \emptyset$ for $t \geq 5$.

Enumerating all the index sets satisfying the constraint, we obtain that $\sup_{T \in \mathcal{T}_a} \mathbb{E}(U_2(T)) = 7$ and the maximum achieved if and only if $S_1 = \{1, 2, 3, 4\}$ and $S_2 = \{1, 2, 3\}$. In addition, $\sup_{T \in \mathcal{T}_a} \mathbb{E}(U_4(T)) = 10$ and the maximum is achieved if and only if $S_1 = \{1, 2, 3, 4\}$, $S_2 = \{1, 4\}$, $S_3 = \{1, 4\}$ and $S_4 = \{1, 4\}$. However, these two maxima cannot be achieved at the same time as they require different choices of $S_2$.
