Estimator-Based Output-Feedback Stabilization of Linear Multi-Delay Systems using SOS

Shuangshuang Wu, Matthew M. Peet, Changchun Hua

Abstract—In this paper, we investigate the estimator-based output feedback control problem of multi-delay systems. This work is an extension of recently developed operator-value LMI framework for infinite-dimensional time-delay systems. Based on the optimal convex state feedback controller and generalized Luenberger observer synthesis conditions we already have, the estimator-based output feedback controller is designed to contain the estimates of both the present state and history of the state. An output feedback controller synthesis condition is proposed using SOS method, which is expressed in a set of LMIs/SOS constraints. The simulation examples are displayed to demonstrate the effectiveness and advantages of the proposed results.

I. INTRODUCTION

Time delay widely exists in natural and engineered systems, often as a source of instability. Many works have been done on the study and control of time-delay systems during the last decades [1], [2], mainly focusing on stability analysis, such as [3] and [4]. Despite the considerable advances that have been made in the area of stability analysis, the problem of stabilization of time-delay systems has been relatively neglected [2], [5]. The primary problem in feedback stabilization of time-delay systems is the bilinearity between the controller and the Lyapunov certificate of stability. This bilinearity implies that combining parameterized controllers with standard approaches to Lyapunov–Krasovskii functional construction will result in Bilinear Matrix Inequalities – a problem for which no efficient optimization algorithms exist. Faced with this bilinearity, some papers use iterative methods to alternately optimize the Lyapunov functional and then the controller as in [6], [7]. However, this iterative approach is not guaranteed to converge. Recently, however, duality-based methods have been proposed within the SOS-based operator-theoretic framework – resulting in an LMI-based solution to the problem of $H_\infty$-optimal full-state-feedback control of multi-delay systems [8]. The primary disadvantage of the full-state feedback controllers proposed in [8] is that they assume accurate knowledge of all states of the system and moreover knowledge of the history of these states.

Specifically, the controllers have the form

\[
 u(t) = K_0 x(t) + \sum_{i=1}^{K_1} K_1 i x(t - \tau_i) + \sum_{i=1}^{K_2} K_2 i (s) x(t + s) ds
\]

where the $H_\infty$-optimal controller gains $K_0, K_1, K_2$ are polynomials chosen to minimize the closed-loop $L_2$-gain bound $\gamma := \sup_{\omega \in L_2} \|L_\omega\|_{L_2}$. This formulation specifically precludes output-feedback controllers of the form $u(t) = K y(t)$ or even $u(t) = K x(t)$. In most practical cases such detailed measurements are not available.

The question of how to use measured outputs to reconstruct the full state is that of estimator design and is itself an area of active study (e.g. the Smith predictor can be thought of as an estimator using delayed output signals [10]). The $H_\infty$-optimal estimator design problem for multi-delay systems was itself directly addressed in the SOS-operator framework in [9], wherein the observer is a simulated PDE running parallel to the real system which corrects both the present states and the history of the states. This observer minimizes an $L_2$-gain bound on the effect of disturbances on a regulated error signal.

In this paper, we propose a framework for using controllers of the form in Eqn. (1) where the controller acts not on the full state, but the state estimate derived from a dynamic estimator constructed using the algorithm proposed in [9]. Specifically, the closed-loop dynamics have the form

\[
 \dot{x}(t) = A_0 x(t) + \sum_{i=1}^{K_1} A_i x(t - \tau_i) + B_1 w(t) + B_2 u(t)
\]

\[
 \dot{\hat{x}}(t) = A_0 \dot{x}(t) + \sum_{i=1}^{K_1} A_i \dot{\hat{x}}(t - \tau_i) + L_1 b_0(t)
\]

\[
 + \sum_{i=1}^{K_1} L_2 i b_i(t, -\tau_i) + \sum_{i=1}^{K_2} L_3 i b_3(s) b_i(t, s) ds
\]

\[
 \partial_\theta \phi(t, s) = \partial_\theta \phi(t, s) + L_4(s) b_0(t) + \sum_{i=1}^{K_1} L_5 i b_j(t, -\tau_i)
\]

\[
 + L_6(s) b_i(t, s) + \sum_{i=1}^{K_1} \int_{-\tau_i}^{0} L_7 i (\tau, \theta) b_j(t, \theta) d\theta
\]

\[
 \hat{\phi}_i(t, 0) = \hat{x}(t) \quad b_i(t, s) = C_2 \phi_i(t, s) - y(t + s)
\]

\[
 b_0(t) = C_2 \hat{x}(t) - y(t)
\]

\[
 u(t) = K_0 x(t) + \sum_{i=1}^{K_1} K_1 i x(t - \tau_i) + \sum_{i=1}^{K_2} K_2 i (s) x(t + s) ds
\]

\[
 y(t) = C_2 x(t) + D_2 w(t)
\]

\[
 z(t) = C_1_0 x(t) + \sum_{i=1}^{K_1} C_1 i x_i(t - \tau_i) + D_1 w(t)
\]

\[
 z_e(t) = C_3_0 e(t) + \sum_{i=1}^{K_1} C_3 i e_i(t, -\tau_i) + D_3 w(t)
\]
where $x(t) \in \mathbb{R}^n$ is the state, $\dot{x}(t) \in \mathbb{R}^n$ is the estimate of state, $\hat{\phi}(t, s) \in \mathbb{R}^n$ is the estimate of history of state, $w \in L^p_2$ is an external disturbance input, $u(t) \in \mathbb{R}^m$ is the actuated input, $y(t) \in \mathbb{R}^q$ is the measured output, $z(t) \in \mathbb{R}^p$ is the regulated output, $z_e(t) \in \mathbb{R}^{p^i}$ is the estimated error of regulated output (not need to be $z(t)$ defined above). The delays $\tau_i > 0$ for $i \in \{1, \ldots, K\}$ are ordered by increasing magnitude and $A_0, A_1, B_1, B_2, C_{10}, C_{11}, C_2, C_{30}, C_{31}, D_1, D_2, D_3$ are constant matrices with appropriate dimensions. We assume $x(0) = \dot{x}(t) = 0$ for all $s \in [-\tau_K, 0]$. The gains $K_0, K_1, K_2$ come from [8] and the gains $L_0, L_1, L_2, L_3, L_4, L_5, L_6$ come from [9]. By exploiting the properties of the gains and examining the dynamics of the closed-loop system, we show that the resulting dynamics are stable and establish a bound on the $H_{\infty}$-gain of the resulting closed-loop system. We furthermore propose a scheme for real-time numerical implementation of the observer-based controller and use numerical simulation to show that the resulting closed-loop system achieves internal stabilization.

A. Notation

Shorthand notation used throughout this paper includes the Hilbert spaces $L^2_2[X] := L_2(X; \mathbb{R}^m)$ of square integrable functions from $X$ to $\mathbb{R}^m$ and $W^{1,2}_2[X] := W^{1,2}(X; \mathbb{R}^m) = H^1(X; \mathbb{R}^m) = \{x : x, \dot{x} \in L^2_2[\{x]\}\}$. We use $L^2_2, W^{1,2}_2$ when domains are clear from context. We also use the extensions $L^{2,\infty}_2[X] := L_2(X; \mathbb{R}^{m \times n})$ and $W^{1,2}_2[X] := W^{1,2}(X; \mathbb{R}^{n \times m})$ for matrix-valued functions. $S^n \subset \mathbb{R}^{n \times n}$ denotes the symmetric matrices. An operator $P : Z \to Z$ is positive on a subset $X$ of Hilbert space $Z$ if $\langle x, Px \rangle \geq 0$ for all $x \in X$. $P$ is coercive on $X$ if $\langle x, Px \rangle \geq \epsilon \|x\|_Z^2$ for some $\epsilon > 0$ for all $x \in X$. Given an operator $P : Z \to Z$ and a set $X \to Z$, we use the shorthand $P(X)$ to denote the image of $P$ on subset $X$. $I_n \in S^n$ denotes the identity matrix. $0_{n \times m} \in \mathbb{R}^{n \times m}$ is the matrix of zeros with shorthand $0_n := 0_{n \times n}$. We will occasionally denote the intervals $T_i := [-\tau_i, 0]$. For a natural number, $K \in N$, we adopt the index shorthand notation which denotes $[K] = 1, \cdots, K$. The symmetric completion of a matrix is denoted $\Sigma^T$.

II. Previous Work on State Estimation and State-Feedback Control of DPS

In this section, we consider the a general class of distributed-parameter system (DPS) given as

\begin{align}
\dot{x}(t) &= Ax(t) + B_1\omega(t) + B_2u(t) \quad x(0) = 0 \\
z(t) &= C_1x(t) + D_1\omega(t) \\
y(t) &= C_2x(t) + D_2\omega(t)
\end{align}

where $A : X \to Z, B_1 : \mathbb{R} \to Z, B_2 : U \to Z, C_1 : X \to \mathbb{R}, C_2 : X \to Y, D_1 : \mathbb{R} \to \mathbb{R}$ and $D_2 : \mathbb{R} \to Y$.

A. Full State feedback controller design

Theorem 1: [8] Suppose $P_1$ is a bounded, coercive linear operator $P_1 : X \to X$ with $P_1(X) = X$ and which is self-adjoint with respect to the $Z$ inner product. Then $P_1^{-1}$ exists; is bounded; is self-adjoint; $P_1^{-1} : X \to X$; and $P_1^{-1}$ is coercive.

Theorem 2: [8] Suppose there exists a scalar $\epsilon_1 > 0$, an operator $P_1 : Z \to Z$ which satisfies the conditions of Theorem 1, and an operator $H : X \to U$ such that

\begin{align}
(A P_1 h, h)_Z + \langle h, A P_1 h \rangle_Z + \langle B_2 H(h, h) \rangle_Z + \langle h, B_3 H(h) \rangle_Z \\
+ \langle B_1 \omega, h \rangle_Z + \langle h, B_1 \omega \rangle_Z - \gamma_1 \|w\|^2 - \gamma_1 \|v\|^2 + v^T (C_1 \Phi h) + \langle C_1 \Phi h, v \rangle + (C_1 \Phi h)^T v + v^T (D_2 \Phi h) + (D_2 \Phi h)^T v + v^T (D_1 \omega) + (D_1 \omega)^T v \leq -\epsilon_1 \|h\|^2
\end{align}

for all $h \in X, \omega \in \mathbb{R}^r$ and $v \in \mathbb{R}^p$. Then if $\omega$ and $z$ satisfy Eqn. (5) and $u(t) = K z(x)$ where $K = \mathcal{H} P_1^{-1}$ we have $\|z\|_{L_2} \leq \gamma_1 \|w\|_{L_2}$.

B. Estimator design

In [9], a $H_\infty$ optimal estimator based on the traditional Luenberger structure is given for Eqn. (6), which can correct both the present states and history of the states and give a real-time estimate of the history of states. This estimator has the following dynamics

\begin{align}
\dot{x}(t) &= Ax(t) + L C z(x) - y(t)
\end{align}

for a given operator $\mathcal{L} : Y \to Z$. By defining $e(t) = \hat{x}(t) - x(t)$, one obtains the error dynamics as

\begin{align}
\dot{e}(t) &= (A + LC_2)e(t) - (B_1 + LD_2)\omega(t) - z_e(t) - C_3 e(t) + D_3 w(t) e(0) = 0
\end{align}

where $C_3 : X \to \mathbb{R}$ and $D_3 : \mathbb{R} \to \mathbb{R}$.

Theorem 3: [9] Suppose there exist a scalar $\epsilon_2 > 0$ and bounded linear operators $P_2 : Z \to Z$ and $Z : Y \to Z$ such that $P_2$ is coercive and

\begin{align}
\langle (P_2 A + ZC_2) e, e \rangle_Z + \langle e, (P_2 A + ZC_2) e \rangle_Z \\
- \langle e, (P_2 B_1 + ZD_2) \omega \rangle_Z - \langle (P_2 B_1 + ZD_2) \omega, e \rangle_Z \\
- \gamma_2 \|e\|^2 - \gamma_2 \|w\|^2 + \langle \nu_e, C_3 e \rangle + \langle C_3 e, \nu_e \rangle \\
+ \nu_e^T D_3 w, \nu_e \| \leq -\epsilon_2 \|e\|_Z^2
\end{align}

for all $e \in X, \omega \in \mathbb{R}^r$ and $\nu_e \in \mathbb{R}^{p_2}$. Then $P_2^{-1}$ is a bounded linear operator and for $\lambda = \mathcal{P}_2^{-1} Z$, the solution of Eqn. (6) satisfies $\|z\|_{L_2} \leq \gamma_2 \|w\|_{L_2}$.

III. MAIN RESULTS

In this section, we give conditions under which the dynamics of the estimator-based controller is stable and give an expression for the $L_2$-gain of the closed-loop system. The conditions are given in abstract form. Later, in Theorem 4 we will given LMI-based sufficient conditions under which the conditions of Theorem 3 is satisfied.

A. Estimator-Based Control for DPS

Combining Eqn. (3), Eqn. (5), and Eqn. (6) with $u(t) = K z(x)$, the closed-loop DPS dynamics are given as follows

\begin{align}
\dot{x}(t) &= (A + B_2 K) x(t) + B_1 \omega(t) + B_2 K e(t) \\
\dot{e}(t) &= (A + LC_2)e(t) - (B_1 + LD_2)\omega(t) \\
z(t) &= C_1 x(t) + D_1 \omega(t) \\
y(t) &= C_2 x(t) + D_2 \omega(t) \\
\dot{z}_e(t) &= C_3 e(t) + D_3 \omega(t)
\end{align}
where $\mathcal{K} : Z \to U$ and $\mathcal{L} : Y \to Z$. We assume $x(0) = e(0) = 0$.

**Theorem 4:** Suppose there exist positive scalars $\epsilon_1, \epsilon_2$, operators $H : Z \to U$ and $P_1 : Z \to Z$ which satisfy the conditions of Theorem 1 with $\gamma_1$, and operators $P_2 : Z \to Z$, and $Z : Y \to Z$ which satisfy Theorems 2 and 3 with $\gamma_2$.

Then if there exists positive scalar $r$ such that
\[
\left\langle \begin{bmatrix} h \\ e \end{bmatrix}, \mathcal{M} \begin{bmatrix} h \\ e \end{bmatrix} \right\rangle \leq 0
\]
for all $h, e \in X$, where
\[
\mathcal{M} = \begin{bmatrix} -\epsilon_1 I & B_2 \mathcal{P}_1^{-1} \\ (B_2 \mathcal{P}_1^{-1})^T & -r \epsilon_2 I \end{bmatrix}.
\]
Then for any $z(t), z_e(t)$ and $w(t)$ which satisfy Eqn. (8), with $\mathcal{K} = \mathcal{H}_P^{-1}$ and $\mathcal{L} = \mathcal{P}_1 Z$, we have $\|z\|_{L_2} \leq \sqrt{\gamma_1 (\gamma_1 + \gamma_2)} \|\omega\|_{L_2}$ and $\|z_e\|_{L_2} \leq \gamma_2 \|\omega\|_{L_2}$.

**Proof:** Suppose $z(t), z_e(t), y(t), w(t), e(t), x(t)$ satisfy Eqn. (8). Since $z_e(t)$ is only affected by $\omega(t)$, we have by Theorem 3 that $\|z_e\|_{L_2} \leq \gamma_2 \|\omega\|_{L_2}$. Define
\[
V_1(t) = V_1(t) + \mathcal{P}_1^{-1} x(t) \in X \text{ and differentiate } V_1(t), \text{ we have}
\]
\[
V_1'(t) = \langle \mathcal{P}_1^{-1} x(t), x(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), e(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), e(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), e(t) \rangle.
\]
Applying Theorem 2, if we define $v(t) = \frac{1}{\sqrt{2}} z(t)$, one gets
\[
V_1'(t) - \gamma_1 \|z(t)\|^2 + \gamma_1 \|v(t)\|^2 \leq -\epsilon_1 \|h(t)\|^2 + B_2 \mathcal{P}_1^{-1} e(t), z(t) \rangle + \langle h(t), h(t) \rangle + \langle \mathcal{P}_1^{-1} e(t), e(t) \rangle.
\]
Combining the results above, we have
\[
\tilde{V}(t) = \langle \mathcal{P}_1^{-1} x(t), \mathcal{P}_1^{-1} x(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), \mathcal{P}_1^{-1} x(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), \mathcal{P}_1^{-1} x(t) \rangle + \langle \mathcal{P}_1^{-1} x(t), \mathcal{P}_1^{-1} x(t) \rangle.
\]
Then if there exists a positive scalar $r$ such that Eqn. (9) is satisfied, it follows
\[
\tilde{V}(t) - \gamma_1 \|z(t)\|^2 + \gamma_1 \|v(t)\|^2 \leq 0.
\]
Integrating in time and using $V(0) = 0$, we have
\[
\|z\|_{L_2} \leq \sqrt{\gamma_1 (\gamma_1 + \gamma_2)} \|\omega\|_{L_2}.
\]
The proof is completed.

**B. Expressing Multi-delay system into DPS**

In this section, we apply Theorem 4 to the case of multi-delay systems. Specifically, we consider solutions to the system of equations given by Eqn. (2).

Firstly, considering $c(t) = x(t) - x(t)$, we write Eqn. (2) into the form in Eqn. (3). Following the mathematical formalism developed in [2], define the inner-product space $Z_{m,n,k} := \mathbb{R}^m \times L_2^k [-\tau_1, 0] \times \cdots \times L_2^k [-\tau_K, 0]$ and for $\{x, \phi_1, \cdots, \phi_K\} \subseteq Z_{m,n,k}$, we use the following notation
\[
\left\langle x, \phi_1 \right\rangle := \{x, \phi_1, \cdots, \phi_K\}
\]
and we define the inner product on $Z_{m,n,k}$ as
\[
\left\langle \left\langle \begin{bmatrix} y(t) \\ \phi_1 \end{bmatrix} \right\rangle, \left\langle \begin{bmatrix} \phi_1 \end{bmatrix} \right\rangle \right\rangle = \tau_{K} y^T x + \sum_{i=1}^{K} \int_{-\tau_i}^{0} \psi_i(s)^T \phi_i(s)ds.
\]
We simplify the notation $Z_{m,n,k}$ when $m = n$ as $Z_{n,k}$.

Then the state-space for system (8) is defined as
\[
X := \left\{ \left\langle \begin{bmatrix} x(t) \\ \phi_1 \end{bmatrix} \right\rangle \subseteq Z_{n,k} : \phi_1 \in W_2^2 [-\tau_i, 0] \text{ and } \phi_i(0) = x \right\}.
\]
We now represent the infinitesimal generator, $A : X \to Z_{n,k}$ of Eqn. (8) as
\[
A \left\langle \begin{bmatrix} x(t) \\ \phi_1 \end{bmatrix} \right\rangle = \left\langle \begin{bmatrix} A_0 x(t) + \sum_{i} A_i \phi_i(-\tau_i) \\ \phi_1(s) \end{bmatrix} \right\rangle.
\]
Furthermore, $B_1 : \mathbb{R}^r \to Z_{n,k}, B_2 : \mathbb{R}^m \to Z_{n,k}, C_1 : Z_{n,k} \to \mathbb{R}^P, C_2 : X \to Z_{q,k}, C_3 : Z_{n,k} \to \mathbb{R}^{p_1}, D_1 : \mathbb{R}^r \to \mathbb{R}^{p_1}$ are defined as
\[
B_1 \omega(t) := \left[ \begin{array}{c} B_1 \omega(t) \\ 0 \end{array} \right], \quad B_2 u(t) := \left[ \begin{array}{c} B_2 u(t) \\ 0 \end{array} \right],
\]
\[
C_j \left\langle \begin{bmatrix} x(t) \\ \phi_1 \end{bmatrix} \right\rangle := C_{j0} x(t) + \sum_{i} C_{j1} \phi_i(-\tau_i) \quad j = 1, 3
\]
\[
C_2 \left\langle \begin{bmatrix} x(t) \\ \phi_1 \end{bmatrix} \right\rangle := \left[ \begin{array}{c} C_2 x(t) \\ 0 \end{array} \right],
\]
\[
D_j \omega(t) := D_j \omega(t) \quad j = 1, 3.
\]
Here we assume $D_2 = 0$. Note for any solution $x(t)$ of Eqn. (2), using the above notation
\[
(x(t))(s) := \left[ \begin{array}{c} x(t) \\ x(t + s) \end{array} \right],
\]
then $x(t)$ satisfies Eqn. (8). The converse statement is also true. The same is true for $e(t), y(t)$.

**C. The framework**

A class of operators $\mathcal{P}((P_i, Q_i, S_i, R_{ij})) : Z_{m,n,k} \to Z_{m,n,k}$ is introduced which is parameterized by matrix $P$ and matrix-valued functions $Q_i \in W_2^m \times n [-\tau_i, 0], S_i \in W_2^m \times n [-\tau_i, 0], R_{ij} \in W_2^m \times n [-\tau_j, 0].$

The proof is completed.
Lemma 5: [8] Suppose that $P \in \mathbb{R}^{n \times n}$, $S_i \in \mathbb{W}^{n \times n}[T_i]$, $R_{ij} \in \mathbb{W}^{n \times n}[T_i \times T_j]$ satisfying $S_i(s) = S_j^T(s)$, $R_{ij}(s, \theta) = R_{ji}(\theta, s)$, $P = \tau Q^T(0)$ and $Q_j(s) = R_{ij}(0, s)$ for all $i, j \in \mathbb{K}$. Moreover suppose $P_{\{P_i, Q_i, S_i, R_{ij}\}}$ is coercive on $Z_{n,k}$. Then $P_{\{P_i, Q_i, S_i, R_{ij}\}}$ is a self-adjoint bounded linear operator with respect to the inner product defined on $Z_{n,k}$.

Now let us turn to the operators used in Theorem 4. We define $P_1 := P_{\{P_1, Q_1, S_1, R_{1j}\}}$ and $P_2 := P_{\{P_2, Q_2, S_2, R_{2j}\}}$ and we parameterize the decision variable $\mathcal{H} : Z_{n,k} \rightarrow \mathbb{R}^m$ using matrices $H_0, H_1$ and functions $H_2$ as

$$\mathcal{H}(y_1) = \left[ H_0 y + \sum_i H_1 y_i(-\tau_i) + \sum_i \int_{-\tau_i}^0 H_2_i(s) y_i(s) ds \right].$$

Similarly, the decision variable $\mathcal{Z}$ is parameterized as

$$\mathcal{Z}(y_1) = \left[ Z_1 y_0 + \sum_i Z_2 y_i(-\tau_i) + \sum_i \int_{-\tau_i}^0 Z_3_i(s) y_i(s) ds \right].$$

In [9], it was shown that for $\mathcal{Z}$ as parameterized above, if $\mathcal{L} = \mathcal{P}_1^{-1} \mathcal{Z}$, then the error injection operator $\mathcal{E} : Z_{n,k} \rightarrow Z_{n,k}$ corresponds to the estimator structure defined in Eqn. (2). The same is true for $K := \mathcal{H} P_2^{-1}$.

To simplify presentation, we do not present the LMI constraints on the coefficients of $\{P, Q_i, S_i, R_{ij}\}$ which ensure $P_{\{P_i, Q_i, S_i, R_{ij}\}} \geq 0$. Rather, we simply represent these constraints using the following notation:

$$\Xi_{d,m,n,K} := \{\{P, Q_i, R_{ij}, S_i\} : P_{\{P_i, Q_i, S_i, R_{ij}\}} \geq 0, \text{ satsify the conditions of Corollary 4 in [9]}\}.$$

By Theorem 8 in [8], if $\{P - \epsilon I, Q_i, R_{ij}, S_i - \epsilon I\} \in \Xi_{d,m,n,K}$, then $P_{\{P_i, Q_i, S_i, R_{ij}\}}$ is coercive and has an inverse of the form $\mathcal{P} := \mathcal{P}_{\{P_i, Q_i, S_i, R_{ij}\}}$. In this paper, we do not explicitly represent the map to $\mathcal{P}, \mathcal{Q}, \mathcal{S}, \mathcal{R}_{ij}$, but rather combine it into a single map from $\{P, Q_i, S_i, R_{ij}\}$ and $\{Z_1, Z_2, Z_3, Z_4, Z_5, Z_6, Z_7\}$ (resp. $\{H_0, H_2, H_2\}$) to $\{L_1, L_2, L_3, L_4, L_5, L_6, L_7\}$ (resp. $\{K_0, K_1, K_2\}$) which we then denote using the following.

Definition of $\mathcal{L}_1$:

$$\{L_1, L_2, \cdots, L_7\} = \mathcal{L}_1(\{P, Q_i, S_i, R_{ij}\}, \{Z_1, Z_2, \cdots, Z_7\})$$

to indicate that if $\{\hat{P}, \hat{Q}, \hat{S}, \hat{R}_{ij}\}$ are as defined in Theorem 8 in [8], then $\{L_1, L_2, \cdots, L_7\}$, $\{P, Q_i, S_i, R_{ij}\}$, and $\{Z_1, Z_2, \cdots, Z_7\}$ satisfy Lemma 7 in [9].

Definition of $\mathcal{L}_2$: Likewise, we say

$$\{K_0, K_{1i}, K_{2i}\} = \mathcal{L}_2(\{P, Q_i, S_i, R_{ij}\}, \{H_0, H_{2i}, H_{2j}\})$$

to indicate that if $\{\hat{P}, \hat{Q}, \hat{S}, \hat{R}_{ij}\}$ are as defined in Theorem 8 in [8], then $\{K_0, K_{1i}, K_{2i}\}$, $\{\hat{P}, \hat{Q}_i, \hat{S}_i, \hat{R}_{ij}\}$, and $\{H_0, H_{2i}, H_{2j}\}$ satisfy Lemma 9 in [8].

D. Theorem 4 applied to Multi-delay systems

In this section, we formulate the conditions of Theorem 4 into multi-delay systems as a linear operator inequality where all operators are the form of Eqn. (12).

Theorem 6: Suppose there exist $d \in \mathbb{N}$, positive scalars $\epsilon, \epsilon_1, \epsilon_2, \gamma_1, \gamma_2, \{P_1, Q_1, S_1, R_{ij}\}$ satisfying Lemma 5, matrices $P_2 \in \mathbb{R}^{n \times n}$, polynomials $S_2i, S_2j \in \mathbb{W}^{n \times n}[T_i]$, $R_{2ij} \in \mathbb{W}^{n \times n}[T_i \times T_j]$, matrices $H_0, H_{2i} \in \mathbb{R}^{p \times n}$, polynomial $H_2i \in \mathbb{W}^{n \times n}[T_i]$, matrices $Z_1, Z_2j \in \mathbb{R}^{n \times q}$, polynomials $Z_3i, Z_4, Z_5, Z_6i, Z_7j \in \mathbb{W}^{n \times q}[T_i]$ and $Z_7ij \in \mathbb{W}^{n \times q}[T_i \times T_j]$ for all $i, j \in \mathbb{K}$ such that

$$\mathcal{P}_{\{P_i, Q_i, S_i, R_{ij}\}}(X) = X.$$
and $\mathcal{K}$ as

$$u(t) = \mathcal{K}x(t)$$

$$= K_0x(t) + \sum_i K_{1i}x(t - \tau_i) + \sum_i \int_{-\tau_i}^0 K_{2i}(s)x(t + s)ds. \quad (17)$$

Since $\{P_1 - \epsilon, Q_{1i}, s_{1i} - \epsilon, R_{1ij}\} \in \Xi_{d,n,K}$ and $\{P_2 - \epsilon, Q_{2i}, s_{2i}, R_{2ij}\} \in \Xi_{d,n,K}$, $P_1 := \mathcal{P}(P_1, Q_{1i}, s_{1i}, R_{1ij})$ and $P_2 := \mathcal{P}(P_2, Q_{2i}, s_{2i}, R_{2ij})$ are coercive. Let $Z$ be as defined in (14) and $H$ be as defined in (14). Now by Theorem 5 and Lemma 10 in [8], $\mathcal{K} = \mathcal{H}P^{-1}$ and by Theorem 5 and Lemma 9 in [9], $L = \mathcal{P}^{-1}Z$.

Next, if we define

$$\mathcal{M} = \begin{bmatrix} -\epsilon_1 I & B_2H^{-1}P^{-1} - r\epsilon_2 I \\ (B_2H^{-1}P^{-1} - r\epsilon_2 I)^* & -r\epsilon_2 I \end{bmatrix} = \begin{bmatrix} -\epsilon_1 I & B_2K \\ (B_2K)^* & -r\epsilon_2 I \end{bmatrix}$$

and for $h, e \in X$, we expand the expression

$$\langle \begin{bmatrix} h \\ e \end{bmatrix}, \mathcal{M}, \begin{bmatrix} h \\ e \end{bmatrix} \rangle = \langle B_2Ke, h \rangle + \langle h, B_2Ke \rangle_Z - \epsilon_1 \|h\|^2 - r\epsilon_2 \|e\|^2$$

Now let

$$h(s) = \begin{bmatrix} h_1 \\ h_{2i}(s) \end{bmatrix}, e(s) = \begin{bmatrix} e_1 \\ e_{2i}(s) \end{bmatrix}$$

We have

$$\langle \begin{bmatrix} h \\ e \end{bmatrix}, \mathcal{M}, \begin{bmatrix} h \\ e \end{bmatrix} \rangle = 2\tau_K h_1^T (B_2Ke) + \sum_i B_2K_{1i}e_{2i}(-\tau_i) + \sum_i \int_{-\tau_K}^0 B_2K_{2i}e_{2i}(s)ds - \epsilon_1 h_1^T h_1 - r\epsilon_2 e_1^T e_1 - \epsilon_1 \sum_i \int_{-\tau_K}^0 h_{2i}(s)h_{2i}(s)ds - r\epsilon_2 \sum_i \int_{-\tau_K}^0 e_{2i}(s)e_{2i}(s)ds.$$
controller is effective in stabilization of systems that are open-loop unstable.

V. CONCLUSION

In this paper, we have proposed a method for designing estimator-based output feedback controllers for systems with multiple delays. This approach combines an $H_\infty$-optimal estimator with an $H_\infty$-optimal full-state feedback controller and proves a bound on the $L_2$-norm of the resulting dynamics. These controllers are applicable to systems with multiple known delays and consider process noise, but not sensor noise. Furthermore, we have developed an efficient numerical implementation of the observer-based controller and have posted this implementation online. Numerical examples indicate that the $L_2$-gain of the resulting estimator-based controllers is relatively close to, but does not exactly achieve the minimum possible closed-loop $L_2$-gain as estimated using a Padé approximation.

APPENDIX

In this appendix, we define the mappings \( \mathcal{L}_1 \) and \( \mathcal{L}_2 \) as used in Theorem 5.

**Operator \( \mathcal{L}_1 \):** We say

\[
\{E_1, F_{11}, N_{11}, G_{11}\} = \mathcal{L}_1(\{P_1, Q_{11}, S_{11}, R_{11}\}, \{H_0, H_{11}, H_{21}\})
\]

if

\[
E_1 = \begin{bmatrix}
-\frac{1}{\tau_K} I & -\frac{1}{\tau_K} D_1 & E_{11} & E_{121} & \cdots & E_{12K} \\
\vdots & \vdots & \vdots & \vdots & & \vdots \\
-\frac{1}{\tau_K} I & \frac{1}{\tau_K} B^T & E_{10} & E_{101} & \cdots & E_{102K} \\
\vdots & \vdots & \vdots & \vdots & & \vdots \\
-\frac{1}{\tau_K} I & \frac{1}{\tau_K} G^T & E_{11} & E_{121} & \cdots & E_{12K} \\
\vdots & \vdots & \vdots & \vdots & & \vdots \\
-\frac{1}{\tau_K} I & \frac{1}{\tau_K} F^T & E_{10} & E_{101} & \cdots & E_{102K} \\
\vdots & \vdots & \vdots & \vdots & & \vdots \\
-\frac{1}{\tau_K} I & \frac{1}{\tau_K} H^T & E_{11} & E_{121} & \cdots & E_{12K}
\end{bmatrix}
\]

\[
\tau_K \left( A_0 Q_{11} + \sum_{j=1}^{K} A_1 R_{1j1} - \tau_j s, \theta \right)
\]

\[
\tau_K \left( A_0 Q_{11} + \sum_{j=1}^{K} A_1 R_{1j1} - \tau_j s, \theta \right)
\]

\[
N_{11}(s) = \dot{S}_{11}(s)
\]

\[
\frac{\partial}{\partial s} R_{11j}(s, \theta) + \frac{\partial}{\partial \theta} R_{11j}(s, \theta)^T, \quad i, j \in [K]
\]

where

\[
E_{10} = A_0 P_1 + \sum_{i=1}^{K} \left( \tau_K A_i Q_{11} - \tau_i s, \theta \right) + \frac{1}{2} S_{11}(0)
\]

\[
E_{11} = \frac{1}{\tau_K} C_{10} P_1 + \sum_{i=1}^{K} C_{1i} Q_{11} - \tau_i s, \theta
\]

\[
E_{121} = C_{11} S_{11} - \tau_1 s, \theta
\]

\[
E_{131} = \tau_K A_1 S_{11} - \tau_1 s, \theta + B_2 H_{11}
\]

**Operator \( \mathcal{L}_2 \):** We say

\[
\{E_2, F_{22}, H_{21}, G_{22}\} = \mathcal{L}_2(\{P_1, Q_{21}, S_{21}, R_{21j}\}, \{Z_0, Z_{11}, Z_{21}, \cdots \})
\]
