1. Introduction

Families of automorphic forms have proven to be a great tool in number theory in the last 30 years. Their construction dates back to Hida, [Hid86], who first constructed families of ordinary modular forms (for the group $GL_2$). This construction was then improved by Coleman in the 1990’s, for overconvergent, finite slope, modular forms and rigid spaces over $\mathbb{Q}_p$ (whereas Hida was able to construct his families integrally). One great and yet surprising achievement was the construction soon after by Coleman and Mazur of one rigid space, the Eigencurve, which parametrizes all possible families of overconvergent, finite slope modular forms, i.e. gluing all the families previously constructed.
Before motivating the construction of this spaces, let us say that these constructions have seen many generalisations in different directions. First dealing with level outside $p$ and quaternion algebra by Buzzard [Buz07], or for other algebraic groups, unitary groups, compact at infinity by Chenevier [Che04], and to more general groups by [AS08] and [Urb11] using families of (generalised) modular symbols. More recently, [AIP15] have been able to construct families and eigenvarieties for Siegel modular forms using families of automorphic sheaves on the Siegel moduli space. These families of sheaves live in the rigid world, they are Banach sheaves on certain strict neighborhoods of the ordinary locus, that interpolate (in some sense) the classical automorphic vector bundles. This strategy has been extended by [Kas04, Bra13] in the case of Shimura curves, [ABI16] for Hilbert modular forms, and [Bra16] for PEL Shimura varieties for which the ordinary locus in non empty.

This spaces are particularly interesting; through their local properties (see for example [BC09] and [CH13] for applications to the Bloch-Kato conjecture, and to constructing Galois representation associated to automorphic representations), but also for their global geometry (see [LWX17] and the application to the parity conjecture), which remains completely mysterious in general.

In all cases, the construction goes by constructing huge Banach spaces $M$ together with an action of a (commutative) Hecke algebra $\mathbb{T}$ containing a distinguished compact operator $U$. With this data, if $M$ is a projective Banach space, we can construct following [Col97b] a rigid space $E$ which parametrises Hecke eigensystems for $\mathbb{T}$ acting on $M$, for which the eigenvalue for $U$ is non-zero. In [AS08] and [Urb11], theses spaces $M$ are the sections on Shimura varieties of $p$-adic overconvergent modular symbols, which interpolate the etale cohomology of these varieties. In [AIP15] and its generalisations, one first construct varying Banach automorphic sheaves $\omega^{\kappa}$, where $\kappa$ is a $p$-adic weight, and take the sections of these sheaves on strict neighborhoods of the ordinary locus. Theses spaces interpolate the coherent cohomology, but are constructed on PEL Shimura varieties (one needs the moduli interpretation), and need the non emptiness of the ordinary locus. Indeed, one central tool to construct $\omega^{\kappa}$ is the theory of the canonical subgroup and its overconvergence (see [Lub79, Far11] for example). In this article, we mainly remove the ordinariness assumption. Let $(G, X)$ be a PEL Shimura datum\(^{(1)}\), and $p$ a prime. Our main result is the following

**Theorem 1.1.** — Suppose that $G$ is unramified at $p$, and let $K^p$ be a level outside $p$, hyperspecial outside a finite set of primes $S$. Let $I$ be a Iwahori subgroup at $p$ and $K = K^pI$. There exists rigid spaces $E$ and $W$, called respectively the eigenvariety and the weight space, together with a locally finite map

$$w : E \longrightarrow W,$$

and $\mathbb{T} = \mathbb{T}^{Sp} \otimes A(p) \longrightarrow \mathcal{O}(E)$ such that, for all $\kappa \in W$, $w^{-1}(\kappa)$ is in bijection with the eigenvalues for the Hecke algebra $\mathbb{T}$ acting on weight $\kappa$, overconvergent, locally analytic modular forms for $G$ which are finite slope for some $U \in A(p)$. Here $A(p)$ is a (commutative) Hecke algebra at $p$ and $\mathbb{T}^{Sp}$ is the unramified Hecke algebra for $G$ outside $Sp$. $E$ and $W$ are

\(^{(1)}\)We exclude factors of type D
equidimensionnal of the same dimension. Moreover there is a Zariski dense subset \( \mathcal{Z} \subset \mathcal{E} \) such that all \( z \in \mathcal{Z} \) coincide with a classical Hecke eigensystem in the previous identification.

Actually, we can only construct families at unramified primes, but we can weaken a bit the assumptions on \( G \) and \( p \), by only constructing deformations in the directions of primes above \( p \) which are unramified for \( G \), see remark 2.1.

We now explain how we prove this theorem. A first step in generalising the construction of [AIP15] to the case when the ordinary locus is empty is to find a substitute for the ordinary locus and the canonical subgroup. A good substitute is to consider the \( \mu \)-ordinary locus (see [Wed99], [Moo04], and also [Bij16]), and the canonical filtration, which exists on it, and overconverges on strict neighborhoods (see [Her16]). This strategy has been followed in [Her19] for \( U(2, 1) \) when \( p > 2 \). Unfortunately, the results of [Her16] rely on a stronger hypothesis on \( p \): being big enough (always \( p \neq 2 \) and for general unitary group for example the bound can be very large). In this article we choose another strategy to avoid any hypothesis on \( p \), and use (integral) Shimura varieties with higher (Iwahori-like) level at \( p \), constructed by normalisation in [Lan16a]. On these Shimura varieties naturally live flags of finite flat subgroups, and if we restrict to strict neighborhoods of the \( \mu \)-ordinary locus (more precisely what we call the \( \mu \)-canonical locus, see definition 5.12), these groups behave as the canonical filtration (and actually coincides with it when we know it exists, see Theorem 5.6). In particular, we can follow the construction of [AIP15] and [Her19] for all \( p \) with these groups, and construct automorphic banach sheaves by introducing level at \( p \). All of this rely on the fact that we can find a basis of strict neighborhood \( X_{\deg \geq N - \varepsilon} \) where our subgroups have high degree, and thus are well behaved.

In the setting where the ordinary locus is non empty, by results of Fargues [Far11] we can relate degree and the Hasse invariant. In our situation we also have an Hasse invariant (by [GN17]; see also [Her18] and Definition 5.10), but we can relate it to the degrees, using [Her16], only if \( p \) is big enough... Thus we chose another strategy: we have a second basis of strict neighborhoods \( X_{(ha \leq v)} \) where the (valuation of) Hasse invariant is small enough (it is invertible on the \( \mu \)-ordinary locus), and we use these two basis of neighborhoods. Using the degree function, we can control our (call them canonical) subgroups easily, and thus as it was already remarked in [Bij16], the action of the Hecke operators. In particular, we can check that we have an operator \( U \) which acts as a compact operator on sections of our sheaves over \( X_{(deg \geq N - \varepsilon)} \). Unfortunately, we can’t prove that the global sections over the opens \( X_{(deg \geq N - \varepsilon)} \) of the automorphic Banach sheaves are projective, thus we can’t a priori use Coleman- Buzzard’s construction. On the other basis \( (X_{(ha \leq v)})_{v > 0} \), we can’t prove even that our expected-to-be compact operator \( U \) (which generalise the operator \( U_p \) on the modular curve) will stabilise each neighborhood (and thus worse, that it acts compactly on sections on \( X_{(ha \leq v)} \)), but using that \( X_{(ha \leq v)} \) is affinoid in rigid fiber, we can prove that global section of our automorphic Banach sheaves on \( X_{(ha \leq v)} \) are projective. Here to be precise we need to work on both the toroidal and minimal compactifications of [Lan16a], the toroidal compactification being needed to construct the automorphic sheaves, and the minimal to get the affinoid result, together with a result of vanishing of higher cohomology due to Lan, see Appendix A. Thus we need to relate both these sections on the two basis of neighborhoods. Fortunately we can and do in section 9 using complexes computing higher cohomology of our Banach sheaves, the action of the
Hecke operators on these complexes, and that we can always intertwine these opens,
\[ X(\text{deg} \geq N - \varepsilon) \supset X(\text{deg} \geq N - \varepsilon') \supset X(\text{deg} \leq v) \supset X(\text{deg} \leq v') \supset X^{\mu - \text{can}}, \]
where \( \varepsilon' \) and \( v' \) are well chosen small enough. Passing to finite slope parts, and using results of [Urb11], we get that \( U \) acts as a compact operator on the finite slope part of sections of our Banach automorphic sheaves on any of our strict neighborhoods, and that these spaces are projective (in some sense). Thus we can apply Coleman-Buzzard's machinery and get the theorem.

As an application of these results, we can extend the result on the Bloch-Kato conjecture we had in [Her19], and prove the following. Let \( E \) be a quadratic imaginary number field, and \( \chi : \hat{A}^\infty_E \to \hat{\mathbb{C}}^\infty \), which is polarised, meaning that \( \chi^\dagger := (\chi^\vee)^{-1} = \chi|.|^{-1} \). Denote by \( L(\chi, s) \) its \( L \)-function. If \( p \) is a prime, denote
\[ \chi_p : \text{Gal}(\bar{E}/E) \to \hat{\mathbb{Q}}_p^\times, \]
the \( p \)-adic Galois character associated to \( \chi \), and denote \( H^1_f(E, \chi_p) \) the Bloch-Kato-Selmer group of \( \chi_p \) (see [BC09] chapter 5). Then we prove

**Theorem 1.2.** — Let \( p \) be a prime, unramified in \( E \). If \( L(\chi, 0) = 0 \) and \( \text{ord}_{s=0} L(\chi, s) \) is even, then
\[ H^1_f(E, \chi_p) \neq 0. \]

In particular we remove the hypothesis that \( p \neq 2 \) when \( p \) is inert in \( E \) and \( p \nmid \text{Cond}(\chi) \) that were in [Her19]. Also, a version of the previous theorem is well-known to be due to Rubin ([Rub91]) but there it is necessary that \( p \neq 2 \) (and \( p \neq 3 \) if \( E = \mathbb{Q}(j) \), which we unfortunately also need to assume...). In particular, we get new cases of the Bloch-Kato conjecture when \( p = 2 \) is unramified in \( E \)!

Of course this result relies heavily, as in [Her19], on works of Bellaïche and Chenevier, [BC04] and [BC09]. As in this last reference, we can even construct independent classes as predicted by the Bloch-Kato conjecture, under some assumption on the eigenvariety \( \mathcal{E} \) for \( U(2, 1) \). The idea is to consider a specific Arthur point \( y \in \mathcal{E} \) (known to exists by results of Rogawski and a calculation of cohomology in [Her19]), see Proposition 10.21. Denote by \( t \) the dimension of the tangent space of \( \mathcal{E} \) at \( y \). As \( \mathcal{E} \) is of dimension 3, we have \( t \geq 3 \). There exists a subspace
\[ \text{Ext}_T(1, \mathfrak{T}) \subset H^1_f(E, \chi_p), \]
and denote its dimension by \( h \). The assumptions of \( \chi \) implies that \( \chi(z) = z^{a-1} \), for all \( z \in \mathbb{C} \), with \( a \in \mathbb{Z}_{\geq 1} \) (up to change \( \chi \) by its conjugate \( \chi^{\dagger} \)). We can prove the following,

**Theorem 1.3.** — Recall that we assume \( L(\chi, 0) = 0 \) and \( \text{ord}_{s=0} L(\chi, s) \) is even. Then, if \( a \geq 2 \) and \( p \) is split,
\[ t \leq h + \frac{3}{2} + 1. \]

(2) Sometimes we denote it by \( \chi^{\dagger} \) instead of \( \chi^{\dagger} \).
In particular this implies the previous theorem for $a \geq 2$ and $p$ split. Also in this case, if $E$ is non regular at $y$, then $h > 1$, and there are thus at least 2 classes in $H^1(E, \chi_p)$. Remark that $a \geq 2$ is exactly the assumption so that the Hecke eigenvalues at $y$ actually appears in etale cohomology, when $a = 1$ we can only prove that these eigenvalues appear in the coherent cohomology, the motives becomes irregular and our argument breaks down. Also, the hypothesis that $p$ is split is necessary to choose a good refinement which is sufficiently far from the ordinary one (we need it to be anti-ordinary see [BC04]) : when $p$ is inert, there is a unique accessible refinement, and it is not anti-ordinary.

Acknowledgements. — I would like to first thank Stephane Bijakowski for many interesting discussions and suggesting to systematically use the degree function instead of the Hasse invariant. I would also warmly thank Vincent Pilloni for introducing me to this subject and explaining his recent results on higher Hida theory, suggesting that they could be useful in the case at hand. Also I would like to warmly thank Gaetan Chenevier and Benjamin Schraen for taking time to explain me in details a lot of their knowledge on the subject. I would also like to thank Fabrizio Andreatta, Christophe Breuil, Laurent Fargues, Eyal Goren and Adrian Iovita for interesting discussions.

2. Algebraic groups, Shimura Datum and weight spaces

Let $p$ be a prime and let $D = (B, *, V, <, O_B, \Lambda, h)$ be an integral Shimura-PEL-datum. Let $G$ be the associated algebraic group over $\mathbb{Q}$, i.e.,

$$(G, h) = \{(g, c(g)) \in GL_B(V \otimes R) \times R^* | <gv, gw> = c(g) <v, w> \forall v, w \in V \otimes R\}.$$ 

$(G, h)$ defines a Shimura datum. Suppose that the datum is unramified at $p$ (see [Kot92] or [VW13]). This means that $B \otimes \mathbb{Q}$ is isomorphic to a product of matrix algebras over finite extensions of $\mathbb{Q}_p$. We can decompose $B = \prod_{i=1}^s B_i$ as a product of simple algebras and we suppose that no factor is of type $D$ (orthogonal), see [VW13] Remark 1.1. As $p$ is unramified in $D$, we can also consider $G$ a reductive model at $p$ for $G$ (over $\mathbb{Z}_p$).

Every interesting object in this article will decomposed accordingly to the previous decomposition of $B$, and we can thus make our construction for each $B_i$. This simple algebras are classified into 2 types (as we excluded case $D$), the type $A$ and the type $C$.

In case $C$, the construction we are interested in is already made in [Bra16] (which also do many cases of type $A$, but not all), and we thus assume for now on that $B_i$ is of type $A$.

As $p$ is unramified for $B$ (and thus $B_i$) we can further decompose. Let $F$ be the center of $B_i$, and $F_0 = (F)^{\times -1}$. As we are in case $A$, $[F : F_0] = 2$. Write $p = \pi_1 \ldots \pi_{s_i}$ the decomposition of $p$ in primes of $F_0$. For $j \in \{1, \ldots, s_i\}$, we say that $j$ (or $\pi_j$ or $(B_i, \pi_j)$ is in case $AL$ is $\pi_j$ splits in $F$, and in case $AU$ otherwise (compare [VW13] Remark 1.3).

Remark 2.1. — Actually we can allow a slightly larger class of Shimura datum than the unramified ones. Suppose that $B \otimes \mathbb{Q}_p = B_1 \times B_2$ where

$$B_1 = \prod_{i=1}^r M_{n_i}(F_i),$$
where and \( K/\mathbb{Q}_p \) is a finite extension, and such that there is no factor of type D appearing in \( B_{\mathbb{Q}_p} \). For all \( i \) denote again \( F_i = (F_i)^{*i-1} \), and denote \( \pi_1, \ldots, \pi_s \) the prime over \( p \). Let then \( G_p^{full} \) be the set of couples \((i, j)\) such that \( \pi^j \) is not ramified in \( F_0 \) and does not ramifies in \( F_i \) either. When \( p \) is unramified in the datum \( D \), we can take \( G_p^{max} \) to be the set of all \((i, j)\). In general, for \( S_p \subset G_p^{max} \), we will be able to construct \( S_p \)-families of automorphic forms for the datum \( D \), i.e. we are able to let the forms vary (only) along the unramified primes of \( D \).

Let then \( S_{\text{full}} \) be the set of couples \( (p, i, j) \) such that \( \pi^j \) is not ramified in \( F_0 \) and does not ramifies in \( F_i \) either. When \( p \) is unramified in the datum \( D \), we can take \( S_{\text{max}} \) to be the set of all \( (p, i, j) \). In general, for \( S_p \subset S_{\text{max}} \), we will be able to construct \( S_p \)-families of automorphic forms for the datum \( D \), i.e. we are able to let the forms vary (only) along the unramified primes of \( D \).

Let \( T \) be the center of \( G_1 = \text{Ker} c \subset G \). We can decompose \( T \) (over \( \mathbb{Z}_p \)) according to the previous decomposition,

\[
T = \prod_{i=1}^r \prod_{j=1}^{s_i} T_{i,j},
\]

(remark that if \( B_i \) is of type C, we can also decompose according to primes over \( p \)).

**Definition 2.2.** — The full weight space associated to the previous PEL datum is the rigid space over \( \mathbb{Q}_p \)

\[
W_{\text{full}} = \text{Hom}_{\text{cont}}(T(\mathbb{Z}_p), G_{m}^{rig}),
\]

which associate to any Banach \( \mathbb{Q}_p \)-algebra \( R \) the set of continuous characters \( \text{Hom}_{\text{cont}}(T(\mathbb{Z}_p), R^x) \).

It is represented by the Banach algebra \( \mathbb{Z}_p[[T(\mathbb{Z}_p)]] \).

If \( S_p \) is a subset of the couples \((i, j)\) (that we see as places over \( p \)) and if we denote \( T_{S_p} \) the torus over \( \mathbb{Z}_p \);

\[
T_{S_p} = \prod_{(i,j) \in S_p} T_{i,j},
\]

we can define the \((S_p)\)-weight space

\[
W_{S_p} = \text{Hom}_{\text{cont}}(T_{S_p}(\mathbb{Z}_p), G_{m}^{rig}).
\]

It is also represented by the Banach algebra \( \mathbb{Z}_p[[T_{S_p}(\mathbb{Z}_p)]] \), and when \( S_p \) contains all couples \((i, j)\), we have \( W_{S_p} = W_{\text{full}} \).

On \( W_{S_p} \) there is a universal character \( \kappa^{\text{univ}} : T_{S_p}(\mathbb{Z}_p) \to \mathbb{Z}_p[[T_{S_p}(\mathbb{Z}_p)]] \). We have the following results,

**Proposition 2.3.** — The space \( W_{S_p} \) is geometrically a finite disjoint union of dimension the rank of \( G_1 \). Moreover there exists a admissible covering by increasing affinoids,

\[
W_{S_p} = \bigcup_{w>0} W_{S_p}(w),
\]

such that \( \kappa^{\text{univ}}|_{W_{S_p}(w)} \) is \( w \)-analytic.

**Proof.** — See [Urb11] 3.4.2 and Lemma 3.4.6. See [AIP15], section 2.2 for a definition of \( W_{S_p}(w) \).

We can decompose \( W_{S_p} = \prod_{(i,j) \in S_p} W_{i,j} \) according to the decomposition of \( B \). In the following we will construct families parametrized by \( W_{S_p} \), as their construction is not more difficult than the case of the full weight space, and following construction can be done on \( W_{S_p} \) when \( p \) ramified at some places of \( D \), but not at other places. To my
3. Classical coherent Automorphic forms

Associated to \((G, h)\) there is a tower of Shimura Varieties of the reflex field \(E\). Because of the assumption of \(p\) in \(D\), these Shimura varieties have good reduction at \(p\) when the level at \(p\) is hyperspecial (see [Kot92]). Suppose this is the case in this section (otherwise all we say here remains true after inverting \(p\), and we will explain how to extends this integrally in section 5). We will describe their integral models as moduli space of Abelian varieties. Let \(K^p \subset \mathcal{G}(\mathbb{A}_{\mathbb{Q}, f})\) be sufficiently small level outside \(p\). Denote \(X_{K^p}\) the functor,

\[
X_{K^p} : S \in \text{Sch} \rightarrow \text{Spec} \mathcal{O}_{E,p} \rightarrow \{(A, i, \lambda, \eta)\}/\sim,
\]

that associated the set of quadruple \((A, i, \lambda, \eta)\) modulo equivalence where,

- \(A/S\) is an abelian scheme
- \(i : \mathcal{O}_B \rightarrow \text{End}(A) \otimes \mathbb{Z}(p)\) is a \(\mathbb{Z}(p)\)-algebra endomorphism.
- \(\lambda\) is a \(\mathbb{Z}(p)\)-equivalence class of \(\mathcal{O}_B\)-linear polarisation of order prime to \(p\) which identifies Rosatti involution and \(*\) through \(i\).
- \(\eta\) is a \(K^p\)-level structure on \(A\) (see [Kot92] section 5, or [Lan13](3)).

where \(i\) is subject to the determinant condition and the equivalence is by prime to \(p\) quasi-isogeny (see also [VW13] and for all details [Lan13]). As \(K^p\) is sufficiently small \(X_{K^p}\) is representable by a quasi-projective smooth scheme.

We choose \(\nu\) a place of \(E\) over \(p\), and denote \(\mathcal{O}_{E, \nu}\) the completion of \(\mathcal{O}_E\) through \(\nu\) and denote \(X = X_{K^p, \nu}\) the base change to \(\mathcal{O}_{E, \nu}\).

According to the decomposition of \(B\), we can decompose \(A = \prod_{i=1}^{n^i} A_i\) (and the other datums) as a product of abelian schemes (with additional structure associated to \(B\)). Moreover, we can further decompose the associated \(p\)-divisible group, writing \(O_{B_i} \simeq \prod_{j=1}^{n_{i,j}} M_{n_J}(\mathcal{O}_{K_{i,j}})\), and using Morita-equivalence,

\[
A_i[p^{\infty}] = \prod_{j=1}^{n_{i,j}} \mathcal{O}_{K_{i,j}}^{n_J} \otimes \mathcal{O}_{K_{i,j}} A_i[\pi_j^{\infty}].
\]

Moreover for a \((i, j)\) of type AL (i.e. \(\pi_j\) splits in \(F = F_i\)), we can further decompose,

\[
A_i[\pi_j^{\infty}] = H_{i,j} \times H_{i,j}^{\text{D}},
\]

such that \(\lambda\) is given by \((x, y) \mapsto (y, x)\) and \(i\) preserve each factor.

Denote \(\omega\) the conormal sheaf of \(A\), it is a locally free sheaf on \(X\) which decompose as previously, and for all \((i, j)\) we get \(\omega_{i,j} = \omega_{A_i[\pi_j^{\infty}]}\) locally free sheaf of rank \(\dim A_i[\pi_j^{\infty}]\).

Let \(P\) be the parabolic in \(G_1\) fixing the cocharacter \(\mu\) and \(M\) the levi of \(P\). \(T\) can be seen as a torus in \(M\) and fix a Borel \(B\) of \(M\). For \(\kappa \in X^+(T)\) a dominant weight for this choice, there exists a locally free sheaf \(\omega^\kappa\) on \(X\). This sheaf can be described this way. Let

\[
T^\kappa = \text{Isom}_{X, \mathcal{O}_X}(\Gamma \otimes \mathbb{Z}_p \mathcal{O}_X)^*, \omega) \simeq \text{Isom}_{X, \mathcal{O}_X}(\Gamma \otimes \mathbb{Z}_p \mathcal{O}_X, \text{Lie}(A/Y)),
\]

(3) Recall that such a level structure includes a (class of) isomorphism \(\mathbb{Z}/p^N\mathbb{Z} \simeq \mu_{p^N}\) for some \(N\), see [Lan13] Definition 1.3.6.1.
where $\Gamma$ is a $O_B$-invariant $O_{E,(p)}$-lattice in $V_1$ (where $V = V_0 \oplus V_1$ under the weight decomposition of $\mu$, see [VW13] p10) and $\pi : T^\times \rightarrow X$, the space of trivialisations of $\omega$. This is a $M$-torsor.

**Definition 3.1.** — Let $\kappa$ be a dominant algebraic character of $T$ and $\kappa^\vee$ its dual, i.e. $-u_0(\kappa)$ where $u_0$ is the longest element of the Weyl group. We see this characters as characters of $B$, extending them trivially on the unipotent. The coherent automorphic sheaf $\omega^\kappa$ is the locally free sheaf over $X$ defined by,

$$\omega^\kappa = \pi_* O_{T^\times} [\kappa^\vee].$$

Let $X^{tor}$ be a toroidal compactification(4) of $X$ (see [Lan13]) and $D$ its boundary.

**Definition 3.2.** — The space of (respectively cuspidal) modular (or coherent automorphic) forms of weight $\kappa$, and level $K\Gamma G(\mathbb{Z}_p)$ is the space,

$$H^0(X^{tor}, \omega^\kappa), \quad \text{(respectively } H^0(X^{tor}, \omega^\kappa(-D))).$$

**Remark 3.3.** — The goal of this article is to deform $p$-adically the previous spaces of automorphic forms. Unfortunately, we can check that in some cases the duality $\kappa \mapsto \kappa^\vee$ does not extend to $p$-adic weights. This is the case for $U(2,1)_{E/\mathbb{Q}}$ when $p$ is inert in $E$, where $T = O^\times_{E,p} \times O^1_{E,p}$. We can see an algebraic weight $(k_1 \geq k_2, k_3)$ as $(x, y) \mapsto \tau(x)^{k_1} \tau(y)^{k_2} \sigma \tau(x)^{k_3}$ and duality sends $(k_1 \geq k_2, k_3)$ on $(-k_2, -k_1, -k_3)$. This does not come from a natural algebraic map on $W$. This is harmless for us as we can work with normalisation of the weight given by $\kappa^\vee$ instead of $\kappa$, and thus we will embed weight $\kappa$ classical automorphic forms into weight $\kappa^\vee$ overconvergent ones.

### 4. Local models and Jones Induction result

To construct families of automorphic forms, we will first construct families of automorphic sheaves, i.e. we will construct automorphic sheaves $\omega^{\kappa^\vee}$ for $\kappa$ not only a dominant algebraic weight but a $p$-adic one, and these sheaves will interpolate the coherent sheaves $\omega^\kappa$ (actually to be more precise the sheaves $\omega^{\kappa^\vee}$, see remark 3.3). This has been done previously in analogous settings (see [AIP15, AIS14, Pil13, Bra16, Her19]), and all these works adapt geometrically constructions that were first developed in the case of compact at infinity groups (see [Buz07, Che04, Urb11]) using interpolations of algebraic representations by locally analytic ones. As our sheaves will be modeled on these construction, let us review the theory. It will be usefull in analysing classicity questions in section 8.

---

(4) A priori the following definition depends on this choice, however by [Lan13] Lemma 7.1.1.3, this is independant of the choice of a toroidal compactification, and in most cases we don’t even need to specify any compactification, by Koecher’s principle, see [Lan16b] Theorem 2.3.
4.1. Inductions. — Let us fix some notations. We will be interested in representations of a $p$-adic groups attached to $\mu$. $\mu$ gives rise to a parabolic in $G$, and denote $M$ the Levi subgroup of this parabolic. The group $M_{\mathbb{Q}_p}$ splits over the couples $(i,j)$ introduced before. As explained in the previous section, $(i,j)$ of type $(C)$ are ordinary and thus have be treated in [Bra16], thus we focus on type $(A)$. In this cases, $M_{(i,j)}$ is isomorphic to a Levi of the group $\text{Res}_{F^+/\mathbb{Q}_p}U(n_i)_{F_i/F^+_i}$.

Denote $T^+_i = T_{(i,j)}^+$ the set of embeddings of $F^+_i$ into $\overline{\mathbb{Q}}_p$ and $T$ the corresponding set for $F$, $M_{(i,j)}$ is thus up to extending scalars isomorphic to some $P = \prod_{\tau \in T^+} \text{GL}_{p_{\tau}} \times \text{GL}_{q_{\tau}}$ say over $K$ a $p$-adic field. The integers $p_{\tau}, q_{\tau}$ are determined by $\mu$, the co-character associated to the Shimura Datum $(G,h)$, and verify that

$$p_{\tau} + q_{\tau} = n_i, \forall \tau \in T^+.$$ 

For now on, we drop the index $(i,j)$ in the notations, thus set $n_i = n = h = p_{\tau} + q_{\tau}$. Still denote by $P = \prod_{\tau \in T^+} \text{GL}_{p_{\tau}} \times \text{GL}_{q_{\tau}}$ an integral model over $O = O_K$. Let $T$ be the maximal (diagonal) torus of $P$, $B$ the upper Borel, and for each $\kappa \in X^+ (T)$, denote the (algebraic, non-normalized) induction,

$$V_\kappa = \{ f : P \longrightarrow \mathbb{A}^1, f(gb) = \kappa (b)f(g) \text{ for all } g,b \in P \times B \}.$$ 

This is a finite dimensional $K$-vector space endowed with an action of $P(K)$ by $(g,f)(z) = f(g^{-1}z)$. The algebraic induction is a local model of the automorphic sheaves $\omega^\kappa$ in the sense that etale locally the later is isomorphic to the former. We will now describe another representation that will interpolate the previous ones and which will be local models of the coherent Banach sheaves constructed later in the paper.

Let $I = I_1$ be the Iwahori subgroup of $P$, i.e. $I = \text{Ker}(P(O) \longrightarrow P(O/p)/B(O/p))$. Denote more generally $I_n$ the level-$n$ Iwahori, i.e. elements that are upper triangular modulo $p^n$. We have a Iwahori decomposition $I = B(O) \times N^0$, and we can identify $N^0$ with

$$ (pO)^N \subset \mathbb{A}^N_{an}, \quad N = \sum_{\tau \in T^+} \frac{p_{\tau}(p_{\tau} - 1) + q_{\tau}(q_{\tau} - 1)}{2}.$$ 

For any $\varepsilon \geq 0$, we define $N^0_\varepsilon$ as the subspace,

$$ \bigcup_{x \in (pO)^N \varepsilon B(x, p^{-\varepsilon})} \subset \mathbb{A}^N_{an},$$

and for $L$ a $p$-adic field, denote $\mathcal{F}^{\varepsilon-an}(N^0, L)$ the function that are restriction to $N^0$ of analytic functions on $N^0_\varepsilon$. Now we can define the $\varepsilon$-analytic induction. Let $\kappa \in \mathcal{W}(L)$ be $\varepsilon$-analytic,

$$V^\varepsilon_{\kappa,L} = \{ f : I \longrightarrow L : f(gb) = \kappa (b)f(g) \forall g,b \in I \times B(O), f_{N^0} \in \mathcal{F}^{\varepsilon-an}(N^0, L) \}.$$ 

Denote $V^\text{loc-an}_{\kappa,L} = \bigcup_{\varepsilon > 0} V^\varepsilon_{\kappa,L}$ and $V^\text{an}_{\kappa,L} = \bigcap_{\varepsilon > 0} V^\varepsilon_{\kappa,L}$. This spaces won’t be local models of our Banach-automorphic sheaves, but they will have the same finite slope eigenvalues.

Choose an ordering, $\{ p_{\tau} : \sigma \in T \} = \{ p_{\tau}, q_{\tau} : \tau \in T^+ \} = \{ p_1 \leq \cdots \leq p_{2f} \}$, and let $P_{(p_{\tau})} \subset \text{GL}_{p_{2j}}$ be the standard parabolic with (ordered) blocs of size $(p_i - p_{i-1})_{i=1,\ldots,2f}$.
where \( p_0 = 0 \). Denote \( I_{(p_r)} \) the Iwahori subgroup of \( P^0_{(p_r)}(O) \) with respect to the standard upper triangular Borel, and \( N^0_{(p_r)} \) the opposite unipotent in \( I_{(p_r)}(O) \). For every \( \sigma \in \mathcal{T} \), every matrix \( M \in P^0_{(p_r)}(O) \) can be written of the form,

\[
M = \begin{pmatrix} A_\sigma & B_\sigma \\ 0 & D_\sigma \end{pmatrix}, \quad A_\sigma \in M_{(p_{2j-p_r} \times (p_{2j-p_r})(O)}, D_\sigma \in M_{p_0 \times p_0}(O).
\]

In particular, we get for each \( \tau \in \mathcal{T}^+ \) a map,

\[
P_{(p_r)}(p_{\bar{\tau}}) \rightarrow GL_{p_\sigma} \times GL_{q_\tau}, \quad M \mapsto (D_\sigma, D_\bar{\tau}),
\]

where \( \sigma, \bar{\tau} \) are the two embeddings over \( \tau \) such that \( p_\sigma = p_\tau, p_{\bar{\tau}} = q_\tau \) and \( D_\sigma \) refers to the previous decomposition.

Denote again \( P^0_{(p_r)} \) the image of the diagonal embedding \( P^0_{(p_r)} \rightarrow \prod GL_{p_\sigma} \times GL_{q_\tau} \) (it is injective, looking at a \( \tau \) such that \( p_\tau = p_{2j} \) or \( q_\tau = p_{2j} \)). Thus, we can see \( I_{(p_r)} \) as a subgroup of \( P \), and consider, for every \( \kappa \in W(L) \) which is \( \varepsilon \)-analytic,

\[
V^0_{\kappa,L} = \{ f : I_{(p_r)}B(O) \rightarrow L : f(g) = \kappa(b)f(g), f|_{N^0_{(p_r)}} \in \mathcal{F}^{\varepsilon-an}(N^0_{(p_r)}, L) \}.
\]

Everything makes sense as \( N^0_{(p_r)} \) can be seen as a subset of \( N^0 \) and we can define \( \varepsilon \)-analytic functions on it (using balls in \( k \supseteq N^0 \) centered on points of \( N^0 \)). It is slightly complicated, but now \( V^0_{\kappa,L} \) will be local models of our forthcoming Banach-automorphic sheaves.

### 4.2. \( U_\rho \)-operator.

Define for all \( i \leq \frac{h}{2} \) an integer,

\[
d_i = \begin{pmatrix} p^{-2}I_{\max(h-2i,0)} & p^{-1}I_{\min(h-2i,2j-i)} \\ 0 & I_i \end{pmatrix} \in P^0_{(p_r)}(K).
\]

We sometimes see \( d_i \) in \( GL_{p_\sigma} \times GL_{q_\tau} \) using the previous embedding. Denote for each \( \sigma \in \mathcal{T}, a_\sigma = \max(p_\sigma - (h-i),0), b_j = \max(\min(h-2i, p_\sigma - i), 0) \) and \( c_\sigma = \min(i, p_\sigma) \) (thus \( a_\sigma + b_j + c_\sigma = p_\sigma \)). This is respectively the number of \( p^{-2}, p^{-1}, 1 \) appearing in \( D_\sigma \) in the previous decomposition for \( d_i \). We can define an operator \( \delta_i \) on \( V^0_{\kappa,L} \) by \( \delta_i f(j) = f(d_i nd_i^{-1} b) \) where \( j = nb \) is the Iwahori decomposition.

### Proposition 4.1.

Let \( f \in V^0_{\kappa,L} \) that we see as a function in \( \mathcal{F}^{\varepsilon-an}(N^0_{(p_r)}, L) \) of variable \( (x_{k,l}, y_{m,n})_{1 \leq k < p_r, 1 \leq n < m < q_\tau, \tau} \). Then,

\[
\delta_i : F^{\varepsilon-an}(N^0_{(p_r)}, L) \rightarrow (x_{k,l}, y_{m,n}) \mapsto f(p^{2k-j}x_{k,l}, p^{w_{m,n}}y_{m,n})
\]

where, if we denote \( \tau = \sigma \bar{\tau} \) in \( F \), with \( p_\tau = p_\sigma \),

\[
u_{k,l} = \begin{cases} 
2 & \text{if } k > a_\sigma + b_j \text{ and } l \leq a_\sigma \\
1 & \text{if } (b_j + a_\sigma) \geq k > a_\sigma \text{ and } l \leq a_\sigma \text{ or } (b_j + a_\sigma) \geq l > a_\sigma \text{ and } k > a_\sigma + b_j \\
0 & \text{otherwise}
\end{cases}
\]
Proof: — This is a direct calculation on matrices of $N^0$.

4.3. Jones’s BGG and a fiberwise classicity result. — Let $P$ our previous algebraic group $T$ its torus and $B$ its upper Borel that defines $\Delta$ a set of positive roots. Then for every dominant weight $\kappa = X^+(T)$, Jones’s [Jon11] proved the exacteness of the following sequence,

\[ 0 \longrightarrow V_{\kappa,L} \longrightarrow V^\kappa_{\kappa,L} \xrightarrow{d} \bigoplus_{\alpha \in \Delta} V^\kappa_{\kappa,\kappa \otimes \kappa,L} \]

where $d$ is an explicite map (see for example [AIP15] for $GSp_{2g}$ ($P = \text{GL}_g$) and [Bra16] for a similar case to ours). Then the following proposition is [Bra16] proposition 6.5

**Proposition 4.3.** — Write $\kappa = (k_{\sigma,i}) \in X^+(T)$ according to the decomposition $P = \prod_{\tau \in \mathcal{T}} \text{GL}_{p_{\tau}} \times \text{GL}_{q_{\tau}} = \prod_{\sigma \in \Delta} \text{GL}_{p_{\sigma}}$ a dominant weight. Set

\[ v^\kappa_i = \inf\{k_{\sigma,i} - k_{\sigma,i+1} : i < p_{\tau}\} \]

Then,

\[ V^0_{\kappa,L} \subset V_{\kappa,L} \]

(The same proposition is true with $V^0_{\kappa,L} \subset V_{\kappa,L}$.)

Proof: — The first thing to check is that if $f \in V^0_{\kappa,L}$ is of non-zero slope, then $f \in V^\kappa_{\kappa,L}$. But as $\prod_{\alpha \in \Delta} \delta_{\alpha}$ is increasing the analytic radius, by proposition 4.1 we get the claim. Now, we can use Jones’s BGG result as in [AIP15] Proposition 2.5.1, or [Bra16] section 6.1, and we get the result.

Remark 4.4. — The previous calculation is made completely explicitely for $G = (G)U(2,1)$ in [Her19].

5. Integral models

5.1. Isogeny Graphs. —

**Definition 5.1.** — Fix $h \in \mathbb{N}^*$ and $n \in \mathbb{N}^*$, and denote $\Gamma_h^n$ the subset of $M_{n \times h}(\mathbb{C})$ such that $M = (m_{i,j})_{1 \leq i \leq n, 1 \leq j \leq h} \in M_{n \times h}(\mathbb{C})$ satisfies,

1. For all $(i, j)$, $m_{i,j} \in \{0, 1\}$,
2. For all \((i, j)\), if \(m_{i,j} = 1\), then \(m_{i-1,j} = 1\) and \(m_{i,j-1} = 1\) (when defined).

Let \(\Gamma^h = (\Gamma^n_h, v)\) be the graph whose points are \(M \in \Gamma_h^n\), and there is an arrow from \(M = (m_{i,j})\) to \(M' = (m'_{i,j})\) if
\[
\{(i, j)|m_{i,j} \neq m'_{i,j}\} = \{(i_0, j_0)\} \quad \text{and} \quad m_{i_0,j_0} = 0, \quad m'_{i_0,j_0} = 1.
\]

When \(n = 0\), define \(\Gamma^h_0\) as \(\ast\), and the map \(\pi_{0,1} : \Gamma^h_0 \ni \ast \mapsto (0, \ldots, 0) \in \Gamma^h_1\). When \(n \geq 2\), we have a natural map,
\[
\pi_{n-1,n} : M = (m_{i,j})_{1 \leq i \leq h, 1 \leq j \leq n-1} \mapsto (m'_{i,j}) \in M_n(\mathbb{C}), m'_{i,j} = m_{i,j} \text{ if } j < n, 0 \text{ otherwise}.
\]

This map preserves vertices, it is an embedding of graphs.

**Remark 5.2.** — If \(n = 1\), the possible matrices are simply given by
\[
M_i = (1, \ldots, 1, 0, \ldots, 0).
\]

They parametrize the lattices appearing in a periodic lattice chain inside \(GL_h(\mathbb{Z}_p)\) as in [RZ96].

### 5.2. Some integral models.

Let \(p\) be a prime, and let \(D\) be an integral Shimura-PEL-data as in section 2.

Denote by \(\mathcal{P} = \{(i, v) | v \text{ place of } F_i^+\}\) the set of places of \(G\), where \(F_i\) is the center of \(B_i\). Fix \(S_p \subset \{(i, j) | i \in \{1, \ldots, r\}, j \in \{1, \ldots, s_i\}\}\) a set of unramified places over \(p\). With our assumptions on \(D\), for all \(v = (i, j) \in S_p\), \(v\) is unramified, and \(B \otimes_{F^+} F^+_i\) is split and isomorphic to \(M_n(F_v)\). Fix \(S\) a finite set of places of \(\mathcal{P}\) such that \(S \cap S_p = \emptyset\), and \(S\) contains all places such that \(B\) doesn’t split or is ramified.

Fix then a compact \(K^{S,S_p}\) outside \(SS_p\) such that, \(K_v\) is maximal hyperspecial for all \(v \notin S \cup S_p\).

For all \((i, j) \in S_p\) we can associate an integer \(h_{i,j} = \text{ht}_{O_{\mathcal{L}_i,j}} A[\pi_j]\) in case (AI) and \(h_{i,j} = \text{ht}_{O_{\mathcal{L}_i,j}} A[\pi^+_j]\) in case (AL). These integers are defined for example by looking at the characteristic \(0\) moduli space as explained in section 3 (or could be read directly on \(G\), and even defined by the integral moduli space of Kottwitz if \(G\) is unramified at \(p\)). We set
\[
\prod_{i} = \prod_{(i, j) \in S_p} \prod_{h_{i,j}}.
\]

Fix once and for all a compact subgroup \(K_S \subset G(F_S)\) and for all \(v \in S_p\), consider \(K_v^{Sph}\) the maximal hyperspecial compact open subgroup. We will study some covering of
\[
X^{Sph} = X_{G,K_0}, \quad K_0 = K^{S,S_p}K_S \prod_{v \in S_p} K_v^{Sph}.
\]

The Shimura variety associated to \(X^{Sph}\) has a good integral model \(X^{Sph}\) over \(\text{Spec}(O_K)\), for \(K/\mathbb{Q}_p\) a well chosen finite extension ([Lan13]) if \(K_v\) is hyperspecial for all \(v|p\), and ([Lan16a]) if \(p\) is unramified in \(D\) for example by normalisation of the hyperspecial level. In general, we fix any integral model \(X^{Sph}\) given by [Lan16a]. If \(K_v\) is hyperspecial for all \(v|p\), \(X^{Sph}\) is smooth.
We will define our base space, and its integral model following [Lan16a]. Let for all \( v \in S_p, I_v \) be an Iwahori subgroup at \( p \) of \( G(F_v) \). Define first its generic fiber, 
\[
X = X_{G,K}, K = K^{S,S_p}K_S \prod_{v \in S_p} I_v.
\]
This space, over some extension \( K \) of \( \mathbb{Q}_p \), classifies quintuples \((A, \iota, \lambda, \eta, H)\) modulo isomorphisms where \((A, \iota, \lambda, \eta_S)\) is a point of \( X^{Sph} \), and \( H \) is a full flag of \( A[v] \), for \( v \in S_p \). Explicitly, for every \((i, j)\) as before, \( H^i_j \) induces,

1. In case \( p\) AL \( q \), a filtration
\[
0 \subset H_1 \subset \cdots \subset H_r = A[\pi_j],
\]
by finite flat \( O_{i,j}\)-group schemes such that \( H_k \) is of rank \( p^k \).

2. In case \( p\) AU \( q \), a filtration,
\[
0 \subset H_1 \subset \cdots \subset H_r = A[\pi_j],
\]
by finite flat \( O_{i,j}\)-groups schemes such that \( H_k \) is of rank \( p^k \) and \( H^i_j = H^j_k \).

This Shimura variety with Iwahori level at \( S_p \) has a natural integral model over \( \text{Spec}(\mathcal{O}_K) \). When all the prime \( v | p \) satisfies that \( K_v \) is parahoric (this is only a condition outside \( S_p \) here), then this is defined by the lattice chain introduced in [RZ96]. See for example [Lan13]. In general, this can be seen as explained in [Lan16a], example 2.4 and 13.12. The abelian scheme \( A \) and the subgroups \( H^i_j \) gives rise to isogenies (precisely, we need to use Zarhin’s trick, see Remark 5.5),
\[
A \longrightarrow A^{i,j}_{k} = A/H^i_j_k.
\]
In particular we get a map,
\[
X \longrightarrow \prod_{\gamma \in \Gamma_1} X^{Sph},
\]
sending \((A, \iota, \lambda, \eta, H)\) to \((A^{i,j}_{k}, \iota, \lambda, \eta)\) (see remark 5.5). Then the integral model \( \mathcal{X} \) is defined as the normalisation of \( X^{Sph} \) in \( X \). This is flat over \( \text{Spec}(\mathcal{O}_K) \).

The same thing applies to compatible choices of toroidal compactification\(^{5}\), and we get spaces, flat, proper over \( \text{Spec}(\mathcal{O}_K) \) (see [Lan16a] Lemma 7.9),

\[
\mathcal{X}^{tor} \quad \text{and} \quad \mathcal{X}^{Sph,tor}.
\]

**Remark 5.3.** — In the following, we will be interested mainly by \( A \) (as opposed to the collection of all the \( A_{\gamma} \)) and the subgroups \( H^i_j[x] \). Thankfully, there is a “universal semi-abelian scheme” (more precisely, a degenerating family) on \( \mathcal{X}^{tor} \) and its covers extending \( A \) on \( X \). If \( p \) is unramified in the PEL datum and we are at hyperspecial level this is [Lan13] Theorem 6.4.1, in general this is [Lan16a] Theorem 11.2.

But we will need slightly more, as for a semi-abelian scheme \( G \), \( G[p^n] \) need not to be finite flat. Fortunately, we can find an étale covering \( \mathcal{U} \) of \( \mathcal{X}^{Sph,tor} \) such that \( G \) is approximated on each open of this covering by a Mumford 1-motive \( M \), i.e. \( G[p^n] = M[p^n] \) (see [Str10] section 2.3 (more precisely Proposition 2.3.3.1) and [Lan16a] Theorem

\(^{5}\) In all the this text, we always assume the rational cone decompositions to be smooth and projective without further comment.
11.2). This étale covering is an isomorphism on the boundary (see [Str10] section 2.4). In particular, there is a semi-abelian scheme of constant rank \( \tilde{G} \) such that \( \tilde{G}[p^n] \subset G[p^n] \) is finite flat, and such that \( \omega_{\tilde{G}[p^n]} = \omega_{G[p^n]} \). We can thus by pullback find also an étale covering of \( X_{tor} \) on which we have the finite flat group scheme \( \tilde{G}[p^n] \). Thus, the \((\mu\text{-}\text{ordinary})\) Hasse invariant or the degree function extends on this covering of \( X^{Sph,tor} \), but we can descend them : see in subsection 5.5.

We have similarly for any \( n \), a Shimura variety with Iwahori level \( p^n, X_0^{tor}(p^n) \), over \( \text{Spec}(K) \), classifying, outside the boundary, \((A, \iota, \lambda, \eta_S, H_\lambda)\), with \( H_\lambda \) a full flag of \( A[p^n] \). More precisely, we have for all \( (i, j) \),

1. In case \((AL)\), a filtration
   \[
   0 \subset H_1 \subset \cdots \subset H_r = A[\pi^+_j],
   \]
   by finite flat \( \mathcal{O}_{i,j} \)-group schemes such that \( H_k \) is of \( \mathcal{O}_{i,j} \)-rank \( p^n_k \) with cyclic graded pieces.

2. In case \((AU)\), a filtration,
   \[
   0 \subset H_1 \subset \cdots \subset H_r = A[\pi_j],
   \]
   by finite flat \( \mathcal{O}_{i,j} \)-groups schemes such that \( H_k \) is of \( \mathcal{O}_{i,j} \)-rank \( p_n^k \) with cyclic graded pieces such that \( H_k^1 = H_{r-1}^\sigma \).

Once again, by [Lan16a] (here we are in characteristics zero, so this is easier) there is a natural map\(^{(6)}\) (again, see remark 5.5),

\[
X_0(p^n)_{tor} \longrightarrow \prod_{\gamma \in \Gamma_n} X^{Sph,tor},
\]

sending \((A, \iota, \lambda, \eta_S, H_\lambda)\) to \((A/(H^k_{i,j}[p^n]), \iota, \lambda, \eta_S, H_\lambda)\) away from the boundary.

There is moreover a map

\[
X_0^{tor}(p^n) \xrightarrow{\pi_{n,n-1}} X_0^{tor}(p^{n-1}),
\]

given by sending the flag \((H^k_{i,j}[p^n])_{\ell \leq n} \subset A[\pi^+_j]_{\ell \leq n}\) to the flag \((H^k_{i,j}[p^n])_{\ell \leq n-1} \subset A[\pi^+_j]_{\ell \leq n-1}\).

In particular, the diagram,

\[
\begin{array}{ccc}
X_0(p^n)_{tor} & \xrightarrow{\pi_{n,n-1}} & X_0(p^{n-1})_{tor} \\
\downarrow \pi_{n,n-1} & & \downarrow \pi_{n,n-1} \\
\prod_{\gamma \in \Gamma_n} X^{Sph,tor} & & \prod_{\gamma \in \Gamma_{n-1}} X^{Sph,tor}
\end{array}
\]

is commutative.

\(^{(6)}\)Cone decomposition must be chosen appropriately, but we suppose so, without further comment, as it is always possible to refine the choices in order to get the compatibility.
Definition 5.4. — Define $X_0(p^n)^\text{tor}$ to be the normalisation of $\prod_{\Gamma_n} X^{Sph, \text{tor}}$ in $X_0(p^n)^\text{tor}$. It is proper and flat over $\text{Spec}(\mathcal{O}_K)$. By normalisation, the map $\pi_{n,n-1}$ extends as a map,
$$
\pi_{n,n-1} : X_0(p^n)^\text{tor} \longrightarrow X_0(p^{n-1})^\text{tor}.
$$

In particular (see also [FC90a] Chap I Prop. 2.7), over $X_0(p^n)^\text{tor}$ we have by pullback natural isogeny graphs,
$$
(A_i)_{\gamma \in \Gamma_n},
$$
such that the Kernel of $A_i[\pi_{\gamma}] : A_{k,m}^i \longrightarrow$ is a finite flat, at least away from the boundary, $O_{i,j}$-subgroup of $A_{i,j}$ rank $p^{km}$. We denote it by $H_{i,j}^k$, or, if $p_{i,j}$ is understood, $H_{i,j}^k$. This makes sense as $H_{i,j}^k = H_{i,j}^k$. We call it the canonical subgroup of height $p_{\gamma}$ if it exists.

Remark 5.5. — Actually the construction is slightly more evolved as what than been said, as the abelian varieties $A_i = A/H_{i,j}^k[p^i]$ appearing in the isogeny graph might not be principally polarized, thus need not to give a map $X_0(p^n)^\text{tor} \longrightarrow X^{Sph}$. But as explained in [Lan16a] Proposition 4.12 and Proposition 6.1, we have a map to an auxiliary moduli problem where $A_i$ is modified to be principally polarized by Zarhin’s trick, extends to the integral model $X_0(p^n)^\text{tor}$ (all this works on the compactifications), and we can then deduce the extension of $A/H_{i,j}^k[p^i]$ itself.

5.3. Results on the canonical filtration and the Hodge-Tate map. —

Theorem 5.6. — Let $L$ be a valued extension of $\mathbb{Q}_p$, and $G$ be a truncated level $n$ $p$-divisible group over $\text{Spec}(\mathcal{O}_L)$ with action of $\mathcal{O}$ and signature $(p_r, q_r)$.

1. Then there exist at most one sub-$\mathcal{O}$-module $H_\tau$ of height $np_\tau$ such that,
$$
\deg H_\tau > \sum_{\gamma} \min(n_p\tau, np_\tau) - \frac{1}{2}.
$$

We call it the canonical subgroup of height $p_\tau$ if it exists.

2. Moreover, if two sub-$\mathcal{O}$-modules $H_\tau, H_\tau'$ of respective height $np_\tau, np_\tau'$ as before exists, then,
$$
p_\tau \leq p_\tau' \quad \text{if and only if} \quad H_\tau \subset H_\tau'.
$$

3. If moreover $G$ is polarized, then $H_\tau$ is polarized, i.e.
$$
H_\tau^\perp := (G/H_\tau)^D \longrightarrow G^D,
$$
is identified with the canonical subgroup of height $q_\tau$ of $G^D$.

4. The group $H_\tau$ verifying the previous hypothesis is a step of the Harder-Narasimhan filtration of $G$, it also coincide with the kernel of the Hodge-Tate map,
$$
\alpha_{G,\tau} : \mathcal{O}_L \longrightarrow \omega_{G^D,\tau},
$$
where $\varepsilon = \deg(G/H_\tau)$.

5. Suppose that $H_\tau$ as in 1. exists. The cokernel of the Hodge-Tate map,
$$
\alpha_{G,\tau} \otimes 1 : \mathcal{O}_L \longrightarrow \omega_{G^D,\tau},
$$
is of degree $p^{\frac{\deg_e(G(p)/H_\tau(p))}{p-1}}$. In particular, write $\varepsilon_\tau = n \min(p_\tau, p_\tau) - \deg_\tau H_\tau$, then the cokernel of the Hodge-Tate map is killed by $p^{\frac{\deg_e(G(p)/H_\tau(p))}{p-1}}$, where

$$K_\tau(p^*) = \sum_{i=1}^f p^{f-i} \max(p_{\alpha'i\tau} - p_\tau, 0) \quad \text{and} \quad S_\tau(\varepsilon^*) = \sum_{i=1}^f p^{f-i} \varepsilon_{\sigma'i\tau}.$$

Proof: — The first three assertions are Bijakowski’s result, [Bij16] Proposition 1.24,1.25, 1.30 (see for example [Her16] Proposition A.2 for something written for the $p^n$-torsion). Assertion 4. is proposition 7.8 and 7.7 of [Her16] (applying 7.8 we get a step $H_\tau'$ and by 7.7 $H_\tau$ and $H_\tau'$ coincide with the Kernel of the Hodge-Tate map). It is sufficient to prove 5. for $n = 1$. Remark that our hypothesis for $H_\tau \subset G$ implies the same for $H_\tau[p] \subset G[p]$. Indeed denote $\deg_\tau H_\tau = n \min(p_\tau, p_\tau) - \varepsilon_\tau$, and write the sequence,

$$0 \longrightarrow H_\tau[p] \longrightarrow H_\tau \longrightarrow pH_\tau \longrightarrow 0$$

which is exact in generic fibre, where $pH_\tau$ is the schematic adherence of $pH_\tau(\mathcal{O}_G)$ in $H_\tau$. Then $pH_\tau \subset G[p^{n-1}]$, and we have,

$$\deg_\tau H_\tau \leq \deg_\tau H_\tau[p] + \deg_\tau pH_\tau,$$

and because $pH_\tau$ is of height $(n-1)p_\tau$ and inside $G[p^{n-1}]$, $\deg_\tau pH_\tau \leq (n-1) \min(p_\tau, p_\tau)$. Thus,

$$\deg_\tau H_\tau[p] \geq \min(p_\tau, p_\tau) - \varepsilon_\tau.$$

(2)

Then denote $E = G[p]/H_\tau[p]$. The hypothesis on the degree of $H_\tau$, and thus of $H_\tau[p]$ implies

$$\omega_{H^p,\tau,\varepsilon} = 0$$

for all $\varepsilon < 1 - \deg_\tau(H_\tau^p)$, in particular, $\varepsilon < 1/2$. Using the same devissage of $E$ as in [Her16], proof of theorem 6.1 implies that

$$\deg \mathrm{Coker}(\alpha_{E,\tau,\varepsilon} \otimes 1) = \deg \mathrm{Coker}(\alpha_{G,\tau,\varepsilon} \otimes 1) = \frac{\deg_\tau(E)}{p^f - 1}.$$

Using the properties of various $\deg_\tau$, and equation (2) we get the result. 

\[ \square \]

Remark 5.7. — 1. The principal difference of the previous theorem with [Her16] is that we don’t a priori have the existence of such groups $H_\tau$. In [Her16], up to taking $p$ big enough to relate the ($\mu$-ordinary) Hasse invariant to the Hodge-Tate map, we have a condition for the existence in terms of the Hasse invariant. In this article, we assure the existence by increasing the level at $p$ in the integral model.

2. The bound given in 5 is interesting in general only when $p$ is big enough compared to $(p_\tau)$. If $p$ is small and $(p_\tau)$ is too big, then it is more interesting to use the bound given by Fargues ([Far11]) which states that (in full generality) the cokernel of the Hodge-Tate map is killed by $p^m$. Note this is because the degree involve taking some determinant.
5.4. Degree function, $\mu$-ordinary locus and Hasse invariants. — As usual, fix a couple $(i, j) \in S_p$, and suppress it from the notation. For each $\tau \in T$ is associated an integer $p_\tau$, and thus a subgroup of height $np_\tau$ over $X_0(p^n)$, $H_\tau \subset G = A[p_\tau]$, which is finite flat and killed by $p^n$. We can thus, following [Bij16], define for each $\tau$ a real-valued function,

$$
deq(H_\tau) : X_0(p^n) \rightarrow \{0, n \sum_\tau \min(p_\tau, p_\tau)\}
$$

and another one, $\prod_\tau \deg(H_\tau)$. Then we have the following result of Bijakowski [Bij16] Proposition 1.34,

**Proposition 5.8.** — The locus where the previous function is maximal in $X_0(p^n)$, i.e.

$$
\prod_{j=0}^{r-1} \{\min(p_\tau, p_\tau)\} \times \{\min(p_{i+j}, p_\tau)\},
$$

is included in $X_0(p^n)^{full-\mu-ord}$, the $\mu$-ordinary locus of $X_0(p^n)$.

**Remark 5.9.** — To be precise, as we have fixed the prime $(i, j) \in S_p$, the $\mu$-ordinary locus above, and in the rest of the text (until the conclusion at the end of section 9) if not stated otherwise, is with respect to the prime $(i, j)$.

**Definition 5.10.** — On $X^{Sph}$ we can define a $\mu$-ordinary Hasse invariant $Ha$ [cf. [Her18], see also [GN17, KW14]] which is a section of the sheaf $\det_\sigma \omega_{G}^{f-1}$ (mod $p$). This defines a function

$$
v(Ha) : X^{Sph} \rightarrow [0, 1],
$$

which sends a $O_K$-point to the (truncated by $1$) valuation of the $\mu$-ordinary Hasse invariant of the reduction of the corresponding point of $X^{Sph}$. In particular we can define by pullback an analogous function on $X_0(p^n)$, and define

$$
X_0(p^n)^{\mu-ord}(v) = v(Ha)^{-1}(0, v).
$$

**Remark 5.11.** —

1. In the previous definition, the valuation is normalized by $v(p) = 1$, and $X_0(p^n)^{\mu-ord}(0)$ is the $\mu$-ordinary locus of $X_0(p^n)$.
2. Actually by construction we have many maps from $X_0(p^n)$ to $X^{Sph}$ (and as much for their integral model), namely one for each $\gamma \in \Gamma_n$. The one we consider above is the canonical one corresponding to the zero-matrix $\gamma$ (which sends $A$ on $A$).

**Definition 5.12.** — Define $X_0(p^n)(v)$ as the (union of) connected components of $X_0(p^n)^{\mu-ord}(v)$ which contains a point of maximal degree for the previous function (equivalently, the components where the subfiltration of $H_\tau$ of height $np_\tau$ coincide where the canonical filtration in sense of theorem 5.6). We will call $X_0(p^n)(0) =: X_0^{can-\mu-ord}(p^n)$ the $\mu$-ordinary-canonical locus of $X_0(p^n)$. It is an open and closed subset of $X_0(p^n)^{\mu-ord}(0)$ and coincide with the locus of maximal degree of proposition 5.8.

**Remark 5.13.** — $X_0(p^n)(v)$ is the analogue of the strict neighborhoods of the ordinary-multiplicative part of the modular curves of level $\Gamma_0(p)$. 
Definition 5.14. — For $(\varepsilon_\tau)_\tau$, define the rigid analytic open,

$$X_0(p^n)((\varepsilon_\tau)_\tau) = \prod_{j=0}^{f-1} \deg(H_{\sigma_\tau}^{-1}) \left( \prod_{j=0}^{f-1} \left[ n \sum_{\tau} \min(p_{\sigma_\tau}, p_\tau) - \varepsilon_{\sigma_\tau}, n \sum_{\tau} \min(p_{\sigma_\tau}, p_\tau) \right] \right).$$

This is a strict neighborhood of the $\mu$-ordinary-canonical locus $X_0(p^n)(0)$ in $X_0(p^n)$.

Remark 5.15. — The map $\pi_{n,n-1}$ sends $X_0(p^n)(x)$ onto $X_0(p^{n-1})(x)$. Indeed, if $\deg H_\tau > n \sum_{\tau} \min(p_\tau, p_\tau) - \varepsilon$, then because of the generic exact sequence,

$$0 \longrightarrow H_\tau[p^{n-1}] \longrightarrow H_\tau \longrightarrow K \longrightarrow 0,$$

and the fact that $K$ is killed by $p$, thus $\deg K \leq \sum \min(p_\tau, p_\tau)$ we have that $\deg H_\tau[p^{n-1}] \geq (n-1) \sum_{\tau} \min(p_\tau, p_\tau) - \varepsilon$.

5.5. Extension to the boundary. — We want to extend the previous opens to all $X_0(p^n)^{tor}$, thus we will need to extend the functions $\deg$ and $\mu$ $\tau$. The function $A_\mu \tau$ can be extended to all $X_0(p^n)^{tor}$ as a section of some $\det(\omega_G) \otimes (O_{X_0(p^n)^{tor}}/p)$ by [Lan17] Theorem 8.7. For the functions $\deg$, we can also extend it. The group $H_\tau$ is the kernel of an isogeny of semi-abelian schemes

$$\pi : A \longrightarrow A_1,$$

on $X_0(p^n)^{tor}$. Thus, looking at the corresponding map on conormal sheaves we get

$$\pi^* : \omega_{A_1} \longrightarrow \omega_A,$$

and taking determinants gives $\det \pi^* \in H^0(X_0(p^n)^{tor}, \det \omega_A \otimes \det \omega_{A_1}^{-1})$. Over $X_0(p^n)$, the valuation at every point of $\det \pi^*$, which can be seen as an element of $\mathbb{R}_+$, coincides with the degree of $H_\tau$. Thus, we have extended the degree map to,

$$\deg(H_\tau) : X_1(p^n)^{tor} \longrightarrow \mathbb{R}_+.$$

To check that this map is actually bounded by $n \sum_{\tau} \min(p_\tau, p'_\tau)$ as on the open Shimura variety $X_0(p^n)^{tor}$, we can do the following. Let $x \in X_0(p^n)^{tor}(K)$, and let $\tilde{G}/\tilde{\mathcal{O}}K$ be the constant toric rank semi-abelian scheme such that $A_x$ is a quotient by some etale sheaf $Y$ of $\tilde{G}$ by Mumford’s construction. Then by [FC90b] Corollary 3.5.11, we have an exact sequence, and taking schematic adherence $H_n$ of $\tilde{G}[n] \otimes K$ in $A_x[n]$, we have that $H_n$ is isomorphic to $\tilde{G}[n]$ and whose quotient in $A_x[n]$ is etale. Decompose accordingly $A_\gamma \tau$ together with the isogeny $\pi$ (see for example [FC90b] Corollary III.7.2), and decompose $\pi_H$ as $\tilde{\pi}_H$ along $\tilde{G}$. Then the degree of $\pi_H$ is the same as $\tilde{\pi}_H$ as its quotient is etale. But ker $\tilde{\pi}_H$ (which is now finite flat) is of signature smaller than $(n \min(p_\tau, p'_\tau))_\tau$, thus the assertion on its degree.

In particular we can define $X_0(p^n)^{tor}((\varepsilon_\tau)_\tau)$ and $X_0(p^n)^{tor}(v)$ as before.

5.6. Two collections of strict neighborhoods. — The previous opens $X_0(p^n)^{tor}((\varepsilon_\tau)_\tau)$ and $X_0(p^n)^{tor}(v)$ both define stricts neighborhoods of the $\mu$-ordinary-canonical locus $X_0(p^n)^{tor}(0)$. Thus we get the following proposition,
Proposition 5.16. — For all \( v > 0 \) there exists \( (\varepsilon, \tau) > 0 \) such that,
\[
\mathcal{X}_0(p^n)^{\text{tor}}((\varepsilon, \tau)_0) \subset \mathcal{X}_0(p^n)^{\text{tor}}(v),
\]
and for all \( (\varepsilon, \tau) > 0 \) there exists \( v > 0 \) such that,
\[
\mathcal{X}_0(p^n)^{\text{tor}}(v) \subset \mathcal{X}_0(p^n)^{\text{tor}}((\varepsilon, \tau)_0).
\]

Proof. — Fix \( \mathcal{V} \) a strict neighborhood of \( \mathcal{X}_0^{\text{can}-\mu-\text{ord. tor}}(p^n) = \mathcal{X}_0(p^n)^{\text{tor}}(0) \). As \((\mathcal{V}, \mathcal{X}_0(p^n)^{\text{tor}}, \mathcal{X}_0(p^n)^{\text{tor}}(0))\) is an admissible covering, \( \mathcal{V} \) contains \( \mathcal{X}_0(p^n)^{\text{tor}}(v) \) for some \( v > 0 \). The same applies for \( \mathcal{X}_0(p^n)^{\text{tor}}((\varepsilon, \tau)_0) \). \( \square \)

Definition 5.17. — We say that \( \varepsilon = (\varepsilon, \tau) \) and \( v \) are \( n \)-compatible, and we say that they satisfies \( (\varepsilon, v, n) \), if,
\[
\mathcal{X}_0(p^n)^{\text{tor}}(v) \subset \mathcal{X}_0(p^n)^{\text{tor}}(\varepsilon).
\]

Let us explain quickly why we chose this two collections of strict neighborhoods. Classically, we use the stricts neighborhoods \( \mathcal{X}(\mathcal{U}) \) given by the Hasse invariant to construct eigenvarieties because this is the classical definition of Katz, and as the Hasse invariant is a section of an ample line bundle on the minimal compactification, we get that the ordinary (or \( \mu \)-ordinary) locus and its strict neighborhoods in the minimal compactification are affinoids. This is a crucial part of the construction described in [AIP15]. In many cases (see [Bra16] or [Her19] in the Picard case, and using [Her16] in all PEL unramified case when \( p \) is big enough), we manage to construct on the opens \( \mathcal{X}(\mathcal{U}) \) a canonical filtration and control the degree of the subgroups of this filtration explicitly in terms of \( v \). Thus the choice of the strict neighborhoods \( \mathcal{X}(\mathcal{V}) \) is enough to do all the constructions in these cases. But the classicity results as in [Buz07, Kas06, Pill, PSI12, BPS16] and in the \( \mu \)-ordinary case [Bij16] relies on the stricts neighborhoods in terms of the degree. So in the unramified PEL case when \( p \) is not big enough, it is not clear a priori how to relate the degrees in terms of the Hasse invariant. Nevertheless, the previous proposition will allow us to use the best of both worlds.

We will need to understand the behavior of the strict neighborhoods along etale maps.

Lemma 5.18. — Let \( \pi : X \longrightarrow Y \) a rigid etale map. Let \( U \subset X \) be a open subset and \( \mathcal{V} = \pi(U) \) the corresponding open in \( Y \). Let \( U_w \subset X \) be a strict neighborhood of \( U \), then \( \pi(U_w) \) is a strict neighborhood of \( \mathcal{V} \).

6. Canonical filtration, Hodge-Tate map and overconvergent modular forms

As before, fix a couple \((i, j) \in S_p\) that will be understood until the rest of this section. In the previous section we defined a rigid open denoted \( \mathcal{X}_0(p^n)^{\text{tor}}(v) \).

Definition 6.1. — We denote by \( \mathcal{X}_0(p^n)^{\text{tor}, \mu-\text{full}}(v) \) the normalisation of the greatest open in the blow-up of \( \mathcal{X}_0(p^n)^{\text{tor}} \) by the ideal \( I = (p^n, \mu \text{ Ha}) \) where this ideal is generated by \( \mu \text{ Ha} \). As this scheme is normal; it has the same connected components than its rigid fiber, and we thus denote \( \mathcal{X}_0(p^n)^{\text{tor}}(v) \) the one whose generic fiber is \( \mathcal{X}_0(p^n)(v) \).
From now on, fix $\varepsilon < \frac{1}{2}$. Recall that over $\mathcal{X}_0(p^n)_{\text{tor}}$ we have subgroups $H^m_{p^r}$ for $m \leq n$ (which are finite flat on $\mathcal{X}_0(p^n)$ of $\mathcal{O}$-rank $mp_r$), but a priori only quasi-finite flat over the boundary.

**Proposition 6.2.** — If $\varepsilon < \frac{1}{2}$, for every $v > 0$ such that

$$\mathcal{X}_0(p^n)_{\text{tor}}(v) \subset \mathcal{X}_0(p^n)_{\text{tor}}(\varepsilon),$$

the groups $H^m_{p^r}$ are finite flat over $\mathcal{X}_0(p^n)_{\text{tor}}(v)$.

**Proof.** — Over $\mathcal{X}_0(p^n)_{\text{tor}}$ there is an isogeny

$$A \longrightarrow A_{\gamma}^j,$$

of semi-abelian schemes whose Kernel is the group $H^m_{p^r}$ (a priori only quasi-finite flat), and this group is finite flat over $\mathcal{X}_0(p^n)$. Moreover, by a classical construction, there is an etale covering $\mathfrak{U}_{\text{tor}}$ of $\mathcal{X}_0(p^n)_{\text{tor}}$ over which the semi abelian schemes $A$ and $A_{\gamma}$ can be approximated by a 1-motive of Mumford $M$ and $M_{\gamma}$ (concretely these $\mathfrak{U}_{\text{tor}}$ exists for $\mathcal{X}^{Sph}$ by construction, see e.g. [Str10] section 3, and we can moreover assure that $M[p^n]$ and $M_{\gamma}[p^n]$ are isomorphic to $A[p^n]$ and $A_{\gamma}[p^n]$, by the arguments of [Str10] section 2.3, and take the pull-back via $\mathcal{X}_0(p^n)_{\text{tor}} \longrightarrow \prod_{\gamma} \mathcal{X}^{Sph, \text{tor}}$). We only need to check that $H^m_{p^r}$ is finite flat over $\mathfrak{U}_{\text{tor}}(v) := \mathfrak{U}_{\text{tor}} \times_{\mathcal{X}_0(p^n)_{\text{tor}}} \mathcal{X}_0(p^n)_{\text{tor}}(v)$. But there is an isogeny over $\mathfrak{U}_{\text{tor}}(v)$

$$\pi : A \longrightarrow A_{\gamma},$$

such that $\text{Ker} \, \pi$ is $H^m_{p^r}$. Thus for every $\mathcal{O}_K$-point of $\mathfrak{U}_{\text{tor}}(v)$, $H^m_{p^r}$ is of high degree (in the sense of theorem 5.6). But over $\mathfrak{U}_{\text{tor}}(v)$, $A$ and $A_{\gamma}$ are associated to Mumford 1-motives $M$ and $M_{\gamma}$ by Mumford construction. Thus there exists semi abelian schemes $G$ and $G_{\gamma}$, of constant toric ranks, in the datum of $M$ and $M_{\gamma}$, such that the isogeny $\pi$ reduces to

$$\pi' : G \longrightarrow G_{\gamma}. $$

Call $H' = \ker \pi'$. It is finite flat as $G$ and $G_{\gamma}$ have constant toric ranks. As $\omega_G \simeq \omega_A$ and $\omega_{G_{\gamma}} \simeq \omega_{A_{\gamma}}$, the degree of $H'$ is the same as the one of $H^m_{p^r} = \text{Ker} \, \pi$. Thus, away from the boundary, over $\mathfrak{U}(v) := \mathfrak{U}_{\text{tor}}(v) \times_{\mathcal{X}_0(p^n)_{\text{tor}}} \mathcal{X}_0(p^n)(v)$, by unicity in $A[p^n]$ of Theorem 5.6, we have $H' = H^m_{p^r}$ (it is true for every $\mathcal{O}_K$-point, thus on $\mathfrak{U}(v)$ by normality). In particular, the semi-abelian schemes

$$A/H^n_{p^r}$$

and

$$A/H',$$

are isomorphic over $\mathfrak{U}(v)$. But by [FC90b] Prop. 1.2.7, this implies by normality of $\mathcal{X}_0(p^n)_{\text{tor}}(v)$, and thus of $\mathfrak{U}_{\text{tor}}(v)$, that they are isomorphic over $\mathfrak{U}_{\text{tor}}(v)$. Thus $H^m_{p^r}$ is finite flat.

---

### 6.1. The sheaves $\mathcal{F}$ and integral automorphic sheaves.

We denote

$$\{p_0 \mid \tau \in \mathcal{T} \} \cup \{0, h\} = \{0 =: p_0 \leq p_1 < p_2 < \cdots < p_r \leq p_{r+1} := h\}.$$

We define for every $v > 0$ such that $\mathcal{X}_0(p^n)(v) \subset \mathcal{X}_0(p^n)(\varepsilon)$, a cover of $\mathcal{X}_0(p^n)(v)$. If $p_r = h$ (in which case $p_1 = 0$ by duality and thus on $\mathfrak{X}$ the universal $p$-divisible group
Remark 6.3

We assert isomorphism follows from theorem 5.6 and normality of $p$-etale coverings enough to check it locally and introduce the formal-etale covering $X$ satisfying the following. There are fixed isomorphisms, 

$$\nu' : (O/p^nO)^D \simeq (O/p^nO)^\sigma,$$

where the condition $pol$ is trivial in case $\langle AL \rangle$, and in case $\langle AL \rangle$ means that we are also given an isomorphism, 

$$\lambda : (O/p^nO)^D \simeq (O/p^nO)^\sigma,$$

i.e.

$$\lambda : (O/p^nO)^D \simeq (O/p^nO)^\sigma,$$

where

$$\lambda : (O/p^nO)^D \simeq (O/p^nO)^\sigma,$$

satisfying the following. There are fixed isomorphisms, 

$$\phi_k : (H_{p_k}/H_{p_{k-1}})^D \simeq (H_{p_{r-k+1}}/H_{p_{r-k+1}})^D,$$

induced by $H_{p_k} \simeq H_{p_{r-k+1}}$, itself induced by the prime-to-$p$ polarisation on $X^D$. (8)

We require that for all $k$, the two isomorphisms, 

$$\psi_k^D : (O/p^nO)^D_{p_k-p_{k-1}} \longrightarrow (H_{p_k}/H_{p_{k-1}})^D,$$

and 

$$\psi_{k+2}^D : (H_{p_{r-k+1}}/H_{p_{r-k+1}})^D \longrightarrow (O/p^nO)^D_{p_k-p_{k-1}}$$

satisfies $\psi_k^D = \psi_{k+2}^{-1}$, after identifying source and target via $\nu'$ and $\phi_k$.

In this definition we have extended slightly the definitions of the (canonical) subgroups $H_k : k = 0$ we set $D_0 = \{0\}$ and for $k = r + 1$ we set $D_{r+1} = G[p^n]$. If $p_r < h$ (in which case $p_1 > 0$ and on $X$ the universal $p$-divisible group $A_1[\pi^{\infty}_f]$ has a non-zero multiplicative and etale part), we set 

$$X_1(p^n)^{tor}(v) := \prod_{k=2}^{r} \text{Isom}_{H_0[p^n]^{tor}(v), pol, \mathcal{O}}(H_{p_k}/H_{p_{k-1}}, O/p^nO^D_{p_k-p_{k-1}}) \times \text{Isom}_{H_0[p^n]^{tor}(v)}(H_{p_1}, (O/p^nO)^D).$$

Remark 6.3. — 1. This is because if $p_r = h$, the group $A_1[\pi^{\infty}_f]$ is finite flat and polarised on the all toroidal compactification, but not if $p_r < h$, because $A_1[\pi^{\infty}_f]/H_{p_r}$, which is generically finite etale, is only quasi-finite on the boundary.

2. The point is that $X_1(p^n)^{tor}(v)$ is a rigid open in (a toroidal compactification of) the Shimura variety for $G$ of some level (which we could make explicit). Indeed, if we use the definition of [Lan13] Definition 1.3.7.4. at our prime $(i, j)$, we see that it amounts to the previous definition. Indeed, the morphism 

$$\nu : \mathbb{Z}/p^n\mathbb{Z} \longrightarrow \mu_{p^n},$$

(7) We now write $H_{p_r}$ instead of $H_r$. Thus $H_{p_k} = H_r$ if $p_r = p_k$ and of $O$-height $n_p_k$.

(8) To be precise, we have on $X_0(p^n)^{tor}(v)$ a semi-abelian scheme $A$ and $H_{p_r}^\sigma$ inside its $p$-torsion. The group homomorphism $\lambda : A \longrightarrow A^{\times/(\sigma)}$ is a polarisation on $X_0[p^n]$, and this polarisation, which identifies $H_{p_k}^\sigma$ with $H_{p_{r-k}}^{\sigma}$, induces an isomorphism $(H_{p_k}/H_{p_{k-1}})^D \simeq (H_{p_{r-k+1}}/H_{p_{r-k+1}})^D$ everywhere. Indeed, it is enough to check it locally and introduce the formal-etale covering $\mathcal{U}^{tor}(v)$ of subsection 5.5. Over $\mathcal{U}^{tor}(v)$, the polarization extend as $\lambda$ an isogeny of $L$-motives, thus induces an isogeny $\lambda^{ab}$ of their abelian parts on which the asserted isomorphism follows from theorem 5.6 and normality of $\mathcal{U}^{tor}(v)$. 

}
there induces a perfect pairing,
\[ \mathcal{O}/p^n \mathcal{O} \times (\mathcal{O}/p^n \mathcal{O})^{(\sigma)} \xrightarrow{\text{tr}(<,>)} \mathbb{Z}/p^n \mathbb{Z} \xrightarrow{\nu} \mu_{p^n}, \]
where \( \text{tr}(a, b) := \text{tr}(\overline{ab}) \) is a perfect pairing, and thus induces an isomorphism of \( \mathcal{O} \)-group schemes
\[ \nu : (\mathcal{O}/p^n \mathcal{O})^D \xrightarrow{\cong} (\mathcal{O}/p^n \mathcal{O})^{(\sigma)}. \]
Let \( \psi_k \) and \( \psi_{r-k+2} \) be the isomorphism induced by a Level structure in the sense of [Lan13], then let \( r = p_k - p_{k-1} \),
\[
\begin{align*}
(H_{p_k}/H_{p_{k-1}}) \times (H_{p_{r-k+2}}/H_{p_{r-k+1}})^{(\sigma)} & \xrightarrow{\text{Weil}} \mu_{p^n} \\
(\mathcal{O}/p^n \mathcal{O})^\tau \times (\mathcal{O}/p^n \mathcal{O})^{\tau'} & \xrightarrow{\text{tr}(<,>)_L} \mathbb{Z}/p^n \mathbb{Z}
\end{align*}
\]
must be commutative, and by compatibility between the polarisations on \( A[p^n] \) and \( L \), the two pairings \( \text{tr}(<,>)_L \circ (\psi_k \times \psi_{r-k+2}^{(\sigma)}) \) and \( \text{tr}(<,>)_L \circ (\psi_k \times (\nu' \circ (\psi_k^{-1} \circ \phi_k^{-1})) \) must coincide, thus \( \psi_{r-k+2} = \nu' \circ (\psi_k^{-1} \circ \phi_k^{-1}) \) by [Lan13] Corollary 11.4.2.

**Definition 6.4.** — Let \( X_1(p^n)^{tor}(v) \) be the normalisation of \( X_0(p^n)^{tor}(v) \) in \( X_1(p^n)^{tor}(v) \).
It is flat, proper and normal over \( \text{Spec}(O_K) \), and moreover we have maps
\[ \pi_{n,n-1} : X_1(p^n)^{tor}(v) \longrightarrow X_1(p^{n-1})^{tor}(v), \]
by normalisation of the map sending \( (\psi_k) \) to \( (\psi_k[p^{n-1}]) \).

**Proposition 6.5.** — Suppose \((\varepsilon, v, n)\). For every \( \tau \), there is on \( X_1(p)^{tor}(v) \) a locally free \( O_{X_1(p)^{tor}} \)-module of rank \( p_{\tau} F_{\tau} \subset \omega_{G^0, \tau} \) (respectively in case (AL) also a sheaf \( F_{\tau}^{+} \subset \omega_{G^0, \tau} \)) containing
\[ p^{(N_{\tau}^{(v, s)} + S_{\tau}(s))} \omega_{\tau} \quad \text{(respectively} \quad p^{(N_{\tau}^{(v, s)} + S_{\tau}(s))} \omega_{G^0, \tau} \text{).} \]
For all \( n \), it induces by pullback by \( \pi_n \) a sheaf \( F_{\tau} \) (resp. \( F_{\tau}^{+} \)) on \( X_1(p^n)^{tor}(v) \), endowed with a compatible map for all \( w_{\tau} \) is \( n - \varepsilon_{\tau} \), for all \( \text{Spec}(R) \subset X_1(p^n)^{tor}(v) \),
\[
\begin{align*}
\text{HT}_{\tau, w_{\tau}} : H_{p_{\tau}, n}^D(R) & \longrightarrow F_{\tau} \otimes R_{w_{\tau}}, \\
\text{HT}^{\perp}_{\tau, w_{\tau}} : (H_{p_{\tau}, n}^{+})^D(R) & = (G[p^n]/H_{p_{\tau}, n})(R) \longrightarrow F^{+}_{\tau} \otimes R_{w_{\tau}},
\end{align*}
\]
which induces an isomorphism,
\[
\begin{align*}
H_{p_{\tau}, n}^D(R) \otimes R_{w_{\tau}} & \longrightarrow F_{\tau} \otimes R_{w_{\tau}}, \\
\text{HT}^{\perp}_{\tau, w_{\tau}} \otimes R_{w_{\tau}} & \text{ is also an isomorphism}. \end{align*}
\]
**Proof.** — Indeed, we can work locally over \( S = \text{Spec}(R) \). We have isomorphisms \( (H_{p_{\tau}}/H_{p_{\tau-1}})^D(R) \cong (\mathcal{O}/p^n \mathcal{O})_{p_{\tau} - p_{\tau-1}} \) but as \( H_{p_{\tau}}^D(R) \) is an \( \mathcal{O}/p^n \mathcal{O} \)-module killed by \( p^n \) and of finite presentation, there exists an isomorphism \( H_{p_{\tau}}^D(R) \cong (\mathcal{O}/p^n \mathcal{O})^{p^n} \). We can thus work as in [AIP15] proposition 4.3.1 (see [Hert19] Proposition 6.1), where the analogs of the proposition are assured by Theorem 5.6, and the construction of \( X_0(p^n)^{tor}(v) \). \( \square \)
Proposition 6.6. — Suppose we are given an isogeny on $X_1(p)_{\text{tor}}(v)$, $\phi : G' \rightarrow G$ where $G'$ is a $p$-divisible group, together with subgroups $H'_{pr} \subseteq G'[p]$ satisfying the properties of Theorem 5.6. We can thus define $F'$ for $G'$ similarly. Then the induced map,

$$\phi^* : \omega_{G'} \rightarrow \omega_G,$$

sends $F'$ in $F$.

Proof. — As the groups in Theorem 5.6 are steps of some Harder-Narasimhan filtration, and this filtration is functorial, $\phi$ induces a map

$$\phi : H'_{pr} \rightarrow H_{pr}.$$

The rest follows easily (see e.g. [AIP15] Proposition 4.4.1).

6.2. Constructing Banach sheaves. — Out of the universal isomorphisms

$$\psi^D : (\mathcal{O}/p^n\mathcal{O})^{\text{Fil}^{p-1} - \text{Fil}^{p-1}} \rightarrow (H_{pk}/H_{pk-1})^D,$$

on $X_1(p^n)_{\text{tor}}(v)$, we get a (full) flag of $(H_{pk}/H_{pk-1})^D$, and thus (inductively) of $H^D_{pk}$ for all $s^{(i)}$ by writing for all $i$, $e_{1}, \ldots, e_{pk-pk_{-1}}$ the natural basis of $(\mathcal{O}/p^n\mathcal{O})^{\text{Fil}^{p-1} - \text{Fil}^{p-1}}$, and we thus denote $x^D_{p}$ the corresponding images in $(H_{s}/H_{s-1})^D$ through $\psi_{k}$. Choose a lift of this basis,

$$(x_1, \ldots, x_{pk_{-1}})$$

of $H^D$, and denote $\text{Fil}^p_{\text{tor}}$ the subgroup of $H^D$ generated by $x_1, \ldots, x_{pk_{-1}}$. These subgroups does not depend on the lifts. From now on, fix $v > 0$ such that $X_0(p^n)_{\text{tor}}(v) \subset X_0(p^n)_{\text{tor}}(v)$ (i.e. such that $(v,n)$ is satisfied). In particular, we have the sheaves $F_\tau$ on $X_0(p^n)_{\text{tor}}(v)$ and the compatibilities with $HT_\tau$ of the proposition 6.5. For simplicity, in case (Al) we call $\tau$ the set of embeddings of $\mathcal{O}$ together with their conjugate, and represent its elements by $\tau, \bar{\tau}$. For all $\tau$, we mean by $\omega_\tau$ the sheaf $\omega_{G^D, \tau}$, for $F^\tau_\tau$ the sheaf $F^\tau_\tau$ and $HT_\tau = HT_\tau$. We hope it will not lead to any confusion.

Definition 6.7. — For all $\tau$ let $G_\tau$ be the Grassmanian parametrizing all complete Flags of $F^\tau$, and $G^\tau_\tau$ which parametrizes same flags, together with a basis of the graded pieces. Let $w \leq n - \varepsilon_\tau$. For all $R' \in R - \text{Adm}_{\bullet}$, an element $\text{Fil}_w F_\tau$ of $G^{\tau}(R')$ (respectively $(\text{Fil}_w F_\tau, w\tau)$ of $G^{\tau}(R')$) is said to be $w$-compatible with $\psi$ if $\text{Fil}_w F_\tau = HT_\tau(\text{Fil}_w^{\text{tor}})$ (mod $p^nR'$) (respectively if moreover $w_1 = \psi(x_1)$ (mod $p^nR'$ + $\text{Fil}_{1-1} F_\tau$)). This definition does not depends on the choice of the lifts $(x_1)$.

Of course $\text{Fil}_w F_\tau$ and $\text{Fil}_w^{\text{tor}}$ are not always defined for the same index set for $\bullet$. It is understood that we restrict $\bullet$ to the smallest of the two index sets.

Proposition 6.8. — For each $\tau \in T$ and $w_\tau < n_\tau - \varepsilon_\tau$, there exists formal schemes,

$$\mathfrak{M}^\tau_{\text{tor},w_\tau, \pi_1 \pi_2, \pi_2} \times \mathfrak{M}^\tau_{\text{tor},w_\tau, \pi_2}, X_1(p^n)_{\text{tor}}(v),$$

where $\pi_1$ is a $\Sigma_{\tau, w_\tau}$-torsor, and $\pi_2$ is affine.

\[\text{(\textbf{9})}\text{By first taking the full flag of } (H_{pk}/H_{pk-1})^D \text{ given previously, and then lifting the one of } (H_{pk}/H_{pk-1})^D/(H_{pk}/H_{pk-1})^D \simeq (H_{pk}/H_{pk-1})^D \text{ and so on.}\]
Proof. — We set, following [AIP15],
\[
\mathcal{M}_{\tau, w} : \begin{array}{ccc}
R - \text{Adm} & \rightarrow & \text{Sets} \\
R' & \rightarrow & \{ w - \text{compatible Fil}_* \mathcal{F}_\tau \in \mathcal{G}_{\tau}(R') \}
\end{array}
\]
\[
\mathcal{M}_{\tau, w}^+ : \begin{array}{ccc}
R - \text{Adm} & \rightarrow & \text{Sets} \\
R' & \rightarrow & \{ w - \text{compatible (Fil}_* \mathcal{F}_\tau, w)_* \mathcal{F}_\tau \in \mathcal{G}_{\tau}(R') \}
\end{array}
\]
These are representable by affine formal schemes (some admissible open in an admissible formal blow-up of the previous Grassmanians).

We denote by,
\[
\mathcal{M}_{\tau, w}^+ = \prod_{\tau} \mathcal{M}_{\tau, w},
\]
and \(\mathcal{W}_{\tau, w}, \mathcal{W}_{\tau, w}, \mathcal{W}_{\tau, w}, \mathcal{W}_w, \mathcal{W}_w\) the corresponding generic fibers.

Denote by \(\pi : \mathcal{M}_{\tau, w}^+ \rightarrow \mathcal{X}_0(p^n)(v)\).

**Definition 6.9.** — Let \(\kappa\) be a \(w\)-analytic character in \(\mathcal{W}\). The formal sheaf,
\[
\mathcal{W}_w^{\kappa} := \pi_* \mathcal{O}_{\mathcal{M}_{\tau, w}^+}[\kappa],
\]
is a small formal Banach sheaf on \(\mathcal{X}_0(p^n)(v)\).

Proof. — Denote \(\kappa^0\) its restriction to \(V^0\) of \(\kappa\). It is analytic on \(\mathcal{T}_w\). The map
\[
\pi_1 : \mathcal{M}_{\tau, w}^+ \rightarrow \mathcal{M}_w,
\]
is a torsor over \(\mathcal{T}_w\), thus \((\pi_1)_* \mathcal{O}_{\mathcal{M}_{\tau, w}^+}[\kappa^0]\) is invertible, and
\[
\pi_2 : \mathcal{M}_w \rightarrow \mathcal{X}_1(p^n)^{tor}(v),
\]
is affine, thus \((\pi_2 \circ \pi_1)_* \mathcal{O}_{\mathcal{M}_{\tau, w}^+}[\kappa^0]\) is a small formal Banach sheaf. As \(\mathcal{X}_0(p^n)^{tor}(v)\) is quasi excellent (finite-type over \(\mathcal{O}_K\)), thus Nagata, the map \(\mathcal{X}_1(p^n)^{tor}(v) \rightarrow \mathcal{X}_0(p^n)^{tor}(v)\) is finite, and we can use [AIP15] with the action of \(T(\mathcal{O})/p^n\mathcal{O}\). Thus,
\[
\mathcal{W}_w^{\kappa} = \left( (\pi_2 \circ \pi_1)_* \mathcal{O}_{\mathcal{M}_{\tau, w}^+}[\kappa^0](\kappa^{-1}) \right)^{T(\mathcal{O}/p^n\mathcal{O})},
\]
is a small Banach sheaf on \(\mathcal{X}_0(p^n)^{tor}(v)\).

We would like to descend further to \(\mathcal{X}^{tor}(v)\), i.e. at Iwahori level, unfortunately the map \(\mathcal{X}_0(p^n)^{tor}(v) \rightarrow \mathcal{X}^{tor}(v)\) is not finite in general...

Let \(\omega_v^{\kappa}\) be the associated rigid sheaf ([AIP15] appendice) on \(\mathcal{X}_0(p^n)^{tor}(v) \subset \mathcal{X}_0(p^n)^{tor}(\mathbb{A})\).
6.3. Descent to Iwahori level. — In order to get an action of Hecke operators at \( p \), which are defined at Iwahori level, we will need to descend our construction at this level. Fortunately, this is possible in rigid fiber.

We haven’t really defined \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}} \) (but see remark 6.3), and it will not be usful for us, but in general \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}} \to \mathcal{X}_0(p^n)^{\text{tor}} \) is a torsor over the group\(^{(10)}\)

\[
I(p^n) := \left\{ \begin{pmatrix} A_1 & * & * \\ A_2 & * & * \\ \vdots & & \ddots \\ pO/p^n & & & A_{r+1} \end{pmatrix} : A_i \in I_p(\mathcal{O}/p^n\mathcal{O}) \subset \text{GL}_{p^{-i-1}}(\mathcal{O}/p^n) \right\} \pmod{U_p},
\]

where we chose an ordering \( \{p_r, q_r \mid \tau \in \mathcal{T}(= T_{i,j}(\mathcal{O})) \cup \{0, h\} \} = \{0 \leq p_1 < p_2 < \cdots < p_r < p_{r+1} = h \} \), and \( h = h_{(i,j)} \) is the \( \mathcal{O}(i,j) \)-height of \( A_i[\pi_j^{-r}] \). \( I_p \) denote the standard Iwahori subgroup, and \( U_p \) is the standard upper-bloc-diagonal unipotent associated to \( p_1 \leq p_2 \cdots \leq p_{r+1} = h \) (remember that we fixed a couple \( (i,j) \) at this point so here everything is related to the group \( G = G_{(i,j)} \) at the place \( (i,j) \)). Of course, here we chose a specific pairing so that this parabolic is upper-triangular.

The group \( I(n) \) does not preserve \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}}(v) \) : the reason is that the condition on \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}}(v) \) to be “close to the \( \mu \)-ordinary canonical locus” \( \text{(i.e. that the group of height} p_r \text{have big enough degree)} \) fixes the group of height \( np_r \) to be equal to the canonical \( \text{(and thus unique)} \) corresponding one. In particular \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}}(v) \to \mathcal{X}_0(p^n)^{\text{tor}}(v) \) is a torsor over,

\[
I^0(n) := \text{Im} \left\{ \begin{pmatrix} A_1 & * & * \\ A_2 & * & * \\ \vdots & & \ddots \\ 0 & & & A_{r} \end{pmatrix} : A_i \in I_p(\mathcal{O}/p^n\mathcal{O}) \subset \text{GL}_{p^{-i-1}}(\mathcal{O}/p^n) \right\} \to I(n)
\]

\( \text{Remark 6.10.} \) — The group \( I^0(n) \) is related to the group \( I_{(p_r)}^0 \) of section 4

Denote by \( U^0(n) \) the (diagonal, not just bloc-diagonal) subgroup,

\[
\begin{pmatrix} 1 & * & * \\ & 1 & \vdots \\ & & \ddots \\ & & & 1 \end{pmatrix} \subset I^0(n)
\]

Define \( \mathcal{X}_0^{+}(p^n)^{\text{tor}}(v) \) as the quotient of \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}}(v) \) by \( U^0(m) \), which doesn’t parametrizes trivialisations of the groups \( H_k/H_{k-1} \) but only full flags of subgroups of this quotients, together with a basis of the graded pieces. Actually we can also define the same way \( \mathcal{F}_r \) over \( \mathcal{X}_0^{+}(p^n)^{\text{tor}}(v) \) \( \text{(i.e. the sheaves} \mathcal{F}_r \text{descend)} \). As the action of \( U^0(m) \) on \( \mathcal{X}_1^{\mu}(p^n)^{\text{tor}}(v) \) lifts to \( \mathcal{F}_r^{\mu} \), denote also by \( \mathcal{F}_r^{\mu} \) the quotient of by \( U^0(m) \).

As \( \mathcal{F}_r \simeq \mathcal{O}_p \) over \( \mathcal{X}_1^{+}(p^n)^{\text{tor}}(v) \) \( \text{(i.e. after inverting} p \text{)} \), we thus have an injection,

\[
\mathcal{F}_r^{\mu} \subset (\mathcal{T}/U)\mathcal{X}_0^{+}(p^n)^{\text{tor}}(v).
\]

\(^{(10)}\text{This is for} p_r = h, \text{there is an analogous description when} p_r < h.\)
Proposition 6.11. — If $n - \epsilon > w > n - 1$, then the composite,
\[
\mathcal{I}W_{w}^{0} \hookrightarrow (\mathcal{T}/U)\chi_{0}^{\tau}(p^{n})^{\text{tor}}(v) \longrightarrow (\mathcal{T}/U)\chi^{\text{tor}}(v),
\]
is an open immersion.

Proof. — Denote by $V \subset \mathcal{X}^{\text{tor}}(v) = \chi_{0}(p^{n})^{\text{tor}}(v)$ the image by $\pi_{n}$ of $\mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v)$. Up to reducing to a suitable affinoide $U \subset \mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v)$, the previous composite map $h$ is given by,
\[
h : \prod_{\tau} \prod_{\gamma \in S} \mathcal{M}_{\tau} \left( \begin{array}{ccc}
1 + p^{\mu}B(0,1) & 1 + p^{\mu}B(0,1) & \ldots \\
p^{\mu}B(0,1) & 1 + p^{\mu}B(0,1) & \ldots \\
\vdots & \vdots & \ddots
\end{array} \right) \gamma \longrightarrow \prod_{\tau}(\text{GL}_{p} \cap U)\pi_{n}(U),
\]
where $S$ is a set of representative of $I^{0}(n)/U^{0}(n)$ in $I(\mathcal{O}) \subset \text{GL}_{p}(\mathcal{O})$, and $\mathcal{M}_{\tau}$ is the matrix relating the basis of $H^{0}_{\mathcal{O}}$ to the fixed one of $\omega_{\tau}$, which is thus related to the Hodge-Tate map (or equivalently relating a fixed basis of $\mathcal{F}_{\tau}$ to a fixed one of $\omega_{\tau}$). In particular there exists $\mathcal{M}^{\tau}_{\ast}$ such that, $\mathcal{M}^{\tau}_{\ast}M_{\tau} = p^{\varepsilon}I_{\mathcal{O}}$, for some $\varepsilon$ (which we could bound in terms of the Hasse invariant or $\frac{1}{p}$, but it is not even necessary). From this, we deduce that $M^{\ast} \circ h$ is injective, thus the same thing for $h$.

Thus we have a map $g_{n} : \mathcal{I}W_{w}^{0} \longrightarrow \mathcal{X}^{\text{tor}}(v)$. It is not clear that the map,
\[
\pi_{n} : \mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v) \longrightarrow \mathcal{X}^{\text{tor}}(v) := \mathcal{X}_{0}(p)^{\text{tor,can}}(v),
\]
is surjective. But still, having $n$ fixed, $\pi_{n}(\mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v))$ describe a basis of strict neighborhoods of $\mathcal{X}^{\text{tor,can}}$ by lemma 5.18.

Definition 6.12. — Suppose $(\varepsilon, n, v)$ is satisfied. The open $\pi_{n}(\mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v))$ is a strict neighborhood of the $\mu$-canonical ordinary locus $\mathcal{X}^{\text{tor}}(0) = \mathcal{X}^{\text{tor}}(0)^{\mu-\text{can}}$ included in $\mathcal{X}^{\text{tor}}(\mathcal{O})$. On $\pi_{n}(\mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v))$, if $w \in [n - 1, n - \varepsilon]$ for all $\tau$, for all $\kappa$ $w$-analytic, we define the following sheaf,
\[
\omega_{w}^{\text{tor}} = (g_{n})_{\ast}(\mathcal{O}_{\mathcal{I}W_{w}^{0}})[\kappa].
\]
It is called the sheaf of overconvergent, $w$-analytic modular forms of weight $\kappa$. For every $v' > 0$ small enough such that $\mathcal{X}^{\text{tor}}(v') \subset \pi_{n}(\mathcal{X}_{0}^{\tau}(p^{n})^{\text{tor}}(v))$, the module
\[
M_{w}^{\text{tor}}(v') = H^{0}(\mathcal{X}^{\text{tor}}(v'), \omega_{w}^{\text{tor}}(-D)),
\]
(respectively $M_{\text{cusp}, w}^{\text{tor}}(v') = H^{0}(\mathcal{X}^{\text{tor}}(v'), \omega_{w}^{\text{tor}}(-D))$) is called the module of $v'$-overconvergent, $w$-analytic (respectively cuspidal) modular forms of weight $\kappa$.

Remark 6.13. — In the previous compatibilities, if $(\varepsilon, n, v)$ is satisfied, $(\varepsilon, n, v')$ is for all $v' < v$. Also, because of the compatibility between $w$ and $n$, $\alpha$ is uniquely defined (and is thus suppressed form the notation of $\omega_{w}^{\text{tor}}$). Thus, we can choose $v$ arbitrarily close to 0 in the previous definition. Also, for every $w$ and $\kappa$, there exists $n_{0}$ such that for all $n \geq n_{0}$, there is $\alpha' > w$, and $\kappa$ is $\alpha'$-analytic with $n - 1 < \alpha' < n - \varepsilon$ for all $\tau$. In particular, there exists constants $v_{0}, w_{0}$ such that $M_{v_{0}, w}^{\text{tor}}(v)$ is defined for all $v < v_{0}$ and $w > w_{0}$ such that $w \in [n - 1, n - \varepsilon] (\text{for some integer } n \text{ large enough})$. 

Suppose $n' - \varepsilon > w' > w$ with $w \in |n - 1, n - \varepsilon|$ and $n \leq n'$. As a flag with graded basis which is $(n', w')$-compatible is also $(n, w)$-compatible, there is an injective map,

$$TW_{n', w'}^+ \hookrightarrow TW_{n, w}^+ \times \mathcal{X}(n, w)_{\text{tor}} \times \mathcal{X}(n')_{\text{tor}}.$$ 

In particular, we have a natural map, for every $w'$-analytic $\kappa$,

$$\omega_{w'}^\kappa \hookrightarrow \omega_{w}^\kappa,$$

over $\pi_n((\mathcal{X}_{\text{tor}}^+ (p^{n'})(\mathcal{V}))(v))$. 

**Definition 6.14.** — For $w > 0$, the module,

$$M_n^\kappa = \lim_{v \to 0, w \to \infty} M^\kappa_{\text{cusp}}(v)$$

(respectively $M^\kappa_{\text{cusp}}(v) = \lim_{v \to 0, w \to \infty} M^\kappa_{\text{cusp}, w}(v)$)

is the module of overconvergent locally analytic (respectively cuspidal) modular forms of weight $\kappa$. 

**Remark 6.15.** — In the previous definition, it is understood that the limit is taken on $v, w$ such that $w \in |n - 1, n - \varepsilon|$ for some $n = n(v, (\varepsilon, n, v_0))$ is satisfied for some $v_0$ and $\mathcal{X}(\mathcal{V}) \subset \pi_n((\mathcal{X}_{\text{tor}}^+ (p^{n'})(\mathcal{V}))(v))$. Thus in particular $(\varepsilon, n, v_0)$ is satisfied and $v \leq v_0$. 

6.4. Some complexes. — For compatibilities reasons with Hecke operators and to control the structure on the previous modules, we will need to define complexes overconvergent sections. Recall that on $\mathcal{X}(\mathcal{V}) = \mathcal{X}_0(p^{n'}(\mathcal{V})$, our rigid toroidal Shimura variety with fixed Iwahori level, we have defined two basis of strict neighborhoods of $\mathcal{X}(\mathcal{V})_0^{\text{tor}}$ (the canonical $\mu$-ordinary locus whose points have maximal degree), one given by

$$\mathcal{X}(\mathcal{V})_{\text{tor}}(\varepsilon),$$

for $\varepsilon = (\varepsilon)^{\tau}$ (of points with degrees bigger than the maximal one minus $\varepsilon$), and

$$\mathcal{X}(\mathcal{V})(v),$$

for $v \in (0, 1]$ (describing the connected components containing $\mathcal{X}(\mathcal{V})_0^{\text{tor}}$ of points with Hasse invariant of valuation smaller than $v$). Because we will need to let the neighborhood described in terms of the degree vary, we from now on call $\varepsilon_n$ a number fixed to be able to define the sheaves $\omega_{w}^\kappa$, and we will always consider small enough opens $\mathcal{X}(v)$ and $\mathcal{X}(\varepsilon)$ so that there exists the sheaves $\omega_{w}^\kappa$ on them. In particular, once $w$ is fixed this just implies that $v$ or $\varepsilon$ are small enough (depending on $w$).

Ultimately we are interested by (finite slope) overconvergent cuspidal modular forms, that is, (finite slope) elements of

$$\lim_{v \to 0, w \to \infty} H^0(\mathcal{X}(\mathcal{V})(v), \omega_{w}^\kappa(-D)) = \lim_{\varepsilon \to 0, w \to \infty} H^0(\mathcal{X}(\mathcal{V})(\varepsilon), \omega_{w}^\kappa(-D)).$$

We temporarily introduce the following complexes,
**Definition 6.16.** — Let \( w > 0, \mathcal{U} = \text{Spm}(A) \subset \mathcal{W} \) an affinoid such that \( \kappa_{\mathcal{U}} \) is \( w \)-analytic, and define for \( \varepsilon, \kappa \) small enough \(^{11}\),

\[
C_{\text{cusp}}(\varepsilon, w, \mathcal{U}) = R\Gamma(\mathcal{A}^\text{tor}(\varepsilon) \times \mathcal{U}, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)),
\]

and

\[
C_{\text{cusp}}(\kappa_{\mathcal{U}}) = R\Gamma(\mathcal{A}^\text{tor}(\kappa_{\mathcal{U}}) \times \mathcal{U}, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)).
\]

We can analogously define the non-cuspidal versions of these complexes.

We also define

\[
H^i_{\text{cusp}, \varepsilon}(\kappa_{\mathcal{U}}) = \lim_{\kappa_{\mathcal{U}} \downarrow 0} H^i(\mathcal{A}^\text{tor}(\varepsilon) \times \mathcal{U}, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)),
\]

and

\[
H^i_{\text{cusp}, \varepsilon}(\kappa_{\mathcal{U}}) = \lim_{\kappa_{\mathcal{U}} \downarrow 0} H^i(\mathcal{A}^\text{tor}(\kappa_{\mathcal{U}}) \times \mathcal{U}, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)).
\]

In particular \( H^0_{\text{cusp}, \varepsilon}(\kappa_{\mathcal{U}}) = H^0_{\text{cusp}, \varepsilon}(\kappa_{\mathcal{U}}) \) is simply the space of overconvergent locally analytic cuspidal modular forms of weight \( \kappa \), and we will see that the higher cohomology groups vanishes (their finite slope part at least).

**Proposition 6.17.** — The previous complexes are represented by bounded complexes of projective \( A[1/p] \)-modules (i.e. perfect complexes in the sense of [Urb11]).

**Proof.** — This is the same proof as [Pil18]. We have maps,

\[
\mathcal{IW}_w^+ \times_{\mathcal{X}(\varepsilon)} \mathcal{U} \xrightarrow{\pi_1} \mathcal{IW}_w \times_{\mathcal{X}(\varepsilon)} \mathcal{U} \rightarrow \mathcal{X}_1(p^n)^\text{tor}(\varepsilon) \times \mathcal{U},
\]

and sheaves \( \mathcal{L}^\kappa \mathcal{U} = [(\pi_1^* \mathcal{O}_{\mathcal{IW}_w^+})[\kappa_{\mathcal{U}}]] \) (for the action of \( \mathcal{T}_w \)), this is a line bundle on \( \mathcal{IW}_w \times_{\mathcal{X}(\varepsilon)} \mathcal{U} \), and \( \omega^{\kappa_{\mathcal{U}} \downarrow} = \pi_2^* \mathcal{L}^\kappa \mathcal{U} \). Moreover

\[
R\Gamma(\mathcal{A}^\text{tor}(\varepsilon) \times U, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)) = R\Gamma(I^0(n), R\Gamma(\mathcal{X}_1(p^n)^\text{tor}(\varepsilon) \times U, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D))(-\kappa))
\]

\[
= R\Gamma(I^0(n), R\Gamma(\mathcal{IW}_w \times U, \mathcal{L}^\kappa \mathcal{U}(-D))(-\kappa)).
\]

The last equality is because \( \mathcal{IW}_w \rightarrow \mathcal{X}_1(p^n)^\text{tor}(\varepsilon) \) is locally affinoid. Now if you choose \( \mathcal{U} \) a covering of \( \mathcal{IW}_w \times \mathcal{U} \) which is \( I^0(n) \)-stable (by adding all translates by \( I^0(n) \) if necessary), then the Cech complex of this covering is perfect and calculates

\[
R\Gamma(\mathcal{IW}_w \times U, \mathcal{L}^\kappa \mathcal{U}(-D)),
\]

and twisting the action of \( I^0(n) \), and looking at the direct factor of invariants by \( I^0(n) \) (we are in characteristic 0), this is still perfect and calculates

\[
R\Gamma(\mathcal{A}^\text{tor}(\varepsilon) \times U, \omega^{\kappa_{\mathcal{U}} \downarrow}(-D)).
\]

The same remains true with \( \mathcal{X}^\text{tor}(\varepsilon) \) (for \( \varepsilon \) small enough) instead of \( \mathcal{X}^\text{tor}(\varepsilon) \).

\(^{11}\) such that the sheaves \( \omega^{\kappa_{\mathcal{U}} \downarrow} \) is defined on \( \mathcal{A}^\text{tor}(\varepsilon) \times \mathcal{U} \) resp. \( \mathcal{X}^\text{tor}(\varepsilon) \times \mathcal{U} \).
7. Hecke Operators

In this section we will construct Hecke operators, both at $p$ and outside $p$. As noted in [AIPl5, Bram16], it is not true that the Hecke correspondences will extend to a fixed choice of a toroidal compactification, nevertheless we can adapt the choice of toroidal compactifications and use results of Harris ([Har90a] Proposition 2.2).

Lemma 7.1 (Harris). — Let $\Sigma, \Sigma'$ be two smooth projective polyhedral cone decomposition, and $X_{\Sigma}(p^n)_{tor}, X_{\Sigma'}(p^n)_{tor}$ the associated toroidal compactifications. Then there is a canonical isomorphism $H^*(X_{\Sigma}(p^n)_{tor}, O_{\Sigma X W^+}) \cong H^*(X_{\Sigma'}(p^n)_{tor}, O_{\Sigma' X W'})$. Proof: — To simplify notation, denote $X_{\Sigma} = X_{\Sigma}(p^n)_{tor}$. Up to choosing a common refinement of $\Sigma$ and $\Sigma'$, we can suppose that $\Sigma'$ refines $\Sigma$ and look at the map $\pi : X_{\Sigma'} \longrightarrow X_{\Sigma}$.

By results of Harris we have $\pi^* \omega_{\Sigma} = \omega'_{\Sigma'}$. Moreover, we can take $\Sigma'$ small enough (which we do) such that it corresponds to a refinement of the auxiliary datum we chose in section 5.2. In particular, on the integral model $X_{\Sigma}(p^n)_{tor}$, the groups $H_k$ are given by pullback of those on $X_{\Sigma}(p^n)_{tor}$. Thus we have a carthesian square,

$$
\begin{array}{ccc}
TW^+_{\Sigma'} & \longrightarrow & X_{\Sigma'} \\
\downarrow \pi' & & \downarrow \pi \\
TW^+_{\Sigma} & \longrightarrow & X_{\Sigma}
\end{array}
$$

Also, by results of Harris ([Har90b] (2.4.3)-(2.4.6)), we have quasi-isomorphisms $\pi_* \mathcal{O}_{X_{\Sigma'}} \longrightarrow R\pi_* \mathcal{O}_{X_{\Sigma'}} = \mathcal{O}_{X_{\Sigma}}$. As $TW^+ \longrightarrow X$ is flat and $\pi$ is proper, we have thus by base change (see e.g. [Sta18] 29.5.2)

$$R\pi'_* \mathcal{O}_{\Sigma W^+_{\Sigma'}} \cong \mathcal{O}_{\Sigma W^+_{\Sigma}}.$$

7.1. Hecke Operator outside $p$. — Let $\lambda$ be a place where our fixed level $K^p$ is hyperspecial, and fix $\gamma \in \mathcal{G}(F^+_{\lambda})$. Denote $C_{\gamma}$ the (analytic space associated to the) moduli space classifying tuples $(A_k, t_k, \lambda_k, \gamma_k), k = 1, 2$, of the type $G$, together with an isogeny $f : A_1 \longrightarrow A_2$ which respects the additionnal structure. It is endowed with two maps,

$$C_{\gamma} \xrightarrow{p_1} \mathcal{Y}_{Iw(p)}(v),$$

where $p_k(f : A_1 \longrightarrow A_2) = A_k$. Denote $C_{\gamma}(p^n) = C_{\gamma} \times_{\mathcal{Y}_{Iw(p)}(v)} \mathcal{Y}_1(p^n)(v)$. But we can find choices of smooth projective polyhedral cone decompositions (see [Lan13] proposition 6.4.3.4) $\Sigma$ and $\Sigma'$ and associated toroidal compactifications $X_{Iw(p), \Sigma}, C_{\gamma, \Sigma}, X_{Iw(p), \Sigma'}$ and maps $p_1 : C_{\gamma, \Sigma} \longrightarrow X_{Iw(p), \Sigma}, p_2 : C_{\gamma, \Sigma} \longrightarrow X_{Iw(p), \Sigma'}$ which extends the previous ones. As $v$ is away from $p$, this correspondance preserves $\mathcal{Y}_{Iw(p)}(v)$, and the universal isogeny induces an isomorphism,

$$f^* : p_2^* \mathcal{F}_{X_{\Sigma}(p^n)_{tor}}(v) \longrightarrow p_1^* \mathcal{F}_{X_{\Sigma}(p^n)_{tor}}(v),$$
and we can thus construct,

\[ H^0(\mathcal{X}(p^n)\Sigma(v), \mathcal{O}_{\mathcal{W}^+}) \xrightarrow{pr^\ast} H^0(\mathcal{C}_\Sigma(p^n), \mathcal{O}_{\mathcal{W}^+}) \xrightarrow{f^n} H^0(\mathcal{X}(p^n)\Sigma(v), \mathcal{O}_{\mathcal{W}^+}) \]

As by the previous lemma, \( H^0(\mathcal{X}(p^n)\Sigma(v), \mathcal{O}_{\mathcal{W}^+}) = H^0(\mathcal{X}(p^n)\Sigma(v), \mathcal{O}_{\mathcal{W}^+}) \), we get an operator \( T_\gamma \) on \( H^0(\mathcal{X}(p^n)\Sigma(v), \mathcal{O}_{\mathcal{W}^+}) \). Similarly \( T_\gamma \) acts on \( C_{\text{cusp}}(v, w, \kappa) \) and \( C_{\text{cusp}}(\xi, w, \kappa) \) (as the isogeny is outside \( p \)) and their non-cuspidal analogues. We can thus forget about the choice of \( \Sigma \) in the notations.

**Remark 7.2.** — Here we made a slight abuse, as we used the notations with a fixed \( (i, j) \). Of course, taking tensor products over the \( (i, j) \) of the correspondings \( \mathcal{W}^+ \) (which depends of the choice of \( (i, j) \)) solves this abuse of notation.

**Definition 7.3.** — Let \( \kappa \in \mathcal{W}(w)(L) \) with \( w \in \mathbb{N} - 1 + c, n - e_\mathfrak{D} \). Restricting the previous operator to homogeneous functions on \( \mathcal{X}_{\text{Ir}(p)}(v) \) for \( \kappa \), we get the Hecke operator,

\[ T_\gamma : M^\kappa \rightarrow M^\kappa. \]

Working over \( \mathcal{X}_{\text{Ir}(p)}(v) \times \mathcal{W}(w) \), considering \( \kappa = \kappa^{\text{univ}} \), we get an operator

\[ T_\gamma^{\text{univ}} : M^\kappa^{\text{univ}} \rightarrow M^\kappa^{\text{univ}}, \]

which is \( \mathcal{O}_{\mathcal{W}(w)} \)-linear, and an operator on \( C_{\text{cusp}}(v, w, \kappa^{\text{univ}}) \) and \( C_{\text{cusp}}(\xi, w, \kappa^{\text{univ}}) \).

Denote by \( \mathcal{H}_{K^p} \) the spherical Hecke algebra of level \( K^p \), the previous construction endow for each \( w \) the modules \( M^\kappa \) (respectively the module \( M^\kappa^{\text{univ}} \) with \( \kappa \in \mathcal{W}_{\text{Ir}} \)) with an action of \( \mathcal{H}_{K^p} \).

### 7.2. Hecke operators at \( p \)

— At \( p \), the construction of Hecke Operators is much more subtle than outside \( p \), and even more subtle than in the ordinary case, as already remarked in [Her19]. Indeed, when the ordinary locus is non empty, only one operator, \( U_{p, g} \) in [AIP15], is compact on classical forms (it improves the "Hodge"-radius, i.e. the Hasse invariant), but does not improves the analyticity radius for overconvergent forms, whereas the other operators, \( U_{p,i} \), \( i < g \) in [AIP15], improves only the analyticity radius (a priori). Already for \( U(2, 1) \) with \( p \) inert in the quadratic imaginary field the situation is different. Indeed, there is only one interesting operator, \( U_\mathfrak{p} \), that improves at the same time both the Hodge-radius and the analyticity radius.

Following [Bij16], we define operators at \( p \).

#### 7.2.1. Linear case.

— This is actually easier than the unitary case, and can be adapted from [Bij16] on \( \omega^\kappa \) to \( \omega^\kappa_{\text{univ}} \). But as this case can be recovered from the general Unitary case (considering \( G \times G^D \) with canonical polarisation instead of \( G \)), we just write the details in the unitary case.
7.2.2. **Unitary case.** — Fix as before \((i, j)\) a prime, that we suppress from now on from the notations, and we can thus use \(i\) as a variable. Let \(G\) be the associated \(p\)-divisible group. Let \(1 \leq i \leq \frac{1}{2} n\) an integer, and define \(C_i\) the moduli space \((A, i, \lambda, \eta, H_\bullet, L)\) where \((A, i, \lambda, \eta, H_\bullet, L) \in \mathcal{Y}_{Iw(p)}(v)\) and \(L \subset G[p^\infty]\) to be a totally isotropic subgroup such that \(H_i \oplus L[p] = G[p]\) and \(H_\bullet^+ \oplus pL = G[p]\), and denote the two maps,

\[
C_i \xrightarrow{p_1} \mathcal{Y}_{Iw(p)}(v),
\]

where \(p_1(A, L) = A\) and \(p_2(A, L) = A/L\). Denote \(C_i(p^\infty) = C_i \times \mathcal{Y}_{Iw}(v) \mathcal{Y}_1(p^n)(v)\), and denote \(f : A \rightarrow A/L\) the universal isogeny. As we are in characteristic zero, we can find smooth projective polyhedral cone decompositions \(\Sigma, \Sigma', \Sigma''\) such that the previous correspondence extends to \(p_1 : C_i, \Sigma' \rightarrow X_{Iw(p), \Sigma}, p_2 : C_i, \Sigma \rightarrow X_{Iw(p), \Sigma''}\). In [Bij16] Proposition 2.11, Bijakowski verifies that the previous correspondence stabilizes the open \(\mathcal{Y}(\varepsilon)\). More precisely, he verifies that the Hecke correspondence \(C_i\) satisfies \(\text{deg} H'_i \geq \text{deg} H_j\) with equality for \(i = j\) if and only if \(\text{deg} H_i\) is an integer. Its proof extend to the case of a 1-motive in case of bad reduction, and thus extend to the boundary.

In particular, if \(\varepsilon_\tau < 1\), by quasi-compactness of

\[
\mathcal{X}_{Iw}(\forall \tau, \text{deg}(H_\tau) \in [\lambda_\tau, \nu_\tau]),
\]

with

\[
\sum_{\tau'} \min(p_{\tau'}, p_\tau) - 1 < \lambda_\tau < \nu_\tau < \sum_{\tau'} \min(p_{\tau'}, p_\tau), \lambda_\tau, \nu_\tau \in \mathbb{Q},
\]

we can thus prove the following,

**Proposition 7.4.** — For all \(w > 0\), for all \(\varepsilon > 0\) sufficiently small, there exists \(\varepsilon' < \varepsilon\) such that the Hecke correspondence \(\prod_i (U_i)\) sends \(\mathcal{X}_{Iw, \Sigma}(\varepsilon')\) into \(\mathcal{X}_{Iw, \Sigma''}(\varepsilon')\). Also, for all \(\varepsilon > 0\), and all \(0 < \varepsilon' < \varepsilon\) there exists \(N > 0\) such that \(\prod_i U_i^N\) send \(\mathcal{X}_{Iw, \Sigma}(\varepsilon')\) in \(\mathcal{X}_{Iw, \Sigma''}(\varepsilon')\).

The universal isogeny \(f\) induces a map,

\[
f^* : p^\infty_{1\tau} \mathcal{T}_{1\tau} \rightarrow p^\infty_{1\tau} \mathcal{T}_{1\tau},
\]

which is an isomorphism, and denote \(\tilde{f}^* = \bigoplus_p f^*_p\) (using the decomposition \(\omega = \bigoplus_p \omega_{G, p}\)) such that \(\tilde{f}^*_p\) sends a basis \(w'_1, \ldots, w'_n\) of \(\omega_{A/L, p}\) to

\[
p^{-2} f^* w'_1, \ldots, p^{-2} f^* w'_{p_a-h+i}, p^{-1} f^* w'_{p_a-h+i+1}, \ldots, p^{-1} f^* w'_{p_a-i}, f^* w'_{p_a-i+1}, \ldots, f^* w'_{p_a},
\]

(being understood that the terms on the left with \(p^{-2}\) only appears if \(p_\sigma > h - i\) and terms with \(p^{-1}\) only if \(p_\sigma > i\)). Another way to write it is to set, \(a_\sigma = \max(p_\sigma - (h - i), 0)\), \(b_\sigma = \max(\min(h - 2i, p_\sigma - i), 0)\) and \(c_\sigma = \min(i, p_\sigma)\) (thus \(a_\sigma + b_\sigma + c_\sigma = 1\)). Then \(f^*_p\) sends \(w'_1, \ldots, w'_n\) to,

\[
p^{-2} f^* w'_1, \ldots, p^{-2} f^* w'_{a_\sigma}, p^{-1} f^* w'_{a_\sigma+1}, \ldots, p^{-1} f^* w'_{a_\sigma+b_\sigma}, f^* w'_{a_\sigma+b_\sigma+c_\sigma}, \ldots, f^* w'_{p_a},
\]

**Remark 7.5.** — This normalisation is made in order to make the operator \(U_i\) vary in a family (it corrects the multiplication by \(p\) that appears on \(\omega\) if we do the quotient by \(L\)). It coincides with normalisation of [Bij16] for classical sheaves.
Definition 7.6. — Let $w = (w^\tau_{i,j})_\tau$, such that for all $(i, j, \tau)$, $w^\tau_{i,j} \in \mathbb{C}; n - \varepsilon_\tau$ and define $TW^{0,+}_w$ to be the open subspace of $T^\tau / U$ over $\pi_n(X^+_0(p^n)(v))$ such that its $L$-points, for all $L$ over $K$, is the datum of a $O_L$-point of $\pi_n(X^+_0(p^n)(v))$ for all $L$ over $K$, thus in particular an abelian scheme $A / \text{Spec}(O_L)$ for which $G[p^n]$ has (canonical by Theorem 5.6) filtration by subgroups $H_\tau$, together with a flag $\text{Fil}_s F_\tau$ for all $\tau$ with graded pieces $w^\tau_s$, such that there exists a (polarized) trivialization $\psi$ (as in section 6.1), such that

$$
\omega^\tau_i \pmod{\text{Fil}_{i-1} F_\tau + p^{\omega_0} F_\tau} = \sum_{j \geq 1} a_{j,i} \text{HT}_{\tau,w_0}(1),
$$

where $w^\tau_i = n - \varepsilon_\tau$ and with $a_{j,i} \in O_L$ such that, $v(a_{j,i}) \geq w^\tau_{j,i}$ if $j > i$ and $v(a_{i,i} - 1) \geq w^\tau_{i,i}$. We then define as before $\omega^{\sigma_1}_w$ on $\pi_n(X^+_0(p^n)(v))$.

Remark 7.7. — In the previous definition, if we take $n' \geq n$, $w^\tau_{i,j} \in \mathbb{C}, n - \varepsilon_\tau$ and we make the previous construction over $\pi_n(X^+_0(p^n)(v))$ for $w_0 = n - \varepsilon_\tau$ or $w_0 = n' - \varepsilon_\tau$, we get the same space. Thus, up to reducing the strict neighborhood, we suppress $n$ from the notation. When $\omega$ is parallel and $0 < w < 1 - \varepsilon_\tau$, then $\omega^{\sigma_1}_w = \omega^{\sigma_1}_w$.

Suppose $w$ satisfies

$$
\begin{aligned}
0 < w^\tau_{i,j} < w_0 - 2 & \quad \text{if } a_{\tau} \neq 0 \\
0 < w^\tau_{i,j} < w_0 - 1 & \quad \text{if } a_{\tau} = 0 \text{ and } b_{\tau} \neq 0 \\
0 < w^\tau_{i,j} < w_0 & \quad \text{otherwise}
\end{aligned}
$$

Proposition 7.8. — Let $f$ the the universal isogeny over $C_1$. Then

$$(f^*)^{-1} p_1^* TW^{0,+}_w \subset p_2^* TW^{0,+}_w,$$

with

$$
\omega^\sigma_{k,l} = \begin{cases} 
w^\sigma_{k,l} + 2 & \text{if } k > a_{\sigma} + b_{\sigma} \text{ and } l \leq a_{\sigma} \\
\omega^\sigma_{k,l} + 1 & \text{if } (b_{\sigma} + a_{\sigma} \geq k > a_{\sigma} \text{ and } l \leq a_{\sigma}), \text{ or } (b_{\sigma} + a_{\sigma} \geq l > a_{\sigma} \text{ and } k > a_{\sigma} + b_{\sigma}) \\
\omega^\sigma_{k,l} & \text{otherwise}
\end{cases}
$$

Proof. — This is similar to 4.1 and [AIP15] Proposition 6.2.2.2. Indeed, in the basis given by the "trivialisation" of $(H_{pr}/H_{pr-1})^D$ on $X^+_0(p^n)(\varepsilon)$, the dual of the isogeny $H_{pr} \rightarrow H_{pr}'$ induced by $f$,

$$
f^D : (H_{pr})^D \rightarrow H_{pr}',
$$

is given by $\text{Diag}(p^2, \ldots, p^2, p, \ldots, p, 1, \ldots, 1)$, where $p^2$ appears $a_{\tau}$-times, $p$ appears $b_{\tau}$-times and $1$ $c_{\tau}$-times. The rest follows exactly as in [AIP15] Proposition 6.2.2.2, as $\pi^* F'_\tau \supset p F_\tau$ is $a_{\tau} = 0$ and $b_{\tau} \neq 0$, $\pi^* F'_\tau \supset p^2 F_\tau$ if $a_{\tau} \neq 0$ and $F_\tau = \pi^* F'_\tau$ otherwise.

We can thus define the operator $U^0_i$,

$$
H^0(X^+_0(\mathbb{C}), \omega^{\sigma_1}_w) \xrightarrow{\pi^*} H^0(C_1, p_2^* \omega^{\sigma_1}_w) \xrightarrow{f^{\tau-1}} H^0(C_1, p_1^* \omega^{\sigma_1}_w) \xrightarrow{\text{HT}_{\tau,w_0}} H^0(X^+_0(\mathbb{C}), \omega^{\sigma_1}_w)
$$
and also
\[ C_{\text{cusp}}(\xi, w', \kappa \mathcal{W}(w)) \xrightarrow{\mathcal{B}} R\Gamma(C_i \times \mathcal{W}(w), p_2^* \omega_{\mathcal{W}}^{\text{univ}}(\xi)) \xrightarrow{\mathcal{T}^{-1}} R\Gamma(C_i \times \mathcal{W}(w), p_1^* \omega_{\mathcal{W}}^{\text{univ}}(\xi)) \xrightarrow{\mathcal{T}_{\text{proj}}} R\Gamma(C_2(\xi) \times W(w), \omega_{\mathcal{W}}^{\text{univ}}(\xi)) = C_{\text{cusp}}(\xi, w, \kappa \mathcal{W}(w)), \]
where \( n_i \) is an integer defined in [Bij6] section 2.3 for example \( p^{12} \). It is related to the inseparability degree of the projection \( p_1 \).

Remark 7.9. —
1. Unfortunately it is not clear how to define the Hecke operator \( U_0^i \) on the neighborhoods \( \mathcal{A}(v) \) as we don’t know how the Hasse invariants behaves with quotients... But we will solve this in the end of the paper.
2. We can define similarly \( U_0^i \) over \( \mathcal{A}(\xi) \times \mathcal{W}(w) \) with \( \kappa^{\text{univ}} \).
3. Thus we can use the different operators \( U_0^i \) to improve the radius of convergence in all directions \( w_{k,l} \) with \( k > l \).

7.3. A compact operator. — Using the previous construction, we can define a compact operator. Fix \( w > 0 \) and \( n \) sufficiently big such that \( n - 2 - \varepsilon > w \). Fix also \( v \) sufficiently small such that \( \xi \) is satisfied.

Define \( w' = (w'_{k,l})_{\sigma, k > l} \) by,
\[ w'_{k,l} = \begin{cases} w & \text{if } k = l \\ w + 1 & \text{otherwise} \end{cases} \]

Remark 7.10. — We could be more precise about the precise values of \( w' \) we can choose for what follows (summing over all \( i \)'s the previous proposition), but the previous will be sufficient.

Denote by \( \xi' < \xi \) the tuple given by Proposition 7.4. Then we have for each \( \kappa \in \mathcal{W}(w) \), the following operator,
\[ \prod_i U_i^0 : H^0(\mathcal{X}^{\text{tor}}(\xi'), \omega_{\mathcal{W}}^{\kappa}) \rightarrow H^0(\mathcal{X}^{\text{tor}}(\xi), \omega_{\mathcal{W}}^{\kappa}), \]
and thus the operator,
\[ \prod_i U_i : H^0(\mathcal{X}^{\text{tor}}(\xi), \omega_{\mathcal{W}}^{\kappa}) \rightarrow H^0(\mathcal{X}^{\text{tor}}(\xi'), \omega_{\mathcal{W}}^{\kappa}) \prod_{i=1}^{\ell} H^0(\mathcal{X}^{\text{tor}}(\xi), \omega_{\mathcal{W}}^{\kappa}), \]
is compact, as the first map is. Similarly, denote \( U_i \) by precomposing \( U_i^0 \) by the map \( H^0(\mathcal{X}^{\text{tor}}(\xi), \omega_{\mathcal{W}}^{\kappa}) \subseteq H^0(\mathcal{X}^{\text{tor}}(\xi'), \omega_{\mathcal{W}}^{\kappa}) \) of the previous subsection. The same construction works also over \( \mathcal{X}^{\text{tor}}(\xi) \times \mathcal{W}(w) \) with \( \kappa^{\text{univ}} \).

\( \text{(12)} \) For us, this integer will not be important as it is useful to normalize the Hecke operators, and as our Hecke eigensystems are constructed on spaces where \( p \) is inverted, this normalization could be changed (we should change Theorem 8.3 accordingly)
8. Classicity results

Let \( w \) and \( \varepsilon \) such that \( 0 < w < 1 - \varepsilon \). Up to reduce \( \varepsilon \) this is always possible for some \( w < 1 \). Then the map \( \mathcal{I} \mathcal{W}_w^0 \to \mathcal{X}^{tor}(\underline{\varepsilon}) \) has connected fibers.

**Proposition 8.1.** Let \( \kappa \) be a classical weight. We have an exact sequences of sheaves over \( \mathcal{X}^{tor}(\underline{\varepsilon}) \),

\[
0 \to \omega_{\kappa}^\dag \to \omega_{\kappa}^\dag \bigoplus_{\alpha \in \Delta} \omega_{\kappa}^{\alpha\alpha} \to \frac{d_1}{1}
\]

which etale locally is isomorphic to the exact sequence (7).

**Proof.** We construct the map \( d_1 \) as in [AIP15] (we don’t need the hypothesis on \( w \) here). Then we have a sequence,

\[
0 \to V_{\kappa} \otimes \mathcal{O}_{\mathcal{X}^{tor}(\underline{\varepsilon})} \to V_{\kappa, L}^{0, w-an} \otimes \mathcal{O}_{\mathcal{X}^{tor}(\underline{\varepsilon})} \to \bigoplus_{\alpha \in \Delta} V_{\kappa, L}^{0, w-an} \otimes \mathcal{O}_{\mathcal{X}^{tor}(\underline{\varepsilon})},
\]

which is exact by hypothesis on \( w \) by Jones result (hypothesis implies that \( N_1 \simeq \mathbb{B} \) as in [Jon11] section 8). Then as this sequence is etale locally isomorphic to the one of the proposition, we get the result. \( \square \)

**Proposition 8.2.** Let \( \kappa = (k_{\sigma,i})_{\sigma, 1 \leq i \leq p_{\sigma}} \) be a classical weight. The submodule of \( M_{\omega}^!(\mathcal{X}^{tor}(\underline{\varepsilon})) \) on which each \( U_i \) acts with slope strictly less than \( \inf \{k_{\sigma,i} - k_{\sigma,i+1} : i < p_{\sigma}\} \) is contained in \( H^0(\mathcal{X}^{tor}(\underline{\varepsilon}), \omega^\kappa) \).

**Proof.** By the previous proposition, and Proposition 7.4 and Proposition 7.8, the proof is identical to [AIP15] Proposition 7.3.1. Indeed, let \( f \in M_{\omega}^!(\mathcal{X}^{tor}(\underline{\varepsilon})) \) on which the \( U_i \) acts with the said slope. Using Proposition 7.8, and that \( f \) is finite slope for \( U_i \), we can suppose that \( w < 1 - \varepsilon \). Thus, by proposition 8.1, because of the slope, we calculate as in [AIP15] that \( d_1 f = 0 \). Thus \( f \in H^0(\mathcal{X}^{tor}(\underline{\varepsilon}), \omega^\kappa) \). \( \square \)

The second result we need for classicity is Bijakowski’s result, [Bij16]. For each \( \tau \in \mathcal{T}^+ \), denote \( A_{\tau} = \min(p_{\tau}, q_{\tau}) \).

**Theorem 8.3 (Bijakowski).** Let \( \kappa = (k_{\tau,j}, \lambda_{\tau,i})_{\tau \in \mathcal{T}^+, 1 \leq j \leq p_{\tau}, 1 \leq i \leq q_{\tau}} \) be a classical weight and let \( f \in H^0(\mathcal{X}^{tor}(\underline{\varepsilon}), \omega^\kappa) \). Suppose that \( f \) is an eigenvector for the Hecke operators \( U_{A_{\tau}} \) of eigenvalue \( \alpha_{\tau} \) such that

\[
n_{A_{\tau}} + v(\alpha_{\tau}) < \inf (k_{\tau,p_{\tau}} + \lambda_{\tau,q_{\tau}}),
\]

for each \( \tau \in \mathcal{T}^+ \) verifying \( A_{\tau} \neq 0 \). Then \( f \) is classical.

9. Projectiveness of the modules of overconvergent forms

Recall that we work over \( \mathcal{X} \), our Shimura variety with Iwahori level at \( p \), and as explained in section 6.3 we have defined for all \( n \) and \( w \in ]n - 1, n - \varepsilon_{0, \tau}[, \) (where \( \varepsilon_{0, \tau} \) was small enough), a sheaf \( \omega_{w}^{\alpha} \) for all \( w \)-analytic \( \kappa \in \mathcal{W} \), and a universal one \( \omega_{w}^{univ} \), both defined on sufficiently small strict neighborhoods of \( \mathcal{X}^{tor} = \mathcal{X}(\underline{\varepsilon} = 0) \), the \( \mu \)-ordinary canonical locus. We have two families of strict neighborhoods of this locus, each having their advantages. In this section, we prove that essentially we have all the advantages
(action and compactness of $U = U_\mu = \prod_i U_i$, the operator of section 7, and vanishing of higher cohomology) on the finite slope part on both kind of strict neighborhoods. In this section, we suppose that on the strict neighborhoods we consider we have the sheaves $\omega_{cusp}^{\text{finite}}$, which means concretely that $x$ and $v$ are small enough (smaller than a constant which depends on $w$). Let $U \subset W(w) \subset W$ an open affinoid such that the universal character $\kappa_U$ is $w$-analytic.

**Proposition 9.1.** — Let $w \leq w'$ and $x \geq x'$. Then the restriction maps,

$$ C_{cusp}(x, w, \kappa_U) \longrightarrow C_{cusp}(x', w', \kappa_U), $$

are isomorphisms on the finite slope part for $U = \prod_i U_i$. In particular, the finite slope part for $U$ of $C_{cusp}(v, w, \kappa_U)$ and $C_{cusp}(x, w, \kappa_U)$ are the same, and thus are their cohomology groups.

As explained in section 7, it is not clear that $C_{cusp}(v, w, \kappa_U)$ or any of its cohomology group is preserved by $U$. But by proposition 7.4, there exists $N > 0$ an integer (which depends on $v$ à priori) such that $U^N$ preserves $C_{cusp}(v, w, \kappa_U)$. We can see that when $U$ acts on a module $M$, the finite slope part for $U$ of $U^N$ are the same (see for example proof of proposition 9.3). We thus define the finite slope part of $C_{cusp}(v, w, \kappa_U)$ for $U$ as the one for $U^N$. It is then a consequence of the equality that the finite slope part of $C_{cusp}(v, w, \kappa_U)$ is actually stable by $U$.$\Box$

**Proof.** — Indeed, it is enough to do it for $v$ given by proposition 7.4, $w' = w - 1$. We have the factorisation,

$$ H^i(C_{cusp}(x', w', \kappa_U)) \longrightarrow H^i(C_{cusp}(x, w, \kappa_U)) \longrightarrow H^i(C_{cusp}(x', w', \kappa_U)) $$

Now for a finite slope section $f \in H^i(C_{cusp}(x', w', \kappa_U))$, by definition there exists a non zero polynomial $P$ with $P(0) = 0$ and $P(U)f = f$. We can extend $f$ to $H^i(C_{cusp}(x, w, \kappa_U))$ by $P(U)f$. In particular, we can find for all $v$, an $x$ and $x' \leq x$ such that,

$$ \mathcal{X}(x') \subset \mathcal{X}(v) \subset \mathcal{X}(x), $$

and the composed restriction map,

$$ C(x, w, \kappa_U) \longrightarrow C(v, w, \kappa_U) \longrightarrow C(x', w, \kappa_U), $$

is an isomorphism on the finite slope part, in particular, $C(v, w, \kappa_U)f_{s} = C(x, w, \kappa_U)f_{s}$ and thus these spaces are stable by $U$.$\Box$

In particular, we get

**Proposition 9.2.** — $C_{cusp}(v, w, \kappa_U)$ has cohomology concentrated in degree zero, and the finite slope part of the cohomology of $C_{cusp}(v, w, \kappa_U)$ is concentrated in degree zero.

**Proof.** — The first part is appendix Theorem A.6. Fix $i$, then we have restriction maps

$$ H^i(C_{cusp}(x, w, \kappa_U)) \longrightarrow H^i(C_{cusp}(v, w, \kappa_U)) \longrightarrow H^i(C_{cusp}(x', w, \kappa_U)), $$

(for well chosen $x, x', v$) whose composite is an isomorphism on finite slope parts, and the middle module vanishes for $i > 0$. $\Box$
According to [Urb11] section 2.3.10, we can form the alternated Fredholm determinant,
\[ \det(1 - XU|C(\varepsilon, w, \kappa_\mathcal{U})). \]
But, because of the results of the previous section, this alternated determinant should actually only be the one in degree 0. Moreover, we will be able to restrict (locally) to the classical construction on an eigenvariety as in [Col197b, Buz07, AIP15].

For this, fix \( \varepsilon, v, w \) and \( \mathcal{U} \) accordingly. By Proposition 6.17, recall that \( C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U}) \) and \( C_{\text{cusp}}(v, w, \kappa_\mathcal{U}) \) are perfect complexes (in the sense of Urban [Urb11]), and the latter one can be represented by the projective (in the sense of Buzzard [Buz07] or [Urb11]) module in degree 0 \( H^0(\mathcal{X}(v) \times \mathcal{U}, \omega_{\mathcal{W}}^{\text{uni}}(-D)) \). The compact operator \( U \) acts on \( C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U}) \), but not a priori on \( C_{\text{cusp}}(v, w, \kappa_\mathcal{U}) \), but by Proposition 7.4, there exists an integer \( N \), which we fix, such that we have \( \varepsilon' < \varepsilon \), inclusions,
\[ \mathcal{X}(\varepsilon) \subset \mathcal{X}(v) \subset \mathcal{X}(\varepsilon'), \]
and \( U^N(\mathcal{X}(\varepsilon)) \subset \mathcal{X}(\varepsilon') \). In particular \( U^N(\mathcal{X}(v)) \subset \mathcal{X}(\varepsilon') \subset \mathcal{X}(v) \). Thus, \( U^N \) is a compact operator on both \( C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U}) \) and \( C_{\text{cusp}}(v, w, \kappa_\mathcal{U}) \). We now need to explain how to construct the Eigenvariety. First, we have three Fredholm series over \( \mathcal{O}_\mathcal{U} \) \( F_{U, \varepsilon} \) and \( F_{U^N, \varepsilon} \) of \( U \) and \( U^N \) acting on \( C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U}) \), and \( F_{U^N, \varepsilon} \) of \( U^N \) acting on \( C_{\text{cusp}}(v, w, \kappa_\mathcal{U}) = H^0(\mathcal{X}(v) \times \mathcal{U}, \omega_{\mathcal{W}}^{\text{uni}}(-D)). \)

First, we need, as in the classical construction, to do things on a specific cover, so choose a slope covering covering for \( \mathcal{U} \) and \( F_{U, \varepsilon} \) in the sense of definition 2.3.1. of [JN19] (this exist, see [JN19] Theorem 2.3.2 for example). Over \( (V, h) \), we can thus decompose the Fredholm series,
\[ F_{U, \varepsilon} = GS, \]
where \( G \in \mathcal{O}_V[T] \) is a slope \( \leq h \) polynomial and \( S \in 1 + T\mathcal{O}_V T \) is an entire series of slopes \( > h \). Accordingly, by [Col197b] Theorem A4.3/5 (or [JN19] Theorem 2.2.2), we have slope decompositions for \( \mathcal{U} \) of complexe,
\[ C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U}) = C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U})_{U, \leq h} \oplus C_{\text{cusp}}(\varepsilon, w, \kappa_\mathcal{U})_{U, > h}. \]

**Lemma 9.3.** — This decomposition is a slope \( Nh \) decomposition for \( U^N \) acting on this module, and it induces a slope \( Nh \) factorisation of
\[ F_{U^N, \varepsilon} = G' S'. \]

**Proof.** — We can work on a single module, say \( M \) and denote the associated decompositions associated to the slope decomposition of \( F_{U, \varepsilon} = GS \),
\[ M = M_{U, \leq h} \oplus M_{U, > h}. \]
As if \( Q(T) \) is a slope \( > Nh \) polynomial, the polynomial \( Q(T^N) \) is of slope \( > h \), we get that \( U^N \) is invertible on \( M_{U, > h} \). Now let
\[ N = \{ m \in M | \exists Q \text{ of slopes } \leq Nh, \text{ such that } Q^*(U^N)m = 0 \}. \]
This is clearly a submodule of \( M \), and has if \( Q(T) \) has slopes \( \leq Nh \), \( Q(T^N) \) has slopes \( \leq h \), we have \( P \subset M_{U, \leq h} \). We claim that \( P = M_{U, \leq h} \). Denote the \( \mathcal{O}_V \)-module
\[ Q = M_{U, \leq h}/P. \]
Fix a point of \( V \), and let \( v \in (M_{U,\leq h})_x = (M_x)_{U,\leq h} \) (which is easily seen to be true, or see e.g. [JN19] Theorem 2.2.13), thus if we denote \( N(v) \) the sub-\( k(x) \)-vector space generated by \( v \) and its images by \( u \) and its powers, \( N(v) \) is finite dimensional (say of dimension \( r \)). Denote \( \mu_{u,v} \) and \( \chi_{u,v} \) the minimal and characteristic polynomials of \( u \) on \( N_p v q \) is finite dimensional (say of dimension \( r \)). Denote \( \mu_{u,v} \) and \( \chi_{u,v} \) the minimal and characteristic polynomials of \( u \) on \( N(v) \). As there exists \( Q \) of slopes \( \leq h \) such that \( Q^* (u) \) kills \( u \), \( \mu_{u,v}^* \), and thus \( \chi_{u,v}^* \) have \( \leq h \) slopes. Up to extending scalars, there is a basis of \( N(v) \) such that the matrix of \( u \) on \( N_p v q \) is given by

\[
\begin{pmatrix}
\lambda_1 \\
\lambda_2 \\
\vdots \\
0 \\
\lambda_r
\end{pmatrix},
\]

and we can thus calculate characteristic polynomial of \( U^N \) : it is of slope \( \leq Nh \). By the theorem of Cayley-Hamilton \( v \in P \). Thus \( Q \otimes k(x) \) is zero, and by Nakayama, \( Q = 0 \). In particular we have that \( M_{U,\leq h} \oplus M_{U,\geq h} \) is a slope \( Nh \) decomposition for \( U^N \), which is functorial with respect to localisations \( \text{Spn}(k(x)) \rightarrow V \) as it comes from the slope decomposition of \( F_{U^N,h} \), thus by [JN19] Theorem 2.2.13 it induces a slope \( Nh \) decomposition

\[
F_{U^N,h} = G'S'.
\]

**Lemma 9.4.** — The restriction map

\[
\text{res} : C_{\text{cusp}}(\varepsilon, w, \kappa_U) \longrightarrow C_{\text{cusp}}(v, w, \kappa_U),
\]

induces an equality

\[
F_{U^N,\varepsilon} = F_{U^N,v}.
\]

In particular, over \( (V, h) \) we have a decomposition

\[
C_{\text{cusp}}(v, w, \kappa_U) = C_{\text{cusp}}(v, w, \kappa_U)_{U^N, \leq Nh} \oplus C_{\text{cusp}}(v, w, \kappa_U)_{U^N, \geq Nh},
\]

such that, \( \text{res} \) induces an isomorphism over \( V \),

\[
C_{\text{cusp}}(\varepsilon, w, \kappa_U)_{U, \leq h} = C_{\text{cusp}}(v, w, \kappa_U)_{U^N, \leq Nh}.
\]

**Proof.** — The first part is because we a diagram

\[
\begin{array}{ccc}
C_{\text{cusp}}(\varepsilon) & \xrightarrow{\text{res}} & C_{\text{cusp}}(v) \\
U^N \downarrow & & \downarrow U^N \\
C_{\text{cusp}}(\varepsilon) & \xrightarrow{\text{res}} & C_{\text{cusp}}(v)
\end{array}
\]

Where the shortened notations speak for themselves, and thus \( U^N : C_{\text{cusp}}(v) \longrightarrow C_{\text{cusp}}(\varepsilon) \) is a link in the sense of [Buz07]. Thus the two power series are equal. The rest follows by lemma 9.3. □
In particular, for each \((w, \varepsilon)\), for \(w\) big enough and \(\varepsilon\) small enough such that for all \(\tau, w \in ]n-1, n-\varepsilon]\) (which determines a unique integer \(n\)), \(v\) doesn’t play a role and can always be chosen so that \(X(\varepsilon) \supset X(v)\), which we do here, we can construct an Eigenvariety for the tuple

\[
(\mathcal{O}_{\mathcal{W}(w)}, C_{\text{cusp}}(\varepsilon, w, \kappa_{\mathcal{W}(w)}), \mathcal{H}^N \otimes \mathcal{A}(p), \prod_{\pi, i} U_{\pi, i}),
\]

as if \(C_{\text{cusp}}(\varepsilon, w, \kappa_{\mathcal{W}(w)})\) were one projective module. Indeed, locally this can be replace \(\pi(v)_{w, \omega_{\mathcal{W}(w)}}(-D)\) where

\[
\pi(v) : X(v) \times \mathcal{W}(w) \longrightarrow \mathcal{W}(w),
\]

and this \(\mathcal{O}_{\mathcal{W}(w)}\)-module is indeed projective, and its finite slope part inherits the action of \(U = \prod_{\alpha_\mathcal{W}} U_{\alpha, i}\), and this constructions glue together. Moreover, we have natural maps between them when \((w, \varepsilon), (w', \varepsilon')\) satisfies \(w' \geq w\) and \(\varepsilon' \leq \varepsilon\).

This is the main ingredient in all the constructions of Eigenvarieties. In particular, we get,

**Theorem 9.5.** — Let \(p\) be a prime. Fix \(S_p\), a set of primes over \(p\) (see section 2) unramified in \(D\) and \((K_J, J)\) a type\(^{(13)}\) outside \(S_p\), \(K \subset \text{Ker} J\), and \(S^p\) the set of places away from \(S_p\) where \(K\) is not maximal. There exists an equidimensionnal rigid analytic space \(\mathcal{E}_{S_p}\), together with a locally finite map,

\[
\mathcal{E}_{S_p} \overset{w}{\longrightarrow} \mathcal{W}_{S_p},
\]

and a Zariski dense subset \(Z\), such that for any \(\kappa \in \mathcal{W}(L)\), \(w^{-1}(\kappa)\) is in bijection with the eigensystems for \(\mathcal{H}^S \otimes \mathcal{A}(p)\) acting on the space of overconvergent, locally analytic, modular forms of weight \(\kappa\), type \((K_J, J)\), and finite slope for \(\mathcal{A}(p)\). Moreover, \(w(Z)\) consists of classical weights and \(Z\) is an Hecke eigensystem for a classical modular form of weight \(w(z)\).

**Proof.** — The construction is classical as soon as we have the previous datum, see [Col97b] and [Buz07]. Just remark that cutting in the datum the piece of type \((K_J, J)\) is possible as we are in characteristic zero (see [Her19], Proposition 9.13). The equidimensionnality results follows from the fact that we locally reduce to a single projective module \(H^0(X(\varepsilon), \omega_{w, \varepsilon}(-D))_{U, \leq, k}\) and [Che04] Lemme 6.2.10. The set \(Z\) is the set of points of \(\mathcal{E}\) which map to a point in \(W\) satisfying the hypotheses of proposition 8.2 and theorem 8.3. This is (Zariski) dense by [Che04] Corollaire 6.4.4. and using that every open of \(W\) contains a point satisfying the previous hypothesis.

**Remark 9.6.** — We will always consider the space \(\mathcal{E}_{S_p}\) with its reduced structure (see [Che05] section 3.6). But in turns out that \(\mathcal{E}_{S_p}\) is almost always automatically reduced with the structure given by \(\mathcal{H} \otimes \mathcal{A}(p)\). For the eigencurve this is [CM98], Proposition 7.4.5., in the quaternionic case see [Che05] Proposition 4.8, and [BC09], section 7.3.6 for a unitary group, compact at infinity. In the next section, we will prove that in the case of \(U(2, 1)\) this is also true.

\(^{(13)}\)Here by type we only mean, as in [Her19], a compact open subgroup \(K_J\) of \(G(\mathbb{A}_p^f)\) together with a finite dimensional representation.
10. Some complements for Picard modular forms (especially when $p = 2$)

In a previous article (see [Her19]), we constructed the Eigenvariety $E$ for $U(2,1)_{E/Q}$ where $E$ is a quadratic imaginary field, under the hypothesis that $p$ was inert (if $p$ splits see [Bra16]) so that the ordinary locus is empty, but also that $p \neq 2$, so that we can apply the main theorem of [Her16] on the canonical filtration. Theorem 9.5 extends this construction also for $p = 2$, and for $E/F$ a general CM-extension (but we only consider $F = \mathbb{Q}$ in this section). Classical points on $E$ correspond to classical forms for $(G)U(2,1)$ with classical weights given by $\kappa = (k_1 \geq k_2, k_3) \in \mathbb{Z}^3$. The corresponding character in $W$ is given by

\[(x,y) \in \mathcal{O}^\times \times \mathcal{O}^1 \mapsto \tau(x)^{k_1} \tau(y)^{k_2} \sigma \tau(x)^{k_3}.
\]

**Proposition 10.1.** The curve $E$ is reduced. This remains true if we had fixed the second weight to $k_2 \in \mathbb{Z}$ on the weight space.

**Proof.** We will use [Che05] Proposition 3.9, and we only need to check assumption (SSG) there. Thus, we need to find sufficiently many classical points $k \in W$ for which the module $M^\text{class}_{k} \cap M^\text{class}_{k}$ is semi-simple as an $\mathcal{H}N \otimes \mathcal{A}(p)$-module. We know already that the space of cuspidal forms for a group $G$ is semi-simple for the action of $\mathcal{H}N$ (spherical Hecke operators being auto-adjoint). Thus, we need to treat the action of $\mathcal{A}(p)$. But the action on an automorphic form $\pi$ of $\mathcal{A}(p)$ determines its refinements. Thus, we only need to prove that we can assure that these refinements are distinct, leading that the action of $\mathcal{A}(p)$ on $\pi'_p$ will be semi-simple ($I$ is an Iwahori subgroup). Let $k = (k_1,k_2,k_3) \in W$ be a classical weight. As the space $H^0(X, \omega^k(-D))$ is finite dimensional, there is a finite number of classical points $f$ in $E$ mapping to $k$ (and for varying $k$ these are strongly Zariski-dense in $E$). But the slopes of Hecke operators at $p$ are locally constant, thus for each of these points we can find an open $U_f$ (intersecting every component of $E$ at $f$) on which the slope is actually constant. Taking the intersection of the image of $U_f$ by $\pi$ in $W$, we can find an open $V \ni k$ in $W$ and for which every classical point $k' \in V$ and every classical $f'$ in the fiber of $k'$ has slopes equal the same as the one of some classical $f$ in the fiber of $k$. But the refinements are given in terms of eigenvalues of Frobenius by (see [Her19] section 10.6 and proofs of propositions II.1 and II.2)

\[(p^{-k_1-k_3} F_1, 1, p^{k_1-k_3} F_1^{-1}) \quad \text{if } p \text{ is inert}, \]

\[(p^{k_2-k} F_3, p^{k_2-k} F_2, p^{k_3} F_3) \quad \text{if } p \text{ splits},
\]

where $F_i \in \mathcal{O}(E)$ corresponds to some operators in $\mathcal{A}(p)$. In particular, as the slopes of $F_i$ are constant on $V \ni k$, for any $k' \in V$ with sufficiently regular weights, the three Frobenius eigenvalues are distincts, thus as are the possible refinements. In particular for those $k'$ (which are Zariski dense in $W$) the action of $\mathcal{H} \otimes \mathcal{A}(p)$ is semi-simple on classical forms in $M^\text{class}_p$. The same proof works if $k_2$ is fixed. \qed

**Remark 10.2.** 1. In particular, by [Che05] this proves that for a classical $k_2 \in \mathbb{Z}$, $E'$ given by the full eigencurve $E$, base changed over

\[\mathcal{W}_{\mathcal{O}^*} \hookrightarrow \mathcal{W}, \quad (k_1,k_3) \mapsto (k_1,k_2,k_3),
\]

and the curve constructed as in the previous section, over $\mathcal{W}_{\mathcal{O}^*}$ with a fixed value for $k_2$ coincide and are reduced.
2. Obviously, the same result where we would suppose \( k_1 = k_3 \) would not be true anymore as it could be that there isn’t enough classical semi-simple points.

In [Her19] (Theorem 1.3), we proved the following theorem,

**Theorem 10.3.** — Let \( E/\mathbb{Q} \) be a quadratic extension, and
\[ \chi : \mathbb{A}_E^\times / E^\times \longrightarrow \mathbb{C}^\times, \]
a a algebraic Hecke character. We suppose \( \chi \) polarized (i.e. \( \chi^\perp := (\chi \circ c)^{-1} = \chi | -1 \) where \( c \) is the complex conjugation on \( E \)). Let \( p \) be a prime such that \( p \) is unramified in \( E \) and \( p \nmid \text{Cond}(\chi) \), and \( p \neq 2 \) if \( p \) is inert in \( E \). Let
\[ \chi_p : G_E \longrightarrow \mathbb{Q}_p^\times, \]
be its \( p \)-adic realisation. Then, if \( \text{ord}_{s=0} L(\chi, s) \) is even and non-zero, the Bloch-Kato Selmer group \( H^1_{\text{f}}(p, E, \chi_p) \) is non-zero.

This result (actually a more general version of it) was almost entirely already proved by Rubin ([Rub91]) at least for CM elliptic curves when \( p \neq 2 \) (and \( p \neq 3 \) for \( E = \mathbb{Q}(i\sqrt{3}) \)).

In particular as \( 2 \) is inert in \( \mathbb{Q}(i\sqrt{3}) \) (and \( 3 \) is ramified in this case), it does not prove anything new for inert primes (only for the split ones).

Fortunately, with Theorem 9.5, we will be able to remove the hypothesis \( p \neq 2 \) if inert. Moreover, we can also remove the hypothesis \( p \nmid \text{Cond}(\chi) \) (as long as \( p \) stays unramified in \( E \)). To do this we focus from now on to the case of \( U(2, 1)_{E/\mathbb{Q}} \), and we will define sheaves of forms with nebentypus.

### 10.1. A remark on \( p = 2 \). —
To construct an integral model for the Picard modular surface, it is needed to choose a lattice for the group \((G)U(2, 1)\), as it appeared in \( D \) in section 3. We do as we did in [Her19] and choose the lattice \( L = \mathcal{O}_E^3 \subset E^3 \), stable for the form of matrix (used to define \((G)U(2, 1)\)) in the canonical basis given by
\[ \psi = \begin{pmatrix} 1 & & \\ & 1 & 1 \\ & & 1 \end{pmatrix}. \]

There is another natural choice, which would be the same lattice but the form
\[ \psi' = \begin{pmatrix} 1 & & \\ & 1 & \\ & & -1 \end{pmatrix}. \]

These two forms are isomorphic over \( \mathbb{Z}[1/2] \) but not modulo 2. Moreover, see [Bel06] Section 3.1, any abelian scheme of type \((2, 1) A/S\) will have a polarized Tate module \((T_p(A), q)\), together with the Weil pairing induced by the polarisation isomorphic either to \((\mathcal{O}_E^3, J)\) or \((\mathcal{O}_E^3, J')\). Any of these form would give an integral model for the Picard modular surface, not isomorphic modulo 2, and we choose \( \psi \), the first one, to define \( U(2, 1)_{E/\mathbb{Q}, \psi} \) over \( \mathbb{Z} \) as in section 3. Apart to construct the Eigenvariety, this choice (for which the construction of the Eigenvariety can be checked to be independant afterwards, even if we don’t need this result) will not appear in this section as we work in characteristic zero.
10.2. Removing the hypothesis \( p \nmid \text{Cond}(\chi) \). — Recall that in [Her19] Section 10, following [BC04], we introduced a type \((K_f, J_f)\) for \( J = \text{Cond}(\chi) \). Fix an auxiliary level \( K^p \subset (\text{Ker} J_f)^p \), and consider \( X_0(p^n)^\text{tor} / \text{Sp}(K) \) the (rigid and compactified) Picard variety of Iwahori level \( p^n \), over some \( p \) adic field \( K \). It is the analytic space of \( X_0(p^n)^\text{tor} \) which away from the boundary its \( S \)-points parametrizes

\[
(A, \iota, \lambda, \eta, H_1 \subset H_2),
\]

where

- \( A \to S \) is an abelian scheme of genus 3
- \( \iota : \mathcal{O}_E \to \text{End}_E(A) \) is a CM-structure of signature \((2,1)\), i.e.

\[
\omega_A = \omega_{A, \tau} \oplus \omega_{A, \varphi}, \quad \omega_{A, \tau} = \{ w \in \omega_A | \iota(x)w = \tau(x)w, \}
\]

with \( \omega_{A, \tau} \) and \( \omega_{A, \varphi} \) are respectively locally free of rank 2 and 1, and where \( \tau : E \to S \) is the canonical morphism and \( \varphi \) its conjugate.
- \( \lambda : A \to \mathcal{A} \lambda \) is a polarisation for which the rossati involution on \( \iota(x) \) coincides with \( \iota(\varphi) \)
- \( \eta \) is a level-\( K^p \)-structure,
- \( H_1 \subset H_2 \subset A[p^n] \) is a filtration by cyclic \( \mathcal{O}_E \otimes \mathbb{Z}_p / p^n \mathbb{Z}_p \)-modules such that \( H_2 = H_1 \). 

This is exactly the rigid space introduced in section 5.

The subgroups \( H_1, H_2 \) extends to \( X_0(p^n)^\text{tor} \), and we can also extend the polarisation of \( H_2 / H_1 \) to the boundary. We will distinguish the cases \( p \) inert (AU) and \( p \) split (AL) in \( E \).

In case (AL), i.e. \( p = e \varphi \) is split, then \( A[p^n] \simeq G^+ \times G^- \) (with \( G^- \) is \( (G^+)^D \) and \( \lambda \) exchange the two factors), and we can suppose that \( G = G^+ \), say, of dimension 2 and height \( p^m \). Under this decomposition, \( H_1 = H_1^+ \times H_1^- \) and \( H_1^+ \) is a cyclic rank \( p^m \)-subgroup of \( G^+ \) and \( H_1^- = (H_2^+)^\perp = (G^+/H_2^+)D \subset G^- \). In this case

\[
X_0(p^n) = \text{Isom}(H_1^+, \mathbb{Z}/p^n \mathbb{Z}) \times \text{Isom}(H_2^+ / H_1^+, \mathbb{Z}/p^n \mathbb{Z}) \times \text{Isom}(G^+/H_2^+, \mathbb{Z}/p^n \mathbb{Z}).
\]

It is a \( T_n \) \( = (\mathbb{Z}/p^n \mathbb{Z})^3 \)-etale torsor. Remark that \( H_2^+ \) is the canonical subgroup in this case. In case (AL) we can also introduce a second space. Using the previous notation, denote by \( X_{P_n}^\text{tor} \) the analytic space associated to a toroidal compactification of the following moduli space \( X_{P_n}^\text{tor} \) over \( \text{Spec}(K) \). A \( S \)-point of \( X_{P_n}^\text{tor} \) is a tuple \((A, \iota, \lambda, \eta, H_1^+, H_2^+, H)\) such that \((A, \iota, \lambda, \eta, H_1^+, H_2^+, H)\) is a \( S \)-point of \( X_0(p) \) (Iwahori level, i.e. \( H_1^+ \subset H_2^+ \subset G^+ [p] \)) together with a subgroup \( H \subset G[p^n] \) locally isomorphic to \((\mathbb{Z}/p^n \mathbb{Z})^2 \) and \( H[p] = H_2^+ \). It is the Shimura variety of level \( P_n \cap I(p) \) where \( I(p) \) is the Iwahori subgroup of \( G\mathbb{L}_3(\mathbb{Z}_p) \) and \( P_n \) is the subgroup of matrices of the form

\[
\begin{pmatrix}
* & * & *
\end{pmatrix}
\]

\[
(\text{mod } p^n).
\]

In particular we have a map \( X_0(p^n) \to X_{P_n} \).

In case (AU), i.e. \( p \) inert, denote

\[
X_0^+(p^n) = \text{Isom}(H_1, \mathcal{O}/p^n \mathcal{O}) \times \text{Isom}_\text{pol}(H_2/H_1, \mathcal{O}/p^n \mathcal{O}).
\]
This is a $T_n = (\mathcal{O}/p^n\mathcal{O})^\times \times (\mathcal{O}/p^n\mathcal{O})^1$-etale torsor.

In both cases, if $\pi : X_0^+(p^n)_{\text{tor}} \to X_0(p^n)_{\text{tor}}$ and $\chi : T_n \to K^\times$ is a character, we can consider $\mathcal{O}_{X_0(p^n)_{\text{tor}}} (\chi)$ to be the subsheaf of $\pi\mathcal{O}_{X_0^+(p^n)_{\text{tor}}}$ of sections which vary like $\chi$. This is an invertible sheaf on $X_0(p^n)_{\text{tor}}$.

**Definition 10.4.** — For all classical weight $\kappa$, we can consider the sheaf,

$$\omega^\kappa(\chi) := \omega^\kappa \otimes \mathcal{O}_{X_0(p^n)_{\text{tor}}} \mathcal{O}_{X_0(p^n)_{\text{tor}}} (\chi),$$

which is a locally free sheaf on $X_0(p^n)_{\text{tor}}$, whose global sections are (classical) Picard modular form of weight $\kappa$ and nebentypus $\chi$. Similarly,

$$H^0(X_0(p^n)_{\text{tor}}, \omega^\kappa(\chi)(-D)),$$

is the set of cuspidal ones.

**Proposition 10.5.** — There is a natural injection

$$\omega^\kappa(\chi) \hookrightarrow \omega^\kappa(\chi^w),$$

for all $w \in \mathbb{Z}[n-1, n - \varepsilon, \kappa\chi, \kappa\chi']$ and $\kappa\chi$ the product of the character $\kappa$ with the character

$$T(\mathbb{Z}_p) \to T_n \xrightarrow{\kappa} K^\times,$$

which we still denote $\chi$.

**Proof.** — Indeed, a section $f$ of $\omega^\kappa(\chi)$ is a law which associate to $(A, x, w)$ where $A \in X^+_{\text{tor}}(K), x$ is a level $X_0^+(p^n)$-structure and $w$ an isomorphism

$$\text{St}_{\mathcal{O}_w} \otimes \mathcal{O}_K \cong \omega_A,$$

an element $f(A, x, w) \in \mathbb{A}^1(K)$, which moreover satisfies,

$$f(A, tx, zw) = \chi(t)\kappa'(z)f(A, x, w).$$

In particular, this defines by restriction a section $g$ of $\mathcal{I}^\kappa(\chi)$ which satisfies, for the induced action of $T(\mathcal{O})$ on $\mathcal{I}^\kappa(\chi)$ which sends $(A, x, w)$ to $(A, tx, tw)$, such that $g(t) = \chi(T)\kappa'(t)g(i)$. Thus $g$ is a section of $\omega^\kappa(\chi^w)$. \hfill $\Box$

Over $X^+_{\text{tor}}$ we also have a $I_{GL_2}(p)(\mathbb{Z}/p^n\mathbb{Z}) \times (\mathbb{Z}/p^n\mathbb{Z})^\times$-torsor (where $I_{GL_2}(p)$ is the Iwahori subgroup of $GL_2(\mathbb{Z}_p)$), given by

$$\text{Isom}_{\text{modp}}(H, (\mathbb{Z}/p^n\mathbb{Z})^2) \times \text{Isom}(G^+ / H, \mathbb{Z}/p^n\mathbb{Z}),$$

where $\text{modp}$ means that an isomorphism $\phi$ induces an isomorphism of $H^1_p$ inside $p^{n-1}\mathbb{Z}/p^n\mathbb{Z}$. Thus, for $\chi$ a character of $I_{GL_2}(p)(\mathbb{Z}/p^n\mathbb{Z}) \times (\mathbb{Z}/p^n\mathbb{Z})^\times$, i.e. of the form $(\chi_1 \circ \text{det}, \chi_3)$, we have an invertible sheaf $\mathcal{O}(\chi')$ on $X^+_{\text{tor}}$ and thus a sheaf $\omega^\kappa(\chi')$. The sheaf $\omega^\kappa(\chi)$ on $X_0(p^n)_{\text{tor}}$ descend to $X^+_{\text{tor}}$ if and only if $\chi = (\chi_1, \chi_1, \chi_3)$ and coincide with $\omega^\kappa(\chi')$ with $\chi' = (\chi_1 \circ \text{det}, \chi_3)$.

**Proposition 10.6.** — In the split case, if $v < \frac{1}{2p}$, the canonical subgroup induces an isomorphism,

$$X_0(p^n)_{\text{tor}}(v) \to X^+_{\text{tor}}(v).$$

Here we really mean the $\mu$-canonical locus (and not the full $\mu$-ordinary locus).
Remark 10.7. — If $p > 2$, is inert, the results of [Her16] give, for $v < \frac{1}{2p^{n-1}}$, an isomorphism $\mathcal{X}(v) \to \mathcal{X}_0(p^n)(v)$.

Recall the following result of Rogawski (see [BC09] section 6.9.6 and [Bell10] section 2.7). Fix first a Hecke character $\mu$ as in [BC09] Lemma 6.9.2(iii).

Theorem 10.8 (Rogawski). — Suppose $\text{ord}_{s=0} L(\chi, s)$ is even and non zero. Then there exists a representation $\pi^n$, automorphic for $U(2, 1)$ and cuspidal such that for every prime $x$ split in $E$,

$$L(\pi^n_x) = \mu_x|.|^{-\frac{1}{2}}(L(\mathcal{X} + 1 \oplus |.|)).$$

Remark 10.9. — This representation $\pi^n$ is slightly different from the one of [BC04] or [Her19], it is a twist of the latter by $L(\mathcal{X})\mu_x|.|^{-\frac{1}{2}}$.

Proposition 10.10. — Suppose $\text{ord}_{s=0} L(\chi, s)$ is even and non zero. Denote $n_0 = v_p(\text{Cond}(\chi))$. Denote by $\chi'$ if $p$ is split the character $(1, 1, \chi_p)$ and if $p$ is inert the character $(\chi_p, 1)$ of $(\mathcal{O}/p^n\mathcal{O})^\times \times (\mathcal{O}/p^n\mathcal{O})^1$. Denote also $\kappa$ the classical weight corresponding to $(a - 1, 0, 1) \in \mathbb{Z}_\text{dom}.

Then the Hecke eigensystem (away from $p \text{Cond}(\chi)$) of $\pi^n$ appears in $H^0(\mathcal{X}(\varepsilon), \omega^{n_0} \chi'^{-1}(-D))$ for all $n \geq n_0$ and $w \in [n - 1, n - \varepsilon]$ for $\varepsilon$ small enough.

Proof. — Indeed we checked that $\pi^n$ contributes to the coherent first cohomology group in [Her19] Proposition D.2. More precisely we checked that its restriction to $SU(2, 1)$ appears with $K$-type corresponding to $\kappa$ restricted to $SU(2, 1)$. As $\pi^n$ is a twist of the representation denoted $\pi^n(\chi)$ in [Her19] by $\mathcal{X}\mu_x|.|^{-1/2}$, which is algebraic, we can calculate its algebraic weight $\kappa$ and check that $\kappa = (a - 1, 0, -1)^{(14)}$. Moreover Bellaiche-Chenevier ([BC04] Proposition 4.2) proved that $\pi^n(\chi) \otimes \chi_0^{-1}$ was of a certain type $(K_J, J)$ at ramified primes for $\chi$. As $\mathcal{X} = \mathcal{X}_0|.|^{\frac{1}{2}} = \mathcal{X}_0|.|^{\frac{1}{2}}$ and both $|.|$ and $\mu$ are unramified at $p$, we deduce that the twist $\pi^n$ is of the same type as $\pi^n(\chi) \otimes \chi_0^{-1}$ (which is obviously trivial if $\chi$ is unramified at $p$). Thus $\pi^n$ is of nebentype $\chi'$, and we deduce the previous result from proposition 10.5.

We need to take care of the action at $p$ of the Iwahori algebra $\mathcal{A}(p)$. This is well known in the case of $GL_2$ (see [Co197a]). Denote the higher-Iwahori subgroup

$$I^+_n = \left( \begin{array}{ccc} 1 + p^n\mathcal{O} & \ast & \ast \\ p^n\mathcal{O} & 1 + p^n\mathcal{O} & \ast \\ p^n\mathcal{O} & p^n\mathcal{O} & 1 + p^n\mathcal{O} \end{array} \right) \cap G(\mathbb{Q}_p),$$

where $G(\mathbb{Q}_p) = GL_3(\mathbb{Q}_p)$ if $p$ is split, and $U(2, 1)(\mathbb{Q}_p) = U(3)(\mathbb{Q}_p)$ otherwise. We could do everything for $GU(2, 1)$ or $GL_3 \times GL_1$ (if $p$ splits) but it doesn’t change anything. $I^+_n$

\footnote{We could also argue directly as in [Her19] relating $\kappa$ to the Hodge-Tate weights of $\rho_{p^n}$ on the Eigenvariety $\mathcal{E}$}
has a natural Iwahori decomposition $I_n^+ = N_n \times T_n^+ \times N_n$ (and $N_n = N$), and thus if we denote $\Sigma^+$ the elements of the form
\[
\begin{pmatrix}
p^{a_1} \\
p^{a_2} \\
p^{a_3}
\end{pmatrix}
\quad \text{with} \quad a_1 \geq a_2 \geq a_3,
\]
if $p$ splits, and
\[
\begin{pmatrix}
p^{a_1} \\
p^{a_2} \\
p^{-a_1}
\end{pmatrix}
\quad \text{with} \quad a_1 \geq a_2,
\]
if $p$ is inert. Denote by $\Sigma$ the group generated by $\Sigma^+$ and their inverse.

**Proposition 10.11.** — Denote by $A_n^{+,0}(p)$ the sub-algebra of $H(G(\mathbb{Q}_p)/I_n^+)$ generated by the double class characteristic functions
\[
1_{I_n^+ a I_n^+}, \quad a \in \Sigma^+.
\]
$A_n^{+,0}(p)$ is commutative. Denote by $A_n^+(p)$ the algebra generated over $\mathbb{Q}_p$ by $A_n^{+,0}(p)$ and the inverse of the elements $1_{I_n^+ a I_n^+}$. It is canonically isomorphic to $\Sigma$ and thus to $A(p)$.

**Proof.** — $A_n^+(p)$ is commutative by [Cas95] Lemma 4.1.5. \(\square\)

**Remark 10.12.** — The canonical isomorphism $\Sigma \longrightarrow A_n^+(p)$ sends $a \in \Sigma^+$ to the corresponding double class, but this is not true for all $a \in \Sigma$, just like the case of $A(p)$. The double class are not invertible in general (if $n > 1$ at least, see [Ogg69] Lemma 2 for (new) modular forms, but this is true if $n = 1$, [Vig16]).

There is thus an Hecke operator acting on $\mathcal{X}_0^+(p^n)$ corresponding to the double class $1_{I_n^+ a I_n^+}$ where in the inert case
\[
a = \begin{pmatrix} p & 1 \\ 1 & p^{-1} \end{pmatrix}
\]
and in the split case,
\[
a = \begin{pmatrix} p & 1 \\ 1 & p \end{pmatrix} \quad \text{or} \quad a = \begin{pmatrix} p & p \\ p & 1 \end{pmatrix}.
\]
We call respectively $U_p^n$, $U_{p,1}^n$, $U_{p,2}^n$ the corresponding operators. These operators can be defined on the moduli problem $\mathcal{X}_0^+(p^n)$ and commutes with their counterparts on $\mathcal{X}_0(p) =: \mathcal{X}$ (see for example [PS17] section 8.2), in the sense that for one of these operators, say $g$, if we denote the correspondance $C$ and $C_n = C \times \mathcal{X}_0^+(p^n)$, with $\pi_n^g$ and $\pi_g$ the universal isogeny on $C_n$ and $C$, we thus have commutatives diagrams,
and a commutative diagram,

\[
\begin{array}{ccc}
\mathcal{X}^+(p^n) & \xrightarrow{\pi} & \mathcal{X}^0_0(p^n) \\
\downarrow{\pi} & & \downarrow{\pi} \\
\mathcal{X} & \xrightarrow{p_1} & \mathcal{X} \ \\
\downarrow{p_2} & & \downarrow{p_2} \\
\mathcal{X}^+ & \xrightarrow{b} & \mathcal{X}^+ \\
\end{array}
\]

The normalisation of the maps \(\pi_n\) and \(\pi_{ng}\) can be done the same way, and we thus deduce that the operators \(U_{p,1}\) in level \(\mathcal{X}\) and \(U_{p,2}^n\) in level \(\mathcal{X}^0_0(p^n)\) commutes with the pullback by \(\pi\) (i.e. \(U_{p,1}^n(\pi^* f) = \pi^* (U_{p,1} f)\)). Thus, these operators defined on \(\omega_n^w\) which appears in \(H^0(\mathcal{X}(v), \omega_n^w)\) for \(v\) small enough, we need to understand the action of \(A_n^+(p)\) on \(\pi_n^a\).

**Definition 10.13.** — If \(\pi\) is a representation of \(G(\mathbb{Q}_p)\), denote by

\[
(pI_n^+)^{fs} := 1_{I_n^+}aI_n^+ (pI_n^+),
\]

where \(a\) is the diagonal element corresponding to \(U_{p,1}\) if \(p\) is inert, and \(U_{p,2}^n\) if \(p\) is split (in other words \(a\) is the double class corresponding to the compact operator \(U_{p,1}\) in the text). This coincides with the space \(V_{X_n^0}\) of [Cas95], Proposition 4.1.6.

By [Cas95] Lemma 4.1.7, this space \((pI_n^+)^{fs}\) is endowed with an action of \(A_n^+(p)\).

**Proposition 10.14.** — Let \(\pi\) be a representation of \(G(\mathbb{Q}_p)\). Write \(I_n^+ = N_n T_n^+ N_n\) its Iwahori decomposition. Then, as \(\Sigma = A_n^+(p)\)-module,

\[
(pI_n^+)^{fs} = (pN_n)T_n^+ \otimes \delta_B^{-1}.
\]

**Proof:** — As in [BC09] Proposition 6.4.3, this is due to [Cas95] Proposition 4.1.4. using the Iwahori decomposition. \(\square\)
Remark 10.15. — We could also extend a bit the previous isomorphism by adding the action of (the split part of) $T/T_n^+$ as in [Cas95].

Moreover, as $\pi^n$ is a quotient of an induction (or the induction from a parabolic subgroup in the split case), we will use the same geometric lemma as [BC09] Proposition 6.4.4. In particular we only need to calculate the admissible refinement using this lemma, and as this does not assume $\chi$ to be unramified, we find exactly the same (automorphic) refinements as if $p \nmid \text{Cond}(\chi)$ in $((\pi^n_p)^{T_n}/(\chi))^{\alpha}$.

Definition 10.16. — Let $\sigma$ be the refinement corresponding to the one when $p \nmid \text{Cond}(\chi)$ used in [Her19] when $p$ is inert (in which case it is unique, see [Her19] Proposition 10.7), and to $(\mu|_{p^{-1/2}}(\chi(p)), 1, p^{-1})$, see [BC09] Lemma 8.2.1 when $p$ is split \(^\text{(15)}\). More precisely, it corresponds to

\[(\mu|_{p^{-1/2}}(\chi(p)), 1, p^{-1}) : T/T_n^+ \to (a, b, c) \mapsto (\mu|_{p^{-1/2}}(abc)\chi(a)|c)\]

in the case where $p$ splits, and to

\[(\mu|_{p^{-1/2}}(1, \chi(p)), p^{-1}) : T/T_n^+ \to (a, e) \mapsto (\mu|_{p^{-1/2}}(a^{-1}e)\chi(e)|a)\]

when $p$ is inert. Recall that $T \simeq (\mathcal{O}[1/p])^3 \times (\mathcal{O}[1/p])^1$ in this case.

10.3. Refinements of De Rham representations. — In this subsection, we slightly generalise the well-known notion of refinements (see e.g. [BC09] section 2.4) to non-necessarily crystalline representations. This is especially useful for us when $p \mid \text{Cond}(\chi)$.

Definition 10.17. — Let $V$ a $n$-dimensional, continuous $L$-representation of $G_K$, where $K$ is a $p$-adic field. Assume that $V$ is De Rham, and denote $WD(V)$ the Weil-Deligne representation associated to $V$ (see [Fon94, BGGT14]). Assume that $L$ is big enough so that all eigenvalues of the Frobenius $\varphi$ on $WD(V)$ are defined on $L$. A refinement of $V$ is the datum $(\mathcal{F}_i)_{i=1, \ldots, n}$ of a filtration

\[0 \subsetneq \mathcal{F}_1 \subsetneq \cdots \subsetneq \mathcal{F}_n = WD(V),\]

by Weil-Deligne representations.

Just as in the crystalline case, the previous definition more generally applies to a general De Rham $(\varphi, \Gamma)$-module $D$, to $WD(D)$ (see [Ber08]).

Remark 10.18. — Obviously when $V$ is crystalline, this definition coincides with the one of [BC09].

\(^{\text{(15)}}\) For theorem 10.24 when $p$ is split, we could also use the same refinement as in [Her19], i.e. $\mu|_{p^{-1/2}}(1, \chi(p), p^{-1})$, but for theorem 10.25, we need to be at the point corresponding to $\sigma$. The reason is that the refinement need to be anti-ordinary, as shown in proposition 10.22. In particular, we choose a priori a different refinement as [BC04, BC09], but this is merely superficial: in our case as in [BC04, BC09] our point (thus our choice of refinement) is anti-ordinary compared to the ordered Hodge-Tate weights, the reason is that when $\text{ord}_{s=0} L(\chi, s)$ is even, the order of the Hodge-Tate weights at our point is not the same as in [BC04, BC09].
Let $D$ be a De Rham $(\varphi, \Gamma)$-module. Let $(\mathcal{F}_i)$ be a refinement of $D$, i.e. a filtration of $WD(D)$. Then we can associate to $(\mathcal{F}_i)$ a filtration of $D$ by
\[\text{Fil}_i(D) = (R^{[1/i]}\mathcal{F}_i) \cap D.\]
This filtration is saturated, and thus defines a triangulation of $D$ (see [BC09], section 2.3).

**Proposition 10.19.** — The previous map $(\mathcal{F}_i) \mapsto (\text{Fil}_i D)$ induces a bijection between the set of refinements of $D$ and the set of triangulations of $D$.

**Proof.** — This is [Ber08] Théorème A and Corollaire III.2.5. \(\square\)

In the particular case of an automorphic representation $\pi$ of our unitary group $G$, with associated Galois representation $\rho_\pi$ (for example $\rho = 1 \oplus \chi_p \oplus \varepsilon$ associated to the automorphic representation $\pi^\infty$ of the previous subsection), we have distinguished – we call them accessible, (galois) refinements for $\rho_{\pi, v}$ which correspond to the (automorphic) refinements for the action of $A_\infty^\infty(p)$ on $\pi_v^\infty$ (for $v \mid p$). Such refinements exist only if $(\pi_v)^{t\varepsilon} \neq 0$ for some $n$. The association is explained in [BC09] (when $G$ is split at $v$) for unramified representations, and for $U(3)(\mathbb{Q}_p)$ (when $v$ is inert) in [Her19] section 10.5. This can be generalized for non-necessarily unramified $\pi_v$, verbatim when there is no monodromy. For example, to the refinement $\sigma$ of definition 10.16, is associated the following refinement of $\rho = 1 \oplus \chi_p \oplus \varepsilon$:

\[
\left\{ \begin{array}{ll}
0 & \subseteq LL(1) \subseteq LL(1) \oplus LL(\chi_p^\infty) \subseteq WD(\rho_{G,p}) & \text{when } p \text{ is inert}, \\
0 & \subseteq LL(\chi_p^\infty) \subseteq LL(1) \oplus LL(\chi_p^\infty) \subseteq WD(\rho_{G,v}) & \text{when } p \text{ is split}.
\end{array} \right.
\]

Here 1 is the trivial representation of $E_v^\times$, and $LL$ denotes the Local-Langlands correspondence.

**10.4. Constructing the extension.** — We thus take a prime $p$ unramified in $E$, which can be 2 or not, and which can divide $\text{Cond}(\chi)$ or not. Let $\mathcal{E}$ be the eigenvariety of level $N = \text{Cond}(\chi)^p$ [the prime-to-$p$-part of the conductor] associated to $U(2,1)_E$ and $p$ by Theorem 9.5. It is equipped with a map $w : \mathcal{E} \longrightarrow \mathcal{W}$, and there is a point $y \in \mathcal{E}$ which coincides with the representation $\pi^n$ together with its refinement $\sigma$ by definition 10.16 and proposition 10.10. For all $Z \subset \mathcal{E}$, we have associated to the automorphic form corresponding to $z$ a Galois representation

$\rho_z : G_E \longrightarrow \text{GL}_3(\overline{\mathbb{Q}}_p),$

which is moreover polarized in the following way:

$\rho_z^+ \simeq \rho_z(-1) := \rho_z \varepsilon^{-1},$

where $\varepsilon$ denote the cyclotomic character. Let us be more precise : we will change a bit the convention used in [Her19] to stick with the one of [BC09] (this will make things easier to treat the case $p \mid \text{Cond}(\chi)$). Denote for an automorphic representation $\pi$ of $U(2,1)$ of regular weight $\rho'_\pi$ the associated $p$-adic Galois representation by [BC09] Conjecture 6.8.1, which is known to exists, see Remark 6.8.3, (vi) of [BC09]. For $z \in Z$ associated to a modular form $f_z$, denote by $\Pi$ any irreducible constituent of the representation of (the restriction to) $U(2,1)(\mathbb{A}_k)$ generated by $f_z$. Then we set

$\rho_z = \rho'_\pi \nu,$
where $\nu$ is defined in [BC09] Lemma 8.2.3, and is associated by class field theory to $\mu^{-1}\cdot 1^{1/2}$. In particular it satisfies $\nu^{-1} = \nu(-3)$. Thus $\rho_z \vdash \rho_z(-1)$. Moreover for $z \in Z$ of classical (automorphic) weight $(k_1 \geq k_2, k_3)$, the Hodge-Tate weights of $\rho_z$ are given by

$$((1 - k_3, k_2 - 1, k_1), (-1 - k_1, -k_2, k_3 - 2)) = \begin{cases} (\text{HT}_\tau, \text{HT}_\tau)(\rho_z) & \text{if } p \text{ is inert} \\ (\text{HT}_\tau, \text{HT}_\tau)(\rho_z) & \text{if } p \text{ splits} \end{cases}$$

**Proposition 10.20.** There exists a pseudo character on $E$,

$$T : G_E \to \mathcal{O}(E),$$

such that for all $z \in Z$, $T_z$ is the trace of $\rho_z$. Moreover, $T^\perp = T(-1)$.

**Proof.** This is [Che04] Proposition 7.1. 

We need a particular point on $E$.

**Proposition 10.21.** Suppose $\text{ord}_{s=0} L(\chi, s)$ is even and $L(\chi, 0) = 0$. There exists a point $y \in E$ corresponding to a (non-tempered) automorphic representation $\pi^n$. The point $y$ is non-classical if $p | \text{Cond} (\chi)$, but is classical otherwise. Moreover its $p$-adic weight $w(\chi)$ is of the form $w(\chi)^{alg} w(\chi)^{sm}$ where $w(\chi)^{sm}$ is the smooth (finite order) character of Proposition 10.10, and $w(\chi)^{alg}$ is the algebraic character

$$\mathcal{O}^\times \times \mathcal{O}^1 \to \frac{\mathbb{Q}_p^\times}{\mathbb{Q}_p^\times} \oplus \frac{\mathbb{Q}_p^\times}{\mathbb{Q}_p^\times}$$

if $p$ is inert

$$\mathbb{Z}_p^2$$

if $p$ is split

At the point $y$, the evaluation $T_y$ is given by the trace of $1 \otimes \chi^c$ and the refinement is given by $\sigma$ of definition 10.16, i.e. it is the refinement (3).

**Proof.** This is a translation of Proposition 10.10 with the normalisation of $T$.

We freely use the notation of [KPX14] concerning $\varphi, \Gamma$-modules. Denote $\delta_i$ for $i = 1, 2, 3$ the character,

$$\delta_i : K^\times \to \mathcal{O}(E)^\times,$$

such that $\delta_i(p) = F_i$ and, in the inert case, recall that we have on $W$ two universal morphisms,

$$\kappa_1 : x \in \mathcal{O}^\times \mapsto \kappa_1(x) \in \mathcal{O}(W)^\times, \quad \text{and} \quad \kappa_2 : y \in \mathcal{O}^1 \mapsto \kappa_2(y) \in \mathcal{O}(W)^\times,$$

such that at classical points $\kappa = (k_1, k_2, k_3) \in Z^3$, we have

$$\kappa_{1|\kappa}(x) = \tau(x)^{k_1} \tau(x)^{k_2} \quad \text{and} \quad \kappa_{2|\kappa}(y) = \tau(y)^{k_2}.$$

---

[16] Carrefoul to the normalisation of the Local Langlands correspondence in [BC09]

[17] More precisely, it is non classical without level at $p$ as its system of Hecke eigenvalues doesn’t appear in $H^0(X, \omega^n)$, but appears in $H^0(X, (p^n)^\omega (\chi))$.

[18] These $F_i \in \mathcal{O}(E)^\times$ already appeared in proof of proposition 10.1, see [Her19] Proposition 11.1 and 11.2. These are the functions given by a basis of the Hecke operator in $\mathcal{A}(p)$. 
We set
\[ \delta_1|_{\mathcal{O}_K} = (\varpi_1)x_{\tau}^{-1}x_{\tau}, \]
\[ \delta_2|_{\mathcal{O}_K} : y \in \mathcal{O}_K \mapsto \kappa_2(\varpi/y)\tau(y), \]
\[ \delta_3|_{\mathcal{O}_K} = (\kappa_1)^{-1}x_{\tau}^2 = (\delta_1|_{\mathcal{O}_K})^{-1}x_{\tau}x_{\tau}. \]

In particular we have \( \delta_3 = \delta_1^{-1} x. \) In the split case, we set
\[ \delta_i : \mathbb{Q}_p^\times \to \mathcal{O}(K)^\times, \]
with \( \delta_i(p) = F_i \) and as we have universal characters on \( W, \)
\[ \kappa_i : \mathbb{Z}_p^\times \to \mathcal{O}(W)^\times, \]
such that for classical weights \( (k_1, k_2, k_3) \in \mathbb{Z}_p^3, \)
\[ \kappa_1(x) = x^{k_1}, \quad \kappa_2(x) = x^{k_2}, \quad \kappa_3(x) = x^{k_3}. \]

We set
\[ \delta_1|_{\mathbb{Z}_p^\times} = \kappa_3 x^{-1}, \quad \delta_2|_{\mathbb{Z}_p^\times} = \kappa_2 x^{-1}, \quad \delta_3|_{\mathbb{Z}_p^\times} = \kappa_1^{-1}. \]

In particular, we can define \( \text{wt}_i := -\text{wt}(\delta_i) \in \mathcal{O}(W)^\Sigma \) the opposite of the derivative at \( 1 \) of \( \delta_i \) (see [KPX14] Definition 6.1.6). In particular \( E, Z \) and the functions \( \delta_i \) satisfies the hypothesis of Corollary 6.3.10 of [KPX14] (excepts possibly the irreducibility condition).

Denote by \( A = \mathcal{O}_y \) the rigid analytic local ring of \( E \) at \( y \) and \( K \) its total fraction ring. The pseudo character \( T \) on \( E \) induces one on \( A \) and denote by \( I_{\text{tot}} \subset A \) its total reducibility ideal (see [BC09] Proposition 1.5.1, Definition 1.5.2.) In particular for any \( J \supset I_{\text{tot}} \) on \( A/J \) we can write
\[ T \otimes A/J = T_1 + T_2 + T_3. \]

**Proposition 10.22.** The reducibility locus \( \text{Spec}(A/I_{\text{tot}}) \) is a proper closed sub-scheme of \( \text{Spec}(A) \), i.e. \( I_{\text{tot}} \neq \{0\} \). More precisely, if \( a \geq 2 \) and \( p \) is split, we have that for all \( i, j \in \{1, 2, 3\}, \)
\[ \text{wt}(\delta_i) - \text{wt}(\delta_j) \equiv \text{wt}(\delta_i)(y) - \text{wt}(\delta_j)(y) \pmod{I_{\text{tot}}}. \]

If \( p \) is inert,
\[ \text{wt}(\delta_2) - \text{wt}(\delta_3) \equiv \text{wt}(\delta_2)(y) - \text{wt}(\delta_3)(y) \pmod{I_{\text{tot}}}, \]
and
\[ \text{wt}(\delta_3) - \text{wt}(\delta_1) \equiv \text{wt}(\delta_3)(y) - \text{wt}(\delta_1)(y) \pmod{I_{\text{tot}}}, \]
and similarly (with \( \tau, \varpi \) changed by \( v, \varpi \)) is \( p \) splits and \( a = 1 \).

**Proof.** Let \( I \supset I_{\text{tot}} \) a finite length ideal of \( \mathcal{O}_y = A \). We thus have for \( j = \{1, \varpi, \varepsilon\}, \)
\[ T_j : G_{E,S} \to A/I, \]
a (continuous) character, such that \( T_j (\text{mod } m_A) = j \).

As \( T_j \) is a character, by [KPX14] Theorem 6.2.14, there exists a character
\[ \delta_j : K^\times \to (A/I)^\times, \]
such that the \( \varphi, \Gamma \)-module associated to \( T_j, D_{rig}(T_j) \) is isomorphic to \( R_{A/I}(\pi_K)(\delta_j) \).
Thus $T_2 = T_{\overline{\chi}}$ when $p$ is inert and $T_3 = T_{\varepsilon}$ in any case, for example. By lemma B.3, we have a in particular a map

$$R(\delta_i) \hookrightarrow D_{rig}(T_i) \simeq R(\delta'_i),$$

and we still want to determine the character $\delta'_i$.

To determine $\delta'_i$ the character of $T_i$, we still need to know the weight of $T_i$. We know by Lemma B.2 that $T_i$ has its Sen operator killed by

$$\prod_{i=1}^{3} (T - \text{wt}(i)) \in A/I[T]^E.$$

Moreover, at $y \in \mathcal{E}$, we have, if $p$ splits,

$$(\text{wt}_1^p, \text{wt}_2^p, \text{wt}_3^p) = (0, -1, a - 1) \quad \text{and} \quad (\text{wt}_{\overline{\chi}}^p, \text{wt}_2^p, \text{wt}_3^p) = (-a, 0, -1)$$

and if $p$ is inert,

$$(\text{wt}_1^p, \text{wt}_2^p, \text{wt}_3^p) = (0, -1, a - 1) \quad \text{and} \quad (\text{wt}_{\overline{\chi}}^p, \text{wt}_2^p, \text{wt}_3^p) = (-a, 0, -1).$$

Thus, if $a \geq 2$ these weights are distincts at $y$. Thus we can calculate the Hodge-Tate-Sen weight of $T_1$: $T_1$ has weight $\text{wt}_1$, $T_{\overline{\chi}}$ has weight $\text{wt}_3$ and $T_{\varepsilon}$ has weight $\text{wt}_2$. If $a = 1$, we can’t a priori distinguish the two weights $h_1, h_3$ at $v$ and $\overline{\chi}$ (or $\tau$ and $\overline{\chi}$), but we know that $T_{\varepsilon} = T_3$ has weight $\text{wt}(\delta_2)$ at $v$, and that $T_1$ has weight $\text{wt}(\delta_2)$ at $\overline{\chi}$.

Suppose $p$ is split, using the lemma B.4 for $T_{\varepsilon}$, we have (evaluating at $y$ to have the value of $t_\varepsilon, k_\varepsilon$),

$$\text{wt}_v(\delta_2) - \text{wt}_v(\delta_3) - (\text{wt}_v(\delta_2)(y) - \text{wt}_v(\delta_3)(y)) \in I.$$

Using that $\delta_3 = \overline{\chi}^{-1} t_\varepsilon$ and similarly for $\delta_2$ (or using lemma B.4 for $T_1$ at $\overline{\chi}$), we get also

$$\text{wt}(\overline{\chi}(\delta_2) - \text{wt}(\overline{\chi}(\delta_1)) - (\text{wt}(\overline{\chi}(\delta_2)(y) - \text{wt}(\overline{\chi}(\delta_1)(y)) \in I.$$

If $a \geq 2$, we can also use Lemma B.4 for $T_1$ and $T_{\overline{\chi}}$ at $v$ and $\overline{\chi}$ to get the remaining,

$$\text{wt}(\delta_i) - \text{wt}(\delta_j) \equiv \text{wt}(\delta_i)(y) - \text{wt}(\delta_j)(y) \pmod{I}.$$

Similarly if $p$ is inert, applying the lemma B.4 at $v$ for $T_{\varepsilon}$ and $\delta_2$ we get

$$\text{wt}(\delta_2) - \text{wt}(\delta_3) - (\text{wt}(\delta_2)(y) - \text{wt}(\delta_3)(y)) \in I,$$

and applying the previous lemma at $\overline{\chi}$ to $T_1$ and $\delta_2$ we have moreover,

$$\text{wt}(\delta_2) - \text{wt}(\delta_1) - (\text{wt}(\delta_2)(y) - \text{wt}(\delta_1)(y)) \in I.$$

Thus if $a \geq 2$ and $p$ is split (and similarly but not for all $i, j$ in the remaining cases), we have

$$\text{wt}(\delta_i) - \text{wt}(\delta_j) - (\text{wt}(\delta_i)(y) - \text{wt}(\delta_j)(y)) \in I,$$
for all $i, j$ and all cofinite length ideal $I$ containing $I_{tot}$, thus, for all $i, j$,
\[
\text{wt}(\delta_i) - \text{wt}(\delta_j) - (\text{wt}(\delta_i)(y) - \text{wt}(\delta_j)(y)) \in I_{tot}.
\]

We also need the following result, which is a corollary of theorem B.5.

**Corollary 10.23.** — $Ext_T(1, i) \subset H^1_T(E, i)$, for $i = \overline{\chi}$ or $\varepsilon$.

**Proof.** — Indeed, the theorem B.5 gives that any extension in $Ext_T(1, i)$ is crystalline at all place above $p$ (as the Frobenius eigenvalues of $i$ are different from 1). At $v$ a place dividing $\ell \neq p$, if $v \not\in \text{Cond}(\chi)$, by hypothesis on the level of $E$, the dense set of classical point $Z$ are unramified at $v$, thus $T(I_v) = 1$ on $E$ (as $\varepsilon$ is reduced) and thus $Ext_T(1, i)$ consist of unramified extension at $v$.

Now suppose $v \in \text{Cond}(\chi)$. If $i = \varepsilon$, any extension is automatically unramified. Suppose $i = \overline{\chi}$. By choice of the type $J$ outside $p$ on $E$, we know [BC04 Proposition 4.2 or Herl9] proposition 10.21) that for all $z \in Z$, there exists a subgroup $I' \subset I_v$ such that $\rho_z(I') = \{1\}$. Thus, $T(I') = 1$ and for all $x \in E, \rho_x(I') = 1$. Thus, $T_{I_v}$ is locally constant, and the same for $\rho_x|_{I_v}$ (as it is semi-simple as $I'$ acts trivially). Up to extending scalars, evaluating at $\rho_y$, we get
\[
T|_{I_v} = (1 \oplus 1 \oplus \overline{\chi}|_{I_v}) \otimes O_U,
\]
for some neighborhood $U$ of $x$. But as we have a morphism
\[
M/I \otimes T_i \longrightarrow \rho_c \longrightarrow 0.
\]
we have that $\rho_c(I') = 1$, thus $\rho_c$ is semi-simple, thus $\rho_c|_{G_v} \in H^1_T(G_v, 1)$.

We have the following improvement of Theorem 10.3 :

**Theorem 10.24.** — Let $\chi$ be a polarized algebraic Hecke character as in Theorem 10.3. Suppose that $L(\chi, s)$ vanishes with even (non-zero) order at $s = 0$. Let $p$ be unramified in $E$. Then
\[
H^1_T(E, \chi_p) \neq \{0\}.
\]

**Proof.** — Let $e_1, e_{\overline{\chi}}, e_\varepsilon$ be the indempotents as in Appendix B, and denote $A_{i,j}$, for $i,j \in \{1, \overline{\chi}, \varepsilon\}$ the corresponding $A$-modules. Then as in [BC09] Lemma 8.3.2, we get
\[
I_{tot} = A_{\overline{\chi}}A_{\varepsilon, 1}.
\]
But if $Ext_T(1, \overline{\chi}) = 0$, then $A_{\overline{\chi}, 1} = A_{\overline{\chi}}A_{\varepsilon, 1}$ ([BC09], Theorem 1.5.5). Thus $A_{\overline{\chi}, 1}A_{\varepsilon, 1} = A_{\overline{\chi}}A_{\varepsilon, 1}A_{1, \varepsilon}$. But as $H^1_T(E, \varepsilon) = \{0\}$, we get by the same reasoning
\[
A_{\varepsilon, 1} = A_{\varepsilon, \overline{\chi}}A_{\varepsilon, 1}.
\]
Thus,
\[
I_{tot} = A_{\varepsilon, \overline{\chi}}A_{\varepsilon, \overline{\chi}}A_{1, \varepsilon}A_{1, \varepsilon} \subset \mathfrak{m}A_{\overline{\chi}, 1}A_{1, \varepsilon} = \mathfrak{m}I_{tot}.
\]
Thus $I_{tot} = 0$, contradicting proposition 10.22 for $2 = i \neq j = 3$.

Actually we can be more precise than Theorem 10.24 if $a \geq 2$ and $p$ splits. Denote from now on by $E'$, the Eigenvariety on which $\kappa_2$ is constant, equal to $\kappa_2(y) = 0$
It is actually the base change of the three-dimensionnal $E$ by $W_{O_\infty} \hookrightarrow W$ (see remark 10.2).
**Theorem 10.25.** — Suppose that $p$ is split. Remember that we assumed that $L(\chi, 0) = 0$ and $\ord_{t=0} L(\chi, s)$ is even. We denoted $y$ the point of $\mathcal{E}'$ with its refinement proposition 10.16. Let $t'$ be the dimension of the tangent space of $\mathcal{E}'$ at $y$, and let $h$ be the dimension of $\Ext_{\mathcal{O}_1}^1(1, \chi)$. Then if $a \geq 2$,

$$t' \leq h + \frac{3}{2}.$$  

In particular as $t' \geq 2$, we have that $h \neq 0$.

**Remark 10.26.** — 1. If $t$ denotes the dimension of the tangent space at $y$ of $\mathcal{E}$, we have $t \leq t' + 1$.

2. If $h = 1$ (in particular if $\dim H^1(E, \chi_\varepsilon) = 1$) and $a > 1$ then $\mathcal{E}$ is regular at $y$, and thus there is a unique component of $\mathcal{E}$ passing through $y$. Unfortunately, because of the Bloch-Kato conjecture, we never expect this to be the case as the order of vanishing is even.

3. In case $a = 1$, unfortunately we don’t have that

$$H^1(E, \chi, -1) = \{0\}$$

(which is a special case of the Bloch-Kato conjecture) nor $\dim H^1(E, \chi(-1)) \leq 1$ (which is a special case of Jannsen conjecture). Indeed, in this case $V = \chi(-1)$ is of motivic weight 1 (and automorphic) thus the $L$-function of $V^*(1)$ doesn’t vanish at $s = 0$. But even if we had these results, the main obstruction to get the previous theorem 10.25 when $a = 1$ is Proposition 10.22, as we can’t control along the reducibility locus the Hodge-Tate weights which have same value at $y$ (as when $p$ is inert).

For now on suppose $a \geq 2$ and $p$ splits (unless otherwise stated). Denote $\Lambda = \mathcal{O}_{\mathcal{E}'}.y$.

The GMA associated to $i_\varepsilon, \chi_{\varepsilon}, \varepsilon_1$ is of the form

$$\begin{pmatrix}
A & A_{\xi, \chi} & A_{\xi, -1} \\
A_{\chi, \varepsilon} & A & A_{\chi, -1} \\
A_{1, \varepsilon} & A_{1, \chi} & A
\end{pmatrix}$$

**Proposition 10.27.** — $I_{\text{tot}}$ is the maximal ideal of $\Lambda = \mathcal{O}_{\mathcal{E}, y}$.

**Proof.** — By proposition 10.22 we already have that Spec$(A / I_{\text{tot}})$ is included in the fiber of $w : \mathcal{E}' \rightarrow W$ at $\kappa$, i.e. $I_{\text{tot}} \supset m_\kappa \mathcal{O}_E$. Let $\psi : A / I_{\text{tot}} \rightarrow k[\varepsilon]$ (where $\varepsilon^2 = 0$) any morphism, and for $i \in \{1, \chi, \varepsilon\}$, denote

$T_{i, \psi} = T_{i} \otimes A / I_{\text{tot}}, \psi k[\varepsilon]$.

We will show that these $T_{i, \psi}$ are constant deformation of $i$ to $k[\varepsilon]$. Indeed, they are all unramified outside $p\text{Cond}(\chi)$ by construction (as $T$ is). If $v\text{Cond}(\chi)$ is prime to $p$, then $T_{i, \psi}$ can be seen as an extension of $i$ by itself, thus gives a class in $H^1(E_{\mathcal{O}_{\mathcal{E}'}, 1} = i^{-1})$. But such a class is trivial (as $\text{Hom}(i, i(-1)) = \{0\}$). If $v| p$, we need to check that the induced class in $H^1(Q_p, \mathcal{Q}_p)$ is crystalline. For all $i$, it suffices to show it for $T_{i, \psi}^{-1}$, which reduces to 1. Thus, in every case we have a deformation of 1 to $k[\varepsilon]$. But we know moreover that its Hodge-Tate weight is an integer as we are in the fiber $w^{-1}(\kappa)$. If $p$ is split, then this is
Thus, by the local Euler Characteristic formula, it is enough to calculate

\[ \text{Proof} \]

\[ p \]

\[ \]
2. \( h_{1,\varepsilon} = 0 \) and \( h_{\varepsilon,1} \leq 1 \).
3. \( h_{\chi,1} = h_{\chi,\varepsilon} \leq 1 \).

But we know (see [BC09] Lemma 9.4.2) that \( h \) is the minimal number of generators of \( A_{\chi,1} \), and similarly, \( A_{1,\chi}A_{\chi,1} = m \), which has by hypothesis \( t' \) as minimal number of generators, can be generated (see [BC09] Lemma 9.4.3, by

\[
h + s
\]
generators, where \( s \) is the minimal number of generators of \( A_{\chi,1} \), thus

\[
s \leq h + \frac{h + 1}{2}.
\]

Putting everything together, we get

\[
t' \leq h + \frac{h + 1}{2} = \frac{h + 3}{2}.
\]

Appendix A. Cohomology of cuspidal automorphic sheaves

**Proposition A.1.** — (Lan, [Lan17] Theorem 6.1) Let \( X_1(p^n)^* \) the minimal compactification of \( X_1(p^n) \), defined by normalisation of the minimal compactification with our fixed auxiliary level, as in [Lan16a], Proposition 6.1. There is a proper surjection \( p : X_1(p^n)_{tor} \to X_1(p^n)^* \).

**Definition A.2.** — The \( \mu \)-ordinary Hasse invariant \( \mu \) Ha descend to \( X_1(p^n)^* \) (modulo \( p \)), and we can thus define \( X_1(p^n)^{\mu-\text{full}}(v) \) to be the normalisation in its generic fiber of the greatest open in the blow up of \( \mu \)-Ha, \( p^n \) where this ideal is generated by \( \mu \) Ha. Its generic fiber is \( X_1(p^n)^{\mu-\text{full}}(v) \), a strict neighborhood of the (full) \( \mu \)-ordinary locus. Denote \( X_1(p^n)^*(v) \) the (union of) connected component which contains a point of maximal degree, and as \( X_1(p^n)^{\mu-\text{full}} \) is normal in its generic fiber, there is an associated open \( X_1(p^n)^*(v) \). We thus have a map,

\[
\pi(v) : X_1(p^n)_{tor}(v) \to X_1(p^n)^*(v).
\]

For all this section, except the last two results (Corollary A.5, Theorem A.6), we forgot the notation concerning the level at \( p \), and denote \( X_1(p^n)_{tor}(v) \) by \( X_{tor}(v) \), and similarly for \( X(v), X^*(v), X_{tor}, X, X^* \). We thus have the previous map,

\[
\pi(v) : X_{tor}(v) \to X^*(v).
\]

We have the following vanishing result.

**Proposition A.3.** — Denote by \( D(v) \) the boundary in \( X_{tor}(v) \). Then, for all \( q > 0 \),

\[
R^q\pi(v)_*\mathcal{O}(-D(v)) = 0.
\]

**Proof.** — This is essentially Lan’s result (see [Lan17] Proposition 8.6), slightly modified because of the neighborhood we chose. First, note that we can prove it for \( X_1^{\mu-\text{full}}(v)_{tor} \) and \( X_1^{\mu-\text{full}}(v)^* \) and then localise (as the schemes are normal and thus have same connected component as their rigid fiber) to \( X_{tor}(v) \) and \( X^*(v) \). From now on and until the end of this proof, we denote \( X(v) \) the neighborhood of the full \( \mu \)-ordinary locus in \( X^* \). By the formal functions theorem we can work on formal completions of points of \( x \in X^*(v) \). Let
us describe the completions at $x$ of $X(v)^\tor$. Let $\mathfrak{Z}$ be a stratum of $X^*$ ([Lan16a] Theorem 12.1), and denote $\mathfrak{Z}(v)$ be the base change of $\mathfrak{Z}$ to $X^*(v)$. As $X^*(v)$ is normal in its generic fiber $X^*(v)$ by construction, by pullback $\mathfrak{Z}(v) = X^*(v) \times_{X^*} \mathfrak{Z}$ is normal in its generic fiber.

Let $C \longrightarrow \mathfrak{Z}$ be the proper scheme, normal over $\mathcal{O}$ ([Lan16a] Proposition 8.4). Then $C(v) := C \times_{X^*} X^*(v) = C \times_{\mathfrak{Z}} \mathfrak{Z}(v)$ is normal in its rigid fiber (again by pullback). Define analogously the local models (see [Lan16b] section 4.) $\mathfrak{U}(v)$ and $\mathfrak{V}((v)$.

We can describe locally $X^\tor$ over $X^*$ by $\mathfrak{V}$ (see [Lan16a] Theorem 10.3, [Lan17] Theorem 6.1 (4)) and also for $X^\tor(v)$ over $X^*(v)$, i.e. in rigid fiber, as this is just localisation over an open subset. Denote by $X^*(v)^0$ denote the open of the blow-up where the ideal is generated by $\mathfrak{c}$ (i.e. before taking the normalisation in its rigid fiber), and similarly for $X^\tor(v)^0$. Then $X^\tor \longrightarrow X^*$ is not flat à priori, but as $(\mathfrak{c}, p^v)$ is in both cases a regular sequence, this implies that the admissible formal blow-up in both cases is given by the closed subset of equation $(\mathfrak{c}^n \mathfrak{c}^{-1} p^v)$ in $\text{Proj}(\mathcal{O}_X[Y,X])$ (see e.g. [Bos14], Proposition 7. (iii)). Thus this admissible blow-up commutes with the base change $X^\tor \longrightarrow X^*$. In particular, $X^\tor(v)^0 = X^\tor \times_{X^*} X^*(v)^0$. Thus $X^\tor(v)$ is the normalisation of $X^\tor \times_{X^*} X^*(v)^0$ in its rigid fiber. The etale, local isomorphism

$$\mathfrak{V} \longrightarrow X^\tor,$$

can thus be base changed over $X^*$ by $X^*(v)^0$, and as etale localisation commutes with normalisation, we only need to check that our chart $\mathfrak{V}(v)$ is the normalisation of $\mathfrak{V}(v)^0 := \mathfrak{V} \times_{X^*} X^*(v)^0$ in its rigid fiber. But $\mathfrak{V}(v) \longrightarrow \mathfrak{V}(v)^0$ is pulled-back from $X^*(v) \longrightarrow X^*(v)^0$, thus $\mathfrak{V}(v)$ is normal in its rigid fiber, and moreover the morphism

$$X^*(v) \longrightarrow X^*(v)^0,$$

is finite by [PS16] Proposition 1.1. Thus, again by [PS16] Proposition 1.1, $\mathfrak{V}(v)$ is the normalisation and we get a local isomorphism

$$\mathfrak{V}(v) \longrightarrow X^\tor(v).$$

Thus, for $x \in \mathfrak{Z}(v)$ we have,

$$(\mathfrak{V}(v)/\mathfrak{U})^\wedge_x \cong (X(v)^\tor)^\wedge_x$$

Then according to [Lan16b] Theorem 3.9 (and especially section 7), and [Lan17] Theorem 8.6 it is sufficient to prove the analog of Proposition 8.3 (of [Lan17]) for $p(v) : C(v) \longrightarrow \mathfrak{Z}(v)$. But $p(v)$ is also proper, and the pullback of the sheaf $\Psi(\ell)$ relatively ample over $\mathfrak{Z}(v)$, thus the same proof applies.

In the following, we denote for a object $X$ over $\text{Spec}(\mathcal{O})$ or $\text{Spf}(\mathcal{O})$ and $n \in \mathbb{N}^*$, $X_n$ the base change to $\text{Spec}(\mathcal{O}/p^n)$. We also denote, as in [AIP15], $\mathfrak{M}(w)^0$ the analogous weight space, but forgetting the torsion part when constructing $\mathfrak{M}(w)$. This can be seen for example as characters in $\mathfrak{M}(w)$ being trivial on the torsion part of $T(\mathbb{Z}_p)$, but we don’t fix such an identification.

**Proposition A.4.** — Consider the following diagram, for $m \geq n$,
\[ \mathcal{X}_{\text{tor}}(v)_m \xrightarrow{i} \mathcal{X}_{\text{tor}}(v)_n \]
\[ \pi_m \quad \pi_n \]
\[ \mathcal{X}^*(v)_m \xrightarrow{i'} \mathcal{X}^*(v)_n \]

We have the equality,
\[ i' \ast [\pi_m]_{\mathcal{X}_{\text{tor}}^*(v)} = [\pi_m]_{\mathcal{X}_{\text{tor}}^*(v)} \ast i. \]

In particular, \( \pi_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) \) is a small formal Banach sheaf on \( \mathcal{X}^*(v) = \mathcal{X}_1(p^n)^{\text{tor}}(v) \). Similarly for \( (\pi \times 1)_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) \) on \( \mathcal{X}^*(v) \times \mathcal{M}(w)^0 \). Moreover \( H^i(\mathcal{X}^*(v), \pi_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D))[1/p] \) vanishes for \( i \geq 1 \) (similarly for the higher direct image of \( (\pi \times 1)_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) \) on \( \mathcal{W}(w) \)).

**Proof.** — The proof is the same as in [AIP15] or [Bral6], except that we stay at level \( \mathcal{X}_1(p^n)(v) \) (which is easier), as the map \( \mathcal{X}_1(p^n)(v) \to \mathcal{X}(v) \) is not finite in our situation. We can prove as in [AIP15] that \( \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) \) is a direct limit of sheaves whose cokernel is a successive extension of the sheaf \( \mathcal{O}_{\mathcal{X}_1(p^n)^{\text{tor}}(v)} \). Thus, it is enough to show that
\[ R^1 \pi_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) = 0, \]
but this is the previous proposition. This implies also that \( R^i \pi_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) = 0 \) for \( i > 0 \). Moreover, as \( \pi_* \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D) \) is small on \( \mathcal{X}^*(v) \) which is generically affinoid, Theorem A.1.2.2 of [AIP15] implies its higher cohomology vanishes after inverting \( p \).

Exactly as in [AIP15], section 8.2, we deduce the following two results. Now we go back to the notation \( \mathcal{X}_1(p^n)^{\text{tor}}(v) \) to denote the (integral toroidal compactification of the) Shimura variety with level \( \mathcal{G}(1)(p^n) \) at \( p \), and \( \mathcal{X}_{\text{tor}}^*(v) \) denote the rigid analog, with Iwahori level \( p \), as in the rest of the text.

**Corollary A.5.** — The module
\[ M_{\mathcal{V}, \mathcal{W}, \mathcal{C}, \text{cusp}}^{\mathcal{X}_{\text{tor}}^*(v)} := H^0(\mathcal{X}_1(p^n)^{\text{tor}}(v) \times \mathcal{M}(w)^0, \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D))[1/p] \]
is a projective \( \mathcal{O}_{\mathcal{W}(w)^0}[1/p] \)-module, and for all \( \kappa \in \mathcal{W}(w)^0 \), the specialisation
\[ M_{\mathcal{V}, \mathcal{W}, \mathcal{C}, \text{cusp}}^{\mathcal{X}_{\text{tor}}^*(v)} \to H^0(\mathcal{X}_1(p^n)^{\text{tor}}(v), \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D))[1/p], \]
is surjective.

**Theorem A.6.** — For all \( v, w \) the module \( M_{\mathcal{V}, \mathcal{W}, \mathcal{C}, \text{cusp}}^{\mathcal{X}_{\text{tor}}^*(v)} := H^0(\mathcal{X}_{\text{tor}}^*(v) \times \mathcal{W}(w), \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D)) \) is a projective \( \mathcal{O}_{\mathcal{W}(w)} \)-module, and for all \( \kappa \in \mathcal{W}(w) \), the specialisation map
\[ M_{\mathcal{V}, \mathcal{W}, \mathcal{C}, \text{cusp}}^{\mathcal{X}_{\text{tor}}^*(v)} \to M_{\mathcal{V}, \mathcal{W}, \mathcal{C}, \text{cusp}}^{\mathcal{X}_{\text{tor}}^*(v), \text{cusp}}, \]
is surjective. Moreover \( H^i(\mathcal{X}_{\text{tor}}^*(v) \times \mathcal{W}(w), \mathcal{M}^{\mathcal{X}_{\text{tor}}^*(v)}(-D)) \) vanishes for \( i > 0 \).
Appendix B. Families and triangulations

In this appendix we generalise the tools used in [BC09] to prove the theorem in section 10. Fortunately, this is mainly a matter of reformulation, as most of the work is done in [KPX14]. From now on, we take \( E \) to be the eigenvariety for \((G) \mathcal{U}(2,1)_{E/\mathbb{Q}} \) and \( p \) a prime unramified in \( E \), constructed in section 9 (see also [Bral6] for \( p \) split in \( E \) and [Her19] for \( p \) inert not equal to 2), which is 3-dimensional or its variant with weight \( k_2 \in \mathbb{Z} \) fixed, which coincide with the base change by \( W_{O^{\mathbb{A}}} \rightarrow W \), which is 2-dimensional. Automorphically, the second construction “fixes the central character” (which can “move” in the three dimensional eigenvariety, but keeping its polarisation; in particular even in the 3-dimensional eigenvariety, we can’t twist automorphic forms by a power of the norm character). In any case we always have \( Z \subset E \) a strongly Zariski-dense subset consisting of classical automorphic forms of integral (= algebraic) weight. This space is not dense for the analytic topology, as it is already the case in \( W \). We can define \( Z_{la} \) the subset of \( E \) of classical automorphic forms possibly with level at \( p \), and locally algebraic weight-character \( \kappa \). \( Z_{la} \) doesn’t accumulate at \( Z \), and as if \( p | \text{Cond}(\chi) \), we will only have a point \( y \in Z_{la} \) corresponding to the automorphic representation \( \pi \) of section 10, we first need to enlarge a bit \( Z^{(19)} \).

Proposition B.1. — There exists \( Z' \subset Z^{(19)} \), which accumulates at every point of \( Z^{(19)} \), such that for all \( z \in Z' \) we have that the Sen polynomial of \( \rho_z \) is killed by

\[
\prod_{i=1}^{3} (T - wt_i(z)).
\]

Proof. — Let \( z \in Z^{(19)} \). In particular, there exists \( w, n \) such that \( z \in \mathcal{E}_{w,c} \) in the notations before Theorem 9.5. This \( \mathcal{E}_{w,c} \) is affinoid. Thus, by [BC09] Lemma 7.8.11, there exists \( g : \mathcal{E}_{w,c}' \rightarrow \mathcal{E}_{w,c} \) on which we have an actual representation on a coherent torsion free of \( G = G_{E,S} \). We can then apply [KPX14] Definition 6.2.11 or [BC09] p125 to have a Sen operator in family over \( \mathcal{E}_{w,c}' \). But \( Z \) is Zariski dense in \( \mathcal{E}_{w,c} \) thus as is its pullback \( Z^{alg} \) in \( \mathcal{E}_{w,c}' \). Moreover, there is \( Y \subset \mathcal{E}_{w,c} \) Zariski open and dense, on which \( Z_{Y} = Y \cap Z^{alg} \) is Zariski dense, with \( \rho_z = \rho_{g(z)} \) for all \( z \in Y \). Thus for all \( z \in Y \cap Z^{alg} \), we have that the Sen operator is killed by

\[
\prod_{i=1}^{3} (T - wt_i(z)).
\]

By density, this is true for all \( x \in \mathcal{E}_{w,c}' \). Thus, for all \( y \in Z_{Y}' = g^{-1}(Z^{alg}) \cap Y \), the Sen polynomial of \( \rho_y = \rho_{g(y)} \) is killed by the same polynomial. Using \( Z' = g(Z_{Y}') \) we get the result. \( \square \)

\(^{19}\)We could actually prove directly the following result on all \( Z^{(19)} \), and even the crystabellianity of these representations, by extending results of [BPS16, Bij16] for all classical modular forms with Nebentypus, as it is done in [PS17]. But the following will be enough for us.
By proposition 10.21 there exists a point \( y \in \mathcal{E} \), whose (semi-simplified) Galois representation is \( 1 \oplus \overline{\chi} \oplus \varepsilon \) and its refinement is \( \sigma \) (see definition 10.16). Let \( A = \mathcal{O}_{\mathcal{E},y} \) be the rigid analytic local ring at \( y \). We want to study this ring and the pseudo-character \( T \) at \( A \).

By [BC09] Theorem 1.4.4 and Lemma 1.8.3 for \( S = A[G]/\text{Ker} T \), we choose idempotents \( e_{\varepsilon}, e_{\overline{\chi}}, e_{1} \) that are compatible with the involution \( \tau \) given by \( i \mapsto i^{\tau}(1) \). We thus have a generalized matrix algebra (GMA) of the form

\[
\begin{pmatrix}
  A & A_{\overline{\chi}, \varepsilon} & A_{\varepsilon, 1} \\
  A_{\overline{\chi}, \varepsilon} & A & A_{\overline{\chi}, 1} \\
  A_{\varepsilon, 1} & A_{\overline{\chi}, 1} & A
\end{pmatrix}
\]

This defines \( \text{Ext}_T(i, j) \) and \( b_{i,j} = \dim \text{Ext}_T(i, j) \) for all \( i \neq j \in \{1, \varepsilon, \overline{\chi} \} \). In the end, we want to study \( I_{\text{tot}} \) the total reducibility locus and this GMA.

On \( A/I_{\text{tot}} \), we have pseudo-characters of dimension 1 (i.e. actual characters)

\[
T_j : G = G_{E,S} \longrightarrow A/I_{\text{tot}}, \quad j \in \{\varepsilon, 1, \overline{\chi}\},
\]

such that \( T_j \otimes A/\mathfrak{m}_A = T_j \otimes k(y) = j \). From now on fix \( I \supset I_{\text{tot}} \) a cofinite length ideal.

**Lemma B.2.** — The Sen operator of \( T_j \) is killed by the polynomial

\[
\prod_{i=1}^{3}(T - \text{wt}_i) \in A/I[T]^{\Sigma}.
\]

**Proof.** — Let \( y \in \mathcal{E} \). As remarked, the set \( Z' \) of \( B.1 \) accumulates at \( y \). Fix \( j \in \{1, \overline{\chi}, \varepsilon\} \) and denote \( S = A[G]/\text{Ker} T \). There exists \( M \) a \( S \)-module, of finite type as \( A \)-module such that \( MK = \bar{K}^3 \) and with an exact sequence

\[
0 \longrightarrow K \longrightarrow M/IM \longrightarrow T_j \longrightarrow 0,
\]

such that \( K \) as a Jordan-Holder sequence with all subquotient isomorphic to \( T_i \) for \( i \neq j \) (see [BC09] Theorem 1.5.6 and Lemma 4.3.9). Thus, it suffices to prove that \( M/IM \) as its Sen operator killed by the previous polynomial. But by [BC09] Lemma 4.3.7 (and because \( Z' \) accumulates at \( y \)) we can find \( U \subset \mathcal{E} \) an affinoïd open containing \( z \), in which \( Z' \) is Zariski dense, together with \( M \) a coherent torsion-free \( \mathcal{O}_U \)-module endowed with an action of \( G \) such that \( M(U) \otimes A \cong M \) as \( A[G] \)-module, and \( M \otimes_{\mathcal{O}(X)} \mathcal{O}(U) \) is free of rank 3, semisimple as \( G \)-module and trace \( T \otimes_{\mathcal{O}(X)} \mathcal{O}(U) \). By generic semisimplicity and generic flatness, there exists \( F \subset U \) a Zariski closed subspace such that for all \( x \in U \setminus F, M_y = M_x^{\psi_x} = \rho_y \). We can change \( Z' \) by \( Z' \cap (U \setminus F) \), which is still Zariski dense in \( U \). Denote by \( \varphi \) the Sen operator of \( D_{\text{Sen}}(M) \) (or \( B = \text{End}_{\mathcal{O}(U)}(M(U)) \) see [KFX14] Définition 6.2.11 or [BC09] proof of lemma 4.3.3). For all \( z \in Z', \varphi_z \) is killed by

\[
P = \prod_{i=1}^{3}(T - \text{wt}_i(z)),
\]

by proposition B.1, and as \( Z' \) is Zariski dense, and \( \mathcal{O}(U) \) is reduced we get that \( P \) kills \( \varphi \) on \( U \), and reducing to \( A/I \) we get the result. \( \square \)
Fix the bijection between \{1, 2, 3\} and \{1, \overline{\chi}, \varepsilon\} corresponding to the refinement 10.16, i.e.

\[
1 \mapsto \overline{\chi} \quad 2 \mapsto \varepsilon \\
3 \mapsto \varepsilon
\]

Thus it makes sense to speak about \( T_i, i \in \{1, 2, 3\} \).

**Lemma B.3.** For all \( i \), the \( A/I\)-module

\[
H^0_{\varphi, \Gamma}(D_{rig}(T_i)(\delta^{-1}_i))
\]

is free of rank 1.

**Proof.** We will consider inductively the pseudocharacters \( T \), \( \Lambda^2T \) and \( \text{det} \ T \) whose reduction is respectively \( 1 \otimes \overline{\chi} \otimes \varepsilon, \overline{\chi} \otimes \varepsilon \) and \( \varepsilon \). In particular they are multiplicity free. Recall that for \( I \supset I_{\text{sh}}, T \) splits, thus also \( \Lambda^2T \), we denote \( T'_i = T_1 \ldots T_i \) for \( i = 1, 2, 3 \). By induction on \( i \), it is enough to prove the result for \( T'_i \). In particular for all \( i \), we can find \( M \) a \( S \)-module, finite type over \( A \), of generic rank 3 (if \( i = 1, 2 \), rank 1 and \( M = T'_3 \) if \( i = 3 \)) such that (\cite{BC09} Theorem 1.5.6 and Lemma 4.3.9).

\[
0 \longrightarrow K \longrightarrow M/I \longrightarrow T'_i \longrightarrow 0,
\]

with \( K^{ss} \) reducing to a direct sum of \( \prod_{k=1}^i T_{j_k} \neq T'_i \). As \( \delta_i(p) = F_i \) and at \( y \) these values are

\[
(\overline{\chi}(p), 1, p^{-1}) \quad \text{if } p \text{ splits}, \quad (1, \overline{\chi}(p), p^{-1}) \quad \text{if } p \text{ is inert},
\]

which are distincts \( (\overline{\chi}(p)) = p^{-1/2} \), the slope of \( \delta_1 \ldots \delta_i \) is distinct from the one appearing in \( K \). In particular

\[
H^0_{\varphi, \Gamma}(D_{rig}(K(\delta_1 \ldots \delta_i)^{-1})) = \{0\}.
\]

Thus, it suffices to show that \( H^0_{\varphi, \Gamma}(D_{rig}(M(\delta_1 \ldots \delta_i)^{-1})) \) is free of rank 1 for every cofinite ideal \( J \) of \( A = \mathcal{O}_y \). But this is assured by \cite{KPX14} Theorem 6.3.9 and \cite{BC09} Theorem 3.3.3 and Lemma 3.3.9. Indeed, first, by \cite{BC09} Lemma 4.3.7 we can find \( U \subset \mathcal{E} \) containing \( y \) an affinoid together with a coherent torsion free module \( M \) with an action of \( G = G_{E, S} \) reducing to \( M \) on \( A = \mathcal{O}_y \), which is generically free of rank 3, and such that the trace of \( G \) on \( M \) coincide with \( T \otimes_{\mathcal{O}_x} \mathcal{O}(U) \). Denote \( \delta^{(i)}_1 = \delta_1 \ldots \delta_i \), and \( H^0_{\varphi, \Gamma}(D_{rig}(\cdot)) \) is a functor as in \cite{BC09} Section 3.2.2. Moreover, by \cite{BC09} Lemma 3.4.2 and \cite{KPX14} Theorem 6.3.9 (applied to \( M^{\varphi} \) and \( \delta = \delta^{(i)}_1 \)) there exists a birational morphism (see \cite{BC09} section 3.2.3)

\[
\pi : U' \longrightarrow U,
\]

such that the strict transform \( M' \) of \( M \) on \( U' \) is locally free, and moreover we have a map

\[
D_{rig}(M^{\varphi}) \longrightarrow R_{U'}(\delta^{(i)}_1)^{-1} \otimes \mathcal{L},
\]

whose kernel is a \( \varphi, \Gamma \)-module of rank 2 (is trivial if \( i = 3 \)) and which is generically surjective. Moreover it is proven in the course of the proof of \cite{KPX14} Theorem 6.3.9 that \( H^0_{\varphi, \Gamma}(D_{rig}(\langle M'^{\varphi} \rangle(\delta^{(i)}_1))) \) is locally free of rank 1. In particular, as these sheaves are coherent, for all \( y' \in \pi^{-1}(y) \), and all cofinite length ideal \( J' \) of \( \mathcal{O}_{y'} \),

\[
H^0_{\varphi, \Gamma}(D_{rig}(\langle M^{\varphi} \rangle(\delta^{(i)}_1)^{-1} \otimes \mathcal{O}_{y'}/J')).
\]
is free of rank 1. Indeed, we have the commuting diagram

\[
\begin{CD}
H^0_{\varphi, \Gamma}(D_{rig}(\mathcal{M}')(\delta_1^{-1})) \otimes \mathcal{O}_{y'}/I' @> f >> H^0_{\varphi, \Gamma}(D_{rig}(\mathcal{M}')(\delta_1^{-1})) \otimes \mathcal{O}_{y'}/I' \\
\end{CD}
\]

where the map \( i \) is injective ([KPX14] eq 6.3.9.1). As the map \( f \) is non-zero, the map \( \text{red} \) is also non-zero. Thus by [BC09] Lemma 3.3.9,

\[
H^0_{\varphi, \Gamma}(D_{rig}(\mathcal{M}')(\delta_1^{-1})) \otimes \mathcal{O}_{y'}/I'
\]
is free of rank one over \( \mathcal{O}_{y'}/I' \). Thus by [BC09] Proposition 3.2.3 and Lemma 3.3.9, for all cofinite length ideal \( J \) of \( \mathcal{O}_y = A \), we have that

\[
H^0_{\varphi, \Gamma}(D_{rig}(\mathcal{M}(\delta_1^{(i-1)}) \otimes \mathcal{O}_y/J)),
\]
is free of rank 1 over \( A/J \).

\[\blacksquare\]

**Lemma B.4.** — Suppose that \( D \) is a \( \varphi, \Gamma \)-module of rank 1 on an artinian ring \( A \), and with Hodge-Tate weight \( k = (k_\sigma)_{\sigma \in \Sigma} \in \mathbb{Z}^\Sigma \). Fix

\[
\delta : K^\times \longrightarrow A^\times,
\]
and denote \( (t_\sigma)_{\sigma \in \Sigma} \in \mathbb{Z}^\Sigma \) its Hodge-Tate weights. Suppose that

\[
H^0_{\varphi, \Gamma}(D(\delta^{-1})),
\]
is free of rank 1 over \( A \). Then \( D = R_A(\delta') \) with \( \delta' = \delta \prod_{\sigma} x_\sigma^{k_\sigma - t_\sigma} \).

**Proof.** — Let \( D = R_A(\delta') \) and by hypothesis we have an injective morphism of \( R_A \)-modules

\[
R(\delta) \hookrightarrow D = R_A(\delta').
\]

Let \( v \) be the image of a basis of \( R(\delta) \), and denote by \( e \) a basis of \( D \). Thus, \( D' = R_A v \) is a sub-\( \varphi, \Gamma \)-module of \( D \), isomorphic to \( R_A(\delta) \). Reducing modulo \( m_A \), by [KPX14] corollary 6.2.9 we have that \( D' = \prod_{\sigma} \mathcal{O}_{l_\sigma} \mathfrak{D} \mathfrak{T}_{d_\sigma} \) for some \( l_\sigma \in \mathbb{Z} \). But \( \Gamma \) acts on \( v \) as \( \delta(\gamma) \). Moreover, using the previous equality, it also acts on \( v \) by

\[
\gamma v = \prod_{\sigma} L T_{d_\sigma}(\gamma)^{l_\sigma} \delta(\gamma) v.
\]

Thus, \( \omega|_{\Gamma} = (\prod_{\sigma} x_\sigma^{l_\sigma} \omega) |_{\Gamma} \), which by hypothesis gives

\[
l_\sigma = t_\sigma - k_\sigma.
\]

Consider \( M = \prod_{\sigma} t_\sigma^{-l_\sigma} R_A v \). Then \( M \) is saturated in \( D' \), thus \( D' = M \). But as \( R_A v \simeq R_A(\delta) \), \( M \simeq R(\prod_{\sigma} x_\sigma^{-l_\sigma} \delta) \), thus, by [KPX14] Lemma 6.2.13,

\[
\delta' = \delta \prod_{\sigma} x_\sigma^{k_\sigma - t_\sigma}.
\]

\[\blacksquare\]
Recall ([BC09] Lemma 8.27, that we have an injective map
\[ \iota_{T,i,j} : \text{Ext}_T(i,j) \hookrightarrow \text{Ext}_k[G_{B,s}](i,j). \]

**Theorem B.5.** — Let \( \rho : G \rightarrow \text{GL}_{d_1+…+d_t} (A/I) \) an extension of \( T_1 \) by \( T \) inside the image of \( \iota_{T,i,j} \). Then, if \( \rho \) splits, for \( * = v, \overline{\tau} \)
\[ D_{\text{cris},*}(\rho_c(\delta_{\iota_{i,j}})^{\rho_{F_1}}) \]
is free of rank 1 over \( A/I \). If \( \rho \) is inert,
\[ D_{\text{cris},*}(\rho_c(\delta_{\iota_{i,j}})^{\rho_{F_1}}) \]
is free of rank 1 over \( A/I \).

**Proof.** — Recall that 1 is the only constituent of \( \rho_y \) which has \( 1 = p^{wt_1} F_1 \) as eigenvalue for its Frobenius. By [BC09] Theorem 1.5.6 (2), there is an exact sequence,
\[ 0 \rightarrow K \rightarrow (M_j/IM_j \oplus \rho_1) \rightarrow \rho_c \rightarrow 0, \]
with \( K^{\times s} \) being a direct sum of \( T_k, k \neq 1 \). Thus, \( D_{\text{cris}}(K(\delta_{1}^{-1}))^{\rho_{F_1}} = D_{\text{cris}}(T_1(\delta_{1}^{-1}))^{\rho_{F_1}} = \{0\} \). In particular, it is enough to prove that
\[ D_{\text{cris}}(M_j(\delta_{1}^{-1}))^{\rho_{F_1}} \]
is free of rank 1 over \( A \). We will use the same devisage as in B.3. By [BC09] Lemma 4.3.9, there exists \( M = M_j \oplus N_j \) such that \( MK = K \) a sub-\( A[G] \) module of \( K \) of finite type over \( A \). Extending this module to an affinoid \( U \subset \mathcal{E} \) containing \( y \), and using the accumulation of \( Z' \) at \( y \) (Proposition B.3), we can find a birational morphism \( \pi : U' \rightarrow U \) and \( M' \) the strict transform of \( M \), locally free on \( U' \), for which the conclusion of [KPX14] Theorem 6.3.9 for \( (M')^\times \) and \( \delta_{1}^{-1} \) applies. In particular
\[ H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1})) \]
is locally free of rank one on \( U' \).

As in Lemma B.3 we can specialize at \( \mathcal{O}_{y'} \) for every \( y' \) above \( y \in U \). But we have the commuting diagram
\[
\begin{array}{ccc}
H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1})) \otimes \mathcal{O}_{y'}/I' & \xrightarrow{f} & H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1})) \otimes \mathcal{O}_{y'}/I' \\
\text{red} & & \\
H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1})) \otimes \mathcal{O}_{y'}/m_{y'} & \xrightarrow{i} & H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1})) \otimes \mathcal{O}_{y'}/m_{y'}
\end{array}
\]
where the map \( i \) is injective ([KPX14] eq 6.3.9.1), the map \( f \) is non-zero, thus the map \( \text{red} \) is also non-zero. By [BC09] Lemma 3.3.9,
\[ H^0_{\varphi,\Gamma}(D_{\text{rig}}(M')(\delta_{1}^{-1}) \otimes \mathcal{O}_{y'}/I') \]
is free of rank one over \( \mathcal{O}_{y'}/I' \) for all \( y' \in \pi^{-1}(y) \) and \( I' \) of cofinite length. Thus the hypothesis of [BC09] Proposition 3.2.3 are satisfied, and by [BC09] Lemma 3.3.9 again,
\[ H^0_{\varphi,\Gamma}(D_{\text{rig}}(M \otimes A/I)(\delta_{1}^{-1})) \]
is free of rank 1. In particular we have an injection of \( R_{A/I} \)-modules,

\[
0 \longrightarrow R_A \longrightarrow D_{cris}(M \otimes A/I)(\delta _1^{-1}) \longrightarrow Q \longrightarrow 0.
\]

Moreover, as the reduction to \( A/\mathfrak{m}_A \) of \( D_{cris}(M(\delta _1^{-1}))^{\varphi =1} \) is of rank 1, using the functor \( D_{cris} \), we have that \( D_{cris}(1) \subset D_{cris}(M(\delta _1^{-1}))^{\varphi =1} \) and thus \( D_{cris}(Q)^{\varphi =1} = \{0\} \). In particular \( D_{cris}(M(\delta ^{-1}))^{\varphi =1} = D_{cris}(1) \) is free of rank 1 over \( A \), and thus

\[
D_{cris}(M(\delta _1|\Gamma )^{-1})^{\varphi =F_1}
\]

is free of rank 1 over \( A \). The same proof remains valid in the case where \( p \) is inert. \( \square \)
