CONFORMAL POSITIVE MASS THEOREMS FOR MANIFOLDS WITH CHARGE

QIZHI WANG

Abstract. In this paper, we prove conformal positive mass theorems for asymptotically flat manifolds with charge. We apply conformal relations to show that if the conformal sum of scalar curvature is not less than the norm square of electric field, the sum of the mass will not less than the modulus of total electric charge. We also study the situation with inner boundary condition and manifolds with scalar charge.

1. Introduction

Positive mass theorem is a celebrated result in general relativity. It shows that the ADM mass [1] is nonnegative for an asymptotically flat manifold satisfying the dominant energy condition. While conformal transformation is also important for many applications in physics, concerning the sum of the ADM masses of two conformal related metrics one can deduce conformal positive mass theorem.

Conformal positive mass theorem is applied in the context of static uniqueness of blackhole on asymptotically flat spacetimes [7, 6]. In [9], it is proved by spinorial method, while it is proved by conformal relation of ADM masses in [6]. Later, some similar conformal positive mass theorems are proved in [12, 10].

One common form of this type of theorem is the following.

**Theorem 1.** Let \((N, h)\) and \((N, h')\) be asymptotically flat Riemannian three-manifolds with compact interior and finite mass, such that \(h\) and \(h\) are \(C^{1,1}\) and related via the conformal rescaling \(h' = f^2 h\) with a \(C^{1,1}\) function \(f > 0\). Assume further that there exists a non-negative constant \(\beta\) such that the corresponding Ricci scalars satisfy \(R + \beta f^2 R' \geq 0\) everywhere. Then the corresponding masses satisfy \(m + \beta m' \geq 0\). Moreover, equality holds iff both \((N, h)\) and \((N, h')\) are flat Euclidean spaces.

In [6], the authors use charge as conformal factors to construct two complete asymptotically flat manifolds both with zero ADM mass. As the scalar curvature may not be nonnegative but their conformal sum is nonnegative, using the rigidity part of Theorem 1 the metrics are both flat, then they can deduce the conformal factor is a function of radial function, i.e., the metric and the conformal factor are spherically symmetric, thus the uniqueness of static blackhole can be proved.
In this paper, we will change our view on Theorem 1, we don’t put change as conformal factors, but we consider charge as one part of geometric invariants, and we get some conformal positive mass theorems. The theorems will show that though we don’t have dominant energy condition for each manifold, their conformal sum will have some positivity property if some local sum of quantity is positive. Our theorems are applications of positive mass theorem for conformal manifolds, and they provide some interesting properties for ADM mass and charge.

In particular, we apply conformal relations of curvature to show that if the conformal sum of scalar curvature is not less than the norm square of electric field, the sum of the mass will not less than the total electric charge. In section 1, we treat the electric conformal positive mass theorem, and then extend to electromagnetic case in section 2, we also study the situation with inner boundary condition with spinorial method in section, at last we study manifolds with scalar charge in section 5.

2. Electric conformal positive mass theorem

In this section, we will consider asymptotically flat manifolds with electric charge.

In general, \((M^n, g)\) is an asymptotically flat manifold \([1]\) means that \(M \setminus K\) is diffeomorphic to \(\mathbb{R}^n \setminus B_1(0)\), where \(K \subseteq M\) is compact and

\[
g_{kl} - \delta_{kl} \in C^{2,\alpha}_r,
\]

the ADM mass on \((M, g)\) is

\[
m = \frac{1}{2(n-1)\omega_{n-1}} \lim_{r \to \infty} \int_{S_r} (\partial_i g_{ij} - \partial_j g_{ii}) \nu^i \, dvol_{S_r}.
\]

First we consider the time symmetric initial data \((M^3, g, E)\) for Einstein-Maxwell equations where \(E\) is a vector field on \(M\) corresponding to the electric field. We assume that \(M\) is asymptotically flat such that the ADM mass is well defined (with decay order \(\tau > \frac{1}{2}\)) and at infinity \(E\) and \(\partial E\) decay as \(O(r^{-2})\) and \(O(r^{-3})\), here \(r = |x|\) for the chart in the asymptotic end.

We define the total electric charge as

\[
Q = \frac{1}{4\pi} \lim_{r \to \infty} \int_{S_r} E \cdot ndS.
\]

We assume that the electric charge density is zero which means that \(\nabla \cdot E = 0\), and the charged dominated condition is \(R_g \geq 2 |E|^2\). By the well-known positive mass theorem with charge\([2]\), if \((M^3, g, E)\) satisfies the charge dominated condition, then the ADM mass of \(M\) should have \(m_g \geq |Q|\).

The rigidity part is complicated by topological reason, in general the rigidity holds for a space slice of Majumdar-Papapetrou solutions\([5]\). For simplicity we just assume the manifold have only one cylindrical end, then \(m_g = |Q|\) holds for manifold arises from an extreme Reissner–Nordström metric.
The general Reissner–Nordstr"om metric is given by:

\( ds^2 = f(r)^2dt^2 - f(r)^{-2}dr^2 - r^2d\Omega_{n-1}. \)

Where \( \Omega_{n-1} \) denote standard \((n-1)\)-sphere, \( f(r) = 1 - X + Y \) and

\[
X = \frac{2M}{r^{n-3}}, \\
Y = \frac{Q^2 + P^2}{r^{2n-6}}.
\]

Here \( Q \) and \( P \) are total electric and magnetic charge respectively, in the following of this section we set \( P = 0 \).

**Theorem 2.** Let \( (M, g) \) and \( (M, g') \) be asymptotically flat Riemannian three-manifolds with only one cylindrical end and finite mass, such that \( g \) and \( g' \) are \( C^2 \) and related via the conformal rescaling \( g' = e^{2f}g \) with a \( C^2 \) function \( f > 0 \). Assume the electric density for \( e^f g \) vanishes, the scalar curvature and charge satisfies \( S_g + e^{2f}S_{g'} \geq 4 |E|_g^2 \) everywhere. Then the corresponding masses satisfy \( m_g + m_{g'} \geq 2 |Q| \). Moreover, equality holds iff both \( (M, g) \) and \( (M, g') \) are both spatial extreme Reissner–Nordstr"om metric with \( m = |Q| \).

**Proof.** Motivated by the definition of asymptotically flat manifolds, see Corollary 2.1 of [10], \( f = O_2(r^{-\tau}) \) for \( \tau > \frac{1}{2} \). Let \( \overline{g} = e^f g \), by the conformal relation of scalar curvature[10], we have

\[
S_{\overline{g}} = e^{-f}(\frac{1}{2}S_g + \frac{1}{2}e^{2f}S_{g'} + \frac{1}{4}(n-1)(n-2) |\nabla g f|^2).
\]

Since

\[
2 |E|^2_{\overline{g}} = 2\overline{g}^{ij}E_i E_j = 2e^{-f}g^{ij}E_i E_j = 2e^{-f} |E|^2_g,
\]

Also, we have \( \nabla_{\overline{g}} \cdot E = 0 \), by the assumptions, we get \( S_{\overline{g}} \geq 2 |E|^2_{\overline{g}} \). So the positive mass theorem with charge is satisfied for the initial data \( (M^3, \overline{g}, E) \), also by \( f = O_2(r^{-\tau}) \), \( Q_g = Q_{\overline{g}} = Q_{g'} \). Thus we can set \( Q = Q_g \) and \( m_{\overline{g}} \geq |Q| \).

By the definition of ADM mass[12], we have \( m_g + m_{g'} = 2m_{\overline{g}} \) and then we get \( m_g + m_{g'} \geq 2 |Q| \). When the equality holds, \( m_{\overline{g}} \geq |Q| \), then \( (M, \overline{g}) \) is the spatial extreme Reissner–Nordstr"om metric with \( m = |Q| \), then \( S_{\overline{g}} = 2 |E|^2_{\overline{g}} \), so by (11) we get \( f = 0 \), so \( (M, g) \) and \( (M, g') \) are isometric and are both spatial extreme Reissner–Nordstr"om metric with \( m = |Q| \).

\( \square \)

**Remark 1.** In this theorem, we assume the electric density vanishes for a conformal metric, but this density \( \nabla \cdot E \) is not a conformal invariant, we can assume another condition for \( g \) so that the positive mass theorem still holds. Let \( n = 3 \) in (4), assume

\[
\frac{1}{2} |\nabla_g f|^2 \geq 3 |f_i E^i|.
\]
and \( \text{div}_g E = 0 \), since \( \text{div}_g E = \text{div}_g E + 3 f_i E^i \) then locally we have \( S_g \geq 2 \left| E \right|^2 \) + \( \left| \text{div}_g E \right| \). By [5] the positive mass theorem can be applied in this dominant charge condition and the nonnegative result still holds.

3. Electromagnetic conformal positive mass theorem

In this section we extend the electric type theorem to the case with magnetic field.

We consider the time symmetric initial data for the time symmetric initial data \((M^3, g, E, B)\) for Einstein-Maxwell equations where \(B\) is a vector field on \(M\) corresponding to the magnetic field. We always assume that \(\nabla \cdot B = 0\) for any metric and let \(B\) and \(\partial B\) decay as \(O(r^{-2})\) and \(O(r^{-3})\) and define the total magnetic charge as

\[
P = \frac{1}{4\pi} \lim_{r \to \infty} \int_{S_r} B \cdot ndS.
\]

The charged dominated condition now becomes \(S_g \geq 2 \left| E \right|^2 + 2 \left| B \right|^2 + \left| \text{div}_g E \right| \). The positive mass theorem will show

\[
m_g \geq |Q^2 + P^2|^{\frac{1}{2}}
\]

with this condition, and equality holds if and only if it arises from extreme Reissner–Nordström metric.

We have

**Theorem 3.** Let \((M, g)\) and \((M, g')\) be asymptotically flat Riemannian three-manifolds with only one cylindrical end and finite mass, such that \(g\) and \(g'\) are \(C^2\) and related via the conformal rescaling \(g' = e^{2f} g\) with a \(C^2\) function \(f > 0\). Assume the electric density for \(e^f g\) vanishes and \(\nabla \cdot B = 0\) for any conformal metric \(e^{2f} g\), the scalar curvature and charge satisfies \(S_g + e^{2f} S_{g'} \geq 4 \left| E \right|^2 \) + \(4 \left| B \right|^2\) everywhere. Then the corresponding masses satisfy \(m_g + m_{g'} \geq 2 \left| Q^2 + P^2 \right|^{\frac{1}{2}}\). Moreover, equality holds iff both \((M, g)\) and \((M, g')\) arise from extreme Reissner–Nordström metric with \(m = |Q^2 + P^2|^{\frac{1}{2}}\).

**Remark 2.** If we consider the initial data \((M, g, k, E, B)\) with second fundamental form, we still need to involve the linear momentum in the mass expression. In this situation, the charged dominant condition becomes more complicated [8], generally one needs

\[
\mu \geq |J| + 2 \left| E \right|^2 + 2 \left| B \right|^2 + \left| E \times B \right| g.
\]

Where \((\mu, J)\) is energy-momentum tensor.

One can follow [10] and the theorem above to get spacetime conformal positive mass theorems.
4. The inner boundary condition

We extend the conformal positive mass theorems with inner boundary $\partial M$ in this section.

Since the inner boundary is not necessarily an event horizon, we need to use spinor field on $M$ to take the boundary into consideration\cite{12}.

Let $(M, g)$ be the Riemannian $n$-dimensional manifold, $e_i$ the $g$- orthonormal frame, the spinors defined on $M$ is denoted by $\sum M$. In fact, we can set $\sum M = \text{Spin}M \times_{\rho} \sum_n$, where Spin$M$ is a Spin$n$ − principal fibre bundle over $M$ and the spinor field $\sum_n \cong C^{2[\frac{n}{2}]}$. We denote the Levi-Civita connection for both the spinor bundle and the tangent bundle by $\nabla$, and the Dirac operator by $\mathcal{D} = e^i \cdot \nabla_i$.

As usual, we need to solve the following Dirac system to deduce the mass expression.

$$\begin{cases} 
\mathcal{D}\psi &= 0 \\
P_-\psi|_{\partial M} &= 0 \\
\psi - \psi_0 &\in W^{2,p}_{-\tau}(\Gamma(\sum M))
\end{cases}$$

where $\psi_0$ is a constant spinor at infinity, $P_{\pm}$ are the $L^2$-orthogonal projections on the spaces of eigenvectors of positive (negative) eigenvalues of $\mathcal{D}$ on $\partial M$, and

$$\|f\|_{W^{k,p}_{-\tau}(M)} := \left( \int_M \sum_{|\alpha| \leq k} \left( |D^\alpha f|_{\rho^{|\alpha|+q}} \right)^p \rho^{-n} dvol_g \right)^{\frac{1}{p}} < \infty.$$

In \cite{12}, we have

**Theorem 4.** Let $(M, g)$ be asymptotically flat $n$ dimensional manifold with inner boundary $\partial M$ which is diffeomorphic to $S^{n-1}$, assume $g' = e^f g$ on $M$ is also asymptotically flat. If $e^f S' + S_g \geq 0$ and $\frac{n-1}{2} H_g + \frac{n-1}{8} df(\nu) \leq \lambda_0$, then $m(g) + m(g') \geq 0$. Here $\lambda_0$ is a lower bound of the first eigenvalue of Dirac operator on the boundary.

**Remark 3.** We can take the lower bound \cite{4} as

$$\lambda \geq \frac{1}{2} \sqrt{\frac{n-1}{n-2} \inf_{\partial M} S} := \lambda_0.$$

In the proof, the sum of mass and the solvability of the Dirac system is due to the nonnegativity of the following:
\[
\int_{S_{\infty}} \langle \psi, \frac{4}{n-1} \sigma_{ij} \nabla_j \psi - \frac{2}{n-2} e^{-\frac{(n-2)t}{s}} (\nabla_i e^{\frac{(n-2)t}{4}}) \psi \rangle_g * \psi \, e^i \\
= \int_M \left( \frac{2}{n-2} \left( \nabla_i \psi + e^{-\frac{(n-2)t}{s}} (\nabla_i e^{\frac{(n-2)t}{4}}) \psi \right)^2 \right) \text{dvol}_g
\]

(8) \[
+ \frac{4}{n-1} \int_{\partial M} (D^0(\pi_\ast \psi) - (\frac{n-1}{2} H_g + \frac{n-1}{8} df(\nu))(\pi_\ast \psi, \pi_\ast \psi) \text{dvol}_g \partial M
\]

+ \int_M \left( \frac{1}{2n-2} e^f S_g^\prime + \frac{1}{2n-2} S_g \right) | \psi |^2

+ \frac{2n-6}{(n-1)(n-2)} \int M | \nabla \psi |^2 - \frac{4}{n-1} | \mathcal{D} \psi |^2 \text{dvol}_g.
\]

where \( \sigma_{ij} = \delta_{ij} + e_i \cdot e_j \) and \( \nu \) is the unit normal points toward inside of \( M \).

Using similar calculation, we get the following theorem:

**Theorem 5.** Let \( (M, g) \) be asymptotically flat 3 dimensional manifold with inner boundary \( \partial M \) which is homeomorphic to \( S^{n-1} \), assume \( g' = e^f g \) on \( M \) is also asymptotically flat. If \( \frac{1}{2} e^f S_g^\prime + \frac{1}{2} S_g \geq | E |^2_g - \text{div}_g E \geq 0 \) and \( H_g + \frac{1}{8} df(\nu) + g(E, \nu) \leq \lambda_0 \), then \( m(g) + m(g') \geq 2 \cdot Q \). Here \( \lambda_0 \) is a lower bound of the first eigenvalue of Dirac operator on the boundary. Moreover, equality holds if both \( (M, g) \) and \( (M, g') \) are spatial extreme Reissner – Nordström metric with \( m = | Q | \).

To make sense for the time symmetric initial data with electric charge, now we set \( D_i = -\nabla_i - A_i \) where \( A_i = \frac{1}{2} E \cdot e_i \), and replace the \( \nabla \) with \( D \) in \( \frac{4}{n-1} \sigma_{ij} \nabla_j \psi \) of (8), apply the calculation of (8)

(9) \[
\int_{S_{\infty}} \langle \psi, \frac{4}{n-1} \sigma_{ij} D_j \psi - \frac{2}{n-2} e^{-\frac{(n-2)t}{s}} (\nabla_i e^{\frac{(n-2)t}{4}}) \psi \rangle_g * \psi \, e^i \\
= \int_M \left( \frac{2}{n-2} \left( \nabla_i \psi + e^{-\frac{(n-2)t}{s}} (\nabla_i e^{\frac{(n-2)t}{4}}) \psi \right)^2 \right) \text{dvol}_g
\]

+ \frac{4}{n-1} \int_{\partial M} (D^0(\pi_\ast \psi) - (\frac{n-1}{2} H_g + \frac{n-1}{8} df(\nu))(\pi_\ast \psi, \pi_\ast \psi) \text{dvol}_g \partial M
\]

+ \int_M \left( \frac{1}{2n-2} e^f S_g^\prime + \frac{1}{2n-2} S_g - \frac{1}{n-1} | E |^2_g - \frac{1}{n-1} \text{div}_g E \right) | \psi |^2

+ \frac{2n-6}{(n-1)(n-2)} \int M | \nabla \psi |^2 - \frac{4}{n-1} | \mathcal{D} \psi |^2 \text{dvol}_g.
\]

Suppose that \( \frac{1}{2} e^f S_g^\prime + \frac{1}{2} S_g \geq | E |^2_g - \text{div}_g E \geq 0 \) and the boundary term nonnegative, by the asymptotic condition we see that \( \mathcal{D} \) is an isomorphism between weighted Sobolev spaces with Atiyah-Patodi-Singer boundary condition, thus the Dirac system can be solved [3].
Let \( \psi \) be the solution of the Dirac system, we put it in (9), when \( n = 3 \) and \( |\psi_0|^2 = 1 \) the left handside of (9) becomes

\[
8\pi (m_g - |Q|) + 4\pi (m_g' - m_g) = 4\pi (m_g + m_g' - 2 |Q|) \geq 0.
\]

When equality holds, (9) shows \( \nabla f = 0 \), since \( f = 0 \) at infinity, we get \( f = 0 \) on \( M \), the rigidity follows by positive mass theorem with electric charge.

**Remark 4.** We explain how the \( |Q| \) come in the expression. Notice that we can assume the charge \( Q \) be nonnegative first in the proof, if not, we can replace \( E \) with \(-E\), and the proof goes through.

5. **Scalar field**

Einstein-Scalar field system is one of the simplest non-vacuum system which arises in coupling gravity to a scalar field. The general scalar field \( \phi \) satisfies \( \Delta_g \phi - V'(\phi) \) for some \( V(\phi) \). In this section we take the conformal scalar hair for static blackhole into consideration.

The energy-momentum tensor \( T_{\mu \nu} \) for conformal scalar field is

\[
T_{\mu \nu} = \nabla_\mu \phi \nabla_\nu \phi - \frac{1}{12} g_{\mu \nu} |\nabla \phi|^2 - \frac{1}{6} (g_{\mu \nu} \nabla^2 \nabla_\mu \nabla_\nu + G_{\mu \nu}) \phi^2
\]

Here \( G_{\mu \nu} \) is the Einstein tensor and the scalar field \( \phi = O(r^{-1}) \) on a static spacetime \( M \times \mathbb{R} \).

Since we don’t have positive mass theorem such that we can relate ADM mass with the scalar field, we cannot get analogue of conformal positive mass theorems. As the spacetime is static, \( \phi \) is independent of time, thus by the constraint equations we can get the dominant energy condition as follows:

\[
T_{00} = \frac{1}{6} S_g \phi^2 - \frac{1}{4} |\nabla \phi|^2 - \frac{1}{3} \phi \Delta_g \phi \geq 0.
\]

Let \( g' = \phi^4 g \), by the conformal relation \( S_{g'} = \phi^{-5}(-8) \Delta_g \phi + S_g \phi \), we get

\[
24T_{00} = 3S_g \phi^2 + R_{g'} \phi^6 - 6 |\nabla \phi|^2 \geq 0.
\]

Since the dominant energy condition for manifold \((M, g)\) is \( T_{00} = S_g \geq 0 \), and this is equivalent to \( S_g \phi^2 + \frac{1}{2} S_{g'} \phi^6 \geq 2 |\nabla \phi|^2 \) by (11). We get the weak positive mass theorem below:

**Theorem 6.** Let \((M, g)\) be an asymptotically flat 3 dimensional manifold with conformal scalar field \( \phi \), assume \( g' = \phi^4 g \). If \( S_g + \frac{1}{7} S_{g'} \phi^4 \geq 2 \phi^{-2} |\nabla \phi|^2 \), then the ADM mass of \((M, g)\) is nonnegative. If mass vanishes, the metric must be flat without scalar field.

In fact we can get more after integration of (11) over \( M \), it is seen that if \( S_g = 0 \) then \( \nabla \phi = 0 \) by divergence theorem, as \( \phi = O(r^{-1}) \), we can see that \( \phi = 0 \). Thus scalar flat manifold does not arise from static spacetime with conformal scalar field.
