Degenerate elastic networks

Abstract

We minimize a linear combination of the Willmore and the length functional among networks in $\mathbb{R}^d$ belonging to a given class determined by the number of curves, the order of the junctions and the angles between curves at the junctions. Since this class lacks compactness, we characterize the set of limits of sequences of networks bounded in energy, providing an explicit representation of the relaxed problem. This is expressed in terms of the new notion of degenerate elastic networks that, rather surprisingly, involves only the properties of the given class, without reference to the curvature. In the case of $d = 2$ we also give an equivalent description of degenerate elastic networks by means of a combinatorial definition easy to validate by a finite algorithm. Moreover we provide examples, counterexamples, and additional results that motivate our study and show the sharpness of our characterization.

Keywords: Networks, relaxation, Willmore functional, elastic energy, singular structures.

1 Introduction

A regular network $\mathcal{N}$ is a connected set in $\mathbb{R}^d$ composed of $N$ regular curves $\gamma^i$ of class $H^2$ that meet at their endpoints in junctions of possibly different order. Moreover the angles at the junctions are assigned by a fixed set of directions $D$ as we will define more precisely in Definition 2.10. The elastic energy functional $\mathcal{E}$ for a network $\mathcal{N}$ is given by

$$\mathcal{E}(\mathcal{N}) := \sum_{i=1}^{N} \left( \int_{\gamma^i} |\vec{k}^i|^2 \, ds + \ell(\gamma^i) \right),$$

where $\vec{k}^i$ is the curvature, $s$ the arclength parameter and $\ell(\gamma^i)$ is the length of the curve $\gamma^i$. We are interested in the minimization of the functional $\mathcal{E}$ among networks with fixed topology and with fixed angles at the junctions assigned by $D$.

Notice that the length $\ell(\gamma^i)$ of each curve of a regular network is strictly positive because the curves are regular by assumption. This property is not preserved by sequences with uniformly bounded energy: along a sequence of networks $\{\mathcal{N}_n\}_{n \in \mathbb{N}}$ with uniformly bounded energy (or even a minimizing sequence) the length of a curve may go to zero as $n \to \infty$.

producing a “degenerate limit” which is no longer a regular network. Hence a remarkable
issue is to understand this lack of compactness of sequences with bounded energy in mini-
mization problems\(^1\).

Our first task is therefore to describe the class of limits of sequences (equibounded in energy)
of regular networks. In other words, we have to characterize the “closure in energy” of the
class \(\mathcal{C}_{\text{Reg}}\) of regular networks.

Then, since the lack of compactness implies that it could not be possible to solve the orig-
inal minimization problem among regular networks, we relax it by considering the lower
semicontinuous envelope of the functional \(\mathcal{E}\), namely

\[
\inf \left\{ \liminf_{n \to \infty} \mathcal{E}(N_n) \mid N_n \in \mathcal{C}_{\text{Reg}} \right\}.
\]

Our second objective is to find an explicit formula of the lower semicontinuous envelope.
We underline that the relaxation of the problem is necessary: Example 4.7 shows that also in
some very simple situations minimizers are not regular networks.

In Proposition 3.8 and Proposition 4.2 we characterize the smallest compact class of (non–
regular) networks in which the class of regular networks is “dense in energy” in terms of
a mixture of algebraic and combinatorial conditions that are easy to verify and rely on the
topological assumptions on the competitors. As the formulation of these conditions involves
some technicalities, a detailed description is postponed to the second part of the introd-
uction. We are then able to give a characterization of the lower semicontinuous envelope of \(\mathcal{E}\)
that strongly relies on the previous result (see Theorem 4.5).

This last point creates a bridge between our problem and another natural research direction:
the extension of the Willmore functional (and more in general of functionals that depend on
the curvature) to singular sets for which at least a weak notion of curvature is well defined,
varifolds for instance. The characterization of the relaxation of the original functional in such
cases turned out to be particularly difficult (for results in this direction see for instance [5, 2,
3, 4, 14, 13, 17]). We notice that networks can be seen as a simple example of sets which are
essentially singular and they can be understood as a boundary of a planar cluster of surfaces.
For problems in which one knows a priori that the boundary of minimal planar clusters
is composed of a finite number of curves, it could be useful to define the curvature of the
cluster by means of (2.1). An advantage is that we have an easy integral representation of
the lower semicontinuous envelope of \(\mathcal{E}\).

To place our paper in the broader context, we mention the minimization of the Willmore
functional among both Riemannian manifolds and singular structures is an extreme flour-
ishing research field. As the simplest possible example of singular structure we mention
surfaces with boundary (possible references are [1, 8, 9, 15, 16, 18]).

The main reason for which we got interested in this problem is a previous study of its dy-
namical counterpart (see [12, 11]). The study of the static problem has often revealed to be
useful for the analysis of the asymptotic behavior of the solutions of the associated gradient
flow and of the singularities that can appear during the evolution. On the contrary, one can
study the flow to find critical points of the functional.

After this detour on the literature, we explain more in detail what can happen along se-
quencies of regular networks \(\{N_n\}_{n \in \mathbb{N}}\) whose elastic energy is uniformly bounded.

\(^1\)By compactness we mean sequential compactness, where the natural notion of convergence for the
sequences of networks is the weak \(H^2\) convergence.
A model problem: Theta–networks

A Theta–network is a regular 3–network whose curves form equal angles at the two junctions (Figure 1). The limit of a sequence of regular Theta–networks with uniformly bounded energy may not exist in the class of regular networks and hence the minimization problem has some form of degeneracy that luckily is not completely wild: the length of at most one curve can go to zero along the sequence, becoming straighter and straighter. If this is the case the “degenerate” limit network is composed of two curves meeting at a quadruple point forming angles equal in pairs of $\frac{\pi}{3}$ and $\frac{2\pi}{3}$.

Figure 1: A Theta–network and a degenerate Theta–network

The general case presents new interesting features with respect to the model problem of Theta–networks. Firstly, one realizes that much more than the length of one single curve can go to zero, since entire parts of the network can vanish as $n \to \infty$. In order to keep track of the complexity of the network we introduce the notion of underlying graph $G$.

The underlying graph

The oriented graph $G$ is composed of edges $E_i$ whose endpoints are identified in vertices of possibly different order (Definition 2.1). A network then is a pair graph–continuous map $\mathcal{N} = (G, \Gamma)$ with $\Gamma : G \to \mathbb{R}^d$ (Definition 2.2). The underlying graph $G$ captures the topology of the networks and allows us to have a reminiscence of their structure even when some curves in a sequence of networks $\mathcal{N}_n = (G, \Gamma_n)$ collapse to a point in the limit.

A necessary angle condition

We say that a curve $\gamma^i := \Gamma|_{E_i}$ of a network is singular if it is a constant map, and regular if it is an immersion of class $H^2$. A network is singular if some of its curves are singular.

Definition 1.1 (Outer tangents). Consider a regular curve of a network $\mathcal{N}$ parametrized by $\gamma^i$. We define $\tau^{z,i}$, with $z \in \{0, 1\}$, as the outward tangent vector at the endpoint $\gamma^i(z)$ to the curve $\gamma^i$ given by

$$\tau^{z,i} = (-1)^z \frac{\dot{\gamma}^i(z)}{|\dot{\gamma}^i(z)|}.$$
**Definition 1.2** (Angle condition). A (possibly) singular network \( \mathcal{N} = (G, \Gamma) \) satisfies the angle condition if for every singular curve \( \gamma^i \) there exist two unit vectors \( \tau^{\pm, i} \), called its virtual tangents, with \( z \in \{0, 1\} \) such that \( \tau^{0, i} = -\tau^{1, i} \) and such that at each junction the angles between the tangent vectors (either the real outward tangents or the virtual ones) coincide with the angles between the directions assigned by \( D \) in the definition of regular network.

Also motivated by what we learn in [6], as a first attempt we defined the class of degenerate networks as all the singular networks that satisfy the angle condition of Definition 1.2. Unfortunately this purely algebraic condition on the angles turns out to be necessary but not sufficient to characterize the closure of the class \( C_{\text{Reg}} \) as we show in the next example. Consider the topology depicted in Figure 3 on the left, with all junctions forming angles of \( \frac{2\pi}{3} \), and define a singular network that collapses the red part to a single point. It is possible to do so satisfying the angle condition of Definition 1.2 (see the picture on the right) but no sequence of regular networks with finite energy and the same angle constraint could converge to the singular network on the right.

![Figure 3: Starting from the represented graph \( G \), it is possible to construct an example from which one deduces that the angle condition is not sufficient to define the closure of the class \( C_{\text{Reg}} \).](image)

Indeed, denoting by \( C \) the cycle in red, by the Gauss–Bonnet Theorem and Hölder inequality

\[
\mathcal{E}(C) \geq \int_C |\vec{k}|^2 \, ds \geq \left( \int_C |\vec{k}| \, ds \right)^2 \geq \frac{4\pi^2}{L(C)},
\]

hence as \( n \to \infty \) the energy diverges as the length of the red loop goes to zero (see Example 3.3 for the details).

**Stratified straight subgraph**

To overcome this issue in the definition of the class, we looked for an extra condition. Again the underlying graph \( G \) helps us.

**Definition 1.3** (Stratified straight subgraph). A subgraph \( H \) of the underlying graph \( G \) is stratified–straight if there exists a finite sequence of subgraphs, called *strata*,

\[
\emptyset = H_q \subset H_{q-1} \subset \ldots \subset H_1 \subset H_0 = H
\]

and maps \( \Sigma_j : H_j \to \mathbb{R}^d \) such that for \( j = 0, \ldots, q - 1 \),
• the (sub)network \((H_j, \Sigma_j)\) satisfies the angle condition 1.2 with (real or virtual) tangent vectors coinciding with the ones associated to \((H_0, \Sigma_0)\) and its regular curves are segments;

• the stratum \(H_{j+1}\) is the union of the singular curves of \((H_j, \Sigma_j)\).

Call \(H\) the subgraph given by the union of the edges \(E_i\) of \(G\) such that the curves \(\gamma^i = \Gamma|_{E_i}\) are singular. With a little abuse of notation we say that the network \(N = (G, \Gamma)\) is stratified straight if \(H\) is stratified straight.

The class of degenerate networks

Finally we come to the characterization: a network is degenerate, of class \(C_{\text{Deg}}\), if it satisfies the angle condition 1.2 and it is stratified straight. It is natural now to define the extension \(\overline{\mathcal{E}}\) of the functional \(\mathcal{E}\) by setting that a curve with zero length of a network in \(C_{\text{Deg}}\) gives a null contribution to the energy and by assigning value \(+\infty\) to the energy of singular networks which are not in \(C_{\text{Deg}}\).

In Proposition 3.8 we prove that a sequence of regular networks with equibounded energy converges to a network in \(C_{\text{Deg}}\), namely that the closure of \(C_{\text{Reg}}\) is contained into \(C_{\text{Deg}}\).

Formula for the lower semicontinuous envelope of the elastic energy functional

A question still remains: is the class \(C_{\text{Deg}}\) the smallest set of generalized network where we have compactness? In Proposition 4.2 we show that any degenerate network can be approximated in energy by a regular one. Hence our guess was correct: the class \(C_{\text{Reg}}\) is “dense in energy” in \(C_{\text{Deg}}\). Moreover the extension \(\overline{\mathcal{E}}\) is the lower semicontinuous envelope of \(\mathcal{E}\).

We stress the fact that we are able to express the lower semicontinuous envelope in integral form and with the very simple formula (4.1). This was possible only thanks to the precise characterization of \(C_{\text{Deg}}\).

Notice that the existence of minimizers of the relaxed functional \(\overline{\mathcal{E}}\) follows trivially by a direct method in the Calculus of Variations.

Stratified straight versus straight subgraph

At first sight considering stratified straight subgraphs could seem uselessly complicated. One can ask whether the class of degenerate networks can be equivalently characterized as the set of networks \((G, \Gamma)\) satisfying the angle condition 1.2 such that there exists only one map \(\Sigma : H \to \mathbb{R}^d\) from the singular edges to \(\mathbb{R}^d\) such that every curve of \(\Sigma\) is a regular segment and \((H, \Sigma)\) satisfies the angle condition (in this case we say that the network \((H, \Sigma)\) is straight). This would mean that in Definition 1.3 the index \(q = 1\) is enough. In Example 3.9 we show a stratified straight but not straight graphs. Nonetheless, there are some cases in which every stratified straight subgraph is in fact straight; an easy example consists in graphs \(G\) with the structure of a tree.

However, the concepts of stratified straight graphs and straight graphs are essentially different, even in non–trivial cases that have some interest from a variational viewpoint; more precisely in Section 6 we study the case of networks in \(\mathbb{R}^2\) with graphs having junctions of order at most four such that at these junctions the tangent vectors are orthogonal (Proposition 6.5) and we find a characterization of the stratified straight graphs that turn out to be straight.

Ambient space: restriction to the plane and extension to Riemannian surfaces
Although we find our characterization of the class $C_{\text{Deg}}$ by combination of algebraic and geometric conditions quite satisfactory, if the ambient space is $\mathbb{R}^2$ we are able to give an equivalent characterization of the class $C_{\text{Deg}}$ (see Definition 3.7) by an algebraic–topological condition that has the great advantage of being verifiable by an algorithm with finitely many steps.

It is also worth to mention that our result extends from the ambient space $\mathbb{R}^2$ to any 2–dimensional closed surface embedded in $\mathbb{R}^3$.

**Plan of the paper**

The structure of the paper is the following: after the definitions of networks and elastic energy contained in Section 2, in Section 3 we introduce the class of degenerate networks (Definition 3.7). The compactness of the class of degenerate networks is proved in Proposition 3.8. In Section 4 we finish the proof of the representation of the relaxed functional by constructing recovery sequences of degenerate networks (Proposition 4.2). Section 5 is devoted to the equivalent algorithmic characterization of the class of degenerate networks when Problem 2.12 is set in $\mathbb{R}^2$. Then in Section 6 we study a non-trivial case in which there exist stratified straight subgraphs that are not straight and we characterize such difference (Proposition 6.5). Subsequently we comment on the extension of our result from the ambient space $\mathbb{R}^2$ to any 2–dimensional closed surface embedded in $\mathbb{R}^3$. We conclude the paper with an appendix A where we compute Euler–Lagrange equations satisfied by critical points of the energy.

**Acknowledgments.** The research of the second and of the third author has been partially supported by INdAM – GNAMPA Project 2019 “Problemi geometrici per strutture singolari” (Geometric problems for singular structures).

### 2 Setting and definition of the problem

We begin by defining the mathematical objects of our interest.

#### 2.1 Elastic energy functional for networks

Fix $N \in \mathbb{N}$, $d \in \mathbb{N}$ with $d \geq 2$ and let $i \in \{1, \ldots, N\}$, $I_i := [0, 1] \times \{i\}$, $E := \bigcup_{i=1}^{N} I_i$ and $V := \bigcup_{i=1}^{N} \partial I_i$.

**Definition 2.1.** ($N$–graph) Let $\sim$ be an equivalence relation that identifies points of $V$. An $N$–graph $G$ is the topological quotient space of $E$ induced by $\sim$, that is

$$G := E / \sim.$$ 

A subgraph $H \subseteq G$ is the quotient

$$H := \bigcup_{j=1}^{M} I_{i_j} / \sim$$

for a given choice of indices $i_1, \ldots, i_M \in \{1, \ldots, N\}$, where $\sim$ is the equivalence relation defining $G$. 

---

7
We notice that the natural projection \( \pi : E \to G \) restricted to \( E \setminus V \) is a homeomorphism with its image.

We call
\[
E_i := I_i / \sim, \quad \text{and} \quad V_G := V / \sim.
\]

**Definition 2.2** (\( N \)-network). An \( N \)-network (or simply a network) is a pair \( N = (G, \Gamma) \) where
\[
\Gamma : G \to \mathbb{R}^d
\]
is a continuous map and \( G \) is an \( N \)-graph. Moreover we ask each \( \gamma^i := \Gamma|_{E_i} \) to be either a constant map (singular curve) or an immersion of class \( H^2 \) (regular curve).

**Definition 2.3** (Singular part). Given a network \( N = (G, \Gamma) \) we define its singular part \( \text{Sing}(N) \) as the subgraph \( H \subset G \) whose edges are exactly those associated to singular curves of \( N \) (mapped by \( \Gamma \) to a point) and we call regular part \( \text{Reg}(N) := G \setminus \text{Sing}(N) \).

If \( E_i \subset \text{Reg}(N) \) has a common vertex \( p \) with \( E_j \in \text{Sing}(N) \) we say that \( p \) belongs to \( \text{Sing}(N) \), i.e. \( \text{Sing}(N) \) is closed.

**Definition 2.4** (Regular and singular networks). We say that a network \( N = (G, \Gamma) \) is regular if \( \text{Sing}(N) = \emptyset \) and singular otherwise.

**Definition 2.5.** Given an network \( N \) we denote by \( \ell(\gamma^i) \) the length of the curve \( \gamma^i \). The length of the network \( N \) is nothing but
\[
L(N) := \sum_{i=1}^{N} \ell(\gamma^i).
\]

Consider a regular curve \( \gamma^i \) of a network \( N \). Then we define its curvature vector as the \( L^2 \) function given by
\[
\vec{k}^i = \frac{\dddot{\gamma}^i}{|\dot{\gamma}^i|^2} + \frac{\dot{\gamma}^i (\dddot{\gamma}^i, \dot{\gamma}^i)}{|\dot{\gamma}^i|^4}.
\]

Observe that by the Sobolev embedding \( \dot{\gamma} \) is Hölder continuous, and thus by the regularity its norm is bounded and bounded away from zero.

We are now in position to introduce the functional of our interest.

**Definition 2.6.** Let \( \alpha, \beta > 0 \). The elastic energy functional \( \mathcal{E}_{\alpha,\beta} \) for a regular network \( N \) is defined as
\[
\mathcal{E}_{\alpha,\beta}(N) := \alpha \int_N |\vec{k}|^2 \, ds + \beta L(N) = \sum_{i=1}^{N} \left( \alpha \int_{N^i} |\vec{k}^i|^2 \, ds^i + \beta \ell(\gamma^i) \right), \tag{2.1}
\]
where \( \vec{k}^i \) is the curvature and \( s^i \) is the arclength parameter.

**Remark 2.7.** Reparametrizing the regular curves of the network with constant speed equal to the length we can write \( \text{(2.1)} \) as
\[
\mathcal{E}(N) = \sum_{i=1}^{N} \left( \alpha \int_0^{\ell(\gamma^i)} |\vec{\dot{\gamma}}^i(x)|^2 \, dx + \beta \ell(\gamma^i) \right).
\]
By assigning to each singular curve of a network a zero curvature $\vec{k}^i = \vec{0}$ we can naturally extend $E$ to the class of all networks maintaining exactly the same formula. The elastic energy $\tilde{E}_{\alpha,\beta}$ of a regular or singular network $\mathcal{N}$ is thus

$$
\tilde{E}_{\alpha,\beta}(\mathcal{N}) := \alpha \int_{\mathcal{N}} |\vec{k}|^2 \, ds + \beta L(\mathcal{N}),
$$

(2.3)

where $\vec{k}^i$ is the curvature of the regular curves of $\mathcal{N}$ or the assigned zero curvature on the singular curves of $\mathcal{N}$.

### 2.2 Definition of the minimization problem

**Definition 2.8 (Junction of order $m$).** Consider an $\mathcal{N}$–graph $G$ and $p \in V_G$. We say that $p$ is a junction of order $m$ (with $m \in \{1, \ldots, N\}$) if

$$
\sharp \pi^{-1}(p) = m,
$$

where $\pi$ is the projection defined below Definition 2.1 and $\sharp$ denotes the cardinality of a set.

**Definition 2.9 (Graph with assigned angles).** We say that an $\mathcal{N}$–graph $G$ has assigned angles if to every junction $p \in V_G$ we assign directions $d^{z_1,i_1}, \ldots, d^{z_m,i_m} \in S^{d-1}$ where $m$ is the order of the junction and where

$$
p = \pi(z_1,i_1) = \ldots = \pi(z_m,i_m),
$$

with $(z_1,i_1), \ldots, (z_m,i_m) \in \{0,1\} \times \{1, \ldots, N\}$ all distinct. We denote by $\mathcal{D}$ the set of all the assigned directions.

**Definition 2.10 (Angle condition for a regular network).** Given $G$ an $\mathcal{N}$–graph with assigned angles, we say that the regular network $\mathcal{N} = (G, \Gamma)$ fulfills the angle condition if for every $p \in V_G$ junction of order $m$ such that

$$
p = \pi(z_1,i_1) = \ldots = \pi(z_m,i_m),
$$

with $(z_1,i_1), \ldots, (z_m,i_m) \in \{0,1\} \times \{1, \ldots, N\}$ all distinct there exists a rotation $R_p : \mathbb{R}^d \to \mathbb{R}^d$

such that

$$
\tau^{z_1,i_1} = R_p(d^{z_1,i_1}), \ldots, \tau^{z_m,i_m} = R_p(d^{z_m,i_m}),
$$

where $\tau^{z,i}$ are the outer tangents.

**Definition 2.11 (Class $C_{\text{Reg}}$).** Fix an $\mathcal{N}$–graph with assigned angles. We say that an network $\mathcal{N} = (G, \Gamma)$ belongs to $C_{\text{Reg}}(\mathcal{D})$ if it is regular and fulfills the angle condition with the directions assigned by $\mathcal{D}$ in the sense of Definition 2.10.

**Problem 2.12.** Given an $\mathcal{N}$–graph $G$ with assigned angles by $\mathcal{D}$ we want to study

$$
\inf \{ \mathcal{E}_{\alpha,\beta}(\mathcal{N}) \mid \mathcal{N} = (G, \Gamma) \in C_{\text{Reg}}(\mathcal{D}) \}.
$$

(2.4)

From now on, for sake of notation, we simply write $C_{\text{Reg}}$ instead of $C_{\text{Reg}}(\mathcal{D})$. 

8
Remark 2.13. It is not restrictive to ask $G$ to be connected, otherwise one minimizes the energy of each connected component of $G$.

Remark 2.14. Let us call $\mathcal{E} := \mathcal{E}_{1,1}$. Thanks to the rescaling properties of the functional $\mathcal{E}_{\alpha,\beta}$ we have

$$\mathcal{E}_{\alpha,\beta}(N) = \sqrt{\alpha \beta} \mathcal{E} \left( \sqrt{\frac{\beta}{\alpha}} N \right),$$

so if $N_{\min}$ is a minimizer for $\mathcal{E}$, then the rescaled network $\sqrt{\frac{\beta}{\alpha}} N_{\min}$ is a minimizer for $\mathcal{E}_{\alpha,\beta}$ and vice versa. Hence it is not restrictive to fix $\alpha = \beta = 1$.

Remark 2.15. Given a graph $G$ with assigned angles, there always exists a map $\Gamma : G \to \mathbb{R}^d$ such that $(G, \Gamma)$ is a regular network with finite energy. It is sufficient to send each vertex $p \in V_G$ to a point $x^i$ in $\mathbb{R}^d$ and to connect the points $x^i$ with curves of finite length and with bounded curvature whose outward tangent vectors are chosen accordingly with the fixed directions $d^{\alpha,\beta}$. The class $C_{\text{Reg}}$ is hence not empty and (2.4) is finite.

3 Compactness

With a little abuse of notation by considering a sequence of networks $\{N_n\}_{n \in \mathbb{N}}$ we mean that we consider a sequence of pairs $(G, \{\Gamma_n\}_{n \in \mathbb{N}})$ where the $N$–graph $G$ with assigned angles is fixed.

Lemma 3.1. Let $\{N_n\}_{n \in \mathbb{N}}$ be a sequence of networks in $C_{\text{Reg}}$ such that

$$\limsup_n \mathcal{E}(N_n) \leq C < +\infty.$$

Suppose that for a certain index $i \in \{1, \ldots, N\}$

$$\lim_{n \to \infty} \ell(\gamma^i_n) = 0,$$

then

$$\lim_{n \to \infty} \sup_{x,y \in [0,1]} \frac{\|\dot{\gamma}^i_n(x) - \dot{\gamma}^i_n(y)\|}{\|\gamma^i_n(x) - \gamma^i_n(y)\|} = 0.$$

Proof. Since $\{N_n\}_{n \in \mathbb{N}}$ is a sequence of regular networks, we can suppose (up to reparametrisation) that for every $n \in \mathbb{N}$, for every $i \in \{1, \ldots, N\}$ the immersion $\gamma^i_n : [0, 1] \to \mathbb{R}^2$ is a regular parametrization with constant speed equal to its length. Given $x, y \in [0, 1]$, we get

$$\frac{\|\dot{\gamma}^i_n(x) - \dot{\gamma}^i_n(y)\|}{\|\gamma^i_n(x) - \gamma^i_n(y)\|} = \frac{1}{\ell(\gamma^i_n)} \frac{\|\gamma^i_n(x) - \gamma^i_n(y)\|}{\|\gamma^i_n(x) - \gamma^i_n(y)\|} = \frac{1}{\ell(\gamma^i_n)} \left( \int_x^y \dot{\gamma}^i_n(t) \, dt \right) \frac{1}{\ell(\gamma^i_n)} \left( \int_x^y 1 \, dt \right)^{1/2} \leq \frac{1}{\ell(\gamma^i_n)} \left( \int_x^y (\dot{\gamma}^i_n(t))^2 \, dt \right)^{1/2} \left( \int_x^y 1 \, dt \right)^{1/2} \leq \mathcal{E}(N_n)^{1/2} \ell(\gamma^i_n) \leq C \ell(\gamma^i_n).$$

We obtain the desired result passing to the limit. \qed
We state here again the angle condition 1.2 with the use of the notation introduced in Section 2.

**Definition 3.2** (Angle condition for a singular network). Consider a (possibly singular) network \( \mathcal{N} = (G, \Gamma) \). We recall that for any \( p \in V_G \) and \( \gamma^i \) regular curve such that \( \pi(z, i) = p \) for some \( z \in \{0, 1\} \) the usual (real) outward tangent vector is \( \tau_z^i = (-1)^z \frac{\gamma'(z)}{|\gamma'(z)|} \).

We say that \( \mathcal{N} \) satisfies the angle condition if for every singular curve \( \gamma^i \) there exist unit vectors \( \tau^0_i \) and \( \tau^1_i \) (called virtual tangent vectors) such that for every \( p \in V_G \) there exists a rotation \( R_p \) in \( \mathbb{R}^d \) such that

\[
\tau_{z_1, i_1}^1 = R_p(d_{z_1, i_1}^1), \ldots, \tau_{z_m, i_m}^m = R_p(d_{z_m, i_m}^m),
\]

(3.1)

where \( \pi^{-1}(p) = \{(z_1, i_1), \ldots, (z_m, i_m)\} \) and \( \tau_{z_j, i_j} \) are either the real outward tangent vectors or the virtual ones.

We repeat here in more details the example of a singular network that satisfies the angle condition 3.2 but cannot be limit of a sequence of regular network with uniformly bounded energy that we gave in the introduction.

**Example 3.3.** Let the dimension of the ambient space be \( d = 2 \). Consider a 6–graph of Figure 4 where in particular the edges \( E_1, E_2, E_3, E_4 \) form a cycle \( C \) and

\[
\angle d^{1,1} = \angle d^{1,3}, \angle d^{0,2} = \frac{2\pi}{3}, \angle d^{1,2} = \angle d^{1,4}, \angle d^{0,1} = -\frac{2\pi}{3}.
\]

![Figure 4: A regular network \( \mathcal{N} = (G, \Gamma) \) satisfying the angle condition defined above.](image)

Consider a sequence of continuous maps \( \{\Gamma_n\}_{n \in \mathbb{N}} \) such that \( \Gamma_1 \) is depicted in Figure 4 and for every \( n \) the map \( \Gamma_n \) shrinks homotetically by \( \frac{1}{n} \) the red loop to a point (the origin of \( \mathbb{R}^2 \)), call \( C_n := \Gamma_n|_C \) and let \( \Gamma_\infty \) be the limit as \( n \to \infty \). Then \( \mathcal{N}_\infty = (G, \Gamma_\infty) \) is a singular network and there exists a choice of virtual tangents for which \( \mathcal{N}_\infty \) satisfies the angle condition in the sense of Definition 3.2. On the other hand combining [6, Theorem A.1] and Hölder inequality we get

\[
\mathcal{E}(\Gamma_n) \geq \mathcal{E}(C_n) \geq \int_{C_n} |\overrightarrow{k}|^2 ds \geq \frac{\left( \int_{C_n} |\overrightarrow{k}| ds \right)^2}{L(C_n)} \geq \frac{4\pi^2}{L(C_n)}.
\]

(3.2)

hence as \( n \to \infty \) the energy diverges as the length of the red loop goes to zero.

---

\( ^2 \)Namely the equivalence relation that defined \( G \) is given by \((1, i) \sim (0, i + 1)\) with the index \( i \) considered modulus 4.
The angle condition for a singular network is thus not sufficient to characterize the set of limit networks with bounded energy.

**Definition 3.4 (Straight graph).** An $N$–graph $G$ with assigned angles is *straight* if there exists a regular network $\mathcal{N} = (G, \Gamma)$ whose curves are segments that fulfills the angle condition in the sense of Definition 2.10.

Suppose that $G$ is an $N$–graph with assigned angles. Then every subgraph $H$ of $G$ inherits the assigned angles from $G$ in the sense that to every vertex $p = \pi(z, i)$ of an edge $E_i$ in $H$ we assign $d^{z,i} \in \mathbb{S}^{d-1}$ coinciding with the assignment of $G$.

**Definition 3.5 (Stratified straight subgraph).** Given a graph $G$ with assigned angles we say that a subgraph $H \subseteq G$ is stratified–straight if there exists a finite sequence of subgraphs, called *strata*,

$$\emptyset = H_q \subset H_{q-1} \subset \ldots \subset H_1 \subset H_0 = H$$

and maps $\Sigma_j : H_j \rightarrow \mathbb{R}^d$ such that for $j = 0, \ldots, q - 1$

- the (sub)network $(H_j, \Sigma_j)$ satisfies the angle condition in the sense of Definition 3.2 with (real or virtual) tangent vectors coinciding with the ones associated to $(H_0, \Sigma_0)$ and whose regular curves are segments;
- and $H_{j+1} = \text{Sing}(H_j, \Sigma_j)$.

We call *step* of $G$ the minimal $q$ for which the above holds.

Every straight graph with assigned angles is trivially stratified-straight, but the converse does not hold in general as shown by the following example.

**Example 3.6.** We consider the graph of Figure 5 characterized by the following identifications:

$$(0, 1) \sim (0, 2), (1, 2) \sim (1, 3) \sim (0, 5), (1, 1) \sim (0, 3) \sim (0, 4), (1, 4) \sim (1, 5),$$

$$\angle d^{0,2}, d^{0,1} = \angle d^{0,3}, d^{0,4} = 0, \angle d^{1,1}, d^{0,3} = \angle d^{1,3}, d^{1,2} = \angle d^{1,4}, d^{1,5} = \frac{\pi}{2}.$$

It is clearly not possible to construct a triangle with strictly positive length of its three edges with angles $0, \frac{\pi}{2}, \frac{\pi}{2}$. The minimal step of $G$ seen as a stratified straight graph is then 2, with $H_0 = G$, $H_1 = E_3 \cup E_4 \cup E_5$ and $H_2 = E_5$.

![Figure 5: Example of stratified straight graph of step two.](image)

Notice that the notion of straight and stratified straight graphs coincide when the underlying graph $G$ has the structure of a tree with no cycles. In Section 6 we introduce a class of graphs possibly with cycles for which every stratified straight subgraph is also straight.

**Definition 3.7 (Degenerate $N$–network).** Let $G$ be an $N$–graph with assigned angles. A network $\mathcal{N} = (G, \Gamma)$ is degenerate if
• it satisfies the angle condition in the sense of Definition 3.2, with (real or virtual) tangents \( \tau_{z,i} \);

• its singular part \( \text{Sing}(N) \) is a stratified-straight subgraph with (real or virtual) tangents coinciding with the \( \tau_{z,i} \) above.

We denote by \( \mathcal{C}_{\text{Deg}} \) the class of degenerate networks.

We remark that by definition \( \mathcal{C}_{\text{Reg}} \subset \mathcal{C}_{\text{Deg}} \).

**Proposition 3.8 (Compactness).** Let \( \{N_n\}_{n \in \mathbb{N}} \) be a sequence of networks in \( \mathcal{C}_{\text{Deg}} \) such that

\[
\limsup_n \delta(N_n) \leq C < +\infty.
\]

Then \( N_n \) converges (up to subsequence and translation) to \( N_\infty \in \mathcal{C}_{\text{Deg}} \) weakly in \( H^2 \) and strongly in \( C^{1,\alpha} \) for every \( \alpha \in (0,1/2) \). In particular if \( \{N_n\}_{n \in \mathbb{N}} \) is a sequence of networks in \( \mathcal{C}_{\text{Reg}} \), then \( N_n \overset{H^2}{\to} N_\infty \in \mathcal{C}_{\text{Deg}} \).

**Proof.** Up to subsequence and up to relabeling the edges \( E_i \) we can suppose that for a certain \( k \in \{1, \ldots, N\} \) for every \( n \in \mathbb{N} \) the curves \( N_{n1}, \ldots, N_{nk} \) are regular and the curves \( N_{nk+1}, \ldots, N_{nN} \) are singular. Without loss of generality we suppose that for every \( n \in \mathbb{N} \) and for every \( i \in \{1, \ldots, k\} \) the immersions \( \gamma^i_n := \Gamma_n|_{E_i} : [0,1] \to \mathbb{R}^d \) are regular parametrizations with constant speed equal to the length and we ask that \( \gamma^i_n(0) \) is mapped into the origin of \( \mathbb{R}^d \). For every \( i \in \{1, \ldots, k\} \) and for every \( n \in \mathbb{N} \) we have that

\[
\| \gamma^i_n \|_\infty = \sup_{x \in [0,1]} |\gamma^i_n(x)| \leq L(N_n) \leq \tilde{E}(N_n) \leq C < \infty, \quad (3.3)
\]

\[
\| \dot{\gamma}^i_n \|_\infty = \sup_{x \in [0,1]} |\dot{\gamma}^i_n(x)| = \ell(N_n) \leq L(N_n) \leq \tilde{E}(N_n) \leq C < \infty, \quad (3.4)
\]

\[
\| \dot{\gamma}^i_n \|_2^2 = \ell(N_n)^3 \int_0^1 |\dot{\gamma}^i_n(x)|^2 \ dx \leq L(N_n) \dot{\tilde{E}}(N_n) \leq C^4 < \infty. \quad (3.5)
\]

Since for every \( i \in \{k+1, \ldots, N\} \) the maps are constant on the bounded interval of parametrization \([0,1]\), a bound on \( \| \cdot \|_{H^2} \) is trivially obtained. Then for every \( i \in \{1, \ldots, N\} \) up to a subsequence (not relabeled) \( \gamma^i_n \rightharpoonup \gamma^i_\infty \) weakly in \( H^2(0,1) \) and thanks to classical compact embedding theorems \( \gamma^i_n \to \gamma^i_\infty \) strongly in \( C^{1,\alpha}([0,1]) \) for every \( \alpha \in (0, 1/2) \).

Since all the networks of the sequence \( \{N_n\}_{n \in \mathbb{N}} \) satisfy the angle condition of Definition 3.2, for each \( n \) there exists a family of unit vectors \( T_n = (\tau_{z,i}^n)_{(z,i) \in \pi^{-1}(V_G)} \) that are either the real or the virtual tangents. By compactness of \( \mathbb{S}^{d-1} \) up to subsequence (not relabeled) \( T_n \) converge to a limit \( T_\infty \) composed of elements denoted by \( \tau_{z,i}^\infty \). Notice that for the the indices \( i \) for which \( \ell(\gamma^i_\infty) > 0 \) we have that (up to subsequence) \(( -1)^{\frac{\alpha}{2} } \frac{\tau^i_{z,i}}{|T_n|} \) converge to \( \tau^i_{z,i} \).

Define \( \Gamma_\infty : G \to \mathbb{R}^d \) in such a way that \( \Gamma_\infty|_{E_i} = \gamma^i_\infty \) and call \( N_\infty := (G, \Gamma_\infty) \). We want to prove that \( N_\infty \in \mathcal{C}_{\text{Deg}} \).

First of all we claim that the angle condition is verified for \( N_\infty \) with the family \( T_\infty \). It is easy to check that there exist rotations \( R_p \) (obtained as limits of those for \( N_n \)) that verify (3.1). It remains to prove that for the regular curves \( \gamma^i_\infty \) the vectors \( \tau_{z,i}^\infty \) coincide with the outer tangents and that for the constant curves we have \( \tau^i_{0,i} = -\tau^i_{1,i} \). For each \( i \in \{1, \ldots, N\} \)
there are three possible cases: a regular curve converges to a regular curve; a regular curve converges to a constant curve; a constant curve converges to a constant curve. In the first case the claim follows from the above argument. In the second case the claim follows by Lemma 3.1. In the third case the claim follows trivially.

It remains to verify that \( H = \text{Sing}(N_\infty) \) is stratified-straight. We proceed by induction: we set \( H_0 = H \) and supposing to have obtained \( H_i \) we construct \( \Sigma_i \) and \( H_{i+1} \). We can assume without loss of generality that \( H_i \) is connected (otherwise we apply the same argument to each connected component) and up to a translation that \( 0 \in \Gamma_n(H_i) \). We define \( L^i_n := L(\Gamma_n(H_i)) \) and consider the rescaled networks \( N^i_n = (H_i, \Gamma^i_n) \) with

\[
\Gamma^i_n = \frac{1}{L_n^i}\Gamma_n .
\]

Then

\[
L(N^i_n) = 1 \quad \text{and} \quad \int_{\gamma^i_n} |\vec{E}|^2 \, ds = \int_{\Gamma^i_n(H_i)} |\vec{E}|^2 \, ds \to 0 \quad \text{as} \ n \to \infty
\]

and in particular \( \tilde{E}(N^i_n) \leq C < \infty \) for some constant \( C \). Hence we can repeat the previous reasoning to conclude that up to subsequence the networks \( N^i_n \) converge weakly in \( H^2 \) and strongly in \( C^1 \) to a network \( N^i_\infty = (H_i, \Gamma^i_\infty) \). By \( C^1 \)-convergence \( L(N^i_\infty) = 1 \) and thus the limit network has at least one regular curve. By Lemma 3.1 we have that the curves of \( N^i_\infty \) are either constant or segments, since all surviving curves have a constant tangent. We then define \( \Sigma_i = \Gamma^i_\infty \) and \( H_{i+1} = \text{Sing}((H_i, \Sigma_i)) \), and we repeat the process until \( \text{Sing}((H_i, \Sigma_i)) = \emptyset \).

After a finite number of steps the process stops and we obtain that the strata \( 0 = H_0 \subset \ldots \subset H_0 = H \) by construction satisfy the condition of Definition 3.5.

We have thus concluded that \( N_\infty \) satisfies the angle condition with (real or virtual) tangents \( T_\infty \) and \( \text{Sing}(N_\infty) \) is stratified-straight whose (real or virtual) tangents are consistent with \( T_\infty \), and thus by Definition 3.7 \( N_\infty \in C_{\text{Deg}} \).

To convince the reader that in Definition 3.7 we cannot replace the notion of stratified straight subgraph by the simpler one of straight subgraphs, and hence the definition of degenerate networks is in a sense sharp, we give an example of a sequence of regular networks with equibounded energy which converges to a singular network whose singular part is stratified straight but not straight.

Example 3.9. Consider a 5–graph \( G \) where in particular

\[
(0, 1) \sim (0, 2), (1, 1) \sim (0, 3), (1, 2) \sim (1, 3) ,
\]

\[
\angle d^{0,1}, d^{0,2} = 0 , \angle d^{1,1} , d^{1,2} = \angle d^{1,2} , d^{1,3} = \frac{\pi}{2} .
\]

We construct a sequence of regular networks \( N_n = (G, \Gamma_n) \) that converge as \( n \to \infty \) to a degenerate network whose singular part is stratified straight.

Consider three immersions \( \gamma^1, \gamma^2, \gamma^3 : [0, 1] \to \mathbb{R}^2 \) such that the curve \( \gamma^3([0, 1]) \) is an arc of circle of radius \( r \) and length \( 2\alpha r \) and both \( \gamma^1([0, 1]) \) and \( \gamma^2([0, 1]) \) are arcs of circle of radius \( R \) and length \( \alpha R \) with \( R = \frac{\sin(\frac{\pi}{2} - \alpha)}{\sin \alpha} r \). Then

\[
\mathcal{E}(\gamma^1) + \mathcal{E}(\gamma^2) + \mathcal{E}(\gamma^3) = 2 \left( r \alpha \cot \alpha + \frac{\alpha \tan \alpha}{r} \right) + 2\alpha r + \frac{2\alpha}{r} .
\]
We construct a sequence of immersions $\gamma_n^1, \gamma_n^2, \gamma_n^3$ simply by taking $r_n = \frac{1}{n}$ and $\alpha_n = \frac{1}{n^2}$. Then as $n \to \infty$ the lengths of the three curves go to zero and

$$E(\gamma_n^1) + E(\gamma_n^2) + E(\gamma_n^3) = 2 \left( \frac{1}{n} + \frac{1}{n^3} \right) + \frac{2}{n^3} + \frac{2}{n} + o \left( \frac{1}{n^5} \right) \xrightarrow{n \to \infty} 0.$$ 

Moreover it is not possible to construct a triangle with three edges of positive length and angles $0, \frac{\pi}{2}, \frac{\pi}{2}$.

### 4 Relaxation

Let us define the following extended problem.

**Problem 4.1.** Given an $N$–graph $G$ with assigned angles we want to find

$$\inf \{ \mathcal{E}(\mathcal{N}) \mid \mathcal{N} = (G, \Gamma) \text{ is a (possibly) singular network} \},$$

where $\mathcal{E}$ is the extension of $E$ defined as

$$\mathcal{E}(\mathcal{N}) := \begin{cases} \mathcal{E}(\mathcal{N}) & \text{if } \mathcal{N} \in C_{\text{Deg}}, \\ +\infty & \text{otherwise}. \end{cases} \quad (4.1)$$

The reason to consider this functional will be clear at the end of this section: we will prove that it coincides with the relaxation of the functional $\mathcal{E}$ defined in (2.2), and thus it is the natural extension of $E$ from $C_{\text{Reg}}$ to $C_{\text{Deg}}$.

**Proposition 4.2** (Recovery sequence). For every network $\mathcal{N} = (G, \Gamma) \in C_{\text{Deg}}$ there exists a sequence of networks $\{\mathcal{N}_n\}_{n \in \mathbb{N}}$ such that

$$\mathcal{N}_n \xrightarrow{H^2} \mathcal{N} \quad \text{and} \quad E(\mathcal{N}_n) \to \mathcal{E}(\mathcal{N}).$$

To prove the above proposition we will take advantage of the following preliminary lemmas.
Lemma 4.3 (Change of train tracks). Consider two parallel horizontal straight lines at distance $h$. There exists an embedded curve contained in between the two lines such that it connects the two lines spanning a horizontal interval of length $b \approx 2\sqrt{h}$ and with energy $\approx 4\sqrt{h}$, asymptotically as $h \to 0$. More precisely, there exists a regular curve $\gamma : [0, 1] \to \mathbb{R}^2$ such that

$$
\frac{\dot{\gamma}(0)}{|\gamma(0)|} = \frac{\dot{\gamma}(1)}{|\gamma(1)|} = e_1, \quad \gamma(0) = (0, 0), \quad \gamma(1) = (b, h),
$$

with

$$
b = 2\sqrt{h}(1 + o(1)), \quad \text{and} \quad E(\gamma) = 4\sqrt{h}(1 + o(1)).
$$

Proof. We construct the curve putting together two congruent arcs of circle of radius 1 as in Figure 7. The modulus of the curvature is 1 and the angle is $\theta$. The total length is $2\theta$ which also equals the total squared curvature of the arcs. The total energy $E(\gamma)$ is thus $4\theta$. The height $h$ and the base $b$ are related to $\theta$ by

$$
h = 2(1 - \cos \theta) \approx \theta^2 \quad \text{as} \quad \theta \to 0,
$$

and therefore given $h$ we can choose $\theta = \arccos \left(1 - \frac{h}{2}\right) \approx \sqrt{h}$ to obtain

$$
b \approx 2\sqrt{h} \quad E(\gamma) \approx 4\sqrt{h}.
$$

Figure 7: The construction of Lemma 4.3

The following lemma allows us to suppose, in the construction of the recovery sequence, that each regular curve of $\mathcal{N}$ is straight near its endpoints, up to a small perturbation and a small change of the value of its elastic energy.

Lemma 4.4 (Straightening at vertices). Consider a regular curve $\gamma : [0, 1] \to \mathbb{R}^d$ of class $H^2$. Then for every sufficiently small $\varepsilon > 0$ there exists a modified curve $\gamma_\varepsilon : [0, 1] \to \mathbb{R}^d$ of class $H^2$ that coincides with $\gamma$ on $\{0\} \cup \left[\frac{3}{4}, 1\right]$, such that on some interval $[0, a]$ its image is a segment of length $\varepsilon$ with direction $\gamma'(0)$ and such that

$$
E(\gamma_\varepsilon) \leq E(\gamma)(1 + C\varepsilon)
$$

for a constant $C$ not depending on $\varepsilon$. 

15
Proof. Without loss of generality we suppose that $\gamma(0) = 0$, $\dot{\gamma}(0) = e_1$, and we define

$$\tilde{\gamma}_\varepsilon(t) = \gamma(t) + \varepsilon \psi(t) e_1,$$

where $\psi : [0, 1] \to \mathbb{R}$ is a fixed $C^2$ map with

$$\psi(t) = 1 \text{ for } t \in [0, \frac{1}{4}] \quad \text{and} \quad \psi(t) = 0 \text{ for } t \in [\frac{1}{4}, 1].$$

Then $E(\tilde{\gamma}_\varepsilon) \leq E(\gamma)(1 + C\varepsilon)$ for some constant $C$ that depends on $\|\psi''\|_{\infty}$ but not on $\varepsilon$. Finally we define $\tilde{\gamma}$ as (a reparametrization on $[0, 1]$ of) the composition of a segment from 0 to $\varepsilon e_1$ and $\tilde{\gamma}_\varepsilon$. The added piece of segment just adds length $\varepsilon$ to the total energy.

We now come to the proof of the recovery sequence.

Proof of Proposition 4.2. Consider $\mathcal{N} = (G, \Gamma) \in \mathcal{C}_{\operatorname{Deg}}$ and let $H = H_0 = \operatorname{Sing}(\mathcal{N})$. For simplicity but without loss of generality we suppose that $H$ is connected and $\Gamma(H)$ is the origin of $\mathbb{R}^d$. In the case of many connected components it is sufficient to repeat the argument for each one of them. By assumption there exist (real or virtual) tangents $T_G = (\tau_{z,i})_{(z,i) \in \pi^{-1}(V_G)}$ of the graph $G$, such that $H$ is stratified–straight with strata $H = H_0 < H_{q-1} < \ldots < H_1 < H_0 = H$

with $\mathbb{N} \ni q \leq N$, and such that the (real or virtual) tangents of $(H_i, \Sigma_i)$ coincide with the corresponding ones of $T_G$.

Fix $\varepsilon > 0$. Consider the family $\mathcal{F}$ of regular curves of $\mathcal{N}$ that have an endpoint in $H$. For every $\gamma^i \in \mathcal{F}$ we have that $\Gamma(\pi(z, i)) = 0$ whenever $p = \pi(z, i) \in H$ and moreover by Lemma 4.4 we can suppose that near $p$ the image of the curve $\gamma^i$ coincides with a segment of length $\varepsilon$, up to adding a small error of order $C\varepsilon$ to the energy.

We consider the first stratum $H = H_0$ and up to rescaling we can suppose that $\Sigma_0(H_0) \subset B_{\varepsilon^3}(0)$ where we recall that $0 = \Gamma(H_0)$. We want to partially desingularize $H$, that is we replace in a neighbourhood of 0 the completely singular subnetwork $(H_0, \Gamma)$ with the first stratum $(H_0, \Sigma_0)$. We have to make sure to connect each curve to the right junction and with the right angle.

Consider a curve $\gamma^i \in \mathcal{F}$, and suppose for instance that $p = \pi((0, i)) \in V_H$ (the case when $p((1, i)) \in V_H$ is completely analogous). Then there exists $a^{0,i}$ such that $\gamma^i|_{[0, a^{0,i}]}$ is a segment of length $\varepsilon$. In particular $\dot{\gamma}^i(a^{0,i})$ is parallel to $\dot{\gamma}^i(0) = \tau_{0,i}$. We now consider the parallel lines with direction $\tau_{0,i}$ passing through the point $\Sigma_0((0, i))$ and through the point $\gamma^i(a^{0,i})$. Their distance is of order $\varepsilon^3$. We can thus apply Lemma 4.3 to modify the curve $\gamma^i$ on the interval $[0, a^{0,i}]$ in order to connect $\Sigma_0((0, i))$ to $\gamma^i(a^{0,i})$ with an energy of order $\varepsilon^{3/2}$ and with outer tangent $\tau_{0,i}$. We repeat this process for every curve $\gamma^i$ and every endpoint in $V_H$. By construction the angle condition is still verified for the newly constructed network, but now the stratum $H_0$ is not completely singular anymore. We then repeat the same process for each stratum until we obtain a regular network $\mathcal{N}_\varepsilon$ whose energy is at most $E(\mathcal{N}) + C\varepsilon$.

Since we can do this for any $\varepsilon > 0$, choosing $\varepsilon_n = \frac{1}{n}$ we obtain a family $\mathcal{N}_n$ of regular networks that approximate $\mathcal{N}$ and thus satisfies the thesis of the theorem.

Theorem 4.5. The functional $\mathcal{E}$ is the lower semicontinuous envelope in $H^2$ of the functional $E$, that is

$$\mathcal{E}(\mathcal{N}_\infty) = \inf \left\{ \liminf_{n \to \infty} E(\mathcal{N}_n) \mid \mathcal{N}_n \in \mathcal{C}_{\operatorname{Reg}}, \mathcal{N}_n \overset{H^2}{\to} \mathcal{N}_\infty \right\}, \quad (4.2)$$

Moreover the relaxed functional $\mathcal{E}$ admits a minimizer.
Proof. The existence of minimizers of the functional $\mathcal{E}$ follows by a direct method in the Calculus of Variations combining the lower semicontinuity of $\mathcal{E}$ and the compactness, that we both gain thanks to Proposition 3.8 and Proposition 4.2.

By definition $\mathcal{E} \leq \mathcal{E}$ in the class $\mathcal{C}_{\text{Reg}}$. Let $\mathcal{F}$ be a lower semincontinuous functional defined in the class of $N$–networks such that $\mathcal{F} \leq \mathcal{E}$ in the class $\mathcal{C}_{\text{Reg}}$. Proposition 4.2 implies that $\mathcal{E}(\mathcal{N}) \geq \mathcal{F}(\mathcal{N})$ in the class of $N$–networks and this concludes also the first part of the statement.

Now that we have shown that the relaxed Problem 4.1 admits a minimizers, one may wonder if in some cases the minimizer is regular, that is if Problem 2.12 has a minimum. We report here on a special case in which we get the desired result.

Definition 4.6. We call Theta–network any planar network $(G, \Gamma)$ where $G$ is a 3–graph composed of $E_1, E_2, E_2$ such that

$$(0, 1) \sim (0, 2) \sim (0, 3) \quad \text{and} \quad (1, 1) \sim (1, 2) \sim (1, 3),$$

$$\angle d_0^{i,j}, d_0^{i,j} = \frac{2\pi}{3} \quad \text{and} \quad \angle d_1^{i,j}, d_1^{i,j} = \frac{2\pi}{3}$$

with $(i, j) \in \{(1, 2), (2, 3), (3, 1)\}$.

![Figure 8: A representation of the graph $G$ of a Theta–network.](image)

The minimization of the elastic energy among Theta–network has been considered in [6]. It turns out that in this class the minimizers of the relaxed problem are regular networks (see [6, Theorem 4.10]) and hence Problem 2.12 admits a minimiser.

Although we have proven that in general sequences of regular networks with equibounded energy converge to a limit network in $\mathcal{C}_{\text{Deg}}$ one may think that for every choice of the topology of the graph $G$ and of the angle condition minimizers are actually in $\mathcal{C}_{\text{Reg}}$. The following example shows that even for very simple topologies of $G$ this could not be the case and so it is hopeless to give always a positive answer to Problem 2.12.

Example 4.7 (The minimizers of the relaxed problem are degenerate). Consider the 3–graph $G$ with assigned angles composed of $E_1, E_2, E_2$ with $\pi(0, 1) = \pi(1, 1) = \pi(0, 2)$ and $\pi(1, 2) = \pi(0, 3) = \pi(1, 3)$ depicted in Figure 9. Then the length of one of the curves of the minimizers is zero.

4.1 Lower bounds on the Energy

We have just seen in Example 4.7 that in some situations the minimizers of Problem 2.12 are degenerate networks. We want to understand under which conditions minimizers have at least some curves with positive length and do not degenerate to a point. To be more precise,
Figure 9: On the left a representation of the graph $G$. On the right a possible minimizer $\mathcal{N}_{\text{min}} = (G, \Gamma_{\text{min}})$.

consider a graph $G$ with assigned angles. We recall that $D$ is the set of the assigned directions $d^{i,z}$ (see Definition 2.9). We call

$$I_D := \min \{ \mathcal{E}(\mathcal{N}) \mid \mathcal{N} = (G, \Gamma) \text{ is a network} \} ,$$

(4.3)

We are interested in conditions on the set $D$ that guarantee that $I_D$ is strictly positive.

Lemma 4.8. Let $\gamma : [0, \ell(\gamma)] \to \mathbb{R}^2$ be a regular, continuous, piecewise $H^2$ curve parametrized by arclength such that $\gamma(0) = 0, \dot{\gamma}(0) = (\cos \theta, \sin \theta)$ and $\dot{\gamma}(\ell(\gamma)) = (1, 0)$. Then

$$\int_\gamma |\vec{k}| \, ds \geq \theta ,$$

and the equality holds if $\gamma$ is convex. Moreover suppose that for every $i \in \{1, \ldots, N\}$ the curve $\gamma_i$ is regular, continuous and of class $H^2$ and suppose that there exists $\alpha > 0$ such that

$$\sum_{i=1}^N \int_{\gamma_i} |\vec{k}_i| \, ds \geq \alpha ,$$

then $\mathcal{E} \left( \cup_{i=1}^N \gamma_i \right) \geq 2\alpha$.

Proof. Denote by $\tau$ the unit tangent vector to the curve $\gamma$. Since the curve $\gamma$ is parametrized by arclength, we have that $\dot{\gamma} = \tau$ and $\ddot{\gamma} = \dot{\tau} = \vec{k}$. By hypothesis the angle spanned by the unit tangent vector equals $\theta$, hence

$$\int_\gamma |\vec{k}(s)| \, ds = \int_0^{\ell(\gamma)} |\dot{\tau}(s)| \, ds \geq \theta .$$

We pass now to prove the second part of the statement. Using Cauchy–Schwarz inequality we get

$$\left( \sum_{i=1}^N \int_{\gamma_i} |\vec{k}_i| \, ds \right)^2 = \left( \sum_{i=1}^N \frac{f_{\gamma_i} |\vec{k}_i| \, ds}{\ell(\gamma_i)^{1/2}} \right)^2 \leq \left( \sum_{i=1}^N \left( \int_{\gamma_i} |\vec{k}_i| \, ds \right)^2 \right) \left( \sum_{i=1}^N \ell(\gamma_i) \right) . \tag{4.4}$$

Moreover by Hölder inequality

$$\left( \int_{\gamma_i} |\vec{k}_i| \, ds \right)^2 \leq \ell(\gamma_i) \int_{\gamma_i} |\vec{k}_i|^2 \, ds ,$$

that combined with (4.4) gives

$$\mathcal{E} \left( \cup_{i=1}^N \gamma_i \right) = \sum_{i=1}^N \left( \int_{\gamma_i} |\vec{k}_i|^2 \, ds + \ell(\gamma_i) \right) \geq \sum_{i=1}^N \left( \frac{f_{\gamma_i} |\vec{k}_i| \, ds}{\ell(\gamma_i)} + \ell(\gamma_i) \right)$$

$$\geq \frac{\left( \sum_{i=1}^N \int_{\gamma_i} |\vec{k}_i| \, ds \right)^2}{\sum_{i=1}^N \ell(\gamma_i)} + \sum_{i=1}^N \ell(\gamma_i) \geq \frac{\alpha^2}{\sum_{i=1}^N \ell(\gamma_i)} + \sum_{i=1}^N \ell(\gamma_i) \geq 2\alpha .$$
Lemma 4.9. We have that $I_D$ defined in (4.3) equals zero if and only if the graph $G$ is stratified straight.

Moreover, suppose that one of the following conditions holds:

i) at every vertex $p$ the convex hull of the outer tangents contains the origin in its interior, that is $0 \in \text{Int} \left( \text{co} \left( \{d_{z,i} \mid (z,i) \in \pi^{-1}(p)\} \right) \right)$,

ii) two edges $E_i$ and $E_j$ have both vertices in common and $\angle d^{z,i}, d^{z,j} = \delta > 0$;

then $I_D > 0$.

Proof. Suppose that $I_D = 0$, then there exists a sequence of networks $\{\mathcal{N}_n\}$ with $\mathcal{E}(\mathcal{N}_n) \to 0$. By Proposition 3.8 we get that $G$ is stratified straight. On the other hand if $G$ is stratified straight, there exists a degenerate immersion $\Sigma_0$ whose regular curves are segments. By Proposition 4.2 there exists a sequence $\{\mathcal{N}_n\}$ of regular networks such that $\Gamma_n \to \Sigma_0$ in $H^2$. Analogously there exists recovery sequences for every rescaling $\frac{1}{2} \Sigma_0$ of $\Sigma_0$ with $\lambda >> 1$. By a diagonal argument one can find a sequence of regular networks whose energy converges to zero.

Consider any regular network $\mathcal{N} = (G, \Gamma)$ with $G$ graph with assigned angles encoded by $\mathcal{D}$.

Suppose now that i) holds. Since the number of vertices is finite there exists at least one junction $p \in \Gamma(V_G)$ that lies on the boundary of the convex hull of $\Gamma(V_G)$, and thus that lies on $\partial H$ where $H$ is a closed half plane containing $\Gamma(V_G)$. Then at least one of the curves arriving at $p$, call it $\gamma$, must have an outer tangent that goes out of $H$ and whose smallest angle with $\partial H$ is at least $c(D)$ where $c(D) > 0$ depends only on $D$ and it is strictly positive by assumption. By Lemma 4.8 the energy of $\gamma$ is at least $2c(D)$, which therefore is a lower bound for any regular network with angles $D$.

Suppose instead that ii) holds. Consider the two maps $\gamma^i := \Gamma|_{E_i}$ and $\gamma^j := \Gamma|_{E_j}$. Then by Lemma 4.8 we have that $\int_{\gamma^i} |\vec{k}^i| \, ds + \int_{\gamma^j} |\vec{k}^j| \, ds \geq \delta$ and hence $\mathcal{E}(\gamma^i) + \mathcal{E}(\gamma^j) \geq 2\delta$ and this concludes the proof.

As another application of Lemma 4.8 we improve the lower bound (cf [6, Lemma 2.5.]) of the elastic energy of a Theta–network that we introduced above in Definition 8.

Lemma 4.10. Let $\Theta$ be a Theta–network. Then

$$\mathcal{E}(\Theta) \geq \frac{16\pi}{3}. \tag{4.10}$$

Proof. In order to prove the required lower bound we can assume that the curves $\gamma^1, \gamma^2, \gamma^3$ realize a minimizing Theta-network, which exists by [6, Theorem 4.10]. Then the curves $\gamma^i$ are injective and real analytic by [6, Proposition 4.11] and by Proposition A.3. Without loss of generality we let

$$\gamma^1(0) = \gamma^2(0) = \gamma^3(0) = (0,0) \quad \text{and} \quad \gamma^1(1) = \gamma^2(1) = \gamma^3(1) = (a,0),$$

for some $a > 0$. We claim that for any $i$ there exists $t_i \in [0, 1]$ such that $\frac{\dot{\gamma}^i(t_i)}{\|\dot{\gamma}^i(t_i)\|} = (1,0)$. Denote by $\alpha^i$ the smallest angle (in modulus) between $\frac{\dot{\gamma}^i(0)}{\|\dot{\gamma}^i(0)\|}$ and $(1,0)$. Up to relabeling the curves and up to a symmetry with respect to the horizontal axis we can assume that

$$\alpha^1 \in [0, \frac{\pi}{3}] \quad \alpha^2 = \alpha^1 + \frac{2}{3}\pi, \quad \alpha^3 = \frac{2}{3}\pi - \alpha^1.$$
By Lemma 4.8 we have that
\[ \sum_{i=1}^{3} E(\sigma^i) \geq \sum_{i=1}^{3} 2\alpha^i \geq \frac{8}{3}\pi. \]
To conclude we prove the above claim. Unless the curve $\gamma^t$ is a horizontal segment (and in this case the result trivially follows) by analyticity there are finitely many intersections with the horizontal axis $(a_j,0) = \gamma^t(t_j)$ with $t_j < t_{j+1}$. Moreover, since $\gamma^t(1) = (a,0)$ with $a > 0$, there exists an index $j$ such that $a_j < a_{j+1}$. We consider the arc $\sigma(t) := \gamma^t(t)$ with $t \in (t_j,t_{j+1})$ that, without loss of generality, lies in the half-plane $\{y > 0\}$. It is possible to complete $\sigma(t)$ to a smooth simple closed curve with $t \in [t_j, s]$ for some $s > t_{j+1}$ such that for every $t \in (t_{j+1}, s)$ $\frac{\dot{\theta}(t)}{\dot{\gamma}(t)} \neq (1,0)$. Then by Hopf’s Umlaufsatz the degree of the tangent map of $\sigma(t)$ is different from zero, and thus the tangent map is surjective. Therefore the value $(1,0)$ must be attained in the interval $[t_j,t_{j+1}]$ and the claim is proved. □

5 A characterization of degenerate networks in $\mathbb{R}^2$

Although the definition of the class of degenerate networks given in Definition 3.7 is very neat and convenient, it has a disadvantage: it is based on the assumption that there exists a family $\mathcal{T}$ of real or virtual tangents. In general one cannot easily verify this condition. At least when the ambient space is $\mathbb{R}^2$ we are able to give an equivalent characterization based on conditions that can be validated by a procedure consisting in a finite number of steps.

From now on we fix the dimension of the ambient space to $d = 2$.

**Definition 5.1** (Path and cycle). Let $G$ be an $N$–graph with assigned angles. A path composed of $\mathcal{J}$ edges is a sequence
\[
\mathcal{P} : \{1, \ldots, \mathcal{J}\} \to \{0,1\} \times \{1, \ldots, N\}
\]
\[
j \to (z_j, i_j)
\]
such that for every $j \in \{1, \ldots, \mathcal{J} - 1\}$ it holds $\pi(1 - z_j, i_j) = \pi(z_{j+1}, i_{j+1})$. A path is a cycle if $\pi(1 - z_{\mathcal{J}}, i_{\mathcal{J}}) = \pi(z_1, i_1)$. If a path is not a cycle we call it open path.

We should think of $(z_j, i_j)$ as encoding the following fact: when we travel through the path, the $j$–th edge is the one with index $i_j$ and its first endpoint that we meet is $z_j$.

When the first element of a path $\mathcal{P}$ is $(z, i)$ and the last is $(w, j)$ sometimes we will simply say that $\mathcal{P}$ is a path from the edge $E_i$ to the edge $E_j$.

Let $\vec{a}$ and $\vec{b}$ two vectors in $\mathbb{R}^2$. Then the counterclockwise angle between $\vec{a}$ and $\vec{b}$, denoted by $\angle \vec{a}, \vec{b}$, is an element of $\mathbb{R}$ (mod $2\pi$).

**Definition 5.2** (Angle of a path). Let $G$ be an $N$–graph with assigned angles in $\mathbb{R}^2$. We define the angle of a path $\mathcal{P}$ composed of $\mathcal{J}$ edges as
\[
\Theta(\mathcal{P}) := \begin{cases} 
\sum_{j=1}^{\mathcal{J}-1} (\angle - d^{1-z_j,i_j}, d^{z_{j+1},i_{j+1}}) \mod 2\pi & \text{if } \mathcal{P} \text{ is an open path} \\
\sum_{j=1}^{\mathcal{J}} (\angle - d^{1-z_j,i_j}, d^{z_{j+1},i_{j+1}}) \mod 2\pi & \text{if } \mathcal{P} \text{ is a cycle}
\end{cases}
\]
with the understanding that the indices are modulo $\mathcal{J}$, so that $\mathcal{J} + 1 = 1$. 20
For the sake of readability when we consider a path composed of $\mathcal{J}$ edges we often suppose that, up to relabeling and reparametrizing the edges, we have
\[
\mathcal{P} : \{1, \ldots, \mathcal{J}\} \rightarrow \{0, 1\} \times \{1, \ldots, \mathcal{J}\}
\]
so that $\pi(1, j) = \pi(0, j + 1)$. Moreover if $\mathcal{P}$ is a cycle we ask that $\pi(1, \mathcal{J}) = \pi(0, 1)$. Then
\[
\Theta(\mathcal{P}) := \begin{cases}
\sum_{j=1}^{\mathcal{J}-1} (\angle - d_{1,j}^{0,1}, d_{0,j+1}^{0,1}) \mod 2\pi & \text{if } \mathcal{P} \text{ is an open path} \\
\sum_{j=1}^{\mathcal{J}} (\angle - d_{1,j}^{0,1}, d_{0,j+1}^{0,1}) \mod 2\pi & \text{if } \mathcal{P} \text{ is a cycle}
\end{cases}
\]
with the understanding that the indices are modulo $\mathcal{J}$, so that $\mathcal{J} + 1 = 1$. When $\mathcal{N} = (G, \Gamma)$ is a network of class $\mathcal{C}_{\text{Reg}}$ and we denote by $\gamma^j = \Gamma|_{E_j}$ we have that $\gamma^j(1) = \gamma^{j+1}(0)$ for $j \in \{1, \ldots, \mathcal{J} - 1\}$ and if $\mathcal{P}$ is a cycle $\gamma^\mathcal{J}(1) = \gamma^1(0)$.

**Lemma 5.3.** Let $\{\mathcal{N}_n\}_{n \in \mathbb{N}}$ be a sequence of networks in $\mathcal{C}_{\text{Reg}}$ such that
\[
\limsup_n \mathcal{E}(\mathcal{N}_n) \leq C < +\infty.
\]

- Suppose that $\mathcal{P}$ is an open path composed of $\mathcal{J}$ edges and that $\lim_{n \to \infty} \ell(\mathcal{N}_n^\mathcal{J}) = 0$ for $j \in \{2, \ldots, \mathcal{J} - 1\}$. Then $\Theta(\mathcal{P}) = \lim_{n \to \infty} \left(\angle - \tau_n^{1,1}, \tau_n^{0,\mathcal{J}}\right)$.

- Suppose that $\mathcal{P}$ is a cycle composed of $\mathcal{J}$ edges and that $\lim_{n \to \infty} \ell(\mathcal{N}_n^\mathcal{J}) = 0$ for $j \in \{1, \ldots, \mathcal{J}\}$. Then $\Theta(\mathcal{P}) = 0 \mod 2\pi$.

**Proof.** Suppose that $\mathcal{P}$ is an open path. For every $n \in \mathbb{N}$ we have that
\[
\angle - \tau_n^{1,1}, \tau_n^{0,\mathcal{J}} = \sum_{j=1}^{\mathcal{J}-1} (\angle - \tau_n^{1,j}, \tau_n^{0,j+1}) + \sum_{j=2}^{\mathcal{J}-1} (\angle - \tau_n^{0,j}, -\tau_n^{1,j})
\]
\[
= \sum_{j=1}^{\mathcal{J}-1} (\angle - d_{1,j}^{1,j}, d_{0,j+1}^{0,1}) + \sum_{j=2}^{\mathcal{J}-1} (\angle - \frac{\gamma_n^j(0)}{|\gamma_n^j(0)|}, \frac{\gamma_n^j(1)}{|\gamma_n^j(1)|}).
\]

Then thanks to Lemma 3.1 one gets the desired result passing to the limit $n \to \infty$.

If instead $\mathcal{P}$ is a cycle, then $\tau_n^{0,\mathcal{J}+1} = \tau_n^{0,1}$ and so using again by Lemma 3.1 we obtain
\[
\Theta(\mathcal{P}) = \lim_{n \to \infty} \angle - \tau_n^{1,1}, \tau_n^{0,1} = 0,
\]
as desired.

It is possible to give an alternative definition of the angle condition for a singular network with respect to Definition 3.2 in term of paths, justified by Lemma 5.3.

**Definition 5.4** (Angle condition for a singular network in term of paths). Let $G$ be an $\mathcal{N}$–graph with assigned angles. We say that a network $\mathcal{N}$ satisfies the angle condition if
i) its regular curves satisfy the angle condition in the sense of Definition 2.10;

ii) if $\mathcal{P}$ is a cycle composed of $\mathcal{J}$ edges such that for every $j \in \{1, \ldots, \mathcal{J}\}$ the edges $E_j$ are in $\text{Sing}(\mathcal{N})$ then $\Theta(\mathcal{P}) = 0 \mod 2\pi$;
iii) if $P$ is an open path composed of $J$ edges such that for every $j \in \{2, \ldots, J - 1\}$ the edges $E_j$ are in $\text{Sing}(N)$ and $E_1 \cup E_J \subset \text{Reg}(N)$ then $\Theta(P) = \angle - z^{1,1}, \tau^{0,J}.$

Remark 5.5. Condition i) can be seen as a particular case of iii) by taking $J = 2.$

Clearly one has to modify also Definition 3.5 and Definition 3.7 accordingly to the above new definition of angle condition.

Definition 5.6. Fix an $N$–graph with assigned angles $G$. A subgraph $H \subseteq G$ is stratified-straight if there exists a finite sequence of subgraphs (called strata)

$$\emptyset = H_0 \subseteq H_1 \subseteq \cdots \subseteq H_q = H$$

and maps $\Sigma_i : H_i \rightarrow \mathbb{R}^2$ such that for $i = 0, \ldots, q - 1$

- $(H_i, \Sigma_i)$ is a (possibly singular) network that satisfies the angle condition in the sense of Definition 5.4 and whose curves are (possibly degenerate) segments;
- $H_{i+1} = \text{Sing}((H_i, \Sigma_i)).$

We call step of $G$ the minimal $q$ for which the above holds.

Definition 5.7. Let $G$ be an $N$–graph with assigned angles. A network $N = (G, \Gamma)$ is degenerate if

- it satisfies the angle condition in the sense of Definition 5.4;
- the singular part $\text{Sing}(N)$ is a stratified-straight subgraph in the sense of Definition 5.6.

Proposition 5.8. Let $G$ be a graph with assigned angles. Suppose that the ambient space is $\mathbb{R}^2.$ Then a network $N = (G, \Gamma)$ satisfies Definition 5.4 if and only if it satisfies Definition 3.2 for some choice of virtual tangent vectors.

Proof. Suppose that $N$ satisfies the angle condition as in Definition 5.4. The outward tangents of the regular curves of $N$ satisfy the requests of Definition 3.2 because of condition i) in Definition 5.4. We have to construct the set of virtual tangents. We assume for the moment that at least one curve of $N$ is regular, for instance $\Gamma|_{E_1} =: \gamma^1.$ Let $H \subset G$ be a closed connected component of $\text{Sing} N$ and suppose that an endpoint $p_0 = \pi(0,1)$ of $E_1$ lies in $H.$ We define $\tau^{w,j}$ for any $\pi(w,j) = p_0$ with $\gamma^j$ singular by setting $\tau^{w,j}$ equal to the counterclockwise rotation of $\tau_0^{w,j}$ of the angle $\angle d^{0,1}, d^{w,j};$ whenever such $\tau^{w,j}$ has been defined, we also set $\tau^{1-w,j} = -\tau^{w,j}.$ It follows that (3.1) is satisfied at $p_0.$ Observe that if $\tau^{z,i}$, $\tau^{y,l}$ are defined by this last step and $\pi(z,i) = \pi(y,l) \neq p_0,$ then

$$\angle \tau^{z,i}, \tau^{y,l} = \angle d^{z,i}, d^{y,l}. \quad (5.1)$$

In fact the path $P$ given by

$$P(1) = (1 - z,i), \quad P(2) = (y,l),$$

is a cycle contained in $\text{Sing} N,$ and thus by assumption we get that

$$\Theta(P) = \angle - d^{z,i}, d^{y,l} + \angle - d^{1-z,i}, d^{1-y,l} = \angle - d^{z,i}, d^{y,l} + \angle - \tau^{1-z,i}, \tau^{1-y,l} =$$

$$= \angle - d^{z,i}, d^{y,l} + \angle \tau^{y,l}, -\tau^{z,i} = \pi + \angle d^{z,i}, d^{y,l} + \pi + \angle \tau^{y,l}, -\tau^{z,i} =$$

$$= 2\pi + \angle d^{z,i}, d^{y,l} + 2\pi - \angle \tau^{z,i}, \tau^{y,l} = 0 \mod 2\pi.$$
With this procedure we have defined every virtual tangent at \( p_0 \) of singular edges with an endpoint at \( p_0 \), and some virtual tangents at \( p \neq p_0 \) of singular edges having endpoints at \( p \) and \( p_0 \).

Let \( p \neq p_0 \) be now any vertex at which at least one virtual or real tangent \( \tau^{z,i} \) is defined. We can perform the very same construction for the still undefined virtual tangents at \( p \) using rotations of \( \tau^{z,i} \) in place of the original \( \tau^{0,1} \). By (5.1) it follows that (3.1) is satisfied at \( p \).

Notice that if \( \pi(x,a) = \pi(z,i) \neq p_0, \pi(y,b) = \pi(1-z,i) \neq p_0 \), and \( \pi(1-x,a) = \pi(1-y,b) = p_0 \) (and thus we have just constructed \( \tau^{z,i} \) as a rotation of \( \tau^{x,a} \) and \( \tau^{1-z,i} \) as a rotation of \( \tau^{y,b} \)), then \( \tau^{z,i} = -\tau^{1-z,i} \) as desired. In fact considering the cycle

\[
\mathcal{P}(1) = (1-y,b), \quad \mathcal{P}(2) = (1-z,i), \quad \mathcal{P}(3) = (x,a),
\]

we get that

\[
\Theta(\mathcal{P}) = \angle -\tau^{y,b}, \tau^{1-z,i} + \angle -\tau^{z,i}, \tau^{x,a} + \angle -\tau^{1-x,a}, \tau^{1-y,b} = 0 \mod 2\pi.
\]

On the other hand, since the sum of the exterior angles of a triangle equals \( 2\pi \), we have that

\[
\angle -\tau^{y,b}, -\tau^{z,i} + \angle -\tau^{z,i}, \tau^{x,a} + \angle -\tau^{1-x,a}, \tau^{1-y,b} = 2\pi = 0 \mod 2\pi,
\]

and subtracting (5.3) to (5.2) we get that \( \angle -\tau^{y,b}, \tau^{1-z,i} = \angle -\tau^{y,b}, -\tau^{z,i} \) mod \( 2\pi \).

Therefore we see that for any newly constructed \( \tau^{w,j} \), we can set \( \tau^{1-w,j} = -\tau^{w,j} \) without getting contradictions clearly by using the same procedure to define the tangents along open path we cannot occur in any contradiction.

Hence eventually, iterating the above argument, we are able to define the virtual tangents at any vertex of the connected component \( H \), getting that Definition 3.2 is satisfied at such vertices. We can apply the same argument to any connected component \( H \) of \( \operatorname{Sing} \mathcal{N} \), completing the implication.

If it occurs that \( \operatorname{Sing} \mathcal{N} = G \), we can just choose \( \tau^{0,1} = (1,0) = -\tau^{1,1} \) arbitrarily. Then we can perform the very same construction described above.

Conversely, suppose now that Definition 3.2 is satisfied. Then obviously the regular curves satisfy the angle condition i) of Definition 5.4. Moreover, if \( \mathcal{P} \) is an open path, then the condition \( \tau^{z,i} = -\tau^{1-z,i} \) on the virtual tangents implies point iii) of Definition 5.4. More generally observe that if the edges seen by a path \( \mathcal{P} \) of step \( J \) are contained in \( \operatorname{Sing} \mathcal{N} \), and for simplicity we write \( \mathcal{P}(i) = (0,i) \), then

\[
\sum_{l=0}^{L-1} \angle -\tau^{1,l}, \tau^{0,l+1} = \angle -\tau^{1,0}, \tau^{0,L} \mod 2\pi.
\]

So, finally suppose that \( \mathcal{P} \) is a cycle in \( \operatorname{Sing} \mathcal{N} \) and we write \( \mathcal{P}(i) = (0,i) \) for simplicity; by the fact that every involved tangent is virtual, using (5.4) we get that

\[
\Theta(\mathcal{P}) = \left( \sum_{i=1}^{J-1} \angle -\tau^{1,i}, \tau^{0,i+1} \right) + \angle -\tau^{1,J}, \tau^{0,1} = \angle -\tau^{1,1}, \tau^{0,J} + \angle -\tau^{1,J}, \tau^{0,1} =
\]

\[
= \angle \tau^{0,1}, \tau^{0,J} + \angle \tau^{0,J}, \tau^{0,1} = 0 \mod 2\pi,
\]

thus completing the equivalence of the definitions. \( \square \)
We underline the fact that in Definition 3.6 we simply replace the angle condition of Definition 3.2 by the one of Definition 5.4, and these replacement directly affect the new Definition 5.7 of degenerate networks. Then it is clear that taking advantage of the above proposition we are also able to prove the following:

**Corollary 5.9.** Let \( G \) be a graph with assigned angles. Suppose that the ambient space is \( \mathbb{R}^2 \). Then a network \( \mathcal{N} = (G, \Gamma) \) is degenerate in the sense of Definition 3.7 if and only if it is degenerate in the sense of Definition 5.7.

**Remark 5.10.** As we already mentioned, we remark again that it is somehow easier to use Definition 3.2 in the technical arguments. However, in the very remarkable case of dimension \( d = 2 \), Definition 5.4 has the great advantage of being verifiable by an algorithm with finitely many steps. This is clearly not true for the general Definition 3.2.

## 6 On the relation between straight and stratified straight subgraphs

In this section we study a simple but remarkable case in which we completely characterize stratified straight or straight subgraphs. This helps us to better understand the algebraic and combinatorial relation between these two concepts, together with providing a non-trivial case in which the two definitions are not equivalent.

In the whole section we study networks in \( \mathbb{R}^2 \) and we take advantage of the equivalent characterization of the class of degenerate networks we presented in Section 5: we use Definition 5.4, Definition 5.6 and Definition 5.7.

Throughout the section we will consider an \( N \)--graph \( G \) with junctions of order at most four and suppose that for every junction \( p = \pi(z_1, i_1) = \ldots = \pi(z_k, i_k) \) with \( k \leq 4 \) the vectors \( d^{z_1,i_1}, \ldots, d^{z_k,i_k} \) are distinct and they form angles that are multiples of \( \frac{\pi}{2} \).

**Remark 6.1.** Let \( \mathcal{N} = (G, \Gamma) \) be a degenerate network of the type considered above, \( H \) a stratified straight subgraph of \( G \) composed of edges \( E_1, \ldots, E_k \) and \( \Sigma : H \to \mathbb{R}^2 \) such that \( (H, \Sigma) \) is a (possibly singular) network that satisfies the angle condition in the sense of Definition 5.4 and whose curves are (possibly degenerate) segments. We observe that there exist only two possible orthogonal directions, identified by two orthogonal unit vectors \( a, b \) such that, if \( \sigma^\perp := \Sigma|_{E_1} \) is a regular segment, then \( \sigma^\perp \) is parallel to \( a \) or \( b \). In particular, up to rotation, we can assume that \( a = (1, 0) \) and \( b = (0, 1) \).

**Remark 6.2** (Canonical assignment of the vectors \( d^{z,i} \)). Let \( \mathcal{N} = (G, \Gamma) \) be a degenerate network and \( H \) a stratified straight subgraph of \( G \) composed of the edges \( E_1, \ldots, E_k \). For every \( (z, i) \in \{0, 1\} \times \{1, \ldots, k\} \) we can give an explicit choice of the vector \( d^{z,i} \), once a first edge is chosen. Fix first \( d^{0,1} = (1, 0) \) for example. For every \( (z, i) \in \{0, 1\} \times \{1, \ldots, k\} \) we want that \( d^{z,i} \in \{(\pm 1, 0), (0, \pm 1)\} \). We require then that for any \( i \) it holds

\[
d^{0,i} = -d^{1,i}. \tag{6.1}
\]

Then this choice is well defined for any \( i \) and uniquely defines the \( d^{z,i} \)'s. In fact, by considering a path from \( \pi(0, 1) \) to \( \pi(z, i) \) and using the rule (6.1) one can determine uniquely \( d^{z,i} \). Suppose by contradiction that following two different paths \( \mathcal{P} \) and \( \mathcal{P}' \) from \( (0, 1) \) to \( (z, i) \) and using the rule (6.1) we get different results \( d^{z,i} = a_\mathcal{P} \) and \( d^{z,i} = b_{\mathcal{P}'} \). Then \( \angle a_\mathcal{P}, b_{\mathcal{P}'} \in \{\frac{\pi}{2}, \pi, \frac{3\pi}{2}\} \). Call \( \mathcal{P}'' \) the inverted path of \( \mathcal{P}' \) from \( \pi(z, i) \) to \( (0, 1) \). We can join
the two paths $\mathcal{P}$ and $\mathcal{P}''$ and the resulting path is a cycle $Q$ starting from $(0,1)$. Then it follows that $\Theta(Q) \in \{\pi, \pi, \pi \}$, a contradiction to the fact that $H$ is stratified straight.

This canonical choice of the $d^{i,j}$ clearly depends on the choice of a starting vertex $\pi(0,1)$ together with the assignment $d^{i,0} = (0,1)$. We can use such canonical choice in order to introduce an order relation $\preceq$ on the set of vertices.

**Definition 6.3.** Let $H$ be a connected stratified straight subgraph of $G$, and suppose that $E_{i_0} \subset H$. Starting from $\pi(0,0)$ define $d^{i,0} = (1,0)$ and canonically assign the vectors $d^{i,j}$ as specified in Remark 6.2. Let $v$ and $w$ be two vertices of $H$. We say that $v \preceq w$ if and only if there exists a path $\mathcal{P} : \{1,\ldots,\mathcal{J}\} \rightarrow \{0,1\} \times \{1,\ldots,N\}$ such that

\[
\mathcal{P}(1) = (z_1, i_1), \quad \mathcal{P}(\mathcal{J}) = (z_{\mathcal{J}}, i_{\mathcal{J}}),
\]

with $v = \pi(z_1, i_1)$ and $w = \pi(z_{\mathcal{J}}, i_{\mathcal{J}})$,

\[
d^{\mathcal{P}(i)} \neq (-1,0) \quad \forall i = 1,\ldots,\mathcal{J} - 1,
\]

Also, we say that $v \prec w$ if and only if $v \preceq w$ and $w \neq v$.

Roughly speaking $v \preceq w$ if and only if we can reach $w$ starting from $v$ with a path that never goes left. Also observe that the order relation depends on the choice of a certain edge $E_{i_0}$ in the considered subgraph.

The order relation defines two subsets of the vertices as defined below.

**Definition 6.4.** Let $H$ be a connected stratified straight subgraph of $G$, and suppose that $E_{i_0} \subset H$. Starting from $\pi(0,0)$ define $d^{i,0} = (1,0)$ and canonically assign the vectors $d^{i,j}$ as specified in Remark 6.2. We define

\[
X(i_0) := \{ w \in V_H \mid \pi(0,i_0) \prec w \},
\]

\[
Y(i_0) := V_H \setminus X(i_0).
\]

**Proposition 6.5.** Let $G$ be an $N$–graph with assigned angles. Suppose that every junction of $G$ has order at most 4 and that, if $p$ is a junction with $\pi^{-1}(p) = \{ (z_1, i_1), \ldots, (z_k, i_k) \}$, then the vectors $d^{i_1,j_1},\ldots,d^{k,j_k}$ form angles equal to $\frac{n\pi}{2}$ with $n \in \{1,2,3\}$. Let $H \subset G$ be a connected stratified straight subgraph and denote by $(H,\Sigma_0)$ the first stratum of $H$.

Suppose that for every $E_{i_0} \subset H \cap \text{Sing} (H,\Sigma_0)$ there do not exist cycles $\mathcal{P} = (\mathcal{P}(1),\ldots,\mathcal{P}(\mathcal{J}))$ such that

\[
\mathcal{P}(1) = (z_0, i_0)
\]

\[
d^{(z_0,i_0)} = (1,0)
\]

\[
d^{\mathcal{P}(j)} \neq (-1,0) \quad \forall j = 2,\ldots,\mathcal{J} - 1.
\]

Then $H$ is straight.

**Proof.** Denote by $(H,\Sigma_0)$ the first stratum of $H$, i.e. $\Sigma_0 : H \rightarrow \mathbb{R}^2$ defines a degenerate network, the regular curves of $\Sigma_0$ are segments and at least one curve, say $\sigma_0^{i_0} = \Sigma_0|_{E_{i_0}}$, is degenerate. We denote by $\sigma_0^j$ the curve $\Sigma_0|_{E_j}$.

We want to prove that we can modify $(H,\Sigma_0)$ into a new degenerate network $(H,\tilde{\Sigma}_0)$ such that $\tilde{\Sigma}_0^{i_0}$ is a regular segment and if $\sigma_0^j$ is a regular segment then so is $\tilde{\sigma}_0^j$. In such a way, since the edges of $H$ are finitely many, iterating the argument we conclude that $H$ is straight.

In order to simplify the notation, let us write that $i_0 = 1$. 

25
Fix $d^{0,1} = (1,0)$ and consider the order relation $\preceq$ induced by this choice as given by Definition 6.3. Clearly $Y(1) \neq \emptyset$, in fact $\pi(0,1) \not\preceq \pi(0,1)$ by definition. Also we have that $\pi(1,1) \in X(1) \neq \emptyset$; indeed $\pi(0,1) \preceq \pi(1,1)$, $\sigma^0_1$ is degenerate, and if by contradiction $\pi(1,1) \preceq \pi(0,1)$ then there exists a path $P$ of step $J$ that for simplicity we denote by

\[
P(1) = (0, k_0),
\]

\[
P(j) = (0, j) \quad \forall j = 2, ..., J - 1,
\]

\[
P(J) = (0, 1),
\]

such that $\pi(0, k_0) = \pi(1,1)$ and $d^{0,j} \neq (-1,0)$ for any $j = k_0, 2, ..., J - 1$. But since $d^{0,1} = (1,0)$, the cycle given by

\[
\mathcal{R}(1) = (0, 1),
\]

\[
\mathcal{R}(j) = P(j - 1) \quad \forall j = 2, ..., J,
\]

contradicts the hypothesis.

Now we construct $\tilde{\Sigma}_0$. Let us first define such map on the set of vertices $V_H$ by setting

\[
\tilde{\Sigma}_0(v) = \begin{cases} 
\Sigma_0(v) & \text{if } v \in Y(1), \\
\Sigma_0(v) + (\varepsilon, 0) & \text{if } v \in X(1),
\end{cases}
\]

for some $\varepsilon > 0$. We need to check that we can extend $\tilde{\Sigma}_0$ to the edges in a consistent way. We claim that for any edge $E_j$, if $\Sigma^j_0(0) \neq \Sigma^j_0(1)$, the images of its boundary points $\Sigma^j_0(0), \Sigma^j_0(1)$ can be connected by a regular segment $\tilde{\sigma}^j_0(t)$ such that $d^{0,j} = \alpha(\tilde{\sigma}^j_0(1) - \tilde{\sigma}^j_0(0))$ with $\alpha > 0$. Assuming that the claim is true, then the map $\tilde{\Sigma}_0$ is defined on every edge in the natural way by connecting with a segment the image through $\Sigma_0$ of its endpoints. For $\varepsilon$ small enough, all the regular segments of $\Sigma_0$ remain regular. Moreover, since $\pi(1,1) \in X(1)$ and $\pi(0,1) \in Y(1)$ then $\tilde{\sigma}^j_0(0) \neq \tilde{\sigma}^j_0(1)$ and thus $\tilde{\sigma}^j_0$ is a regular segment, and the proof is completed.

In order to prove the claim we distinguish two cases, adopting the following notation:

\[
A(1) = \{ \text{edge of } H \mid \pi(0,i) \in X(1), \pi(1,i) \in X(1) \},
\]

\[
B(1) = \{ \text{edge of } H \mid \pi(0,i) \notin X(1), \pi(1,i) \notin X(1) \},
\]

\[
C(1) = \{ \text{edge of } H \} \setminus (A \cup B).
\]

Case 1: Assume first that $E_j \in A \cup B$. Then both endpoints of $E_j$ have been moved or both remained unchanged, that is

\[
\tilde{\Sigma}_0(0) = \Sigma_0(0) \quad \text{and} \quad \tilde{\Sigma}_0(1) = \Sigma_0(1),
\]

or

\[
\tilde{\Sigma}_0(0) = \Sigma_0(0) + (\varepsilon, 0) \quad \text{and} \quad \tilde{\Sigma}_0(1) = \Sigma_0(1) + (\varepsilon, 0).
\]

If $\Sigma_0(0) = \Sigma_0(1)$, that is $\sigma^0_0$ is degenerate, then $\tilde{\Sigma}_0(0) = \tilde{\Sigma}_0(1)$ as well and $\tilde{\sigma}^j_0$ will be degenerate. If otherwise $\Sigma_0(0) \neq \Sigma_0(1)$, that is $\sigma^j_0$ is a regular segment, then there is $\alpha > 0$ such that $d^{0,j} = \alpha(\tilde{\sigma}^j_0(1) - \tilde{\sigma}^j_0(0))$, and then $d^{0,j} = \alpha(\Sigma_0(1) - \Sigma_0(0))$ as well and a segment $\tilde{\sigma}_0$ satisfies the claim.
Case 2: We are then left with the case of $E_j \in C$, that is when one of the endpoints of $E_j$ has been moved and the other has not. In such a case, up to relabeling, we can assume $\pi(1,j) \in X(1)$ (i.e. $\pi(0,1) \prec \pi(1,j)$) and $\pi(0,j) \in Y(1)$. Thus

$$\tilde{\Sigma}_0(\pi(0,j)) = \Sigma_0(\pi(0,j)) \quad \text{and} \quad \tilde{\Sigma}_0(\pi(1,j)) = \Sigma_0(\pi(1,j)) + (\varepsilon, 0).$$

If $d^{0,j} = (1,0)$, the claim is proved. Let us show that this is the case. We have that $d^{0,j} \neq \pm(0,1)$, otherwise $E_j$ would belong to $A \cup B$, because $\pi(1,j) \preceq \pi(0,j) \preceq \pi(1,j)$. Suppose by contradiction that $d^{0,j} = -(1,0)$. In this case $d^{1,j} = -d^{0,j} = (1,0)$, and thus $\pi(1,j) \preceq \pi(0,j)$. By assumption there exists a path $P$ with $\pi(P(1)) = \pi(0,1)$, $P(J) = (1,j)$ such that $d^{P(i)} \neq (-1,0)$ for any $i = 1$, ..., $J-1$. Extending $P$ to a longer path by setting $P(J+1) = (0,j)$ it follows that $\pi(0,1) \preceq \pi(0,j)$. Actually we have that $\pi(0,1) \prec \pi(0,j)$, for otherwise, as shown before in the case of $\pi(1,1)$, we could construct a cycle $Q$ of step $K$ starting at $Q(1) = (1,j)$ such that $d^{(1,j)} = (1,0)$ and $d^{Q(k)} \neq (-1,0)$ for any $k = 2$, ..., $K-1$, contradicting the hypothesis.

But then we have that $\pi(0,j) \in X(1) \cap Y(1) = \emptyset$, that is impossible. Therefore $d^{0,j} \neq (-1,0)$ and the proof of the claim, and then of the proposition, is completed.

The assumption of Proposition 6.5 has the advantage of being verifiable just by looking at all the possible cycles starting from the degenerate edges of a stratified straight graph.

In the next example we show that the assumption of Proposition 6.5 is also necessary, and thus the statement of such proposition is sharp.

Example 6.6. Here we give a simple but remarkable example of a graph $G$ with assigned angles such that every junction of $G$ has order at most 4 and that, if $p$ is a junction with $\pi^{-1}(p) = \{(z_1,i_1), ..., (z_k,i_k)\}$, then the vectors $d^{z_1,i_1}, ..., d^{z_k,i_k}$ form angles equal to $\frac{n\pi}{2}$ with $n \in \{1,2,3\}$; moreover $G$ is stratified straight, but it is not straight, and in fact the assumption of Proposition 6.5 is violated.

Consider the image in $\mathbb{R}^2$ of the regular network drawn in Figure 10.

![Figure 10: In the picture we have the image in $\mathbb{R}^2$ of a regular network $(G, \Gamma)$.](image-url)
Such graph $G$ is stratified straight, in fact one can easily construct a sequence of maps $\Gamma_n : G \to \mathbb{R}^2$ such that $(G, \Gamma_n)$ is regular and $\Gamma_n$ converges strongly in $H^2$ to a constant map, i.e. the image of the graph disappears with elastic energy going to zero. However $G$ is not straight and a stratification of $G$ is given by

$$H_0 = G, \quad H_1 = E_1 \cup E_3.$$ 

We remark that, in fact, the assumption of Proposition 6.5 is not satisfied. More generally we see that as long as a stratified straight subgraph $H$ contains a cycle like the one in Figure 10, then $H$ is not straight, the assumption of Proposition 6.5 is not satisfied, and its proof does not work.

## 7 Side Remarks

### 7.1 Curves on surfaces/manifolds

We comment on the fact that the very same kind of definitions about degenerate networks characterize a suitably defined problem for networks of curves into a 2-dimensional surface in $\mathbb{R}^3$.

Fix a 2-dimensional closed surface $S \subset \mathbb{R}^3$ and consider a network $N = (G, \Gamma)$ with $\Gamma : G \to S$. Given a curve $\gamma : I \to S$, the geodesic curvature is given by

$$\vec{\kappa}_g(t) = \pi T_{\gamma(t)}^S \vec{\kappa}(t),$$

where $\vec{\kappa}(t)$ is the standard curvature of $\gamma$ seen as a curve in $\mathbb{R}^3$ and $T_x S$ is the tangent plane to $S$ at the point $x \in S$. Therefore we define the general elastic energy of the curve $\gamma$ as

$$E_{\alpha,\beta}(\gamma) := \alpha \int_\gamma |\vec{\kappa}_g|^2 \, ds + \beta L(\gamma).$$

(7.1)

Observe that, since the normal component of the curvature vector $\vec{\kappa}$ of $\gamma$ is bounded in terms of the second fundamental form of $S$, then a bound on $E_{\alpha,\beta}$ actually is a bound on the $L^2$ norm of the whole vector $\vec{\kappa}$.

Analogous definitions of angle condition and degenerate network can be given for the class of networks having image in $S$. So, the compactness result of Proposition 3.8 can be still easily proved in this case. Then, also the proof of the recovery sequence presented in Proposition 4.2 can be adapted to the current situation. Maintaining the notation of the proof of Proposition 4.2, let us say that $H_0 \subset \text{Sing } N$ is connected and $\Gamma(H_0) = p \in S$; we want to provide an immersion of $H_0$ in $S$. Since $S$ is a surface, there exists a local chart $\varphi : U \to \mathbb{R}^2$ at $p$ such that $\varphi$ is isothermal, i.e. the metric tensor $g$ of $S$ can be expressed as $g_{ij} = \lambda^2 \delta_{ij}$ on $U$ in the chart $\varphi$. In particular we have that $\varphi$ is a conformal diffeomorphism with its image and its differential preserves angles between tangent vectors. Hence we can construct immersions of $H_0$ in $\varphi(U)$ exactly as in Proposition 4.2 and then we get the desired recovery sequence by applying $\varphi^{-1}$.

### 7.2 Fixed length

We briefly discuss here an easier variant of Problem 2.12 of some interest in the applications.

**Remark 7.1 (Fixed length).** Putting $\alpha = 1$ and $\beta = 0$ into (2.3), the functional $\tilde{E}$ reduces to the Willmore functional for networks that we denote by $\mathcal{W}$. 

28
Problem 7.2. Given an $N$–graph $G$ with assigned angles we consider
\[
\inf \{ \mathcal{W}(N) \mid N = (G, \Gamma) \in \mathcal{C}_{\text{Reg}} \text{ with } \ell(N^1), \ldots, \ell(N^N) \text{ fixed} \}. 
\]
It is easy to prove that Problem 7.2 admits a minimizer in the class of regular networks by a direct method in the Calculus of Variations, as we shall now briefly sketch.

Consider a minimizing sequence of networks $\{N_n\}_{n \in \mathbb{N}}$ composed of curves $\gamma_n^i$. Combining the bounds (3.3), (3.4) and (3.5) together with the fact that the length of each curve is fixed, we get that up to subsequence each $\gamma_n^i$ converges to a regular curve $\gamma^i$ weakly in $H^2$. The limit networks satisfies the angle condition in the sense of Definition 2.10 thanks to the strong $C^1$ convergence. Moreover the functional $\mathcal{W}$ is clearly lower semicontinuous.

Notice that fixing the length of each curve avoids any form of degeneracy of the limit networks and makes the question on existence of minimizers trivial.

A Critical points

We want now to derive the Euler Lagrange equations satisfied by regular critical points of the functional $\mathcal{E}$.

Let $\mathcal{N}$ be a regular network whose curves are parametrized by arclength by $\gamma : [0, \ell(\gamma)] \to \mathbb{R}^2$. We denote by $s$ the arclength parameter of $\gamma^i$. We recall that $\partial_s \gamma = \tau$ and $\partial_s \tau = \vec{k}$. For sake of notation we introduce the operator $\partial_s^\perp$ that acts on a vector field $\varphi$ giving the normal component of $\partial_s \varphi$ along the curve $\gamma$, that is
\[
\partial_s^\perp \varphi = \partial_s \varphi - \langle \partial_s \varphi, \partial_s \gamma \rangle \partial_s \gamma.
\]
Similarly we call $\partial_s^\parallel \varphi := \langle \partial_s \varphi, \partial_s \gamma \rangle \partial_s \gamma = \langle \partial_s \varphi, \tau \rangle \tau$. In $\mathbb{R}^2$ it holds that $\partial_s^\perp \varphi = \langle \partial_s \varphi, \nu \rangle \nu$, where $\nu$ is the counterclockwise rotation of $\partial_s \gamma$ by an angle equal to $\frac{\pi}{2}$.

We compute a “regular” variation $N_\varepsilon$ of $N$. Each curve of $\mathcal{N}$ is parametrized by arclength by $\gamma^i$. Let us consider $\varepsilon \in \mathbb{R}$ and smooth functions $\psi^i : [0, \ell(\gamma^i)] \to \mathbb{R}^2$. This defines the variation $\gamma^i_\varepsilon : [0, \ell(\gamma^i)] \to \mathbb{R}^2$ of a curve $\gamma^i$ by setting $\gamma^i_\varepsilon := \gamma^i + \varepsilon \psi^i$. Observe that the variation $\gamma^i_\varepsilon$ is not necessarily parametrized by arclength. However, for $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$ with $\varepsilon_0 > 0$ sufficiently small, $\gamma^i_\varepsilon$ is a regular curve with tangent vector $\tau^i_\varepsilon = \frac{\partial_s \gamma^i_\varepsilon + \varepsilon \partial_s \psi^i}{|\partial_s \gamma^i_\varepsilon + \varepsilon \partial_s \psi^i|}$.

Consider a junction of order $m$ of $\mathcal{N}$, so that
\[
\gamma^{i_1}(z_1) = \ldots = \gamma^{i_m}(z_m),
\]
with $(z_1, i_1), \ldots, (z_m, i_m) \in \{0, \ell(\gamma^{i_1}), \ldots, \ell(\gamma^{i_m})\} \times \{1, \ldots, N\}$ all distinct. The scalar product of unit tangent vectors is given by
\[
\langle \tau^{i_1}(z_1), \tau^{i_2}(z_2) \rangle = c^{1,2}, \ldots, \langle \tau^{i_{m-1}}(z_{m-1}), \tau^{i_m}(z_m) \rangle = c^{m-1,m}.
\]
To generate admissible competitors for the Problem 2.12 for any $\varepsilon$ small enough, we need to require that
\[
\gamma^i_{\varepsilon}(z_1) = \ldots = \gamma^i_{\varepsilon}(z_m),
\]
together with the fact that the angle condition is preserved, that is to say that for every $i, j, z, w$ such that $\gamma^i(z) = \gamma^j(w)$ it holds that
\[
\frac{d}{d\varepsilon} \langle \tau^i_{\varepsilon}(z), \tau^j_{\varepsilon}(w) \rangle = 0,
\]
29
for every $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$.

First this implies that the variation fields $\psi^i$ satisfy that

$$\psi^{i1}(z_1) = \ldots = \psi^{im}(z_m). \quad \text{(A.1)}$$

Secondly, writing

$$\partial_s \psi^i = \partial_s^1 \psi^i + \partial_s^2 \psi^i = \langle \partial_s \psi^i, \nu^i \rangle \nu^i + \langle \partial_s \psi^i, \tau^i \rangle \tau^i =: \tilde{\psi}_s^i \nu^i + \tilde{\psi}_s^i \tau^i,$$

a direct calculation yields

$$0 = \frac{d}{d\varepsilon} \langle \tau^i(z), \tau^j(w) \rangle = \left\langle \frac{\partial_s \psi^i - \langle \partial_s \psi^i, \tau^i \rangle \tau^i}{|\partial_s \gamma^i + \varepsilon \partial_s \psi^i|}, \tau^i(z) \right\rangle + \left\langle \frac{\partial_s \psi^i - \langle \partial_s \psi^i, \tau^i \rangle \tau^i}{|\partial_s \gamma^i + \varepsilon \partial_s \psi^i|}, \tau^i(w) \right\rangle.$$

Evaluating at $\varepsilon = 0$ we get

$$0 = \left\langle \frac{\partial_s^1 \psi^i(z)}{\partial_s^1 \gamma^i}, \tau^i(w) \right\rangle + \left\langle \tau^i(z), \frac{\partial_s^2 \psi^i(w)}{\partial_s^2 \gamma^i} \right\rangle
\tilde{\psi}_s^i(z) \langle \nu^i(z), \tau^i(w) \rangle + \tilde{\psi}_s^i(w) \langle \tau^i(z), \nu^i(w) \rangle
\tilde{\psi}_s^i(z) \langle \nu^i(z), \tau^i(w) \rangle - \tilde{\psi}_s^i(w) \langle \nu^i(z), \tau^i(w) \rangle.$$

Therefore as a second requirement on the fields $\psi^i$ we impose that

$$\tilde{\psi}_s^i(z_1) = \ldots = \tilde{\psi}_s^i(z_m). \quad \text{(A.2)}$$

**Definition A.1.** Consider a regular network $\mathcal{N} = (G, \Gamma)$ composed of the curves $\gamma^i$ parametrized by arclength with $i \in \{1, \ldots, N\}$, $\varepsilon \in \mathbb{R}$ and smooth functions $\psi^i : [0, \ell(\gamma^i)] \to \mathbb{R}^2$. We say that $\mathcal{N}_\varepsilon$ composed of the curves $\gamma^i_\varepsilon = \gamma^i + \varepsilon \psi^i$ is a regular variation of $\mathcal{N}$ if the functions $\psi^i$ satisfy the properties (A.1) and (A.2).

**Definition A.2.** A regular network $\mathcal{N} = (G, \Gamma)$ is a critical point for the functional $\mathcal{E}$ if for every regular variation $\mathcal{N}_\varepsilon$ of $\mathcal{N}$ it holds

$$\frac{d}{d\varepsilon} \mathcal{E}(\mathcal{N}_\varepsilon)|_{\varepsilon=0} = 0.$$

We recall that the oriented curvature of a planar curve $\gamma$ is defined as the scalar $k$ such that $\tilde{k} = k \nu$ where the unit normal vector $\nu$ is the counterclockwise rotation of $\frac{\tilde{\gamma}}{\|\tilde{\gamma}\|}$ of the unit tangent vector $\tau$ to the curve $\gamma$.

**Proposition A.3.** Let $\mathcal{N} = (G, \Gamma)$ be a critical point for $\mathcal{E}$. Then the arclength parametrization $\gamma^i : [0, \ell(\gamma^i)] \to \mathbb{R}^2$ of any curve of $\mathcal{N}$ is real analytic and satisfies the equation

$$2(\partial_s^2 \tilde{k}^i)^2 \tilde{k}^i + |\tilde{k}^i|^2 \tilde{k}^i - \tilde{k}^i = 0 \quad \text{on } (0, \ell(\gamma^i)), \quad \text{(A.3)}$$

or, equivalently, in terms of the oriented curvature

$$2\partial_s^2 k^i + (k^i)^3 - k^i = 0 \quad \text{on } (0, \ell(\gamma^i)).$$
Also, the curves satisfy the following boundary conditions. If \( p = \pi(z_1, i_1) = \ldots = \pi(z_m, i_m) \) is a junction of order \( m \) of \( N \), then

\[
\sum_{(z_j,i_j) \in \pi^{-1}(p): \atop z_j = \ell(\gamma^j)} k^{ij}(\ell(\gamma^j)) = \sum_{(z_j,i_j) \in \pi^{-1}(p): \atop z_j = \ell(\gamma^j)} k^{ij}(0),
\]

(A.4)

\[
\sum_{(z_j,i_j) \in \pi^{-1}(p): \atop z_j = \ell(\gamma^j)} \left[ 2\partial_{\bar{s}}^j k^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{\ell(\gamma^j)} = \sum_{(z_j,i_j) \in \pi^{-1}(p): \atop z_j = \ell(\gamma^j)} \left[ 2\partial_{\bar{s}}^j \bar{k}^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{0}.
\]

(A.5)

**Remark A.4.** Let us observe that the boundary conditions (A.4) and (A.5) do not depend on the parametrizations of the curves \( \gamma^i \). More precisely, even if such boundary conditions are expressed in terms of quantities evaluated at 0 or at \( \ell(\gamma^j) \), if a curve \( \gamma^j \) is reparametrized into the new arclength parametrized immersion \( \bar{\gamma}^j(t) = \gamma^j(\ell(\gamma^j) - t) \), then

\[
\bar{k}^{ij}(\ell(\gamma^j)) = -k^{ij}(0), \quad \bar{k}^{ij}(0) = -k^{ij}(\ell(\gamma^j)),
\]

\[
\left[ 2\partial_{\bar{s}}^j \bar{k}^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{\ell(\gamma^j)} = -\left[ 2\partial_{\bar{s}}^j k^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{0},
\]

\[
\left[ 2\partial_{\bar{s}}^j \bar{k}^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{0} = -\left[ 2\partial_{\bar{s}}^j k^{ij} + (k^{ij})^2 \tau^j - \tau^{ij} \right]_{\ell(\gamma^j)},
\]

where symbols with the tilde identify the obvious geometric quantities in terms of the parametrization \( \gamma^k \).

**Proof of Proposition A.3.** In order to calculate the first variation of the functional, we can fix a junction \( p \) of \( N \) of order \( m \) and consider a regular variation given by fields \( \psi^{ij} \) for \( j = 1, \ldots, m \) such that: if \( \pi(z_j, i_j) = p \) but \( \pi(1 - z_j, i_j) \neq p \), then \( \psi^{ij} \equiv 0 \) in a neighborhood of \( 1 - z_j \). By direct computations (for the details for example see [7]) one shows that the curves are of class \( C^\infty \) and they satisfy the first variation formula

\[
\frac{d}{dc} \mathcal{E}(N_c)|_{c=0} = \sum_{j=1}^{m} \int_{\gamma^j} \left\langle 2(\partial_{\bar{s}}^j)^2 \bar{k}^{ij} + |\bar{k}^{ij}|^2 \tau^{ij} - \bar{k}^{ij}, \psi^{ij} \right\rangle \, ds
\]

\[\quad + \sum_{j=1}^{m} \left[ 2 \left( \bar{k}^{ij}, \partial_{s} \psi^{ij} \right)_{0}^{\ell(\gamma^j)} + \left( -2\partial_{\bar{s}}^j \bar{k}^{ij} - |\bar{k}^{ij}|^2 \tau^{ij} + \tau^{ij}, \psi^{ij} \right)_{0}^{\ell(\gamma^j)} \right] = 0.\]

This immediately leads to the interior equations (A.3).

In order to get the boundary conditions, we can first set

\[
\psi^{ij}(0) = \psi^{ij}(\ell(\gamma^j)) = 0,
\]

so that

\[
\sum_{j=1}^{m} \bar{\psi}^{ij}_{s} \bar{k}^{ij}_{0}^{\ell(\gamma^j)} = 0,
\]

and by (A.2) we get the first boundary condition (A.4) Similarly, letting \( \bar{\psi}^{ij}_{s}(0) = \bar{\psi}^{ij}_{s}(\ell(\gamma^j)) = 0 \) and using (A.1), the second boundary condition (A.5) is achieved.
Now we prove that each $\gamma^i$ is an analytic curve. Fix $i = 1$, and suppose that $\pi(0, 1)$ is a junction of order $m$. The first boundary condition equation gives that

$$k^1(0) = \sum_{(z_j, i_j) \in \pi^{-1}(p): z_j = \ell(\gamma^i)} k^i_j(\ell(\gamma^i)) - \sum_{(z_j, i_j) \in \pi^{-1}(p): z_j = 0, j \neq 1} k^i_j(0) =: C_1.$$ 

While, since $\langle \partial^s_\perp \vec{k}^1(0), \nu^1(0) \rangle = \partial_s k^1(0)$, by multiplying the second boundary condition equation by $\nu^1(0)$ we can write that

$$\partial_s k^1(0) = \frac{1}{2} \sum_{(z_j, i_j) \in \pi^{-1}(p): z_j = \ell(\gamma^i)} \left[ 2 \partial^s_\perp k^i_j + (k^i_j)^2 \tau^i_j - \tau^i_j \right] |_{\ell(\gamma^i)} +$$

$$- \sum_{(z_j, i_j) \in \pi^{-1}(p): z_j = 0, j \neq 1} \left[ 2 \partial^s_\perp k^i_j + (k^i_j)^2 \tau^i_j - \tau^i_j \right] |_0, \nu^1(0) \right) =: C_2.$$ 

Therefore a direct application of the Cauchy-Kovaleskaya Theorem (see for instance [10, p.240]) on the Cauchy problem

$$\begin{cases}
2 \partial^2_\perp k^1 + (k^1)^2 - k^1 = 0 & \text{on } [0, \varepsilon), \\
k^1(0) = C_1, \\
\partial_s k^1(0) = C_2,
\end{cases}$$

gives that $k^1$ is real analytic on some interval $[0, \varepsilon)$. Analogously, the same holds on $(\ell(\gamma^1) - \varepsilon, \ell(\gamma^1)]$, and therefore $k^1$ is real analytic. Writing $\tau^1(s) = (\cos(\theta(s)), \sin(\theta(s)))$ we get that

$$\partial_s \tau^1 = (-\sin(\theta), \cos(\theta)) \partial_s \theta,$$

so that

$$k^1(s) = \partial_s \theta(s).$$

Hence $\theta$ is analytic, that implies that $\partial_s \gamma^1 = \tau^1$ is analytic, and so is $\gamma^1$. By the arbitrary of the choice of $\gamma^1$, the result follows for each $\gamma^i$.
