Slow Recurrences

Sam Spiro

September 17, 2019

Abstract

For positive integers $\alpha$ and $\beta$, we define an $(\alpha, \beta)$-walk to be any sequence of positive integers satisfying $w_{k+2} = \alpha w_{k+1} + \beta w_k$. We say that an $(\alpha, \beta)$-walk is $n$-slow if $w_s = n$ with $s$ as large as possible. Slow $(1,1)$-walks have been investigated by several authors. In this paper we consider $(\alpha, \beta)$-walks for arbitrary positive $\alpha, \beta$. We derive a characterization theorem for these walks, and with this we prove several results concerning the total number of $n$-slow walks for a given $n$. In addition to this, we study the slowest $n$-slow walk for a given $n$ amongst all possible $\alpha, \beta$.

1 Introduction

Let $\alpha, \beta$ be relatively prime positive integers. Given a pair of positive integers $(a_1, a_2)$, we define its associated $(\alpha, \beta)$-walk $w_k^{\alpha, \beta} = w_k^{\alpha, \beta}(a_1, a_2)$ to be the sequence with $w_1^{\alpha, \beta} = a_1$, $w_2^{\alpha, \beta} = a_2$, and $w_{k+2}^{\alpha, \beta} = \alpha w_{k+1}^{\alpha, \beta} + \beta w_k^{\alpha, \beta}$ for $k \geq 1$.

Given $n$, we are interested in finding $(\alpha, \beta)$-walks which have $n = w_k^{\alpha, \beta}$ for some $k$. Trivial examples of this include $w_k^{\alpha, \beta}(x, n)$ for any $x$. In order to make the problem more interesting, we will demand that our walks generate $n$ as slowly as possible. To this end, define $s^{\alpha, \beta}(n; a_1, a_2)$ to be the integer $s$ such that $w_s^{\alpha, \beta}(a_1, a_2) = n$, with this value being $-\infty$ if no such $s$ exists. Let $s^{\alpha, \beta}(n) = \max_{a_1, a_2 \geq 1} s^{\alpha, \beta}(n; a_1, a_2)$. We will say that $(a_1, a_2)$ is $(n, \alpha, \beta)$-good.

*Dept. of Mathematics, UCSD ssapiro@ucsd.edu. This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1650112.
if \(a_1, a_2 \geq 1\) and if \(s^{\alpha, \beta}(n) = s^{\alpha, \beta}(n; a_1, a_2)\). If \((a_1, a_2)\) is an \((n, \alpha, \beta)\)-good pair, then we will say that its associated sequence \(w^{\alpha, \beta}_k(a_1, a_2)\) is an \(n\)-slow \((\alpha, \beta)\)-walk.

For example, it is easy to verify that \(s^{1,1}(6) = 4\) and that the only 6-slow \((1, 1)\)-walks are \(w^{1,1}_k(2, 2)\) and \(w^{1,1}_k(4, 1)\). As another example, observe that \(s^{\alpha, \beta}(1) = 2\) for all \(\alpha, \beta \geq 1\) since \(w^{\alpha, \beta}_3(a_1, a_2) = \alpha a_1 + \beta a_2 \geq 2\) when \(a_1, a_2 \geq 1\). Thus for all \(\alpha, \beta\) we have that \((x, 1)\) is a \((1, \alpha, \beta)\)-good pair for all \(x\). Similarly, if \(s^{\alpha, \beta}(n) = 2\), then \((x, n)\) will be an \((n, \alpha, \beta)\)-good pair for all \(x\). Because of this, the only \(n\) which have “interesting” \(n\)-slow walks are those with \(s^{\alpha, \beta}(n) > 2\).

The case \(\alpha = \beta = 1\) has been considered several times \([2, 4, 8]\), and a number of results for this case have been produced independently by several authors \([1, 5, 6]\). In particular, one can prove a certain “characterization theorem” that completely classifies \((n, 1, 1)\)-good pairs given any choice of \(n\).

The main goal of this paper is to prove a generalized characterization theorem for \((\alpha, \beta)\)-walks. When \(\beta = 1\) this result and proof is quite similar to the \(\alpha = \beta = 1\) case. However, for \(\beta > 1\) the situation becomes somewhat more complicated. To state our result, we first define a generalization of the Fibonacci numbers. Let \(g^{\alpha, \beta}_k\) denote the sequence with

\[
g^{\alpha, \beta}_1 = 1, \quad g^{\alpha, \beta}_2 = \alpha,
\]

\[
g^{\alpha, \beta}_k = \alpha g^{\alpha, \beta}_{k-1} + \beta g^{\alpha, \beta}_{k-2} \quad \text{for} \quad k \geq 1.
\]

Also define

\[
\gamma_{\alpha, \beta} = \frac{1}{2}(\alpha + \sqrt{\alpha^2 + 4\beta}), \quad \lambda_{\alpha, \beta} = \frac{1}{2}(\alpha - \sqrt{\alpha^2 + 4\beta}).
\]

Note that if \(f_k\) denotes the \(k\)th Fibonacci number and \(\phi\) denotes the golden ratio, then we have \(g^{1,1}_k = f_k\) and \(\gamma_{1,1} = \phi\).

**Theorem 1.1.** Let \(\alpha, \beta\) be relatively prime positive integers. Let \(n\) be such that \(s = s^{\alpha, \beta}(n) > 2\). Then there exists unique integers \(a = a^{\alpha, \beta}(n), b = b^{\alpha, \beta}(n), \) and \(t = t^{\alpha, \beta}(n)\) satisfying the following.

- \(n = ag^{\alpha, \beta}_t + \beta bg^{\alpha, \beta}_{t-1}\).
- \(t \geq 2, \quad a \leq (\beta - 1)g^{\alpha, \beta}_{t+1} + \alpha b, \) and \(b \leq g^{\alpha, \beta}_t\).
- \(a - \alpha b - \ell g^{\alpha, \beta}_{t+1}\) is not a positive multiple of \(\beta\) for any \(\ell \geq 0\).
Further, we have the following.

- The pair \((b, a)\) is \((n, \alpha, \beta)\)-good and \(s = t + 1\).
- We have \(|w_{s+1}^{\alpha, \beta}(b, a) - \gamma_{\alpha, \beta}n| = |\lambda_{\alpha, \beta}^t(\gamma_{\alpha, \beta}b - a)| \leq 2\beta^{t+1}\).
- A pair \((b', a')\) of positive integers is \((n, \alpha, \beta)\)-good if and only if \((b', a') = (b + kg_t^{\alpha, \beta}, a - k\beta g_{t-1}^{\alpha, \beta})\) for some \(k \geq 0\).
- With \(a', b', k\) as above, we have \(w_{s+1}^{\alpha, \beta}(b', a') - w_{s+1}^{\alpha, \beta}(b, a) = k(-\beta)^t\).

In Lemma 3.3 we show that \(s^{\alpha, \beta}(n) > 2\) provided \(n > \alpha\beta\), so for any fixed \(\alpha, \beta\) this theorem applies to all but finitely many \(n\).

For the rest of the paper we omit writing \(\alpha, \beta\) whenever these are clear from context. For example, we write \(g_k\) instead of \(g_k^{\alpha, \beta}\), say that a pair is \(n\)-good instead of \((n, \alpha, \beta)\)-good, and so on. We also will assume \(\alpha, \beta\) are positive relatively prime integers unless stated otherwise. As usual, let \([x]\) denote the floor of \(x\) and let \(\lceil x \rceil\) denote the ceiling of \(x\).

One can prove a number of results concerning slow walks by utilizing Theorem 1.1. For example, let \(p(n) = p^{\alpha, \beta}(n)\) denote the number of \(n\)-good pairs.

**Theorem 1.2.** Let \(\alpha, \beta\) be relatively prime positive integers.

- If \(s(n) > 2\), then \(p(n) \leq \alpha^2 + 2\beta - 1\). Moreover, there exists an \(n\) achieving this bound.

- There exist infinitely many \(n\) with
  \[
p(n) = \lceil \gamma^2 \rceil - 1 = \alpha^2 + \beta + \lceil \alpha\beta^{-1} \rceil - 1,
\]
  and only finitely many \(n\) with
  \[
p(n) \geq \lceil \gamma^2 \rceil = \alpha^2 + \beta + \lceil \alpha\beta^{-1} \rceil.
\]

- There exists infinitely many \(n\) with \(p(n) = \alpha^2 + 2\beta - 1\) if and only if \(\alpha \geq \beta\).

One can prove a density result for the number of \(n\) with \(p(n) > p\). To this end, for \(p\) an integer, let \(S_p = \{m : p(m) > p\}\). We emphasize that \(S_p\) is
the set consisting of \( n \) with strictly more than \( p \) good pairs. For \( c \) real and \( r \) an integer, define \( n_{c,r} := \left\lfloor \frac{c \beta}{(\gamma - \lambda)^2} \gamma^{2r+1} \right\rfloor \).

**Theorem 1.3.** Let \( \alpha, \beta \) denote relatively prime positive integers. Given an integer \( p \), let \( d \) denote the smallest integer such that \( \delta := \beta \gamma^{-1} p - \gamma d \leq \alpha \). If \( \beta \leq p \leq \lceil \gamma^2 \rceil - 2 \) and \( 1 \leq c \leq (p - \beta + 1)\gamma/\alpha \), then

\[
|n_{c,r}|S_p \cap [n_{c,r}]| = c^{-1} \left( \frac{(2\beta - 2d - 1)\gamma(\alpha - 2\delta + \alpha^{-1}\delta^2)}{2\beta^2(\gamma^2 - 1)} + \frac{\gamma^2}{\gamma^2 - 1} \sum_{q=d+1}^{\beta-1} \frac{\beta - q}{\beta^2} \right) + O(\gamma^{-r} + (\beta \gamma^{-2})^r).
\]

A few comments are in order. The first is that for \( p \geq \lceil \gamma^2 \rceil - 1 \) the density of \( S_p \) is 0 by Theorem 1.2, so it makes sense to only consider \( p \leq \lceil \gamma^2 \rceil - 2 \). Because \( \beta \gamma^{-2} < 1 \) for all \( \alpha \), this error term is \( o(1) \), though it is the case that \( \beta \gamma^{-2} \) can be made arbitrarily close to 1. We note that this result implies in particular that \( \lim_{n \to \infty} n^{-1}|S_p \cap [n]| \) does not exist, and instead this exact value oscillates with \( n \). We have included concrete examples and data illustrating these density results in the Appendix.

The statement of Theorem 1.3 becomes significantly cleaner if \( d = \beta - 1 \), which occurs when \( p \) is sufficiently large. Specifically, we will show the following.

**Corollary 1.4.** Let \( \alpha, \beta \) be relatively prime integers. For \( p \) an integer, let \( \delta = \beta \gamma^{-1} p - \gamma(\beta - 1) \). If \( \max\{\beta, \lceil (1 - \beta^{-1}) \gamma^2 \rceil \} \leq p \leq \lceil \gamma^2 \rceil - 2 \) and \( 1 \leq c \leq (p - \beta + 1)\gamma/\alpha \), then

\[
n_{c,r}^{-1}|S_p \cap [n_{c,r}]| = \gamma(\alpha - 2\delta + \alpha^{-1}\delta^2) \frac{2\beta^2(\gamma^2 - 1)}{2c\gamma^2} + O(\gamma^{-r} + (\beta \gamma^{-2})^r).
\]

When \( \beta = 1 \), the statement of Corollary 1.4 becomes even simpler.

**Corollary 1.5.** Let \( \alpha \) and \( 1 \leq p \leq \alpha^2 \) be integers and \( 1 \leq c \leq p\gamma/\alpha \) real. Then

\[
n_{c,r}^{-1}|S_p \cap [n_{c,r}]| = \frac{1}{2} c^{-1}(1 - (\alpha \gamma)^{-1}p)^2 + O(\gamma^{-r}).
\]

In particular, for \( p = \alpha^2 \) and \( 1 \leq c \leq \alpha \gamma \) we have

\[
n_{c,r}^{-1}|S_p \cap [n_{c,r}]| = \frac{1}{2} c^{-1} \gamma^{-4} + O(\gamma^{-r}).
\]
Given $n$, one might ask how slow the slowest $n$-slow walk is. To this end, we define
\[ s(n) = \max_{\alpha, \beta \geq 1, \gcd(\alpha, \beta) = 1} s^{\alpha, \beta}(n), \]
as well as the set of $\alpha, \beta$ pairs achieving this value,
\[ S(n) = \{ (\alpha, \beta) : s^{\alpha, \beta}(n) = s(n) \}. \]

A priori, any pair $(\alpha, \beta)$ could be an element of $S(n)$ for some $n$. However, it turns out that only a finite number of pairs have this property.

**Theorem 1.6.** Let $R = \{ (1,1), (2,1), (1,2), (1,3), (1,4) \}$:

- For all $n > 1$, we have $S(n) \subseteq R$.
- For all $(\alpha, \beta) \in R$, there exists an $n$ with $(\alpha, \beta) \in S(n)$.
- The set of $n$ with $S(n) = \{ (1,1) \}$ has density 1.

The rest of the paper is organized as follows. In Section 2 we prove Theorem 1.1. In Section 3 we apply this result to prove Theorem 1.2, along with several other results about slow walks. In Section 4 we develop a general theory for proving density results for $n$-slow walks, and we use this theory to prove Theorem 1.3. In Section 5 we prove results concerning slowest $n$-slow walks. We end with some open problems in Section 6.

Throughout this paper we use various identities and inequalities involving $\gamma$ and $\lambda$ to simplify our expressions. Essentially all of these identities follow from the fact that these are the two solutions to the equation $x^2 = \alpha x + \beta$, and all of the inequalities are immediate from the definitions. In particular, we will make frequent use of the following:

- $\gamma^2 = \alpha \gamma + \beta$,
- $\gamma + \lambda = \alpha$,
- $\gamma \lambda = -\beta$,
- $\lambda < 0$,
- $\gamma > \alpha, \beta^{1/2}, |\lambda|$.
2 The Characterization Theorem

Recall that we assume that $\alpha$ and $\beta$ are relatively prime positive integers. We adopt the convention that $g_0 = 0$ and $g_{-1} = \beta^{-1}$. Note that with this we have $g_{k+2} = \alpha g_{k+1} + \beta g_k$ for all $k \geq -1$.

The sequence $g_k$ is very similar to the Fibonacci numbers $f_k$. In particular, we have the following.

Lemma 2.1.

(a) For $k \geq 1$, $\gcd(g_k, \beta) = 1$.

(b) For $k \geq 1$, $\gcd(g_{k+1}, \beta g_k) = 1$.

(c) For $k \geq -1$, $g_{k+1}^2 - g_k g_{k+2} = (-\beta)^k$.

(d) For $k \geq -1$, we have $g_k = \frac{\gamma^k - \lambda^k}{\gamma - \lambda}$.

Proof. Observe that (a) and (b) hold for $k = 1$, and that (c) holds for $k = -1, 0$. For (a), inductively assume that we have proven the statement up to $k > 1$. We then have

$$\gcd(g_k, \beta) = \gcd(\alpha g_{k-1} + \beta g_{k-2}, \beta) = \gcd(\alpha g_{k-1}, \beta) = 1,$$

where we used that both $\alpha$ and $g_{k-1}$ are relatively prime to $\beta$.

For (b), inductively assume we have proven the statement up to $k > 1$. We then have

$$\gcd(g_{k+1}, g_k) = \gcd(\alpha g_k + \beta g_{k-1}, g_k) = \gcd(\beta g_{k-1}, g_k) = 1.$$

This shows that $g_{k+1}$ is relatively prime to $g_k$. We know that $g_{k+1}$ is also relatively prime to $\beta$ by (a), so we conclude the result.

For (c), inductively assume we have proven the statement up to $k > 0$. We then have

$$g_{k+1}^2 - g_k g_{k+2} = (\alpha g_k + \beta g_{k-1}) g_{k+1} - (\alpha g_{k+1} + \beta g_k) g_k$$
$$= \beta g_{k-1} g_{k+1} - \beta g_k^2 = -\beta (-\beta)^{k-1} = (-\beta)^k.$$

The formula in (d) is well known, see [9], for example. The statement can also be proven inductively, or by plugging the formula into the recurrence relation. \qed
We can use $g_k$ to write formulas for $w_k(b,a)$ and $w_{k+1}(b,a)$.

**Lemma 2.2.** The following formulas hold for $a, b, k \geq 1$.

(a) \[ w_k(b,a) = ag_{k-1} + \beta bg_{k-2}. \]

(b) \[ w_{k+1}(b,a) = \gamma w_k(b,a) + \lambda^{k-1}(a - \gamma b). \]

**Proof.** The statement for (a) is true for $k = 1, 2$, and an easy induction argument gives the full result. For (b), we use (a) and the closed form for $g_k$ provided by Lemma 2.1(d) to conclude that

\[
(\gamma - \lambda)w_{k+1}(b,a) = a(\gamma^k - \lambda^k) + \beta b(\gamma^{k-1} - \lambda^{k-1})
\]
\[
= (a(\gamma^k - \gamma \lambda^{k-1}) + \beta b(\gamma^{k-1} - \gamma \lambda^{k-2})
\]
\[
+ a(\gamma \lambda^{k-1} - \lambda^k) + \beta b(\gamma \lambda^{k-2} - \lambda^{k-1})
\]
\[
= (\gamma - \lambda)w_k(b,a) + \lambda^{k-1}(\gamma - \lambda)(a + \beta \lambda^{-1}b).
\]

Dividing both sides by $\gamma - \lambda$ and using $\lambda^{-1} = -\beta^{-1}\gamma$ gives the final result. \qed

**Corollary 2.3.** Let $n$ be a positive integer with $s(n) = s$. Then there exists no $a', b' \geq 1$ with $n = a'g_s + \beta b'g_{s-1}$. Moreover, $(b,a)$ is an $n$-good pair if and only if $n = ag_{s-1} + \beta bg_{s-2}$ and $a, b \geq 1$.

**Proof.** If there existed such $a', b'$, then this would imply that $w_{s+1}(b', a') = n$ by Lemma 2.2(a), a contradiction to how $s$ was defined. If $(b,a)$ is an $n$-good pair, then again by this lemma we have $n = w_s(b,a) = ag_{s-1} + \beta bg_{s-2}$. Conversely, if $n = ag_{s-1} + \beta bg_{s-2}$, then $w_k(b,a)$ satisfies $w_s(b,a) = n$, so this pair is $n$-good. \qed

We can now derive some structural results for $n$-good pairs.

**Lemma 2.4.** Let $(b,a)$ be an $n$-good pair with $s = s(n) > 2$.

(a) $a - ab - \ell g_s$ is not a positive multiple of $\beta$ for any $\ell \geq 0$.

(b) The pair $(b', a')$ is $n$-good if and only if there exists some $k \in \mathbb{Z}$ such that $a' = a + \beta k g_{s-2} \geq 1$ and $b' = b - kg_{s-1} \geq 1$. 

7
(c) With $a', b'$, and $k$ as above, we have $w_{s+1}(b', a') - w_{s+1}(b, a) = k(-\beta)^{s-1}$.

Proof. For (a), assume that this were not the case for some $\ell \geq 0$. Set $a' = b + \ell g_{s-1}$ and $b' = \beta^{-1}(a - \alpha b - \ell g_s)$, noting that by assumption these are positive integers. With this we have that $n$ is equal to

$$ag_{s-1} + \beta bg_{s-2} = (a - \alpha b + \alpha a' - \ell g_s)g_{s-1} + \beta bg_{s-2} = (\alpha a' + \beta b')g_{s-1} + \beta a'g_{s-2} = a'g_s + \beta b'g_{s-2}.$$ 

This contradicts Corollary 2.3 and the assumption $s(n) = s$, so we conclude (a).

For (b), note that by Corollary 2.3 we have that $(b', a')$ is $n$-good if and only if this is a positive solution to the Diophantine equation $n = a'g_{s-1} + \beta b'g_{s-2}$. The result follows from Lemma 2.1(b) since $s > 2$.

For (c), we have by Lemma 2.2(a) and Lemma 2.1(c) that

$$w_{s+1}(b', a') - w_{s+1}(b, a) = (a + k\beta g_{s-2})g_s + (b - k g_{s-1})\beta g_{s-1} - ag_{s-1} - bg_{s-1} = -k\beta(g_{s-1}^2 - g_s g_{s-2}) = -k\beta(-\beta)^{s-2} = k(-\beta)^{s-1}.$$ 

To prove the next lemma, we make use of the following special case of the Frobenius coin problem [7].

**Lemma 2.5.** If $x, y, n$ are positive integers with $\gcd(x, y) = 1$ and $n > xy$, then there exist integers $a, b \geq 1$ such that $n = ax + by$.

**Lemma 2.6.** If $(b, a)$ is $n$-good with $s(n) = s > 2$, then $a \leq (\beta - 1)g_s + \alpha b$.

Proof. If $a - \alpha b + g_s > \beta g_s$, then because $\gcd(\beta, g_s) = 1$ by Lemma 2.1(b), there exist positive $r, \ell$ such that $a - \alpha b + g_s = r\beta + \ell g_s$ by Lemma 2.5. This implies that $a - \alpha b - (\ell - 1)g_s$ is a positive multiple of $\beta$. This contradicts Lemma 2.4(a), so we conclude that $a - \alpha b \leq (\beta - 1)g_s$. 

From this proof, we see that the condition $a \leq (\beta - 1)g_s + \alpha b$ in Theorem 1.1 is already implied by the condition stating that $a - \alpha b - \ell g_{s+1}$ is not a positive multiple of $\beta$ and hence could be omitted. However, we feel it is useful to state this condition explicitly.

We are now ready to prove our characterization theorem.
Proof of Theorem 1.1. Let \((b', a')\) be an \(n\)-good pair, and let \(k\) be the non-negative integer such that \(1 \leq b' - kg_{s-1} \leq g_{s-1}\). By Lemma 2.4(b) we have that \((b, a) := (b' - kg_{s-1}, a' + k\beta g_{s-2})\) is an \(n\)-good pair, and hence \(n = ag_{s-1} + \beta bg_{s-2}\) by Corollary 2.3. By construction we have \(b \leq g_{s-1}\), and because the pair \((b, a)\) is \(n\)-good, we also have \(a \leq (\beta - 1)g_{s} + \alpha b\) and that \(a - \alpha b - \ell g_{s}\) is not a positive multiple of \(\beta\) for any \(\ell \geq 0\) by Lemmas 2.6 and 2.4. By taking \(a^{\alpha, \beta}(n) = a\), \(b^{\alpha, \beta}(n) = b\), and \(t^{\alpha, \beta}(n) = s - 1\), we conclude that such integers exist.

We next show that these integers are unique. Assume that \(n = ag_{t} + \beta bg_{t-1}\) with \(a, b, t\) as in the hypothesis of the theorem. This implies that \(s \geq t + 1\) by Lemma 2.2(a). Assume that \(s > t + 1\). This implies by Lemma 2.2(a) that there exist \(a', b' \geq 1\) such that

\[
ag_{t} + \beta bg_{t-1} = n = a'g_{t+1} + \beta b'g_{t} = (\alpha a' + \beta b')g_{t} + \beta a'g_{t-1}.
\]

Because \(t \geq 2\) by assumption, \(g_{t}\) and \(\beta g_{t-1}\) are relatively prime. Thus having two solutions to the Diophantine equation \(n = xg_{t} + y\beta g_{t-1}\) implies that there exists a \(k\) such that

\[
a' = b + kg_{t}, \quad \beta b' = a - \alpha a' - k\beta g_{t-1} = a - \alpha b - k\alpha g_{t} - k\beta g_{t-1}.
\]

Because \(b \leq g_{t}\) and \(a' \geq 1\), we must have \(k \geq 0\) in order for the first equation to hold. We assumed for \(\ell \geq 0\) that \(a - \alpha b - \ell g_{t+1}\) is not a positive multiple of \(\beta\), and since \(b' \geq 1\) this implies that we can not have \(k \geq 0\). We conclude that no such \(k\) exists, and hence we must have \(s(n) = t + 1\), from which it follows that \((b, a)\) is an \(n\)-good pair. This is the unique pair with \(1 \leq b \leq g_{t}\) by Lemma 2.4(b), so we conclude that \(a, b\) are also unique.

For the final results, note that in this proof we have already shown that \(s = t + 1\), and the results concerning \((b', a')\) follow from Lemma 2.4. Thus it only remains to bound \(|w_{s+1}(b, a) - \gamma n|\). Because \(w_{s}(b, a) = n\), it follows from Lemma 2.2(b) that this is equal to \(|\lambda^{s-1}(a - \gamma b)| = |\lambda^{t}(a - \gamma b)|\). In order to bound this quantity, note that

\[
a - \gamma b \leq (\beta - 1)g_{t+1} + (\alpha - \gamma)b \leq \frac{\beta - 1}{\gamma - \lambda}(\gamma^{t+1} - \lambda^{t+1}),
\]

where we used that \(\alpha < \gamma\) and the closed form of \(g_{t+1}\). On the other hand, we have

\[
a - \gamma b > -\gamma g_{t} = \frac{-\gamma}{\gamma - \lambda}(\gamma^{t} - \lambda^{t}).
\]
By using the rough bounds $\gamma^k - \lambda^k \leq 2\gamma^k$ and $1, \beta - 1 \leq \beta$, we in total find that

$$|a - \gamma b| \leq \frac{2\beta}{\gamma - \lambda} \beta^{t+1}.$$ 

Multiplying this by $|\lambda^t|$ and using $\lambda \gamma = -\beta$ gives

$$|\lambda^t(a - \gamma b)| \leq \frac{2\gamma}{\gamma - \lambda} \beta^{t+1},$$

Because $-\lambda > 0$, we conclude the result. $\Box$

We can prove a somewhat nicer result when $\beta = 1$.

**Corollary 2.7.** Let $n$ be such that $s = s^{\alpha,1}(n) > 2$ and let $a, b, t$ be the integers of Theorem 1.1.

- The values $a, b, t$ are the unique integers satisfying $n = ag_{t}^{\alpha,1} + bg_{t-1}^{\alpha,1}$, $t \geq 2$, and $1 \leq a \leq \alpha b \leq \alpha g_{t}^{\alpha,1}$.

- Every $(n, \alpha, 1)$-good pair $(b', a')$ is of the form $(b + kg_{t}^{\alpha,1}, a - kg_{t-1}^{\alpha,1})$ for some $k \geq 0$.

- With $a', b', k$ as above, we have $w_{s+1}^{\alpha,1}(b', a') = [\gamma_{\alpha,1} n] - k$ if and only if $t$ is even and $w_{s+1}^{\alpha,1}(b', a') = [\gamma_{\alpha,1} n] + k$ if and only if $t$ is odd.

*Proof.* Because $\beta = 1$, we have by Theorem 1.1 that $a \leq \alpha b$, and from this it is immediate that $a - \alpha b - \ell g_{t+1}$ is not positive for any $\ell \geq 0$, so we can drop this condition. It remains to prove the results concerning $w_{s+1}$.

Assume that $t$ is even. We know from Theorem 1.1 that $s = t - 1$ and that

$$w_{s+1}(b', a') - w_{s+1}(b, a) = k(-1)^s = -k,$$

so it suffices to show that $w_{s+1}(b, a) = [\gamma n]$. Observe that this is equivalent to having $\gamma n - w_{s+1}(b, a)$ being non-negative and less than one. Since $n = w_{s}(b, a)$, by Lemma 2.2(b) this is equivalent to having

$$0 \leq \lambda^{t}(\gamma b - a) < 1.$$  \hspace{1cm} (1)

Note that when $\beta = 1$ we have $-1 < \lambda < 0$ for all $\alpha \geq 1$. Because $t$ is even, the only way (1) could be negative is if $\gamma b - a < 0$, but this is impossible
since $a \leq ab < \gamma b$. For the upper bound, using $\gamma \lambda = -1$ and that $t$ is even, we have

$$
\lambda^t(\gamma b - a) \leq -\lambda^{t-1}g_t - \lambda^t = \frac{-(\lambda \gamma)^t \lambda^{-1} - \lambda^{2t-1}}{\gamma - \lambda} - \lambda^t
$$

where we obtained the first strict inequality by using $|\lambda| < 1$ and that $t \geq 2$. This proves the result for $t$ even, and the proof for $t$ odd is essentially the same. We omit the details.

\section{Applications}

An immediate corollary of the second to last point of Theorem 1.1 is the following.

\textbf{Corollary 3.1.} Let $n$ be such that $s(n) > 2$ and let $a = a(n)$, $b = b(n)$, and $t = t(n)$ be as in Theorem 1.1. Then for any integer $p$, there are more than $p$ distinct $n$-good pairs if and only if $a > \beta pg_{t-1}$.

\textbf{Proof.} If $a > \beta pg_{t-1}$, then the pairs $(b + kg_t, a - k\beta g_{t-1})$ with $0 \leq k \leq p$ are all $n$-good. Otherwise strictly fewer $k$ work.

In order to prove Theorem 1.2, it will be convenient to make use of the following.

\textbf{Lemma 3.2.} For $t \geq 2$, let $n_t = \beta g_t g_{t+1}$, $a_t = (\beta - 1)g_{t+1} + \alpha g_t$, and $b_t = g_t$. In the notation of Theorem 1.1, we have $a(n_t) = a_t$, $b(n_t) = b_t$, and $t(n_t) = t$.

\textbf{Proof.} One can verify that $n = a_t g_t + \beta b_t g_{t-1}$ and that the relevant bounds of Theorem 1.1 hold for $t, a_t, b_t$. For any $\ell$, $a_t - \alpha b_t - \ell g_{t+1} = (\beta - 1 - \ell)g_{t+1}$. If $\ell \geq \beta - 1$ this quantity is not positive. If $0 \leq \ell < \beta - 1$ we have $\text{gcd}(\beta, \beta - 1 - \ell) < \beta$, and because $\text{gcd}(\beta, g_{t+1}) = 1$ by Lemma 2.1, we conclude that $a_t - \alpha b_t - \ell g_{t+1}$ is never a positive multiple of $\beta$ for $\ell \geq 0$. Thus $a_t, b_t$ must be equal to $a(n_t), b(n_t)$ by the uniqueness of these integers.
We are now ready to prove our bounds on the number of \( n \)-good pairs.

**Proof of Theorem 1.2.** Given \( n \), let \( a, b, t \) be as in Theorem 1.1. By Corollary 3.1, \( p(n) \) is the largest integer such that

\[
a > (p(n) - 1) \beta g_{t-1}.
\]

(2)

Because \( b \leq g_t \) and \( a \leq (\beta - 1)g_{t+1} + ab \), we have \( a \leq a_t \) as defined in Lemma 3.2. It follows that \( p(n) \leq p(n_t) \), so it will be enough to bound \( p(n_t) \).

Observe that

\[
a_t = (\beta - 1)g_{t+1} + \alpha g_t = (\beta - 1)(\alpha g_t + \beta g_{t-1}) + \alpha g_t
\]

\[
= \alpha \beta g_t + (\beta - 1)\beta g_{t-1} = (\alpha^2 + \beta - 1)\beta g_{t-1} + \alpha \beta^2 g_{t-2}.
\]

Let \( p_t = p(n_t) \) and let \( k_t \) be the largest integer such that \( \alpha \beta g_{t-2} > k_t g_{t-1} \). From the above equation and (2), we have \( p_t = \alpha^2 + \beta + k_t \). One can inductively prove that \( \alpha g_{t-2} \leq g_{t-1} \) for \( t \geq 2 \), and hence we must have \( k_t < \beta \). From this it follows that \( p(n) \leq p_t \leq \alpha^2 + 2\beta - 1 \). To show that an \( n \) achieves this bound, we consider \( n_3 \). Because \( g_1 = 1 \) and \( g_2 = \alpha \), we have that \( k_3 = \beta - 1 \), from which it follows that \( p_3 = \alpha^2 + 2\beta - 1 \).

Regarding the statement of the second result, we note that the equality of \([\gamma^2]\) and \( \alpha^2 + \beta + [\alpha \beta \gamma^{-1}] \) follows from the fact that \( \gamma^2 = \alpha^2 + \beta + \alpha \beta \gamma^{-1} \).

We claim that proving the second result is equivalent to proving that \( k_t \) as defined above is equal to \( [\alpha \beta \gamma^{-1}] - 1 \) for all sufficiently large \( t \). Indeed, the second result is equivalent to the existence of infinitely many \( n \) with \( p(n) \geq \alpha^2 + \beta + \alpha \beta \gamma^{-1} \) and only finitely many \( n \) with \( p(n) \geq \alpha^2 + \beta + \alpha \beta \gamma^{-1} \).

Because there are only finitely many \( n \) with \( t(n) = t \) for any fixed \( t \), having infinitely many \( n \) with \( p(n) \geq p \) is equivalent to having infinitely many \( t \) such that \( p(n) \geq p \) for some \( n \) with \( t(n) = t \), and this is equivalent to having infinitely many \( t \) such that \( p_t \geq p \) since \( p_t \geq p(n) \) for all \( n \) with \( t(n) = t \).

Because \( p_t = \alpha^2 + \beta + k_t \), we are left with proving that \( k_t = [\alpha \beta \gamma^{-1}] - 1 \) for all sufficiently large \( t \).

Recall that \( k_t \) is the integer satisfying \( \alpha \beta g_{t-2} > k_t g_{t-1} \). By using the closed form of \( g_t \), this is equivalent to \( \gamma^{t-2}(\alpha \beta - \gamma k_t) - \lambda^{t-2}(\alpha \beta - \lambda k_t) > 0 \).

Because \( \lambda' = o(\gamma') \), for \( t \) sufficiently large this quantity will be positive if and only if \( \alpha \beta > k_t \gamma \). By the maximality of \( k_t \), we conclude that for \( t \) sufficiently large we have \( k_t = [\alpha \beta \gamma^{-1}] - 1 \) as desired.

The final result follows from the first two after verifying that having \( (\beta - 1) > \alpha \beta \gamma^{-1} \) for reals \( \alpha, \beta \) with \( \alpha \geq 1 \) is equivalent to having \( \beta <
\(\alpha + 1\), and since we are interested in the case where \(\alpha, \beta\) are integers, this is equivalent to having \(\beta \leq \alpha\).

We now prove several results that will be of use to us in later sections and which are also of independent interest. The first is an implicit bound on \(s(n)\) given \(n\).

**Lemma 3.3.** Let \(s \geq 2\) be an integer. If \(n > \beta g_{s-1} g_{s-2}\), then \(s(n) \geq s\).

**Proof.** The result is trivial if \(s = 2\), so assume \(s > 2\). Note that this implies \(\gcd(g_{s-1}, \beta g_{s-2}) = 1\) by Lemma 2.1(b). By Corollary 2.3, \(s(n)\) is the largest integer such that there exists some \(a, b \geq 1\) with \(n = ag_{s(n)-1} + \beta bg_{s(n)-2}\). Thus it will be enough to show that there exist positive \(a, b\) such that \(n = ag_{s-1} + \beta bg_{s-2}\), and this immediately follows from Lemma 2.5.

From this we can get a more explicit bound on \(s(n)\).

**Proposition 3.4.** For all \(n\) with \(s = s(n) > 2\), we have

\[
\frac{1}{2} \log \gamma(n) - 1 \leq s^{\alpha, \beta}(n) \leq \log \gamma(n) + 2.
\]

Moreover, we have \(s^{1,1}(n) \geq \frac{1}{2} \log \phi(n) + 2\), where \(\phi\) denotes the golden ratio.

**Proof.** Let \(t = s - 1\). From Theorem 1.1 and Lemma 3.3, we have

\[
g_t + \beta g_{t-1} \leq n \leq \beta g_t g_{t+1}
\]

We wish to turn these bounds for \(n\) into bounds for \(t\).

By using the closed form for \(g_t\), \(t \gamma^{-1} = -\beta \gamma^{-2}\), and \(\gamma \geq 1\); we find

\[
n \geq g_t + \beta g_{t-1} = \frac{1}{\gamma + \beta \gamma^{-1}} (\gamma^t - \lambda^t + \beta \gamma^{t-1} + \beta \lambda^{t-1})
\]

\[
= \frac{\gamma^t}{\gamma + \beta \gamma^{-1}} (1 - (-\beta \gamma^{-2})^t + \beta \gamma^{-1} + \beta (-\beta \gamma^{-2})^{t-1} \gamma^{-1})
\]

\[
= \frac{\gamma^t}{\gamma + \beta \gamma^{-1}} (1 + \beta \gamma^{-1} - (-\beta \gamma^{-2})^t (1 - \gamma))
\]

\[
\geq \frac{\gamma^t}{\gamma + \beta \gamma^{-1}} (1 + \beta \gamma^{-1} - (\beta \gamma^{-2})^t (\gamma - 1)).
\]
Note that by definition, $\gamma^2 \geq (\gamma - \alpha/2)^2 = \frac{1}{4}(\alpha^2 + 4\beta) \geq \beta$, and in particular $\beta^{t-1} \leq \gamma^{2t-2}$. By using this and $t \geq 1$, we find that the above quantity is at least

$$\frac{\gamma^{t}}{\gamma + \beta\gamma^{-1}}(1 + \beta\gamma^{-2}(\gamma - 1)) = \frac{\gamma^{t}}{\gamma + \beta\gamma^{-1}}(1 + \beta\gamma^{-2}) = \gamma^{t-1}.$$  

Thus $n \geq \gamma^{t-1}$, which implies $\log_{\gamma} n \geq t - 1$. Plugging in $t = s - 1$ gives our desired upper bound on $s$.

To establish a lower bound, we observe that $n \leq \beta g_{i+1}^2$ since $t \geq 2$. Because $g_{i+1} = \frac{1}{\gamma-\lambda} (\gamma^{t+1} - \lambda^{t+1})$ with $\lambda < 0$, we have $g_{i+1} \leq \frac{1}{\gamma-\lambda} \gamma^{t+1}$ if $t$ is odd, and if $t$ is even we have $g_{i+1} \leq g_{i+2} \leq \frac{1}{\gamma-\lambda} \gamma^{t+2}$. Further observe that $(\gamma - \lambda)^2 = \alpha^2 + 4\beta \geq \beta$. In total we conclude that

$$\log_{\gamma} n \leq \log_{\gamma} \beta g_{i+1}^2 \leq \log_{\gamma} \frac{\beta \gamma^{2t+4}}{(\gamma - \lambda)^2} \leq \log_{\gamma} \gamma^{2t+4} = 2t + 4,$$

and plugging in $t = s - 1$ gives the desired general lower bound for $s$.

For $\alpha = \beta = 1$, we use the more familiar notation $f_k = g_k$. By using the closed form for $f_k$ and that $t \geq 2$, we find that

$$n \leq f_t f_{t+1} = \frac{1}{5}(\phi^t - (-\phi^{-1})^t)(\phi^{t+1} - (-\phi^{-1})^{t+1})$$

$$= \frac{1}{5} \phi^{2t+1}(1 - (-1)^{t+1})(1 + (-1)^t \phi^{-2t-2}).$$

Because $\phi > 1$ and $2t, 2t + 2 \geq 0$, we have

$$(1 - (-1)^t \phi^{-2t})(1 + (-1)^t \phi^{-2t-2}) \leq (1 + \phi^{-2t})(1 - \phi^{-2t-2}),$$

and this is then maximized when $t$ is as small as possible. Because $t \geq 2$, we have $n \leq \frac{1}{5} \phi^{2t+1}(1 + \phi^{-4})(1 - \phi^{-6})$. Taking logarithms on both sides gives $\log_{\phi} n \geq 2t - 2$, and plugging in $t = s - 1$ gives the desired result.

We next consider an algorithm for efficiently finding $n$-slow walks. We note that this is essentially a generalization of the algorithm given in [6].

**Proposition 3.5.** For any fixed $\alpha, \beta$, there exists an algorithm that runs in $O((\log n)^2)$ time which takes as input $n$ and returns all $(n, \alpha, \beta)$-good pairs.
Proof. If \( n \leq \alpha \beta \) then one can determine all of this information in \( O(1) \) time, so assume \( n > \alpha \beta \). By Lemma 3.3, this implies that \( s(n) > 2 \). By Theorem 1.1 it is enough to determine \( a(n) \), \( b(n) \), and \( t(n) \).

Set \( t = 0 \) and compute \( g_0, g_1 \). Assume that one has computed \( g_t, g_{t-1} \) and that the list of \( n \)-good pairs have not yet been found. Set \( t := t + 1 \) and then \( g_t := \alpha g_{t-1} + \beta g_{t-2} \) in \( O(1) \) time. Compute \( b := n(\beta g_{t-1})^{-1} \mod g_t \), which can be done in \( O(\log g_t) \) time by using the extended Euclidean algorithm [3], and choose the representative of \( b \) so that \( 1 \leq b \leq g_t \). If \((a, b)\) satisfies the remaining conditions of Theorem 1.1 (which can be checked in \( O(1) \) time), then we conclude that \( a(n) = a \), \( b(n) = b \), \( t(n) = t \) by the uniqueness of these integers. Otherwise it must be that \( t(n) \neq t \).

One continues through the above procedure until it eventually computes \( a(n) \), \( b(n) \), and \( t(n) \). Checking each value of \( t \) takes at most \( O(\log n) \) time, and because \( t(n) \leq \log_s(n) + 1 \) by Proposition 3.4, we need to check at most \( O(\log n) \) values of \( t \). We conclude the result.

This algorithm can be improved when \( \beta = 1 \).

**Proposition 3.6.** For any fixed \( \alpha \), there exists an algorithm that runs in \( O(\log n) \) time which takes as input \( n \) and returns all \((n, \alpha, 1)\)-good pairs.

Proof. By Corollary 2.7, we know that \( w_{s(n)+1}(b(n), a(n)) = \lfloor \gamma n \rfloor \) or \( \lceil \gamma n \rceil \). Motivated by this, we compute the two sequences \( u_k, v_k \) defined by \( u_1 = \lfloor \gamma n \rfloor \), \( u_2 = n \), \( u_{k+2} = u_k - \alpha u_{k+1} \) for \( k > 2 \); and \( v_1 = \lceil \gamma n \rceil \), \( v_2 = n \), \( v_{k+2} = v_k - \alpha v_{k+1} \) for \( k > 2 \). The point with this is that if, say, \( w_{s(n)+1}(b(n), a(n)) = \lfloor \gamma n \rfloor \), the terms of \( u_k \) will be exactly the terms of \( w_k(b(n), a(n)) \) but written in reverse order. Thus by Corollary 2.7, exactly one of these sequences \( u_k, v_k \) will be the reverse of the sequence we are looking for.

With this in mind, the algorithm works by computing each of these two sequences until the terms become non-positive. Whichever sequence has more terms must correspond to \( w_k(b(n), a(n)) \). In particular, its last two positive numbers will be \( a(n) \) and \( b(n) \), and from this we can find every \((n, \alpha, 1)\)-good pair. It takes \( O(1) \) time to compute each term in each of the sequences, and the longest sequence has length at most \( O(\log n) \) by Proposition 3.4, so we conclude the result.

\[ \Box \]
4 Densities

4.1 A General Method

A number of density results related to slow (1,1)-walks were proven in [1]. The same proof ideas easily generalize to \((\alpha, 1)\)-walks for any fixed \(\alpha\), though the computations become messier. However, it is not immediately obvious how to apply these ideas to \((\alpha, \beta)\)-walks for \(\beta > 1\) due to the divisibility condition of Theorem 1.1. Before proving Theorem 1.3, we first present a general method that can be used to get around this obstacle.

We will say that a pair \((a, b)\) is \(t\)-divisible if 
\[
a - \alpha b - \ell g_{t+1} \text{ is not a positive multiple of } \beta \text{ for any } \ell \geq 0.
\]
Let \(a - b, t\) and \(a + b, t\) be real numbers depending on \(b\) and \(t\). We will say that a set of positive integers \(S\) is an interval set with respect to \(a - b, t\) and \(a + b, t\) if for all integers \(t \geq 2\) and \(1 \leq b \leq g_{t}\) we have
\[
\{m \in S : b(m) = b, t(m) = t\} = \{ag_t + \beta bg_{t-1} : a_{b,t}^- < a \leq a_{b,t}^+, (a, b) \text{ is } t\text{-divisible}\}. \tag{3}
\]

By Theorem 1.1, this essentially says that \(S\) can be defined as the set of \(m\) whose \(a(m)\) lies in some interval depending only on \(b(m)\) and \(t(m)\). We note that we do not require \(a - b, t\) and \(a + b, t\) to be integers.

All of the density results of [1] were for interval sets or the complements of interval sets. The main interval set of interest to us will be the following.

**Lemma 4.1.** Let \(S_p\) be the set of integers with \(p(n) > p\). Then \(S_p\) is an interval set with respect to \(a_{b,t}^- = \beta pg_{t-1}\) and \(a_{b,t}^+ = (\beta - 1)g_{t+1} + \alpha b\).

**Proof.** Fix \(t \geq 2\) and \(1 \leq b \leq g_t\). With \(S = S_p\), let \(L\) denote the set defined on the left-hand set of (3) and let \(R\) be the right-hand set. We wish to show that \(L = R\).

If \(m = ag_t + \beta bg_{t-1}\) is an element of \(R\), then by Theorem 1.1 we have \(a(m) = a, b(m) = b,\) and \(t(m) = t\). Because \(a(m) > \beta pg_{t-1}\), we have \(n \in S_p\) by Corollary 3.1, and hence \(m \in L\). Conversely, if \(m \in S_p\) with \(t(m) = t\) and \(b(m) = b\), then by Corollary 3.1 and Theorem 1.1 we have \(a_{b,t}^- < a(m) \leq a_{b,t}^+\), 
\[
n = a(m)g_t + \beta bg_{t-1},\text{ and that } (a(m), b) \text{ is } t\text{-divisible. Thus } m \in R \text{ and we conclude the result.}\]

We now wish to refine our interval sets to deal more precisely with the divisibility condition. For \(0 \leq q \leq \beta - 1\) and \(t \geq 2\), we will say that a pair \((a, b)\) is \((q, t)\)-good if
\[
1 \leq b \leq g_t,
\]

16
Given a set of positive integers $S$, we define

$$S(n, q, t) = \{ m \in S : m \leq n \ t(m) = t, \ (a(m), b(m)) \text{ is } (q,t)\text{-good}\}.$$ 

Note that by Theorem 1.1, every $m \in S$ with $m \leq n$ lies in exactly one $S(n, q, t)$ set.

Lemma 4.2. If $S$ is an interval set with respect to $a_{b,t}^-$ and $a_{b,t}^+$, then $S(n, q, t)$ is an interval set with respect to $\hat{a}_{b,t}^-$ and $\hat{a}_{b,t}^+$, where

$$\hat{a}_{b,t}^- = \max\{0, a_{b,t}^-, (q-1)g_{t+1} + \alpha b\},$$
$$\hat{a}_{b,t}^+ = \min\{a_{b,t}^+, qq_{t+1} + \alpha b, (n - \beta bg_{t-1})g_t^{-1}\}.$$ 

We note that $\hat{a}_{b,t}^-$ and $\hat{a}_{b,t}^+$ technically depend on $n$ and $q$, but we suppress this notation whenever $n$ and $q$ are understood.

Proof. Fix $t \geq 2$ and $1 \leq b \leq g_t$. Let $L$ denote the set defined on the left-hand side of (3), with us now using $S(n, q, t)$ instead of $S$, and let $R$ be the set on the right-hand side. We wish to show that $L = R$.

For any $m \in L$, we have that $a_{b,t}^- < a(m) \leq a_{b,t}^+$ since $m \in S$, that $\max\{0, (q-1)g_{t+1} + \alpha b\} < a(m) \leq qg_{t+1} + \alpha b$ since $(a(m), b)$ is $(q,t)$-good, and that $a(m)g_t + \beta bg_{t-1} \leq n$ since $m \leq n$. Thus $m \in R$. Conversely, if $m \in R$ then $b(m) = b$ and $t(m) = t$. Because $S$ is an interval set and $a_{b,t}^- < a(n) \leq a_{b,t}^+$, we have $m \in S$, and the other inequalities imply that $m \in S(n, q, t)$, so $m \in L$ and we conclude the result.

When $\hat{a}_{b,t}^-$ and $\hat{a}_{b,t}^+$ are as in Lemma 4.2 and clear from context, we define

$$T(n, q, t) = \{(a, b) \in \mathbb{Z}^2 : \hat{a}_{b,t}^- < a \leq \hat{a}_{b,t}^+, \ 1 \leq b \leq g_t\}.$$ 

Intuitively, $T(n, q, t)$ is obtained by taking $S(n, q, t)$, looking at $m$-good pairs instead of the numbers $m \in S(n, q, t)$, and then forgetting about the divisibility condition. More precisely, we have the following.

Lemma 4.3. Let $S$ be an interval set with respect to $a_{b,t}^-$ and $a_{b,t}^+$. Then for all $0 \leq q \leq \beta - 1$ and $t \geq 2$, we have

$$|S(n, q, t)| - \frac{\beta - q}{\beta} |T(n, q, t)| \leq \beta \min\{g_t, n/g_{t-1}\}.$$ 

17
Proof. Let \( T^*(n, q, t) \subseteq T(n, q, t) \) denote the subset of pairs which are \( t \)-divisible. We claim that \( |S(n, q, t)| = |T^*(n, q, t)| \). Indeed, consider the map sending \( m \in S(n, q, t) \) to \((a(m), b(m))\). Because \( S(n, q, t) \) is interval with respect to \( \tilde{a}_{b,t}^- \) and \( \tilde{a}_{b,t}^+ \), this pair is in \( T(n, q, t) \). By Theorem 1.1 this pair is also \( t \)-divisible, so \((a(m), b(m)) \in T^*(n, q, t)\). Conversely, each \((a, b) \in T^*(n, q, t)\) can only be mapped to by \( m = ag_t + \beta bg_{t-1} \), which is in \( S(n, q, t) \) by the interval condition. Thus this map defines a bijection between these two sets, proving the claim.

We now wish to estimate \( |T^*(n, q, t)| \). To this end, let \( 1 \leq b \leq g_t \) be fixed. Let \( T_b(n, q, t) = \{(a', b') \in T(n, q, t) : b' = b\} \) and \( T^*_b(n, q, t) = T_b(n, q, t) \) be the set of pairs which are \( t \)-divisible. Define

\[
R_b = \{-(ab + \ell g_{t+1}) \bmod \beta : 0 \leq \ell < q\}.
\]

Observe that \( R_b \) consists of \( q \) distinct values since \( q < \beta \) and \( \gcd(g_{t+1}, \beta) = 1 \) by Lemma 2.1.

By construction, every element of \( T(n, q, t) \) is \((q, t)\)-good. This implies that any \((a, b) \in T_b(n, q, t)\) has \( a - ab - \ell g_{t+1} \leq 0 \) if \( \ell \geq q \), and otherwise this quantity is positive. Thus \((a, b)\) will be in \( T^*_b(n, q, t) \) if and only if \( a \) modulo \( \beta \) is any of the \( \beta - q \) values not in \( R_b \). We claim that roughly a \( \frac{\beta - q}{\beta} \) fraction of pairs in \( T_b(n, q, t) \) will satisfy this condition. More precisely, we claim that

\[
\left\lfloor \frac{\beta - q}{\beta} |T_b(n, q, t)| \right\rfloor \leq |T^*_b(n, q, t)| \leq \left\lfloor \frac{\beta - q}{\beta} |T_b(n, q, t)| \right\rfloor + \beta - 1.
\]

Indeed, one can break up the elements of \( T_b(n, q, t) \) into \( \left\lfloor \frac{1}{\beta} |T_b(n, q, t)| \right\rfloor \) disjoint sets of the form \( \{(a, b), (a + 1, b), \ldots, (a + \beta - 1, b)\} \), together with one remaining set of size at most \( \beta - 1 \). Each of these disjoint sets of size \( \beta \) will contain exactly \( \beta - q \) pairs \((a, b)\) with \( a \mod \beta \) not in \( R_b \), and the remaining set could have anywhere from 0 to \( \beta - 1 \) elements with this property. This proves the claim.

Since we only consider \((a, b)\) that are \((q, t)\)-good, we only consider \( b \) with \( 1 \leq b \leq g_t \). Since we also require \( ag_t + \beta bg_{t-1} \leq n \), we also have \( b \leq n/g_{t-1} \). Thus by summing the above bound over all \( 1 \leq b \leq \min\{g_t, n/g_{t-1}\} \), we find

\[
\frac{\beta - q}{\beta} |T(n, q, t)| - \min\{g_t, n/g_{t-1}\} \leq |T^*(n, q, t)| \leq \frac{\beta - q}{\beta} |T(n, q, t)| + (\beta - 1) \min\{g_t, n/g_{t-1}\}.
\]

By using \( 1, \beta - 1 \leq \beta \), we conclude the result. \(\square\)
The \( T(n,q,t) \) sets are relatively easy to work with since they have no divisibility conditions. In particular, the cardinality of these sets is exactly \( \max\{0, a_{b,t}^+ - a_{b,t}^-\} \cdot g_t \). One often needs to further refine \( T(n,q,t) \) by replacing its bounds with asymptotic estimates, and we will see an example of this in the proof of Theorem 1.3. For now we record a general result that can be used in computing densities of interval sets.

**Corollary 4.4.** If \( S \) is an interval set, then

\[
\left| S \cap [n] \right| - \sum_{q,t} \frac{\beta - q}{\beta} |T(n,q,t)| = O(\sqrt{n}).
\]

**Proof.** The sum \( \sum_{t,q} |S(n,q,t)| \) counts every element of \( |S| \cap [n] \) exactly once, except for those \( m \in S \) with \( t(m) = 1 \). By Lemma 3.3 there are at most \( \alpha \beta \) such exceptions. Thus by Lemma 4.3, the triangle inequality, and the fact that \( g_t = \Theta(\gamma^t) \), we find that

\[
\left| S \cap [n] \right| - \sum_{q,t} \frac{\beta - q}{\beta} |T(n,q,t)| \leq \alpha \beta + \sum_{q,t} \left| S(n,q,t) \right| - \frac{\beta - q}{\beta} |T(n,q,t)| \leq O(1) + \sum_{t:g_t \leq n} O(\gamma^t) + \sum_{t:g_t \geq n} O(n \gamma^{-t}) = O(\sqrt{n}),
\]

where we used that the largest terms of the geometric sums are \( O(\sqrt{n}) \). \( \square \)

### 4.2 Proving Theorem 1.3

Recall that we define \( n_{c,r} := \left\lfloor \frac{\epsilon \beta}{(\gamma-\lambda)^2} \right\rfloor^{2r+1} \). Before proving Theorem 1.3, we first show that most \( n \) with \( p(n) \) large and \( n \leq n_{c,r} \) have \( t(n) \leq r \), and we also establish a more precise cutoff for when this occurs.

**Lemma 4.5.** Let \( r \geq 2 \). For any \( p \geq \beta \), there are at most \( O(\beta^r) \) many \( n \) with \( p(n) > p \), \( n \leq \frac{\beta(p-\beta+1)}{\epsilon(\gamma-\lambda)^2} \gamma^{2r+2} \), and \( t(n) > r \). Further, all \( n \) with \( p(n) > \beta \) and \( n \leq \beta g_r g_{r+1} \) satisfy \( t(n) \leq r \).

**Proof.** Fix some \( n \) with \( p(n) > p \geq \beta \), and let \( a = a(n), b = b(n) \), and \( t = t(n) \). By Theorem 1.1 and Corollary 3.1 we have

\[
\beta pg_{t-1} < a \leq (\beta - 1) g_{t+1} + \alpha b.
\]
Using these lower bounds on $a$ and $b$, we find

$$n = ag_t + bg_{t-1}$$

$$> \beta pg_{t-1}g_t + \left(\frac{\beta p}{\alpha}\beta g_{t-1} - \frac{\beta - 1}{\alpha}\beta g_{t+1}\right) g_{t-1}$$

$$= \frac{\beta p}{\alpha}g_{t-1}(\alpha g_t + \beta g_{t-1}) - \frac{(\beta - 1)\beta}{\alpha}g_{t-1}g_{t+1}$$

$$= \frac{\beta p}{\alpha}g_{t-1}g_{t+1} - \frac{(\beta - 1)\beta}{\alpha}g_{t-1}g_{t+1} = \frac{\beta(p - \beta + 1)}{\alpha}g_{t-1}g_{t+1}.$$

Now assume $t > r$, so that we conclude $n > \frac{\beta(p - \beta + 1)}{\alpha}g_r; g_{r+2}$. Our first result follows by observing that this implies that $n$ is at least

$$\frac{\beta(p - \beta + 1)}{\alpha}g_r; g_{r+2} = \frac{\beta(p - \beta + 1)}{\alpha}g_r; g_{r+2} + O(\beta^r).$$

For the second result, note that $g_{r+2} = \alpha g_{r+1} + \beta g_r = \alpha g_{r+1}$ since $r \geq 2$, and since $p \geq \beta$ we conclude that $n > \beta g_r; g_{r+1}$. \qed

**Proof of Theorem 1.3.** Define $n_r = \beta g_r; g_{r+1}$. By Lemma 3.3, the only elements in $S_p \cap [n_{c,r}]$ that are not in $S_p \cap [n_r]$ are $n$ with $n \leq n_{c,r}$, $p(n) > p \geq \beta$, and $t(n) > r$. By Lemma 4.5 there are at most $O(\beta^r)$ such $n$. The number of elements in $S_p \cap [n_r]$ that are not in $S_p \cap [n_{c,r}]$ is at most $n_r - n_{c,r} \leq n_r - n_{1,r} = O(\beta^r).$ In total we conclude

$$||S_p \cap [n_r]|| - ||S_p \cap [n_{c,r}]|| = O(\beta^r), \quad (4)$$

so it will be enough for us to estimate the size of $S_p \cap [n_r]$.

By Lemma 4.1, $S_p$ is an interval set with respect to $a_{b,t}^- = \beta pg_{t-1}$ and $a_{b,t}^+ = (\beta - 1)g_{t+1} + \alpha b$. With $S = S_p$, let $S(n_r, q, t)$ and $T(n_r, q, t)$ be the sets as defined before Lemmas 4.2 and 4.3. Our goal at this point is, for each $q$ and $t$, to estimate the sizes of either $S(n_r, q, t)$ or $T(n_r, q, t)$.

By Lemma 4.5, there exists no $m \in S_p \cap [n_r]$ with $t(m) > r$. Thus $|S(n_r, q, t)| = 0$ for $t > r$. Note that for all $t \leq r$, $q \leq \beta - 1$, and $b \leq g_t$; we have $qg_t g_{t+1} + bg_{t+1} \leq \beta g_r g_{r+1} = n_r$. This inequality is equivalent to $qg_t + \alpha b \leq (n_r - \beta bg_{t-1})g_t^{-1}$. Thus for $t \leq r$ we have $a_{b,t}^+ = qg_t + \alpha b$, and we recall that $a_{b,t}^- = \max\{0, \beta pg_{t-1}, (q - 1)g_{t+1} + \alpha b, \}.$

Recall that $d$ is the smallest integer such that $\delta := \beta \gamma^{-1}p - \gamma d \leq \alpha$. We first establish the range that $d$ and $\delta$ can lie in.
Claim 4.6. We have $0 \leq d \leq \beta - 1$ and $\alpha - \gamma < \delta \leq \alpha$.

Proof. Because $p \geq 1$, we have

$$\beta \gamma^{-1} p + \gamma \geq -\lambda + \gamma = \alpha,$$

so $d \geq 0$. Because $p \leq \lceil \gamma^2 \rceil - 2 < \gamma^2 - 1$, we have

$$\beta \gamma^{-1} p - (\beta - 1) \gamma < \gamma - \beta \gamma^{-1} = \alpha,$$

where we used $\gamma^2 - \beta = \alpha \gamma$, so $d \leq \beta - 1$. We have $\delta \leq \alpha$ by definition. If $\alpha - \gamma \geq \delta$, then $\beta \gamma^{-1} p - \gamma(d - 1) \leq \alpha$, a contradiction to the definition of $d$. \hfill \Box

Now that we understand the range that $d$ can take on, we turn to estimating $|T(n_r, q, t)|$. First consider any $q$ with $0 \leq q < d$ (if such a $q$ exists). In this case we have for $b \leq g_t$ and $t \leq r$ that

$$\hat{a}_{b,t} - \hat{a}_{b,t}^\dagger \geq \beta pg_{t-1} - qg_{t+1} - \alpha b = \frac{\beta p \gamma^{-1} - q \gamma'}{\gamma - \lambda} \gamma' - \alpha b + \Omega(\lambda^t)$$

$$\geq \frac{\beta p \gamma^{-1} - (d - 1) \gamma - \alpha}{\gamma - \lambda} \gamma' + o(\gamma')$$

$$= \frac{\gamma + \delta - \alpha}{\gamma - \lambda} \gamma' + o(\gamma').$$

By the previous claim, $\gamma + \delta - \alpha > 0$. Thus for any $0 \leq q < d$ and $t$ sufficiently larger than some constant depending only on $p$, $\alpha$, and $\beta$; we have $\hat{a}_{b,t}^\dagger > \hat{a}_{b,t}$, and hence $|T(n_r, q, t)| = \max\{0, a_{b,t}^\dagger - a_{b,t}^\dagger\} \cdot g_t = 0$ for such $q$ and $t$. Thus in total we have

$$\sum_{0 \leq q < d} \sum_t |T(n_r, q, t)| = \Omega(1). \quad (5)$$

Observe that $d+1 \geq \beta \gamma^{-2} p - \alpha \gamma^{-1} + 1$. Thus for $q$ with $0 < d+1 < q < \beta$, we have

$$(q - 1)g_{t+1} + \alpha b \geq (d + 1)g_{t+1} \geq \frac{\beta \gamma^{-2} p - \alpha \gamma^{-1} + 1}{\gamma - \lambda} \gamma^t + \Omega(\lambda^t)$$

$$= \frac{\beta p - \alpha \gamma + \gamma^t}{\gamma - \lambda} g_{t-1} + \Omega(\lambda^t) > \beta pg_{t-1} + \Omega(\lambda^t),$$

21
where we used that $\gamma > \alpha$ for all $\alpha, \beta$. Thus for any $d + 1 < q < \beta$ we have $\tilde{a}_{b,t} = (q - 1)g_{t+1} + \alpha b + O(\lambda^t)$, and hence

$$|T(n_r, q, t)| = \max\{0, a^+_{b,t} - a^-_{b,t}\} \cdot g_t = g_{t+1}g_t + O(\beta^t) = \frac{1}{(\gamma - \lambda)^2}\gamma^{2t+1} + O(\beta^t). \quad (6)$$

It remains to deal with the cases $q = d$ and $q = d + 1$. In these cases it will be easier to work with an asymptotic version of $T(n_r, q, t)$. To this end, define

$$\tilde{a}_{b,t}^- = \max\{0, \frac{q - 1}{\gamma - \lambda}\gamma^{t+1} + \alpha b, \frac{\beta p}{\gamma - \lambda}\gamma^{t-1}\},$$
$$\tilde{a}_{b,t}^+ = \frac{q}{\gamma - \lambda}\gamma^{t+1} + \alpha b.$$  

Technically $\tilde{a}_{b,t}^\pm$ depend on $q$, but we suppress this from the notation. Let $U(q, t) = \{(a, b) \in \mathbb{Z}^2 : \tilde{a}_{b,t}^- < a < \tilde{a}_{b,t}^+, \ 0 \leq b \leq \frac{1}{\gamma - \lambda}\gamma^t\}.$

**Claim 4.7.** For all $t \leq r$ we have $|T(n_r, q, t) - U(q, t)| = O(\gamma^t + \beta^t).$

**Proof.** Let $U'(q, t) = \{(a, b) \in \mathbb{Z}^2 : \tilde{a}_{b,t}^- < a < \tilde{a}_{b,t}^+, \ 0 \leq b \leq \frac{1}{\gamma - \lambda}\gamma^t\}.$ Any pair $(a, b) \in U'(q, t)$ that is not in $T(n_r, q, t)$ must have either $b = 0$ or $g_t < b \leq \frac{1}{\gamma - \lambda}\gamma^t.$ Note that the number of $b$ in this latter range is at most

$$\left| g_t - \frac{1}{\gamma - \lambda}\gamma^t \right| \leq 1 + \frac{1}{\gamma - \lambda}(-\lambda)^t.$$  

For these $b$, there are at most $\tilde{a}_{b,t}^- - \tilde{a}_{b,t}^- + 1 \leq g_{t+1} + 1 = O(\gamma^t)$ values that $a$ can take on. Thus $U'(q, t)$ has at most $O((1 + \lambda^t)\gamma^t) = O(\gamma^t + \beta^t)$ more pairs than $T(n_r, q, t).$ Using similar logic, we find that the same bound holds for the number of pairs in $T(n_r, q, t)$ but not $U'(q, t),$ and hence $|T(n_r, q, t)| - |U'(q, t)| = O(\gamma^t + \beta^t)$.

Similarly, note that $|\tilde{a}_{b,t}^+ - \tilde{a}_{b,t}^-|$ and $|\tilde{a}_{b,t}^- - \tilde{a}_{b,t}^-|$ are $O(1 + \lambda^t).$ Thus for any fixed $b$ there are at most $O(1 + \lambda^t)$ values of $a$ such that $(a, b) \in U(q, t)$ and $(a, b) \notin U'(q, t),$ and vice versa. Thus we have $|U'(q, t) - U(q, t)| = O(\gamma^t + \beta^t),$ and from this the result follows.

\[\square\]

From this point forward we will omit floors and ceilings whenever they do not significantly affect our computations. We first consider $U(d, t)$. One can verify from the definition of $d$ that for $q = d$ we have $\tilde{a}_{b,t}^- = \frac{\beta p}{\gamma - \lambda}\gamma^{t-1}$ for all $b \leq \frac{1}{\gamma - \lambda}\gamma^t.$ Thus

$$\tilde{a}_{b,t}^+ - \tilde{a}_{b,t}^- = \frac{\gamma d - \beta \gamma^{-1}p}{\gamma - \lambda}\gamma^t + \alpha b = \frac{-\delta}{\gamma - \lambda}\gamma^t + \alpha b.$$
Hence for each fixed value of $b$, the number of $(a, b)$ we have in $U(d, t)$ will be $\max\{0, \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^t + ab\}$. Note that this value is non-zero precisely when $b \geq \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^t := b'$. We conclude that

$$|U(d, t)| = \sum_{b=b'}^{\gamma^t/(\gamma - \lambda)} \left( \frac{-\delta}{\gamma - \lambda} \gamma^t + ab \right).$$  \hspace{1cm} (7)

Using the general fact that $\sum_{i=x}^{y} z + i = z(y - x + 1) + \frac{1}{2}(y^2 - x^2) + O(y)$, we find that this equals

$$\frac{-\delta + \alpha^{-1} \delta^2}{(\gamma - \lambda)^2} \gamma^{2t} + \frac{\alpha - \alpha^{-1} \delta^2}{2(\gamma - \lambda)^2} \gamma^{2t} + O(\gamma^t) = \frac{\alpha - 2\delta + \alpha^{-1} \delta^2}{2(\gamma - \lambda)^2} \gamma^{2t} + O(\gamma^t). \hspace{1cm} (8)$$

Now consider $U(d + 1, t)$. Again let $b' := \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^t$. One can verify that we have $\tilde{a}_{b', t} = \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^{t+1} + ab$ if $b \leq b'$ and $\tilde{a}_{b', t} = \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^{t+1}$ otherwise. First we count the pairs $(a, b)$ with $b \leq b'$. Because $\tilde{a}_{b', t} = \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^{t+1} + ab$, for each of the $b'$ possible values for $b$ in this range, there are exactly $\tilde{a}_{b', t} - \tilde{a}_{b', t} = \frac{\gamma - \lambda}{\gamma - \lambda} \gamma^{t+1}$ choices for $a$, so in total there are $\frac{\gamma^t}{\gamma^t} \gamma^{2t} + O(\gamma^t)$ many pairs with $b$ in this range. For pairs with $b \geq b'$, we again take $\tilde{a}_{b', t} - \tilde{a}_{b', t}$ and sum over all $b$ to find that the number of such pairs is

$$\sum_{b=b'}^{\gamma^t/(\gamma - \lambda)} \frac{\gamma - \delta}{\gamma - \lambda} \gamma^t + \alpha b = \frac{\alpha - 2\delta + \alpha^{-1} \delta^2 + 2\gamma - 2\alpha^{-1} \delta \gamma}{2(\gamma - \lambda)^2} \gamma^{2t} + O(\gamma^t), \hspace{1cm} (9)$$

where one can use that the summand of (9) is simply the summand of (7) plus $\frac{\gamma - \lambda}{\gamma - \lambda} \gamma^t$ to quickly compute this sum.

In total then we conclude that

$$|U(d + 1, t)| = \frac{\alpha^{-1} \gamma}{(\gamma - \lambda)^2} \gamma^{2t} + \frac{\alpha - 2\delta + \alpha^{-1} \delta^2 + 2\gamma - 2\alpha^{-1} \delta \gamma}{2(\gamma - \lambda)^2} \gamma^{2t} + O(\gamma^t)$$

$$= \frac{\alpha - 2\delta + \alpha^{-1} \delta^2 + 2\gamma}{2(\gamma - \lambda)^2} \gamma^{2t} + O(\gamma^t). \hspace{1cm} (10)$$

Let $S(n_r, q) = \bigcup_{t \leq r} S(n_r, q, t)$, and similarly define $T(n_r, q)$ and $U(q)$. As mentioned earlier, $|S(n_r, q, t)| = 0$ for $t > r$, so we have

$$|S_p \cap [n_r]| = \sum_{q=0}^{\beta-1} |S(n_r, q)|.$$
By Lemma 4.3, Claim 4.7, and (5); this sum is equal to
\[
\frac{\beta - d}{\beta} |U(d)| + \frac{\beta - d - 1}{\beta} |U(d + 1)| + \sum_{q = d + 2}^{\beta - 1} \frac{\beta - q}{\beta} |T(n_r, q)| + O(\gamma^r + \beta^r),
\]
where implicitly we used that the error term from Lemma 4.3 is at most \(\sum_q \sum_{t \leq r} g_t = O(\gamma^r)\). We also recall that (11) is equal to \(|S_p \cap [n_{c,r}]| + O(\beta^r)\) by (4) (note the use of \(n_{c,r}\) instead of \(n_r\)), which is ultimately what we wish to compute. Note that by (6), for all \(q\) with \(d + 2 \leq q \leq \beta - 1\) we have
\[
|T(n_r, q)| = \sum_{t \leq r} \frac{1}{(\gamma - \lambda)^2 \gamma^{2t + 1} + O(\gamma^r)} = \frac{\gamma^3}{(\gamma - \lambda)^2 (\gamma^2 - 1)} \gamma^{2r} + O(\gamma^r).
\]
Similarly from (8) we find
\[
|U(d)| = \frac{\gamma^2 (\alpha - 2\delta + \alpha^{-1} \delta^2)}{2(\gamma - \lambda)^2 (\gamma^2 - 1)} \gamma^{2r} + O(\gamma^r),
\]
and from (10),
\[
|U(d + 1)| = \frac{\gamma^2 (\alpha - 2\delta + \alpha^{-1} \delta^2)}{2(\gamma - \lambda)^2 (\gamma^2 - 1)} \gamma^{2r} + \frac{\gamma^3}{(\gamma - \lambda)^2 (\gamma^2 - 1)} \gamma^{2r} + O(\gamma^r).
\]
Plugging these values into (11) and dividing by \(n_{c,r} \sim \frac{c}{(\gamma - \lambda)^2} \gamma^{2r+1}\) gives the desired result.

We note that in principle one can use these same methods to prove stronger results. For example, one can prove density results for \(p < \beta\) or for \(c > \gamma/\alpha\). In these cases the condition \(ag_t + \beta bg_{t-1} \leq n\) becomes non-trivial, which makes the computations messier. We refer the reader to [1] for examples of such results when \(\alpha = \beta = 1\).

We now prove our corollaries to Theorem 1.3.

**Proof of Corollary 1.4.** By looking at the formula of Theorem 1.3, we see that we need to show \(d = \beta - 1\) for these values of \(p\). Note that from Claim 4.6 we already know \(d \leq \beta - 1\), so it remains to show \(d > \beta - 2\), or equivalently that \(\beta \gamma^{-1} p - \gamma (\beta - 2) - \alpha > 0\). This is equivalent to
\[
p > \gamma^2 - 2\beta^{-1} \gamma^2 + \alpha \gamma \beta^{-1} = (1 - \beta^{-1}) \gamma^2 + \beta^{-1} \gamma (\alpha - \gamma) = (1 - \beta^{-1}) \gamma^2 - 1,
\]
where in the last equality we used \(\alpha - \gamma = \lambda\) and \(\beta^{-1} \gamma = -\lambda^{-1}\). Because \([x] > x - 1\), this result holds for \(p \geq [(1 - \beta^{-1}) \gamma^2]\) as desired. \(\square\)
Proof of Corollary 1.5. The first result follows by plugging $\beta = 1$ into Corollary 1.4, and then using $\gamma^2 - 1 = \alpha \gamma$ and that $\alpha - 2\gamma^{-1} p + \alpha^{-1} \gamma^{-2} p^2 = (\alpha^{1/2} - \alpha^{-1/2} \gamma^{-1} p)^2$. The second result follows from $1 - \alpha \gamma^{-1} = \gamma^{-2}$.

5 Slowest Slow Walks

Before proving Theorem 1.6, we first consider a slightly more general setting. We say that a set $T$ is valid if $T \subseteq \{ (\alpha, \beta) : \alpha, \beta \geq 1, \gcd(\alpha, \beta) = 1 \}$.

Given any valid $T$, define $s_T(n) = \max_{(\alpha, \beta) \in T} s^{\alpha, \beta}(n)$ and $S_T(n) = \{ (\alpha, \beta) : s^{\alpha, \beta}(n) = s_T(n) \}$. Thus $s(n)$ and $S(n)$ correspond to the case when $T$ is every pair of relatively prime positive integers. It will be of use to define $\Gamma_T = \min_{(\alpha, \beta) \in T} \gamma_{\alpha, \beta}$, and for ease of notation we will simply write this as $\Gamma$ whenever $T$ is understood.

Theorem 5.1. For any valid set $T$, there exists a finite set $R_T$ and number $n_T$ such that $S_T(n) \subseteq R_T$ for all $n \geq n_T$.

Proof. Let $(\alpha', \beta')$ be any pair in $T$ with $\gamma_{\alpha', \beta'} = \Gamma$. For $n > \alpha' \beta'$ we have $s^{\alpha', \beta'}(n) > 2$ by Lemma 3.3, and hence $s_T(n) > 2$ for sufficiently large $n$. If $(\alpha, \beta) \in S_T(n)$ and $\gamma := \gamma_{\alpha, \beta}$, then by applying Proposition 3.4 twice we find, for $n$ sufficiently large,

$$\log \gamma n + 2 \geq s^{\alpha, \beta}(n) = s_T(n) \geq s^{\alpha', \beta'}(n) \geq \frac{1}{2} \log \Gamma n - 1 > \frac{1}{4} \log \Gamma n + 2.$$

In particular this implies $\log \Gamma \gamma < 4$. Since $\gamma_{\alpha, \beta}$ is monotonically increasing in $\alpha$ and $\beta$, the set $R' = \{ (\alpha, \beta) : \log \Gamma \gamma_{\alpha, \beta} < 4 \}$ is finite, so we conclude the result by taking $R_T = R' \cap T$.

It is natural to ask how often a given $(\alpha, \beta)$ lies in $S_T(n)$. To this end, for any set of pairs $S$, we define

$$I_T(S) = \{ n : S \subseteq S_T(n) \}, \quad E_T(S) = \{ n : S = S_T(n) \}.$$

For ease of notation we write $I_T(\alpha, \beta)$ and $E_T(\alpha, \beta)$ instead of $I_T(\{ (\alpha, \beta) \})$ and $E_T(\{ (\alpha, \beta) \})$. We first provide an upper bound on the number of $n$ which have $(\alpha, \beta) \in S_T(n)$.
Proposition 5.2. Let $T$ be a valid set. Given $(\alpha, \beta) \in T$, let $\gamma = \gamma_{\alpha, \beta}$ and $c = \log_{\Gamma} \gamma$. Then

$$|I_T(\alpha, \beta) \cap [n]| = O(n^{2-c}).$$

Proof. Let $(\alpha', \beta')$ be any pair in $T$ with $\gamma_{\alpha', \beta'} = \Gamma$, let $I = I_T(\alpha, \beta)$, and let $G_t = g^\alpha_{t, \beta}$. For the rest of the proof let $g_t = g^\alpha_{t, \beta}$.

Fix an integer $t$. If $t^\alpha_{\gamma}(m) = t$, then by Theorem 1.1 we have $m = ag_t + \beta g_{t-1}$ for some $a, b \geq 1$. If $m \in I$, then we require $t^\alpha_{\gamma}(m) \leq t$. In particular, by Lemma 3.3 we require $ag_t + \beta g_{t-1} = m \leq \beta G_t G_{t-1} = O(\Gamma^{2t})$.

Because $g_t, g_{t-1} = \Omega(\gamma^t)$, we have

$$a + b = O(\Gamma^{2t} \gamma^{-t}) = O(\Gamma^{(2-c)t}).$$

There are at most $O(\Gamma^{(4-2c)t})$ positive $a, b$ satisfying this, and because $m$ is uniquely determined by $a$ and $b$ given $t$, we conclude that there are at most $O(\Gamma^{(4-2c)t})$ integers $m$ with $t^\alpha_{\gamma}(m) = t$ and $m \in I$.

Let $r$ be the smallest integer such that $n \leq \beta G_r G_{r-1}$, and note that $n = \Theta(\Gamma^{2r})$. By summing our above bound for all $t \leq r$, we find

$$|I \cap [n]| = O(\Gamma^{(4-2c)r}) = O(n^{2-c}),$$

as desired. \qed

We do not suspect that this bound is sharp in general. However, it is strong enough to give the following.

Corollary 5.3. If $T$ is a valid set such that there exists a unique pair $(\alpha', \beta') \in T$ with $\gamma_{\alpha', \beta'} = \Gamma$, then

$$n^{-1}|E_T(\alpha', \beta') \cap [n]| \sim 1.$$

That is, almost every $n$ has $S_T(n) = \{(\alpha', \beta')\}$.

Proof. Let $R_T$ be as in Theorem 5.1. For each pair $(\alpha, \beta) \in R_T \setminus \{(\alpha', \beta')\}$, we have $\gamma_{\alpha, \beta} > \Gamma$ by assumption, so $n^{-1}|I_T(\alpha, \beta) \cap [n]| = o(1)$ by Proposition 5.2. Because $E_T(S) \subseteq I_T(\alpha, \beta)$ whenever $(\alpha, \beta) \in S$, this implies that $n^{-1}|E_T(S) \cap [n]| = o(1)$ for each of the finitely many subsets $S \subseteq R_T$ with $S \neq \{(\alpha', \beta')\}$. Because every $m$ with $n_T \leq m \leq n$ has $m \in E_T(S)$ for some $S \subseteq R_T$, we conclude the result. \qed
We now use the ideas developed in this section to prove Theorem 1.6.

Proof of Theorem 1.6. Because $n > 1$, we have $s^{1,1}(n) > 2$ by Lemma 3.3, and hence $s(n) > 2$. If $(\alpha, \beta) \in S(n)$, then by applying Proposition 3.4 twice we find

$$\log_{\gamma_{\alpha,\beta}} n + 2 \geq s^{\alpha,\beta}(n) = s(n) \geq s^{1,1}(n) \geq \frac{1}{2} \log_{\phi} n + 2.$$  

For $n > 1$, this inequality is equivalent to $\log_{\phi} \gamma \leq 2$. Note that $\log_{\phi} \gamma_{3,1} \geq 2.4$, $\log_{\phi} \gamma_{2,2} \geq 2.08$, and $\log_{\phi} \gamma_{1,5} \geq 2.1$. Because $\gamma_{\alpha,\beta}$ is monotonic in $\alpha$ and $\beta$, we conclude that no element not in $R$ can be in $S(n)$. In other words, $S(n) \subseteq R$.

The above result implies $s(n) = \max \{s^{\alpha,\beta}(n) : (\alpha, \beta) \in R\}$. Because $R$ is a finite set, one can compute (in finite time) $s(n)$ and $S(n)$ for any fixed $n$ by computing $s^{\alpha,\beta}(n)$ for each $(\alpha, \beta) \in R$. In particular, one can verify (using the algorithm of Proposition 3.5) that

$$S(32) = \{(1,1), (1,2)\}, S(40) = \{(1,1), (1,3)\}, S(3363) = \{(1,1), (2,1)\},$$

$$S(5307721328585529) = \{(1,1), (1,4)\}.$$  

proving the second part of the theorem. The third part of the theorem follows from Corollary 5.3 and the monotonicity of $\gamma_{\alpha,\beta}$ in $\alpha$ and $\beta$.

We note that $5307721328585529 = g^{1.4}_{39} + 4g^{1.4}_{38}$, and in general it seems that $n$ of the form $n = g^{\alpha,\beta}_t + \beta g^{\alpha,\beta}_t$ are more likely to have $(\alpha, \beta) \in S(n)$.

6 Further Problems

There are a number of questions about slow walks which remain to be answered. For example, one could try and extend other results and problems from [1] to $(\alpha, \beta)$-walks in general. There are also many questions one can ask about slowest slow walks. Recall that for $T$ a set of relatively prime pairs, we define $s_T(n) = \max_{(\alpha, \beta) \in T} s^{\alpha,\beta}(n)$, $S_T(n) = \{(\alpha, \beta) : s^{\alpha,\beta}(n) = s_T(n)\}$, and $\Gamma = \Gamma_T = \min\{\gamma_{\alpha,\beta} : (\alpha, \beta) \in T\}$. From now on we fix such a set of pairs $T$. Define $R'_T = \{(\alpha, \beta) \in T : \gamma_{\alpha,\beta} < \Gamma^2\}$.

Conjecture 6.1. There exist infinitely many $n$ with $(\alpha, \beta) \in S_T(n)$ if and only if $(\alpha, \beta) \in R'_T$.  

27
We note that a sharper analysis of the proof of Theorem 5.1 shows that one can take \( R_T \subseteq \{ (\alpha, \beta) \in T : \log_T \gamma_{\alpha,\beta} \leq 2 \} \), so for the “only if” direction one need only verify the case \( \gamma_{\alpha,\beta} = \Gamma^2 \). One possible direction to prove the “if” direction is the following.

**Conjecture 6.2.** Let \( (\alpha, \beta) \in R'_T \). There exist infinitely many \( t \) such that \( (\alpha, \beta) \in S_T(\alpha^\alpha \beta + \beta \alpha^\beta) \).

We note that it was by looking at integers of the above type that we found an \( n \) with \( (1, 4) \in S(n) \). Using this same approach, we were also able to verify that

\[
\begin{align*}
S(22619537) &= \{(2, 1)\}, \\
S(171) &= \{(1, 2)\}, \\
S(11228332) &= \{(1, 3)\}, \\
S(5000966512101628011743180761388223) &= \{(1, 4)\}.
\end{align*}
\]

Thus for every \( (\alpha, \beta) \in R \) we have \( S(n) = \{ (\alpha, \beta) \} \) for some \( n \). However, other than \( n = 1 \) we have no examples where \( |S(n)| > 2 \). This discussion motivates the following questions. Recall \( I_T(S) = \{ n : S \subseteq S_T(n) \} \) and \( E_T(S) = \{ n : S = S_T(n) \} \).

**Question 6.3.** Which sets of pairs \( S \) have \( |E_T(S)| > 0 \)? Which have \( |E_T(S)| = \infty \)?

In addition to determining the cardinality of these sets, it would be of interest to determine the growth rates of \( |I_T(S) \cap [n]| \) and \( |E_T(S) \cap [n]| \).

**Question 6.4.** Can one effectively bound \( |I_T(S) \cap [n]| \) and \( |E_T(S) \cap [n]| \) for various sets of pairs \( S \)?

An interesting case is \( T = \{(1, 6), (2, 3)\} \). Note that \( \gamma_{1,6} = \gamma_{2,3} = 3 \), so Corollary 5.3 does not apply here.

**Question 6.5.** With \( T = \{(1, 6), (2, 3)\} \), can one bound \( |E_T(1, 6) \cap [n]| \) and \( |E_T(2, 3) \cap [n]| \)?

We show some computational data regarding this question in the appendix.

In this paper we defined \( w_k^{\alpha,\beta} \) to follow a recurrence of depth two. More generally, if \( \alpha = (\alpha_0, \ldots, \alpha_{r-1}) \) is any tuple of positive relatively prime integers, one can define an \( n \)-slow \( \alpha \)-walk to be a sequence \( w_k^{\alpha} \) of positive integers satisfying \( w_{k+r}^{\alpha} = \sum_{i=0}^{r-1} \alpha_i w_{k+i}^{\alpha} \) and which generates \( n \) as slowly as possible.

28
Question 6.6. What can be said about \( n \)-slow \( \alpha \)-walks? In particular, what can be said about “tribonacci walks” which have \( \alpha = (1, 1, 1) \)?

Given these definitions, for any set \( T \) of tuples of positive relatively prime integers, one could define \( s_T(n) = \max\{s^\alpha(n) + 2 - |\alpha| : \alpha \in T\} \) and \( S_T(n) = \{\alpha \in T : s^\alpha(n) = s_T(n)\} \). Note that we subtract the length of \( \alpha \) in the definition of \( s_T(n) \) to make this quantity finite, as otherwise one could always consider the tuple \((1, 1, \ldots, 1, n)\) with any number of 1’s. This issue could also be resolved by only considering \( T \) consisting of tuples of bounded length.

Question 6.7. What can be said about \( s_T(n) \) and \( S_T(n) \) when \( T \) is a set of tuples?

Appendix: Computational Data

We first present results concerning densities of the sets $S_p$. Throughout we denote the asymptotic densities that Theorem 1.3 predicts by gray curves and the actual data by black dots. We show the data curve for all $n_{c,r}$ with $1 \leq c \leq \gamma^2$ and some fixed value $r$, though we recall that Theorem 1.3 only gives information in the range $1 \leq c \leq (p - \beta + 1)\gamma/\alpha$.

We first consider the case $\alpha = \beta = 1$. The data we show corresponds to the case $r = 12$ and $p = 1$ in the statement of Theorem 1.3.

We note that [1] includes figures with this theory curve extended to all $1 \leq c \leq \gamma$.

Next we show data for $\alpha = 2, \beta = 1, r = 7$ and $1 \leq p \leq 4$. 

\[ \begin{array}{c}
\alpha = 1, \beta = 1, r = 12, p = 1 \\
\end{array} \]
\( \alpha = 2, \beta = 1, r = 7, p = 1 \)

\( \alpha = 2, \beta = 1, r = 7, p = 2 \)
We now show all four of these data plots for $\alpha = 2, \beta = 1$ together in a single plot.
We next show data for $\alpha = 1$, $\beta = 5$, $r = 4$, and $5 \leq p \leq 6$. We note that amongst the data we show, the $p = 5$ case here is the only case where the simpler formula of Corollary 1.4 does not apply.

$\alpha = 1, \beta = 5, r = 4, p = 5$
Finally, we show all of the data plots for $1 \leq p \leq 6$.

We next present data regarding slowest slow walks. Let $i_{\alpha,\beta}(n) = |\{m : m \leq n, (\alpha, \beta) \in S(m)\}|$. Note that Proposition 5.2 gives an upper bound on this values. Below we give a plot of $i_{1,2}(n)$ for $1 \leq n \leq 50,000$. We note that $i_{1,3}(n)$, $i_{1,4}(n)$, and $i_{2,1}(n)$ are all too small in this range to extrapolate anything from their plots.
Below is a log-log plot of $i_{1,2}(n)$ in the range $30,000 \leq n \leq 50,000$. The line is $y = (2 - \log_2(2))x - .47$. As $\gamma_{1,2} = 2$, this may suggest that in this case the upper bound of Proposition 5.2 is close to tight.

Let $T = \{(1, 6), (2, 3)\}$ and $e_{\alpha,\beta}(n) = n^{-1}|\{m : m \leq n, S_T(m) = \{(\alpha, \beta)\}\}|$. Recall that for this $T$ Corollary 5.3 does not apply. Below we plot $e_{1,6}(n)$ with solid blue dots and $e_{2,3}(n)$ with open black circles for $1 \leq n \leq 500,000.$
Based on this data, it seems that both of these values are $\Omega(1)$, that $e_{2,3}(n) \geq e_{1,6}(n)$ for all $n$, and that these exact values oscillate in some way. We emphasize that we do not have proofs of any of these observations. We end this section with a plot of the ratio $e_{2,3}(n)/e_{1,6}(n)$.
