LOWER SETS IN $\mathbb{N}^m$

HARRY ALTMAN AND ANDREAS WEIERMANN

Abstract. We compute the type (maximum linearization) of the well partial order of bounded lower sets in $\mathbb{N}^m$, ordered under inclusion, and find it is $\omega^{\omega^{m-1}}$; we give two proofs of this statement. Moreover we compute the type of the set of all lower sets in $\mathbb{N}^m$, as was asked about by Aschenbrenner and Pong [3], and find that it is

$$\omega \sum_{k=1}^{m} \omega^{m-k} \binom{m}{k-1} + 1.$$  

As a consequence we deduce corresponding bounds on sequences of monomial ideals.

1. Introduction

In this paper we compute the type of several well partial orders. The type of a well partial order $X$, denoted $o(X)$, is the largest order type of a well-order extending the order on $X$; this was proven to exist by De Jongh and Parikh [4], and the theory has been rediscovered several times; the term “type” comes from Kriz and Thomas [5]. The type $o(X)$ can also be characterized inductively as the smallest ordinal greater than $o(Y)$ for any proper lower set $Y$ of $X$.

In this paper we are interested in well partial orders whose elements are lower sets in the partial order $\mathbb{N}^m$. We define:

Definition 1.1. If $X$ is a partial order, we define $I(X)$ to be the poset of lower sets in $X$ ordered under inclusion, and define $D(X)$ to consist of those elements of $I(X)$ that can be obtained as the downward closure of finitely many elements.

Then we are interested in $D(\mathbb{N}^m)$ and $I(\mathbb{N}^m)$. (Note that in the case of $\mathbb{N}^m$, we could equivalently define $D(\mathbb{N}^m)$ to be the set of bounded lower sets, or the set of finite lower sets.) We prove the following two theorems:

Theorem 1.2.

$$o(D(\mathbb{N}^m)) = \omega^{\omega^{m-1}}.$$ 

Furthermore,

$$o(D(\mathbb{N}^m \times k)) = \omega^{\omega^{m-1}k}.$$ 

Theorem 1.3.

$$o(I(\mathbb{N}^m)) = \omega \sum_{k=1}^{m} \omega^{m-k} \binom{m}{k-1} + 1.$$ 

The second of these questions, that of determining $o(I(\mathbb{N}^m))$, was asked about earlier by Aschenbrenner and Pong [3], who provided upper and lower bounds. Theorem 1.3 now provides an exact answer to this question.

Theorem 1.2, the case of $D(\mathbb{N}^m)$, is the “core” case, handled inductively, via the inductive characterization of $o(X)$ above. Meanwhile, the case of $D(\mathbb{N}^m \times k)$
is handled combinatorially, by taking our result for \( D(\mathbb{N}^m) \) and combining it with itself, via De Jongh and Parikh’s theorems that \( o(X \sqcup Y) = o(X) \oplus o(Y) \) and \( o(X \times Y) = o(X) \otimes o(Y) \), where \( \oplus \) and \( \otimes \) are the natural (or Hessenberg) sum and product of ordinals.

By using these two approaches we can determine \( o(D(\mathbb{N}^m)) \) and \( o(D(\mathbb{N}^m \times k)) \) for arbitrarily \( m \) and \( k \). The case of \( I(\mathbb{N}^m) \) is also handled by a combinatorial argument, putting together \( D(\mathbb{N}^m) \) together with \( D(\mathbb{N}^C) \), where \( C \) ranges over nonempty subsets of \( \{1, \ldots, m\} \).

In Section 3 we will show how to apply these results to sequences of monomial ideals.

In a future paper 2, we will extend these results to lower sets in products of larger ordinals as well.

2. Bounded lower sets in \( \mathbb{N}^m \)

In this section we show how to compute \( o(D(\mathbb{N}^m)) \), proving Theorem 1.2. First, some notation:

**Notation 2.1.** For \( X \) a partially-ordered set and \( x \in X \), we define \( U(x) \) to be \( \{ y \in X : y \geq x \} \), the upward closure of \( X \).

Now, we prove Theorem 1.2.

**Proof of Theorem 1.2.** We induct on \( m \).

To prove the first statement, assume both statements are true for smaller values of \( m \). We want to find the smallest ordinal greater than \( o(D(\mathbb{N}^m) \setminus U(S)) \) for any \( S \in D(\mathbb{N}^m) \). First we will prove the upper bound. Any such \( S \) is contained in a rectangle \( k_1 \times \ldots \times k_m \), so we may assume that \( S \) is such a rectangle.

So consider \( T \in D(\mathbb{N}^m) \) not containing \( S \). If \( k_i \subseteq \pi_i(T) \) for all \( i \), then we’d have \( S \subseteq T \); so there is at least one \( i \) for which \( k_i \nsubseteq \pi_i(T) \), and thus \( \pi_i(T) \subseteq k_i \). Thus \( T \) is an element of \( D((k_1 \times \mathbb{N} \times \ldots \times \mathbb{N}) \cup \ldots \cup (\mathbb{N} \times \ldots \times \mathbb{N} \times k_m)) \).

In other words,

\[
D(\mathbb{N}^m) \setminus U(S) \subseteq D((k_1 \times \mathbb{N} \times \ldots \times \mathbb{N}) \cup \ldots \cup (\mathbb{N} \times \ldots \times \mathbb{N} \times k_m)).
\]

Moreover, there is an obvious inclusion from

\[
D((k_1 \times \mathbb{N} \times \ldots \times \mathbb{N}) \cup \ldots \cup (\mathbb{N} \times \ldots \times \mathbb{N} \times k_m))
\]

into

\[
D(k_1 \times \mathbb{N} \times \ldots \times \mathbb{N}) \times \ldots \times D(\mathbb{N} \times \ldots \times \mathbb{N} \times k_m).
\]

Therefore, \( o(D(\mathbb{N}^m) \setminus U(S)) \) is at most a finite natural product of ordinals of the form \( o(D(\mathbb{N}^{m-1} \times k)) \), which, by the inductive hypothesis, is equal to \( \omega^{\omega^{m-2}k} \). In particular it is less than \( \omega^{\omega^{m-1}} \). Therefore \( o(D(\mathbb{N}^m)) \leq \omega^{\omega^{m-1}} \).

The lower bound follows immediately as well from the fact that \( o(D(\mathbb{N}^m)) \geq o(D(\mathbb{N}^{m-1} \times k)) \) for any \( k \).

Now we prove the second statement, assuming the first statement for the same value of \( m \).

The upper bound is clear, since there’s an obvious embedding of \( D(\mathbb{N}^m \times k) \) into \( D(\mathbb{N}^m \times k) \). That leaves the lower bound. For this, we induct on \( k \). The case \( k = 1 \) has already been proven above, so that leaves the inductive step.
We will construct a total order extending $D(\mathbb{N}^m \times k)$ that has the required order type. First, choose an total order extending $D(\mathbb{N}^m \times \{k-1\})$ of type $\omega^{m-1}$; this is possible by the above. We will sort the elements $S$ of $D(\mathbb{N}^m \times k)$ first by the value of $S \cap (\mathbb{N}^m \times \{k-1\})$ (according to this order), and then find some way to break the ties.

So consider some element $T \in D(\mathbb{N}^m \times \{k-1\})$ and consider the set $P_T$ of $S \in D(\mathbb{N}^m \times k)$ such that $S \cap (\mathbb{N}^m \times \{k-1\}) = T$. What is the maximum extending ordinal of this set? Well, observe that there is some element $x \in \mathbb{N}^m$ such that $(x, k-1) \notin T$. So in fact $U(x) \times \{k-1\}$ is disjoint from $T$; and $U(x)$ is isomorphic to $\mathbb{N}^m$. This gives us an inclusion of $D(\mathbb{N}^m \times \{k-1\})$ into $P_T$, so $o(P_T)$ is (by the induction hypothesis) at least $\omega^{m-1}(k-1)$.

Therefore $o(D(\mathbb{N}^m \times k)) \geq \omega^{m-1}(k-1)\omega^{m-1} = \omega^{m-1}k$. This completes the proof. \hfill \Box

2.1. An alternate proof. It is worth noting that if one merely wants to prove that $o(D(\mathbb{N}^m)) \leq \omega^{m-1}$, there is actually a substantially simpler proof. An unpublished lemma of Schnoebeelen and Schmitz states:

Lemma 2.2 (Schnoebeelen, Schmitz). Let $X$ be a well partial order. Then

$$o(D(X)) \leq 2^{o(X)}.$$ 

Applying this with $X = \mathbb{N}^m$ immediately yields the upper bound above, since $o(\mathbb{N}^m) = \omega^m$ and $2\omega^m = \omega^{m-1}$.

Note that Schnoebeelen and Schmitz actually stated their lemma not for $D(X)$, but rather for the more commonly-studied $\wp_{\text{fin}}(X), \subseteq_m$, where we define $S \leq T$ if for every $s \in S$, there is some $t \in T$ with $s \leq t$. Of course, $\wp_{\text{fin}}(X), \subseteq_m$ is not actually isomorphic to $D(X)$, as the former lacks antisymmetry, being only a quasi-order rather than a partial order; but after quotienting out by equivalences the resulting partial order is isomorphic to $D(X)$. So in essence these are the same.

Since no proof of Lemma 2.2 appears in the literature, we provide one:

Proof. We use standard arguments from [3] (following the lines of [4]). First note that if $o(X) = 0$ (i.e., $X$ is empty), the statement is trivial.

Now suppose that $o(X)$ is a limit ordinal. Then $2^{o(X)}$ is a power of $\omega$, i.e., additively closed. Let $I$ be a an element of $D(X)$. We know that $I$ is the downward closure of a finite set; call this set $F$. We have to show that the type of $\{ J \in D(X) : J \not\supset I \}$ is less than $2^{o(X)}$. So assume that $J$ is an element of $D(X)$ not containing $I$. Then there is some $x \in F$ not contained in $J$. Hence $J \in D(\{y : y \not\supset x\})$. So $\{ J \in D(X) : J \not\supset I \}$ is contained in the union of the sets $D(\{y : y \not\supset x\})$ for $x \in F$, and so its type is at most the natural sum of their types. By the inductive hypothesis, $o(\{ y : y \not\supset x \}) < o(X)$ since the former is a proper lower set in $X$, so $o(D(\{ y : y \not\supset x \})) < 2^{o(X)}$. As $2^{o(X)}$ is additively closed, the natural sum of these types is also less than $2^{o(X)}$.

Finally suppose that $o(X)$ is a successor; say $o(X) = \alpha + 1$. Then there exists $x \in X$ such that $x$ is maximal in $X$ and $o(X \setminus \{x\}) = \eta$; this $x$ exists as a corollary of De Jongh and Parikh [4]. So if $I \in D(X)$, then either $I \in D(X \setminus \{x\})$ or $x \in I$. Moreover, there is a monotonic surjection from $D(X \setminus \{x\})$ to $\{ I \in D(X) : x \in I \}$ given by taking the union with $\{x\}$. So, applying the inductive hypothesis, $o(D(X)) \leq 2^\eta \oplus 2^\eta = 2^{\eta+1} = 2^{o(X)}$. (This equation holds since $2^n$
necessarily contains only a single distinct power of \( \omega \) in its Cantor normal form.) This completes the proof.

\[ \text{Corollary 2.3.} \quad o(D(\mathbb{N}^m)) \leq \omega^{m-1}. \]

We also provide an alternate, more direct proof of the lower bound:

\[ \text{Proposition 2.4.} \quad o(D(\mathbb{N}^m)) \geq \omega^k. \]

\[ \text{Proof.} \quad \text{For a sequence} \ a = (a_1, \ldots, a_k) \text{of length} \ k \text{we define} \ ord(a) = \omega^{k-1} \cdot a_1 + \cdots + \omega^0 \cdot a_k. \text{For a finite non empty downward closed subset} \ F \text{in} \ \mathbb{N}^m \text{assume that} \ F \text{is the downward closure of} \ s(F) = \{(a_1, b_1), \ldots, (a_l, b_l)\} \text{where} \ a_i \text{is in} \ \mathbb{N}^{m-1} \text{and} \ b_i \text{is in} \ \mathbb{N} \text{and each} \ (a_j, b_j) \text{is maximal with respect to the pointwise ordering. Let} \ ord(s(F)) \text{be the natural sum over} \ 1 \leq i \leq l \text{of the terms} \ \omega^{ord(a_j)} \cdot b_j. \text{Let} \ ord(F) := 1 + ord(s(F)). \text{If} \ F \text{is empty then} \ ord(F) := 0. \text{(Note the the zero vector describes the second minimal element.) We prove by induction on the cardinality of} \ s(G) \text{that} \ F \subseteq G \text{implies} \ ord(F) \leq ord(G). \text{The claim follows from this.}

\text{So assume} \ \emptyset \neq F \leq G \text{and assume that} \ s(F) = \{(a_1, b_1), \ldots, (a_l, b_l)\} \text{and} \ s(G) = \{(c_1, d_1), \ldots, (c_m, d_m)\}. \text{Let} \ S_1 := \{(a, b) \in s(F) : -(a, b) \leq (c_1, d_1)\} \text{and} \ S_2 := \{(a, b) \in s(F) : (a, b) \leq (c_1, d_1)\}. \text{Then} \ S_1 \leq s(G) \setminus \{(c_1, d_1)\} \text{and by induction hypothesis we may assume that} \ ord(s(S_1)) \leq ord(s(G) \setminus \{(c_1, d_1)\}) \text{if} \ S_1 \text{is not empty. It thus suffices to show} \ ord(S_2) \leq ord(\{(c_1, d_1)\}). \text{If} \ S_2 \text{is a singleton then the assertion follows easily. Problems might occur when} \ S_2 \text{is not a singleton because} \ ord(\{(c_1, d_1)\}) \text{is in general not additively closed. We may assume after renumbering that} \ S_2 = \{(a_1, b_1), \ldots, (a_n, b_n)\}. \text{Assume that there is one} \ (a_i, b_i) \in S_2 \text{such that} \ a_i = c_1. \text{Then} \ b_i = d_1 \text{is excluded because if} \ (a_j, b_j) \in S_2 \text{is another element then} \ (a_j, b_j) \leq (c_1, d_1) = (a_i, b_i) \text{and} \ (a_j, b_j) \text{would not be maximal. Therefore} b_i < d_1. \text{Now pick any} \ (a_j, b_j) \in S_2 \text{different from} \ (a_i, b_i). \text{Then} a_j = a_i \text{is impossible since then either} \ (a_i, b_i) \text{is not maximal if} b_i < b_j \text{or} \ (a_j, b_j) \text{is not maximal if} b_j < b_i. \text{Since} \ (a_j, b_j) \leq (c_1, d_1) \text{we conclude} a_j < c_1 = a_i \text{. Since} a_j \neq c_1 \text{we conclude that} a_j < c_1 \text{so that} \ ord(a_j) < ord(c_1). \text{This means that all such terms} \ (a_j, b_j) \text{get assigned ordinals} \ \omega^{ord(a_j)} \cdot b_j < \omega^{ord(c_1)}. \text{Summing up all terms for elements in} \ S_2 \text{we get a strict upper bound provided by} \ \omega^{ord(c_1)} \cdot b_1 + \omega^{ord(c_1)} \cdot \sum_{j=2}^n a_j < \omega^{ord(c_1)} \cdot d_1 = ord(\{(c_1, d_1)\}). \] \[ \Box \]

\[ \text{Corollary 2.5.} \quad o(D(\mathbb{N}^m)) = \omega^{m-1}. \]

3. General lower sets in \( \mathbb{N}^m \)

In this section we show how to compute \( o(I(\mathbb{N}^m)) \). As we will see, \( I_0(\mathbb{N}^m) \) can be approximately decomposed as a product over nonempty \( C \subseteq \{1, \ldots, m\} \) of \( D(\mathbb{N}^C) \); however, the exact nature of this decomposition will be slightly different in the upper bound proof and in the lower bound proof.

3.1. The upper bound proof. We begin with some definitions and a proposition that will allow us to express one half of this decomposition:

\[ \text{Definition 3.1.} \quad \text{Given a function} \ f : S \to T \text{and} \ A \subseteq S, \text{define the "intersection image"} \ \tilde{f}(A) \text{to be} \ T \setminus f(S \setminus A), \text{or equivalently to be} \ \{p \in T : f^{-1}(p) \subseteq A\}. \]

\[ \text{Definition 3.2.} \quad \text{For a partial order} \ X, \text{define} \ I_0(X) = I(X) \setminus \{X\}. \]

We will also need the following lemma. Since we are unaware of any reference for it in the literature, we include a proof ourselves.
Lemma 3.3. Let $X = \alpha_1 \times \ldots \times \alpha_m$ be a finite Cartesian product of well-orders. Then any lower set of $X$ is a finite union of rectangles $\beta_1 \times \ldots \times \beta_m$ for some $\beta_i \leq \alpha_i$.

Proof. We induct on $m$. For $m = 0$, the statement is trivial (and additionally it is well-known for $m = 1$). So suppose it is true for $m$ and we wish to show it for $m + 1$.

Let $X$ be a lower set in $\alpha_1 \times \ldots \times \alpha_{m+1}$. For $\eta < \alpha_{m+1}$, define $X_\eta = X \cap (\alpha_1 \times \ldots \times \alpha_m \times \{\eta\})$; we can then ignore the last coordinate and consider $X_\eta$ as a subset of $\alpha_1 \times \ldots \times \alpha_m$; more specifically, as a lower set. Since $X$ itself is a lower set, the $X_\eta$ form a weakly decreasing sequence in $I(\alpha_1 \times \ldots \times \alpha_m)$.

Since this set is a well partial order (or simply because it is well-founded), this sequence must take on only finitely many values. Call these values $Y_1, \ldots, Y_k$; we may also define corresponding ordinals $\gamma_1, \ldots, \gamma_k$, such that $X_\eta = Y_i$ if and only if $\gamma_{i-1} \leq \eta < \gamma_i$ (we consider $\gamma_0$ to be 0). Note that $\gamma_k$ may be equal to $\alpha_{m+1}$, rather than less than it. Also note that since the sequence of $Y_i$ is decreasing, one always has $Y_i \times \gamma_i \subseteq X$. Conversely, it’s clear from the definition of $Y_i$ and $\gamma_i$ that $X$ is the union of the $Y_i \times \gamma_i$.

Now, by the inductive hypothesis, each $Y_i$ is a finite union of rectangles as described above, and thus so is each $Y_i \times \gamma_i$, and thus so is $X$, their union. \qed

Now, we can prove:

Proposition 3.4. Take ordinals $\alpha_1, \ldots, \alpha_m > 0$, with $m \geq 1$. For a subset $C$ of $\{1, \ldots, m\}$, let $\pi_C$ be the projection from $\alpha_1 \times \ldots \times \alpha_m$ onto $\prod_{i \in C} \alpha_i$ (all products here are Cartesian). Define a map

$$\varphi : \prod_{\emptyset \neq C \subseteq \{1, \ldots, m\}} D(\prod_{i \in C} \alpha_i) \to I_0(\alpha_1 \times \ldots \times \alpha_m)$$

by

$$\varphi((S\cap C)_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\}}) = \bigcup_{\emptyset \neq C \subseteq \{1, \ldots, m\}} \pi_C^{-1}(S\cap C).$$

Then $\varphi$ is monotonic, surjective, and well-defined (i.e., its image lies within $I(\alpha_1 \times \ldots \times \alpha_m)$, and does not contain $\alpha_1 \times \ldots \times \alpha_m$ as an element).

Proof. That $\varphi$ is monotonic is obvious. To see that $\varphi$ is well-defined, note that any bounded lower set $T \subseteq \prod_{i \in C}$, is, so long as $C \neq \emptyset$, a proper lower set, and thus its inverse image $\pi_C^{-1}(T)$ is a proper lower subset of $\alpha_1 \times \ldots \times \alpha_m$. Moreover, the union of any two proper lower subsets of $\alpha_1 \times \ldots \times \alpha_m$ is again a proper lower subset, since if one excludes a point $x$ and the other excludes a point $y$, then their union will exclude any point that is at least both $x$ and $y$, such as their join.

This leaves surjectivity. So say we have some $T \in I_0(\alpha_1 \times \ldots \times \alpha_m)$; by Lemma 3.3, write it as a finite union of rectangles $T = \bigcup_{k=1}^r T_k$, where each $T_k$ can be written as $\beta_{k,1} \times \ldots \times \beta_{k,m}$ for $\beta_{k,i} \leq \alpha_i$.

Now, it’s easy to see that if we have two tuples $((U\cap C)_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\}}$ and $((V\cap C)_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\}}$, then

$$\varphi((U \cup V)\cap C_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\}) = \varphi((U\cap C)_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\}} \cup \varphi((V\cap C)_{C \in \mathcal{P}(\{1, \ldots, m\}) \setminus \{\emptyset\})).$$
As such it suffices to prove that each rectangle $T_k$ lies in the image of $\varphi$; so for simplicity just assume $T = T_1$ and write $T = \beta_1 \times \ldots \times \beta_m$.

So define $C_0 = \{ i : \beta_i < \alpha_i \}$; since $T \neq \alpha_1 \times \ldots \times \alpha_m$, this means that $C_0 \neq \emptyset$.

Then define $S_{C_0} = \pi_{C_0}(T)$, and $S_C = \emptyset$ for $C \neq C_0$. Then since $\pi_{C_0}^{-1}(S_{C_0}) = T$, we have $\varphi((S_C)_{C \in \mathcal{C}(\{1, \ldots, m\}) \setminus \emptyset}) = T$, as needed. $\square$

Thus we can conclude the upper bound:

**Theorem 3.5.**

$$o(I(\mathbb{N}^m)) \leq \omega \sum_{k=1}^m \omega^{-k}(m_k) + 1.$$ 

**Proof.** Applying Proposition 3.4 with $\alpha_i = \omega$ for all $i$, together with Theorem 1.2 yields that

$$o(I_0(\mathbb{N}^m)) \leq \omega \sum_{k=1}^m \omega^{-k}(m_k);$$

since $I(\mathbb{N}^m) = I_0(\mathbb{N}^m) \cup \{\mathbb{N}^m\}$, we conclude

$$o(I_0(\mathbb{N}^m)) \leq \omega \sum_{i=1}^m \omega^{-k}(m_i) + 1. \quad \square$$

### 3.2. The lower bound proof.

For the proof of the lower bound, we will need an additional definition. Rather than deal with fully specified lower sets in $I(\mathbb{N}^m)$, we will also define “partial specifications” of such sets.

**Definition 3.6.** A partial specification $X$ on $\mathbb{N}^m$ consists of a nonempty set $\mathcal{C} \subseteq I(\{1, \ldots, m\})$ with the additional property that if $|C| < |D|$ and $D \in \mathcal{C}$, then $C \in \mathcal{C}$; together with, for each $C \in \mathcal{C}$, a set $X_C \in I_0(\prod_{i \in C} \mathbb{N})$ such that, whenever $C$ and $D$ are two sets in $\mathcal{C}$ and $D \subseteq C$, we have $X_D = \pi_D(X_C)$. We refer to $\mathcal{C}$ as the domain of $X$.

Given a partial specification $X$ on $\mathbb{N}^m$ and a set $S \in I_0(\mathbb{N}^m)$, we will say that $S$ is compatible with $X$ if $\pi_C(S) = X_C$ for each $C \in \mathcal{C}$. We define $\mathcal{X}_X$ to be the set of all $S \in I_0(\mathbb{N}^m)$ compatible with $X$.

We will show here how to get a lower bound on $o(\mathcal{X}_X)$ for any partial specification $X$, based only on the domain of $X$. Then, to get a lower bound on $o(I_0(\mathbb{N}^m))$, we need only take $X$ to be the unique partial specification on $\mathbb{N}^m$ with domain $\{\emptyset\}$, since every proper lower set in $\mathbb{N}^m$ is compatible with this specification. (Conversely, if the domain of $X$ is $\varphi(\{1, \ldots, m\})$, then $X_{\{1, \ldots, m\}}$ is the unique element of $I_0(\mathbb{N}^m)$ that is compatible with $X$.)

With both the components of the upper and lower bounds laid out, we can now prove the theorem.

**Proposition 3.7.** Let $X$ be a partial specification $X$ on $\mathbb{N}^m$ with domain $\mathcal{C}$. Then

$$o(\mathcal{X}_X) \geq \bigotimes_{C \notin \mathcal{C}} \omega^{|C|-1}. \quad (*)$$

In fact, by the arguments above, this lower bound will actually be an equality, but we only care about the lower bound. Note $o(\mathcal{X}_X)$ increases as the domain of $X$ gets smaller; the less-specified $X$ is, the more sets are compatible with it.

**Proof.** We prove this by induction on the domain. It’s trivially true for any partial specification $X$ on $\mathbb{N}^m$ with domain $\varphi(\{1, \ldots, m\})$, since in this case one will have $|\mathcal{X}_X| = 1$ and the product will be 1 as well. So suppose $\mathcal{C}$ is a lower set in $\{1, \ldots, m\}$
and the statement holds for all partial specifications on \( \mathbb{N}^m \) with domain \( \mathcal{C} \). Pick some \( C \in \mathcal{C} \) of maximum cardinality; we want to show the statement holds for any partial specification with domain \( \mathcal{C} \setminus C \).

So let \( X \) be a partial specification with domain \( \mathcal{C} \setminus C \). We want to put a total order on \( \mathcal{A}_X \) in order to get a lower bound on \( o(\mathcal{A}_X) \). Given any \( S \in \mathcal{A}_X \), we can obtain a partial specification \( Y \) with domain \( \mathcal{C} \) by taking \( Y_D = \pi_D(S) \) for \( D \in \mathcal{C} \); observe then that \( S \in \mathcal{A}_Y \). Obviously, any such \( Y \) has \( Y_D = X_D \) for any \( D \neq C \); the only distinguishing feature of \( Y \) is the value of \( Y_C \).

Note that not every \( T \in I_0(\prod_{i \in C} \mathbb{N}) \) is a possible value of \( Y_C \), since if \( T = Y_C \) we have the restriction that for \( D \subseteq C \) we have \( \pi_D(T) = X_D \). But given such a \( T \) we can define \( Y(T) \) to be \( Y \) obtained by setting \( Y_C = T \). So we will put a total order on \( \mathcal{A}_X \) by first putting a total order on the set of such \( T \) (call this set \( \mathcal{T} \)), and sorting elements \( S \) of \( \mathcal{A}_X \) by the value of \( \pi_C(S) \); and then, for each such \( T \), putting a total order on \( \mathcal{A}_Y(T) \). So we will get a lower bound on \( o(\mathcal{A}_X) \) of the form \( \sum_{T \in \mathcal{T}} o(\mathcal{A}_Y(T)) \) (using the total order on \( \mathcal{T} \) that we have picked).

In fact, by the inductive hypothesis, for any \( T \in \mathcal{T} \), we know that

\[
o(\mathcal{A}_Y(T)) \geq \bigotimes_{D \notin \mathcal{C}} \omega^{\omega^{\omega|D|-1}}.
\]

Thus, we immediately get that

\[
o(\mathcal{A}_X) \geq \left( \bigotimes_{D \notin \mathcal{C}} \omega^{\omega^{\omega|D|-1}} \right) o(\mathcal{T}).
\]

It then remains to show that \( o(\mathcal{T}) \geq \omega^{\omega^{|C|-1}} \). Once we know this, we will have

\[
o(\mathcal{A}_X) \geq \bigotimes_{D \notin \mathcal{C}} \omega^{\omega^{\omega|D|-1}},
\]

because, by assumption, \( |C| \leq |D| \) for any \( D \notin \mathcal{C} \), and so the ordinary product here coincides with the natural product.

So let \( A \subseteq \prod_{i \in C} \mathbb{N} \) be defined by \( A = \bigcup_{D \subseteq C} \pi_D^{-1}(X_D) \). Then for any \( V \in D(\prod_{i \in C} \mathbb{N}), A \cup V \in \mathcal{T} \). Pick some \( b \in (\prod_{i \in C} \mathbb{N}) \setminus A \), and let \( U(b) \) be the set of elements of \( \prod_{i \in C} \mathbb{N} \) that are at least \( b \). Given \( V \in D(U(b)) \) let \( L(V) \) be the downward closure of \( V \) in \( \prod_{i \in C} \mathbb{N} \). Observe that the map from \( D(U(b)) \) to \( \mathcal{T} \) given by \( U \mapsto A \cup L(V) \) is injective and indeed an embedding. Also observe that \( U(b) \) is isomorphic to \( \mathbb{N}^{|C|} \). So by Theorem 1.2, \( o(D(U(b))) = \omega^{\omega^{|C|-1}} \), and so \( o(\mathcal{T}) \geq \omega^{\omega^{|C|-1}} \), as needed. This completes the proof.

We can now prove the lower bound:

**Theorem 3.8.**

\[
o(I(\mathbb{N}^m)) \geq \omega^{\sum_{k=1}^{m} \omega^{m-k}(k-1)} + 1.
\]

**Proof.** Let \( X \) be the unique partial specification on \( \mathbb{N}^m \) with domain \( \{0\} \); then \( I_0(\mathbb{N}^m) = \mathcal{A}_X \). By Proposition 3.7, then,

\[
o(I_0(\mathbb{N}^m)) = o(\mathcal{A}_X) \geq \omega^{\sum_{k=1}^{m} \omega^{m-k}(k-1)}.
\]

Therefore

\[
o(I(\mathbb{N}^m)) \geq \omega^{\sum_{k=1}^{m} \omega^{m-k}(k-1)} + 1,
\]

proving the theorem.
3.3. **Putting together the proof.** Finally, we can put the above together to yield the proof.

**Proof of Theorem 3.3.** The upper bound is Theorem 3.3 and the lower bound is Theorem 3.8. □

4. **Application to monomial ideals**

We now discuss possible applications to computational complexity and provide complementary results to Corollary 3.27 in [4]. In the sequel we work with ordinals below $\omega^\omega$. For these ordinals we look at the multiply recursive functions defined by the Hardy functions $H_\alpha : \mathbb{N} \to \mathbb{N}$ which are defined recursively as follows. Let $H_0(x) := x$, $H_{\alpha+1}(x) := H_\alpha(x + 1)$ and for a limit $\lambda$ let $H_\lambda(x) := H_{\lambda[\beta]}(x + 1)$ where $\lambda[x]$ denotes the $x$-th member of the canonical fundamental sequence for $\lambda$.

These fundamental sequences are defined by recursion as follows. If $\lambda = \omega^\alpha$ with $\alpha$ a limit then $\lambda[x] = \omega^{\alpha[x]}$. If $\lambda = \omega^{\beta+1}$ then $\lambda[x] = \omega^\beta \cdot x$. If $\lambda = \omega^\beta + \lambda'$ with $\lambda' < \lambda$ a limit then $\lambda[x] = \omega^\beta + \lambda'[x]$.

By standard results (see, for example, Lemma 4 in [1]) it is known that $H_{\omega^\alpha}$ is a variant of the non primitive recursive Ackermann function, and $H_{\omega^{\alpha+2}}$ is roughly the result of iterating the Ackermann function twice.

Let us define a complexity measure for downward closed sets in $\mathbb{N}^k$. For finite $\alpha$ put $N\alpha = \alpha$ and for $\alpha = \omega$ put $N\alpha = 0$. This measure is extended to initial intervals as follows: put $N(\alpha_1 \times \cdots \times \alpha_k) := \max\{N\alpha_i : i \leq k\}$. If downward closed set $D$ is a finite union of intervals $J_i$ then we put $ND := \max\{N(J_i)\}$.

**Lemma 4.1.** For a given $K \in \mathbb{N}$ there exists a sequence $(D_i)_{i=1}^L$ of downward closed sets contained in $\mathbb{N}^2$ such that $L \geq H_{\omega^{\alpha+2}}(K) - K$, such that $ND_i \leq (K + i)^2$ for $1 \leq i \leq L$, and such that $D_i$ is not contained in $D_j$ for $1 \leq i < j \leq L$.

**Proof.** Let $\alpha_0 := \omega^{\alpha+2}$ and let $\alpha_{i+1} := \alpha_i [k + i]$. Then

$H_{\alpha_0}(K) = H_{\alpha_0}[K](K + 1) = \ldots = H_{\alpha_0}[K][K + 1] \ldots [K + l - 1](K + L) = K + L$

where $l$ is minimal with $\alpha_0[K][K + 1] \ldots [K + l - 1] = 0$.

For $\alpha = \omega^{\alpha+1} \cdot p + \omega^\beta \cdot q + \omega^{\alpha_1} \cdot b_1 + \ldots + \omega^{\alpha_r} \cdot b_r$ let

$N\alpha := p + q + b_1 + \cdots + b_r + \max\{a_i\}$.

Then an induction on $i$ yields $N\alpha_i \leq (K + i)^2$.

For $\alpha = \omega^{\alpha+1} \cdot p + \omega^\beta \cdot q + \omega^{\alpha_1} \cdot b_1 + \ldots + \omega^{\alpha_r} \cdot b_r$, define a downward closed set $D(\alpha)$ as follows:

$D(\alpha) := p^* \times \mathbb{N} \cup x' \cup (p^* + a^*_1, q^* + b^*_1), \ldots, (p^* + a^*_r, q^* + b^* + b_1 + \ldots + b_r)$

where $x^*$ stands for $x + 1$. Then $N(D(\alpha)) \leq N\alpha$.

Assume that $\alpha' = \omega^{\alpha+1} \cdot p' + \omega^\beta \cdot q' + \omega^{\alpha_1} \cdot b'_1 + \ldots + \omega^{\alpha_r} \cdot b'_r$ and assume $\alpha' < \alpha'$. We show that $D(\alpha)$ is not a subset of $D(\alpha')$. The proof can be established by a simple case distinction.

Case 1. $p' < p$. Then $p^* \times \mathbb{N}$ is not contained in $D(\alpha')$.

Case 2. $p' = p$ and $q' < q$. Then $\mathbb{N} \times q^*$ is not contained in $D(\alpha')$.

Case 3. $p = p'$ and $q = q'$ and there exists a $j_0$ such that $a_{j_0} < a_{j_0}$ or $a_{j_0} = a_{j_0}$ and $b_{j_0} < b_{j_0}$ and for all $l < j_0$ we have $a_l = a'_l$ and $b_l = b'_l$.

Then $\{(p^* + a^*_0, q^* + b^*_0 + b_1 + \ldots + b^*_0)\} \leq$ is not contained in $D(\alpha')$. This can be checked by verifying that $(p^* + a^*_0, q + b_1 + \ldots + b^*_0)$ is in no interval showing up in
the representation of $D(\alpha')$. The first two intervals are left out since $p^* < p^* + a_{j_0}$ and $q^* < q^* + b_1 + \cdots b^*_{j_0}$. The intervals with index $l \geq j_0$ do not contain $p^* + a_{j_0}$ in their left coordinates and the intervals with index $i < j$ do not contain $q^* + b_1 + \cdots b^*_{j_0}$ in their right coordinates. The result follows by putting things together. \hfill $\Box$

As before let us consider polynomial rings in finitely many variables over a field $F$. The degree of a monomial ideal is the maximum degree of the minimal generating set of monomials. We denote by $(m_1, \ldots, m_l)$ the monomial ideal generated by the monomials $m_i$. The degree of a monomial ideal with minimal representation $(m_1, \ldots, m_l)$ is equal to $\max \{ \deg(m_i) \}$

**Lemma 4.2.** For a given $K \in \mathbb{N}$ there exists a sequence $(I_i)_{i=1}^L$ of monomials contained in $F(X, Y)$ such that $L \leq H_{\omega^2} + K$ and such that $\deg(I_i) \leq (K+i)^2$ for $1 \leq i \leq L$ and such for $i < j$ the ideal $I_i$ is not contained in the ideal $I_j$.

**Proof.** We associate with a given downward closed set $D$ in $\mathbb{N}^2$ a monomial ideal $I(D)$ such that for the sequence of downward closed set from the last lemma we find $\deg(I(D_i)) \leq (K+i)^2$ and that $i < j$ yields that $I(D_j)$ is not contained in $I(D_i)$.

Assume that $D(\alpha) := p \times N \cup N \times q \cup \{(a_1, b_1), \ldots, (a_r, b_r)\} \leq a_1 > \ldots > a_r > p$ and $b_1 > \ldots > b_r > q$. Let $a_{r+1} := p$ and $b_0 := q$. Let $I(D(\alpha)) := (X^{a_1}Y^{b_0}, X^{a_2}Y^{b_1}, \ldots, X^{a_r}Y^{b_{r-1}}, XY^{b_r})$. Note that in this definition we switch in the corresponding Young diagram from extremal points to inner points. This models a basic construction in commutative algebra namely the switch from generators from intersecting monomial ideals to generators of the intersection.

Assume that $\alpha' = \omega^{a+1} \cdot p' + \omega^{q'} \cdot q' + \omega^{a_1} \cdot b_1' + \ldots + \omega^{a_i} \cdot b_i' > \alpha$. We show that $I(D(\alpha'))$ is not a subset of $I(D(\alpha'))$.

The proof can be established by a simple case distinction.

Case 1. $p < p'$. Then $X^{p}Y^{b_r}$ is not an element of $I(D(\alpha'))$.

Case 2. $p = p'$ and $q < q'$. Then $X^{a_1}Y^{q'}$ is not an element of $I(D(\alpha'))$.

Case 3. $p = p'$, $q = q'$ and there exists a $j_0$ such that $a_{j_0} < a'_{j_0}$ or $(a_{j_0} = a'_{j_0}$ and $b_{j_0} < b'_{j_0})$ and for all $l < j_0$ we have $a_1 = a'_1$ and $b_1 = b'_1$.

Case 3.1. $a_{j_0} < a'_{j_0}$. Then $X^{a_{j_0}}Y^{b_{j_0}-1} \notin I(D(\alpha'))$. Indeed, for $i < j_0$ we have $a_{j_0} = a'_i$ and hence $X^{a_{j_0}}Y^{b_{j_0}-1} \notin (X^{a_i}Y^{b_{j_0}})$. From $a_{j_0} < a'_{j_0}$ we conclude $X^{a_{j_0}}Y^{b_{j_0}-1} \notin (X^{a_{j_0}}Y^{b_{j_0}-1})$ because $b_{j_0-1} = b'_{j_0-1} < b'_{j_0-1}$.

Case 3.2. $(a_{j_0} = a'_{j_0}$ and $b_{j_0} = b'_{j_0}$). Then $X^{a_{j_0}}Y^{b_{j_0}} \notin I(D(\alpha'))$. Indeed, for $i < j_0$ we obtain $X^{a_{j_0}+1}Y^{b_{j_0}} \notin (X^{a_i+1}Y^{b_{j_0}})$ since $a'_{j_0} = a_i \geq a_{j_0} > a_{j_0}+1$. For $i \geq j_0$ we conclude $X^{a_{j_0}+1}Y^{b_{j_0}} \notin (X^{a_i+1}Y^{b_{j_0}})$ since $b_{j_0} < b'_{j_0} < b'_{j_0}$.

The last two lemmas generalize to any dimension $k > 2$. For simplicity of exposition we treat the (sufficiently general) case $k = 3$ and leave the case $k > 3$ to the patience of the reader.

**Lemma 4.3.** For a given $K \in \mathbb{N}$ there exists a sequence $(D_i)_{i=1}^L$ of downward closed sets contained in $\mathbb{N}^3$ such that $L \leq H_{\omega^2 + \omega^3 + 3} + (K+1)$ and such that $ND_i \leq (K+i)^2$ for $1 \leq i \leq L$ and such that $D_i$ is not contained in $D_j$ for $i < j$.

**Proof.** Let $\alpha_0 := \omega^{a_0} + \omega^{b_0} + \omega^{c_0}$ and let $\alpha_{i+1} := \alpha_i + [k+i]$. Then $H_{\alpha_0}(K) = H_{\alpha_0}(K) + K = \ldots = H_{\alpha_0}[K][K+1] \ldots [K+l-1] = K + L$.
where $l$ is minimal with $\alpha_0[K][K+1] \ldots [K+\ell-1] = 0$. For
\[
\alpha = \omega^2 + \omega^3 + 2 \cdot a_1 + \omega^2 + \omega^3 + 1 \cdot a_2 + \omega^2 + \omega^3 \cdot a_3 \\
+ \omega^2 + \omega^2 + b_1 \cdot c_1 + \ldots + \omega^2 + \omega^2 + b_u \cdot c_u \\
+ \omega^2 + \omega^2 + d_1 \cdot e_1 + \ldots + \omega^2 + \omega^2 + d_v \cdot e_v \\
+ \omega^2 + \omega^2 + f_1 \cdot g_1 + \ldots + \omega^2 + \omega^2 + f_w \cdot g_w \\
+ \omega^2 + h_1 + \ldots + \omega^2 + h_r + j_r,
\]

let $N\alpha := \max\{bd, dl, fl, hl, il\} + \sum ai + \sum ci + \sum ei + \sum fi + \sum ji$. Then an
description on $i$ yields $N\alpha_i \leq (K + i)^2$.

For $\alpha$ as above, define a downward closed set $D(\alpha)$ as follows:
\[
D(\alpha) = a_1^* \times \mathbb{N}^2 \cup \mathbb{N} \times a_2^* \times \mathbb{N} \cup \mathbb{N}^2 \times a_3^*
\]
\[
\cup \{ (a_1^* + b_1^*, a_2^* + c_1^*), \ldots, (a_1^* + b_u^*, a_2^* + c_1 + \ldots + c_u^*) \} \times \mathbb{N}
\]
\[
\cup \{ (a_1^* + d_1^*, l, a_2^* + e_1^*), \ldots, (a_1^* + d_v^*, l, a_2^* + c_1 + \ldots + e_v^*) : l \in \mathbb{N} \} \times \mathbb{N}
\]
\[
\cup \mathbb{N} \times \{ (a_2^* + f_1^*, a_3^* + g_1^*), \ldots, (a_2^* + f_w^*, a_3^* + g_1 + \ldots + g_w^*) \} \times \mathbb{N}
\]
\[
\cup \{ (m_1^* + h_1^*, m_2^* + i_1^*, m_3^* + j_1^*), \ldots, (m_1^* + h_r^*, m_2^* + i_r^*, m_3^* + j_r^*) \} \times \mathbb{N}
\]

where $m_1 := \max(a_1 + b_1, a_1 + d_1, a_2 + d_1), m_2 := \max(f_1, \sum c_1)$ and $m_3 := \max(\sum e_1, \sum g_1)$.

Assume that
\[
\alpha' = \omega^2 + \omega^3 + 2 \cdot a_1' + \omega^2 + \omega^3 + 1 \cdot a_2' + \omega^2 + \omega^3 \cdot a_3' \\
+ \omega^2 + \omega^2 + b_1' \cdot c_1' + \ldots + \omega^2 + \omega^2 + b_u' \cdot c_u' \\
+ \omega^2 + \omega^2 + d_1' \cdot e_1' + \ldots + \omega^2 + \omega^2 + d_v' \cdot e_v' \\
+ \omega^2 + \omega^2 + f_1' \cdot g_1' + \ldots + \omega^2 + \omega^2 + f_w' \cdot g_w' \\
+ \omega^2 + h_1' + i_1' + \ldots + \omega^2 + h_r' + i_r' + j_r',
\]

and that $\alpha' < \alpha$.

We show that $D(\alpha)$ is not contained in $D(\alpha')$.

The proof can be established by a simple case distinction.

Case 1. $a_1' < a_1$. Then $a_1^* \times \mathbb{N}^2$ is not contained in $D(\alpha')$.

Case 2. $a_1 = a_1'$ and $a_2 < a_2$. Then $\mathbb{N} \times a_2^* \times \mathbb{N}$ is not contained in $D(\alpha')$.

Case 3. $a_1 = a_1'$ and $a_2 = a_2'$ and $a_3 < a_3$. Then $\mathbb{N}^2 \times a_3^*$ is not contained in $D(\alpha')$.

Case 4. $a_1 = a_1'$ and $a_2 = a_2'$ and $a_3 = a_3'$ and there exists a $j_0$ such that $b_{j_0} < b_{j_0}$
or $(b_{j_0} = b_{j_0}$ and $c_{j_0} < c_{j_0})$ and for all $l < j_0$ we have $b_l = b_l'$ and $c_l = c_l'$. Then
\[
\{ (a_1^* + b_{j_0}^*, a_2^* + c_{j_0} + \ldots + c_{j_0}^*) \} \times \mathbb{N}
\]
is not contained in $D(\alpha')$. This follows by investigating the intervals which make up $D(\alpha')$. The first three
are excluded since $a_1^* + b_{j_0} > a_1^*$ and $a_2^* + c_{j_0} + \ldots + c_{j_0}^*$, $a_2^* + c_{j_0} + \ldots + c_{j_0}^*$
and $\mathbb{N} > a_3^*$. The latter fact is shown as in Lemma 11. The set
\[
\{ (a_1^* + b_{j_0}^*, a_2^* + c_{j_0}^*) \}, \ldots, (a_2^* + b_{j_0}^*, a_2^* + c_{j_0} + \ldots + c_{j_0}^*) \}
\]
is not contained in the other intervals having one unbounded component because of its own infinite component does
not fit in a bounded interval. $\{ (a_1^* + b_{j_0}^*, a_2^* + c_{j_0}^*) \}, \ldots, (a_2^* + b_{j_0}^*, a_2^* + c_{j_0} + \ldots + c_{j_0}^*) \}
\]
is of course also not contained in a bounded component of $D(\alpha')$. 

Case 5. \( a_1 = a_1' \) and \( a_2 = a_2' \) and \( a_3 = a_3' \) and \( b_1 = b_1' \) and \( c_1 = c_1' \) and there exists a \( j_0 \) such that \( d_{j_0}' < d_{j_0} \) or \( (d_{j_0} = d_{j_0}' \text{ and } e_{j_0}' < e_{j_0}) \) and for all \( l < j_0 \) we have \( d_l = d_l' \) and \( e_l = e_l' \). This case is similar to case 4.

Case 6. \( a_1 = a_1' \) and \( a_2 = a_2' \) and \( a_3 = a_3' \) and \( b_1 = b_1' \) and \( c_1 = c_1' \) and \( d_l = d_l' \) and \( e_l = e_l' \) and there exists a \( j_0 \) such that \( f_{j_0}' < f_{j_0} \) or \( (f_{j_0} = f_{j_0}' \text{ and } g_{j_0}' < g_{j_0}) \) and for all \( l < j_0 \) we have \( f_l = f_l' \) and \( g_l = g_l' \). This case is similar to case 4.

Case 7. \( a_1 = a_1' \) and \( a_2 = a_2' \) and \( a_3 = a_3' \) and \( b_1 = b_1' \) and \( c_1 = c_1' \) and \( d_l = d_l' \) and \( e_l = e_l' \) and \( f_l = f_l' \) and \( g_l = g_l' \) and there exists an index \( k \) such that for all \( l < k \) we have \( h_l = h_l' \) and \( i_l = i_l' \) and \( j_l < j_l' \) and we have \( h_k < h_k' \) or \( (h_k = h_k' \text{ and } i_k < i_k') \) or \( (h_k = h_k' \text{ and } i_k = i_k' \text{ and } j_k < j_k') \).

We assume that the \( h_1 \geq \ldots \geq h_n \) and that \( h_l = h_{l+1} \) implies \( i_l < i_l' \).

Case 7.1. \( h_k' < h_k \). Then \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not an element of \( D(\alpha') \). The inclusion of \( m_1^* \) keeps it out of the unbounded intervals of \( D(\alpha') \). \( h_k < h_k' \) and the strict monotonicity of \( j_1 + \ldots + j_r \) in \( r \) guarantee that \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not contained in any of the bounded intervals for \( D(\alpha') \).

Case 7.2. \( h_k = h_k' \) and \( i_k < i_k' \). Then \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not an element of \( D(\alpha') \). The inclusion of \( m_1^* \) keeps it out of the unbounded intervals of \( D(\alpha') \). The weak monotonicity of \( h_l \) and \( i_l' < i_k \) and the strict monotonicity of \( j_1 + \ldots + j_r \) in \( r \) guarantee that \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not contained in any of the bounded intervals for \( D(\alpha') \).

Case 7.3. \( h_k = h_k' \) and \( i_k = i_k' \) and \( j_k < j_k' \). Then \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not an element of \( D(\alpha) \). The inclusion of \( m_1^* \) keeps it out of the unbounded intervals of \( D(\alpha') \). The weak monotonicity of \( h_l \) and \( i_l, j_l' < j_k \) and the strict monotonicity of \( j_1 + \ldots + j_r \) in \( r \) guarantee that \( (m_1 + h_k^*, m_2^* + i_k^*, m_3^* + j_1 + \ldots + j_k^*) \) is not contained in any of the bounded intervals for \( D(\alpha') \).

Lemma 4.4. For a given \( K \in \mathbb{N} \) there exists a sequence \((I_j)_{j=1}^L\) of monomials contained in \( F(X, Y, Z) \) such that \( L \geq H_{w_2+\ldots+z+3}(K) - K \) and such that \( \deg(I_i) \leq (K + i)^2 \) for \( 1 \leq i \leq L \) and such for \( i < j \) we have that \( I_j \) is not contained in \( I_i \).

Proof. We associate to a given downward closed set \( D \) in \( \mathbb{N}^2 \) a monomial ideal \( I(D) \) such that for the sequence of downward closed sets from the last lemma we find \( \deg(I(D_j)) \leq (K + i)^2 \) and that \( i < j \) yields that \( I(D_j) \) is not contained in \( I(D_i) \). Assume that

\[
D(\alpha) = \bigcup\{(b_1,c_1), \ldots, (b_u, c_u)\} \times \mathbb{N} \times \{d_1, \ldots, d_L\} \times \{e_1, \ldots, e_v\} \times \{(f_1, g_1), \ldots, (f_w, g_w)\} \times \{(h_1, i_1, j_1), \ldots, (h_r, i_r, j_r)\}
\]

where \( m_1 := \max(b_l, d_1) \), \( m_2 := \max(f_1, c_1) \) and \( m_3 := \max(e_1, g_1) \) and where \( b_1 > \ldots > b_u > a_1 > a_2 > c_1 > \ldots < c_u \), \( d_1 > \ldots > d_L > a_1 > a_2 > e_1 > \ldots < e_v \), \( f_1 > \ldots > f_w > a_1 > a_2 > g_1 > \ldots < g_w \) weakly decreasing such that \( h_l = h_{l+1} \) implies \( i_l > i_{l+1} \) and \( m_3 < j_1 < \ldots < j_r \) and \( h_l > m_3 \) and \( i_l > m_2 \).

The complement of this downward closed set can be written as an intersection of monomial ideals as follows.
\[ I(D(\alpha)) = (X^{a_1}) \cap (Y^{a_2}) \cap (Z^{a_3}) \]
\[ \cap (X^{b_1}, Y^{c_1}) \cap \ldots \cap (X^{b_u}, Y^{c_u}) \]
\[ \cap (X^{d_1}, Z^{e_1}) \cap \ldots \cap (X^{d_v}, Z^{e_v}) \]
\[ \cap (Y^{f_1}, Z^{g_1}) \cap \ldots \cap (Y^{f_w}, Z^{g_w}) \]
\[ \cap (X^{h_1}, Y^{i_1}, Z^{j_1}) \cap \ldots \cap (X^{h_r}, Y^{i_r}, Z^{j_r}) \]

\[ I(D(\alpha)) \] is, as an intersection of monomial ideals, again a monomial ideal. We see that \( D \subseteq D' \) if and only if \( I(D') \subseteq I(D) \). Therefore the ideals \( I(D_i) \) form a bad sequence of monomial ideals. We find that \( \deg(I(D)) \leq ND \) by Proposition 2.1.5 in [6] which in fact yields the desired property for any dimension \( k \). In particular there is an easy and very effective procedure to calculate generators for an intersection of monomial ideals from the generators of the intersecting ideals.

The lower bounds provided by previous lemmas are essentially sharp in the sense that \( k \rightarrow L \) depends elementary recursively on \( H_\alpha \) where \( \alpha \) is the maximal order type under consideration. This can be shown by a reification analysis using the results on the upper bound for the maximal order type involved. For this one can exploit that the lengths of elementary descending sequences of ordinals can be bounded in terms of the Hardy functions as shown for example in [1].
