ON THE CONTINUITY OF THE ELEMENTS OF THE ELLIS SEMIGROUP 
AND OTHER PROPERTIES

S. GARCÍA-FERREIRA, Y. RODRÍGUEZ-LÓPEZ, AND C. UZCÁTEGUI

Abstract. We consider discrete dynamical systems whose phase spaces are compact metrizable countable spaces. In the first part of the article, we study some properties that guarantee the continuity of all functions of the corresponding Ellis semigroup. For instance, if every accumulation point of $X$ is fixed, we give a necessary and sufficient condition on a point $a \in X'$ in order that all functions of the Ellis semigroup $E(X, f)$ be continuous at the given point $a$. In the second part, we consider transitive dynamical systems. We show that if $(X, f)$ is a transitive dynamical system and either every function of $E(X, f)$ is continuous or $|\omega_f(x)| = 1$ for each accumulation point $x$ of $X$, then $E(X, f)$ is homeomorphic to $X$. Several examples are given to illustrate our results.

1. Introduction and preliminaries

A dynamical system $(X, f)$ will consist of a compact metric space $X$ and a continuous function $f : X \rightarrow X$ (usually, this kind of dynamical systems are called discrete dynamical systems and we short the name for convenience). The orbit of point $x \in X$ is the set $O_f(x) := \{f^n(x) : n \in \mathbb{N}\}$. The system $(X, f)$ is transitive if there is a point with dense orbit. A point $x \in X$ is called periodic if there is $n \geq 1$ such that $f^n(x) = x$, and its period is $\text{min}\{n \in \mathbb{N} : f^n(x) = x\}$. The symbol $P_f$ stands for the set of all periods of the periodic points of a dynamical systems $(X, f)$. A point $x$ is called eventually periodic if its orbit is finite. The $\omega$-limit set of $x \in X$, denoted by $\omega_f(x)$, is the set of points $y \in X$ for which there exists an increasing sequence $(n_k)_{k \in \mathbb{N}}$ such that $f^{n_k}(x) \rightarrow y$. Observe that for each $y \in O_f(x)$, we have that $\omega_f(y) = \omega_f(x)$. If $O_f(y)$ contains a periodic point $x$, then $\omega_f(y) = O_f(x)$. For a space $X$ we denote by $\mathcal{N}(x)$ the set of all neighborhoods of $x \in X$, and the set of all accumulation points of $X$ will be simply denoted by $X'$. The Stone-Čech compactification $\beta(\mathbb{N})$ of $\mathbb{N}$ with the discrete topology will be identified with the set of ultrafilters over $\mathbb{N}$. Its remainder is denoted by $\mathbb{N}^* = \beta(\mathbb{N}) \setminus \mathbb{N}$ is the set of all free ultrafilters on $\mathbb{N}$, where, as usual, each natural number $n$ is identified with the fixed ultrafilter consisting of all subsets of $\mathbb{N}$ containing $n$.

Since our phase spaces are compact metric countable spaces, we remind the reader the classical result from [12] which asserts that every compact metric countable space is homeomorphic to a countable successor ordinal with the order topology. In this context, some of the most attractive phase spaces have the form $\omega^\alpha + 1$, where $\alpha \geq 1$ is a countable ordinal.

The Ellis semigroup of a dynamical system $(X, f)$, denoted $E(X, f)$, is defined as the pointwise closure of $\{f^n : n \in \mathbb{N}\}$ in the compact space $X^X$ with composition of functions as its algebraic operation. The Ellis semigroup is equipped with the topology inherited from the product space $X^X$. This semigroup was introduced by R. Ellis in [3], and it is a very important tool in the study of the topological behavior of dynamical systems. The article [10] offers an excellent survey...
concerning applications of the Ellis semigroup. In the paper [9], the authors initiated the study of the continuity and discontinuity of the elements of \( E(X, f) \setminus \{ f^n : n \in \mathbb{N} \} \). For instance, they point out that if \( X \) is a convergent sequence with its limit point, then all the elements of \( E(X, f) \) are either continuous or discontinuous (this result was later improved in [7]). In a different context, P. Szuca [13] showed that if \( X = [0, 1] \), the function \( f : [0, 1] \to [0, 1] \) is onto and \( f^p \) is continuous for some \( p \in \mathbb{N}^* \), then all the elements of \( E([0, 1], f) \) are continuous. Using the Cantor set as a phase space and a generalized ship maps, the continuity and discontinuity of the elements of the Ellis semigroup where studied in [6]. The main tool that have been used in all these investigations is the combinatorial properties of the ultrafilters on \( \mathbb{N} \). Certainly, the Ellis semigroup can be described in terms of the notion of convergence with respect to an ultrafilter. Indeed, given \( p \in \mathbb{N}^* \) and a sequence \((x_n)_{n \in \mathbb{N}}\) in a space \( X \), we say that a point \( x \in X \) is the \( p \)-limit point of the sequence, in symbols \( x = p - \lim_{n\to\infty} x_n \), if for every neighborhood \( V \) of \( x \), \( \{ n \in \mathbb{N} : f^n(x) \in V \} \in p \). Observe that a point \( x \in X \) is an accumulation point of a countable set \( \{ x_n : n \in \mathbb{N} \} \) of \( X \) if there is \( p \in \mathbb{N}^* \) such that \( x = p - \lim_{n\to\infty} x_n \).

The notion of a \( p \)-limit point has been used in several branches of mathematics (see for instance [2] and [4, p. 179]). A. Blass [1] and N. Hindman [11] formally established the connection between “the iteration in topological dynamics” and “the convergence with respect to an ultrafilter” by considering a more general iteration of the function \( f \) as follows: Let \( X \) be a compact space and \( f : X \to X \) a continuous function. For \( p \in \mathbb{N}^* \), the \( p \)-iterate of \( f \) is the function \( f^p : X \to X \) defined by

\[
f^p(x) = p - \lim_{n\to\infty} f^n(x),
\]

for each \( x \in X \). The description of the Ellis semigroup and its operation in terms of the \( p \)-iterates are the following (see [1], [11]):

\[
E(X, f) = \{ f^p : p \in \beta\mathbb{N} \}
\]

\[
f^p \circ f^q = f^{p+q} \quad \text{for each } p, q \in \beta\mathbb{N}.
\]

We will use the following notation

\[
E(X, f)^* := E(X, f) \setminus \{ f^n : n \in \mathbb{N} \}.
\]

Besides, we have that \( \omega_f(x) = \{ f^p(x) : p \in \mathbb{N}^* \} \) for each \( x \in X \).

Recently (for instance see [7] and [8]), we have investigated the structure of the Ellis semigroup of a dynamical system and the topological properties of some of its elements. Our main purpose moves in two directions: The first one concerns with the continuity and discontinuity of the \( p \)-iterates which is dealt in the third section, and the second one concerns about a general question stated in [8]:

**Question 1.1.** Given two compact metric countable spaces \( X \) and \( Y \), is there a continuous function \( f : X \to X \) such that \( E(X, f) \) is homeomorphic to \( Y \)?

We provide a partial answer to this question in the forth section.

### 2. Basic Properties

In this section, we state several useful results that were proved in the articles [7] and [8]. Our first lemma is precisely Lemma 2.1 from [8].

**Lemma 2.1.** Let \((X, f)\) be a dynamical system and \( x \in X \).

(i) Assume that \( x \) is periodic with period \( n \) and let \( l < n \). Then, \( p \in (n\mathbb{N} + l)^* \iff f^p(x) = f^l(x) \).
Suppose that $x$ is eventually periodic and that $m \in \mathbb{N}$ is the smallest positive integer such that $f^m(x)$ is a periodic point. If $n$ is the period of $f^m(x)$ and $p \in (n\mathbb{N} + l)^*$ for some $l < n$, then $f^p(x) = f^j(f^{n+j}(x))$ where $j = \min\{i : m \leq ni + l\}$.

(iii) Suppose that the orbit of $x$ is infinite and $\omega_f(x) = O_f(y)$ for some periodic point $y \in X$ with period $n$. If $p, q \in (n\mathbb{N} + l)^*$ for some $l < n$, then $f^p(x) = f^q(x)$.

(iv) $f^p(f^n(x)) = f^n(f^p(x))$ for every $n \in \mathbb{N}$, $x \in X$ and every $p \in \mathbb{N}^*$.

The next statement is Lemma 2.4 of [7].

**Lemma 2.2.** Let $(X, f)$ be a dynamical system. If $\omega_f(x)$ is finite, then every point of $\omega_f(x)$ is periodic. In particular, if $\omega_f(x)$ has an isolated point in $O_f(x)$, then every point of $\omega_f(x)$ is periodic.

The following lemma is a reformulation of Theorem 2.2 from [8].

**Lemma 2.3.** Let $(X, f)$ be a dynamical system, $x \in X$ and $m \in \mathbb{N}$. Then $|O_f(x)| > m$ iff $f^m(x) \neq f^n(x)$ for every $m \neq n$. In particular, there is an integer $M > 0$ such that $|O_f(x)| < M$ for each $x \in X$ iff $E(X, f)$ is finite.

We omit the proof of the following well-known result.

**Lemma 2.4.** Let $(X, f)$ be a dynamical system such that $X$ has a dense subset consisting of isolated points. If $X$ has a point with infinite orbit, then $\{f^n : n \in \mathbb{N}\}$ is infinite and discrete in $E(X, f)$ and $f^n \neq f^m$ for every $(n, m) \in \mathbb{N} \times \mathbb{N}^*$. In addition, if the orbit of $w$ is dense in $X$, then $X = \{f^p(w) : p \in \beta(\mathbb{N})\}$ and thus $X$ is a continuous image of $\beta(\mathbb{N})$.

3. Continuity of the $p$-iterates

In the context of compact metric countable spaces, we showed in [7 Th. 3.11] that if all points of $a \in X'$ are periodic, then for $b \in X'$ either each $f^q$ is discontinuous at $b$ for every $q \in \mathbb{N}^*$ or each $f^q$ is continuous at $b$ for all $q \in \mathbb{N}^*$. An example where this assertion fails assuming that all points of $X'$ are eventually periodic is also given in [7]. Here, our main task is to give a necessary and sufficient condition on the space $X$ in order that all $p$-iterates be discontinuous at a given point. To have this done we shall need some preliminary lemmas.

The next two results correspond to Lemma 3.7 and Theorem 3.8 of [7], respectively.

**Lemma 3.1.** Let $(X, f)$ be a dynamical system such that $X$ is a compact metric countable space and every point of $X'$ is periodic. If $x$ has an infinite orbit and $y \in \omega_f(x)$ is fixed, then $f^m(x) \rightarrow y$.

**Lemma 3.2.** Let $(X, f)$ be a dynamical system such that $X$ is a compact metric countable space and every point of $X'$ is periodic. For every $x \in X$, there exists a periodic point $y \in X$ such that $\omega_f(x) = O_f(y)$.

The following two additional results are needed to establish our theorems.

**Lemma 3.3.** Let $f : X \rightarrow X$ be a continuous function such that every accumulation point is fixed. If $V, W$ are nonempty open sets such that $\overline{V} \cap \overline{W} = \emptyset$, then the set $\{x \in X : x \in V \text{ and } f(x) \in W\}$ is finite.

**Proof.** Assume, towards a contradiction, that $H = \{x \in X : x \in V \text{ and } f(x) \in W\}$ is infinite. Since $X$ is compact and metric, there is a non constant sequence $(a_n)_{n \in \mathbb{N}}$ in $H$ and $a \in \overline{V} \cap X'$ such that $a_n \rightarrow a$. As $f$ is continuous and $a$ is fixed, then $f(a_n) \rightarrow f(a) = a$ which implies that $a \in \overline{W}$. But this is a contradiction. This shows that $H$ is finite. \qed

**Lemma 3.4.** Let $(X, f)$ be a dynamical system such that $X$ is a compact metric countable space and every accumulation point is periodic. Let $p \in \mathbb{N}^*$ and $b \in X$ be an isolated point. If there is a sequence $(a_n)_{n \in \mathbb{N}}$ in $X$ such that $f^p(a_n) \rightarrow b$, then $b$ is periodic and $O_f(b) = \omega_f(b) = \omega_f(a_n)$ for every positive integer except finitely many.
Proof. It follows directly from the assumption that \( B = \{ n \in \mathbb{N} : f^n(a_n) = b \} \) is cofinite and hence \( b \in \omega_f(a_n) \subseteq \mathcal{O}_f(a_n) \) for every \( n \in B \). By Lemma 2.2, we have that \( b \) is a periodic point. So, \( \mathcal{O}_f(b) = \omega_f(b) \). By Lemma 3.2, for every \( n \in B \) there is a periodic point \( y_n \in X \) such that \( \omega_f(a_n) = \mathcal{O}_f(y_n) \) and since \( b \in \mathcal{O}_f(y_n) \), we conclude that \( \omega_f(b) = \mathcal{O}_f(b) = \mathcal{O}_f(y_n) = \omega_f(a_n) \) for all \( n \in B \).

\[ \Box \]

**Theorem 3.5.** Let \((X, f)\) be a dynamical system such that \( X \) is a compact metric countable space and every accumulation point of \( X \) is fixed. For every \( a \in X' \), the following statements are equivalent:

1. There is \( p \in \mathbb{N}^* \) such that \( f^p \) is discontinuous at \( a \in X' \).
2. There are a periodic point \( b \in X \setminus \{ a \} \) and a sequence \( (a_n)_{n \in \mathbb{N}} \) in \( X \) such that \( a_n \to a \) and \( b \in \mathcal{O}_f(a_n) \) for all \( n \in \mathbb{N} \).
3. \( f^p \) is discontinuous at \( a \), for each \( p \in \mathbb{N}^* \).

*Proof.* (1) \( \Rightarrow \) (2). Suppose that \( f^p \) is discontinuous at \( a \in X' \). Then, there is a nontrivial sequence \( (a_n)_{n \in \mathbb{N}} \) in \( X \) such that \( a_n \to a \) and \( f^p(a_n) \) does not converge to \( a \). Since \( X \) is compact and metric, there are a sequence of positive integers \( (n_k)_{k \in \mathbb{N}} \) and \( b \in X \setminus \{ a \} \) such that \( f^p(a_{n_k}) \to b \). Assume, without loss of generality, that this subsequence is \( (a_n)_{n \in \mathbb{N}} \). In virtue of Lemma 3.3, we only consider the case when \( b \in X' \). Since \( a \neq b \), \( f^p(a_n) \to b \) and \( a_n \to a \), there are a clopen set \( V \in \mathcal{N}(a) \) and \( N \in \mathbb{N} \) such that \( b \notin V \), \( a_n \in V \) and \( f^p(a_n) \in X \setminus V \) for each \( n \geq N \). For every \( n \geq N \) there is \( d_n \in \mathcal{O}_f(a_n) \cap V \) such that \( f(d_n) \in X \setminus V \), this is possible since the set \( A_n = \{ m \in \mathbb{N} : f^m(a_n) \notin V \} \) is infinite. Then, by Lemma 3.3, we have that \( \{ d_n : n \geq N \} \) is finite. Hence, there exists \( d \in B \) for which the set \( H = \{ n \in \mathbb{N} : d = d_n \} \) is infinite. To finish the proof it suffices to show that \( b \in \omega_f(a_n) \) for all \( n \in H \). Indeed, we consider two cases. Suppose first that \( \mathcal{O}_f(d) \) is finite, then there is \( e \in X' \) such that \( e \in \omega_f(d) \). As \( e \) is fixed, by Lemma 3.1, \( f^m(d) \to e \). Analogously it is shown that \( f^m(a_n) \to e \) because of \( e \in \omega_f(a_n) \), for each \( n \in H \). Consequently, we obtain that \( f^q(a_n) = e \) for each \( q \in \mathbb{N}^* \) and for each all \( n \in H \). This implies that \( b = e \) since \( f^p(a_n) \to b \). Thus \( b \in \omega_f(a_n) \) for all \( n \in H \). For the second case, we assume that \( \mathcal{O}_f(d) \) is infinite. As \( d \in \mathcal{O}_f(a_n) \) for each \( n \in H \), we also have that the orbit of \( a_n \) is finite for all \( n \in H \). By Lemma 3.2, we may choose a periodic point \( e \in X \) such that \( \mathcal{O}_f(e) = \omega_f(d) \) \( = \{ f^q(d) : q \in \mathbb{N}^* \} = \{ f^q(a_n) : q \in \mathbb{N}^* \} = \omega_f(a_n) \) for each \( n \in H \). Since \( \mathcal{O}_f(e) \) is finite and \( f^p(a_n) \to b \), we obtain that \( b \in \omega_f(a_n) \), for each \( n \in H \).

(2) \( \Rightarrow \) (3). We have to analyze two possible cases.

Caso I. Suppose \( b \) is isolated. By assumption, \( b \) is periodic. Hence, if \( b \in \mathcal{O}_f(y) \), then \( \mathcal{O}_f(y) \) is finite and so \( \mathcal{O}_f(b) = \omega_f(y) = \{ f^p(y) : p \in \mathbb{N}^* \} \). Thus, from the hypothesis we obtain that \( f^p(a_n) \in \omega_f(a_n) = \mathcal{O}_f(b) \) for every \( n \in \mathbb{N} \) and \( p \in \mathbb{N}^* \). As \( a \) is fixed and \( b \neq a \), then \( a \notin \mathcal{O}_f(b) \) and the sequence \( \{ f^p(a_n) \} \) cannot converge to \( a \) for any \( p \in \mathbb{N}^* \). Thus \( f \) is discontinuous at \( a \).

Caso II. Suppose \( b \in X' \). Observe that if \( b \in \overline{\mathcal{O}_f(y)} \) and \( \mathcal{O}_f(y) \) is finite, then \( \omega_f(y) = \{ b \} \). On the other hand, if \( b \in \overline{\mathcal{O}_f(y)} \) and \( \mathcal{O}_f(y) \) is infinite, then it follows from Lemma 3.1 that \( \omega_f(y) = \{ b \} \). Thus, we have that \( f^p(a_n) = b \) for each \( p \in \mathbb{N}^* \) and for each all \( n \in \mathbb{N} \). Thus \( f \) is discontinuous at \( a \).

(3) \( \Rightarrow \) (1). It is evident.

**Corollary 3.6.** Let \((X, f)\) be a dynamical system such that \( X \) is a compact metric countable space and every accumulation point of \( X \) is fixed. If the orbit of every isolated point of \( X \) is finite, then every function of \( E(X, f) \) is continuous.

*Proof.* Assume that there is \( p \in \mathbb{N}^* \) such that \( f^p \) is discontinuous at \( a \in X' \). It follows from Theorem 3.5 (2) that there are a periodic point \( b \in X \setminus \{ a \} \) and a sequence \( (a_n)_{n \in \mathbb{N}} \) in \( X \) such that \( a_n \to a \) and \( b \in \overline{\mathcal{O}_f(a_n)} \) for all \( n \in \mathbb{N} \). Since each accumulation point of \( X \) is fixed, we may
assume that \( a_n \) is isolated for every \( n \in \mathbb{N}^* \), hence \( b \in \mathcal{O}_f(a_n) \) for all \( n \in \mathbb{N} \). Now, let \( V \) and \( W \) be disjoint open sets such that \( V \cap W = \emptyset \), \( a \in V \) and \( b \in W \). Without loss of generality, we may assume that \( a_n \in V \) for all \( n \in \mathbb{N} \). Then we can find a sequence \((k_n)_{n \in \mathbb{N}}\) such that \( f^{k_n}(a_n) \in V \) and \( f^{k_n+1}(a_n) \in W \) for every \( n \in \mathbb{N} \). We may assume that \( f^{k_n}(a_n) \to c \in \overline{V} \), but this is impossible since \( f^{k_n+1}(a_n) \to f(c) = c \in \overline{W} \). Therefore, \( f^p \) is continuous. \( \square \)

The conclusion of Theorem 3.5 is not true if we replace the hypothesis “every accumulation point is fixed” by the hypothesis “every accumulation point is periodic”. Indeed, the next two examples witness that the condition (2) of Theorem 3.5 holds together with either the assumption “\( f^p \) is continuous for every \( p \in \mathbb{N}^* \)” or the assumption “\( f^p \) is discontinuous for all \( p \in \mathbb{N}^* \)”.

The phase space of the following dynamical systems is the ordinal space \( 2\omega + 1 \) (two disjoint convergent sequences) which will be identified with the following subspace of \( \mathbb{R} \):

\[
X = \{a_n : n \in \mathbb{N}\} \cup \{b_n : n \in \mathbb{N}\} \cup \{a, b\},
\]

where \( a_n < a_{n+1} < a < b_n < b_{n+1} < b \) for every \( n \in \mathbb{N} \), \( a_n \to a \) and \( b_n \to b \).

**Example 3.7.** Define a function \( f : X \to X \) as follows:

\[
a) \ f(a) = b \ and \ f(b) = a,
\]

\[
b) \ f(a_n) = b_n \ for \ each \ n \in \mathbb{N}, \ and
\]

\[
c) \ f(b_n) = a_{n+1} \ for \ each \ n \in \mathbb{N}.
\]

That is,

\[
a_0 \to b_0 \to a_1 \to b_1 \to a_2 \to b_2 \to a_3 \to b_3 \cdots \to a_n \to b_n \to a_{n+1} \to b_{n+1} \to a_{n+2} \to b_{n+2} \to \cdots
\]

It is evident that \( f \) is continuous. From the definition of \( f \) we have, for all \( n, m \in \mathbb{N} \), the following:

\[
i) \ f^{2m}(a_n) = a_{n+m},
\]

\[
ii) \ f^{2m+1}(a_n) = b_{n+m},
\]

\[
iii) \ f^{2m}(b_n) = b_{n+m}, \ and
\]

\[
iv) \ f^{2m+1}(b_n) = a_{n+m+1}.
\]

Conditions i) – iv) imply the following:

\[
(1) \ f^p(a_n) = f^p(a) = a \ for \ every \ p \ in (2\mathbb{N})^*,
\]

\[
(2) \ f^p(a_n) = f^p(b) = b \ for \ every \ p \ in (2\mathbb{N} + 1)^*,
\]

\[
(3) \ f^p(b_n) = f^p(b) = b \ for \ every \ p \ in (2\mathbb{N})^*, \ and
\]

\[
(4) \ f^p(b_n) = f^p(a) = a \ for \ every \ p \ in (2\mathbb{N} + 1)^*.
\]

Then we have that the accumulation points \( a \) and \( b \) have period equal to 2 and both satisfy the second condition of Theorem 3.5. However, the function \( f^p \) is continuous for every \( p \in \mathbb{N}^* \).

**Example 3.8.** We define a function \( f : X \to X \) as follows:

\[
a) \ f(a) = b \ and \ f(b) = a,
\]

\[
b) \ f(a_0) = a_0,
\]

\[
c) \ f(a_n) = b_{n-1} \ for \ every \ 0 < n \in \mathbb{N}, \ and
\]

\[
d) \ f(b_n) = a_n, \ for \ every \ n \in \mathbb{N}.
\]

That is,

\[
b_n \to a_n \to b_{n-1} \to a_{n-1} \to b_{n-2} \to a_{n-2} \to b_{n-3} \to a_{n-3} \cdots \to b_2 \to a_2 \to b_1 \to a_1 \to b_0 \to a_0.
\]

It is not hard to prove that \( f \) is continuous. From the definition of \( f \) we easily have that for each \( x \in X \setminus \{a, b\} \) there exists \( n \in \mathbb{N} \) such that \( f^n(x) = a_0 \). Hence, \( f^p(x) = a_0 \) for every \( x \in X \setminus \{a, b\} \) and every \( p \in \mathbb{N}^* \). Since \( f^p(a) = a \) and \( f^p(b) = b \) for all \( p \in (2\mathbb{N})^* \); and \( f^p(a) = b \) and \( f^p(b) = a \) for all \( p \in (2\mathbb{N} + 1)^* \), we conclude that \( f^p \) is discontinuous at \( a \) and \( b \) for each \( p \in \mathbb{N}^* \). Finally, observe that \( a_0 \in \mathcal{O}_f(a_n) \) for all \( n \in \mathbb{N} \), so (2) of Theorem 3.5 is satisfied.
In the next theorem, we show a generalization of (2) ⇒ (3) in Theorem 3.5.

**Theorem 3.9.** Let $(X, f)$ be a dynamical system such that $X$ is a compact metric countable space and every accumulation point of $X$ is periodic. Let $a \in X'$. If there are a sequence $(a_n)_{n \in \mathbb{N}}$ in $X$ and a periodic point $b \in X \setminus \mathcal{O}_f(a)$ such that $a_n \to a$ and $b \in \overline{\mathcal{O}_f(a)}$ for every $n \in \mathbb{N}$, then $f^p$ is discontinuous at $a$ for each $p \in \mathbb{N}^*$.\[\square\]

**Proof.** First we show a particular case. Suppose that $b \in \mathcal{O}_f(a_n)$ for infinitely many $n \in \mathbb{N}$. Hence, from the periodicity of $b$, we have that $\mathcal{O}_f(b) = \omega_f(b) = \omega_f(a_n) = \{f^p(a_n) : p \in \mathbb{N}^*\}$ is finite for infinitely many $n \in \mathbb{N}$. Since $\mathcal{O}_f(a) \cap \mathcal{O}_f(b) = \emptyset$, the sequence $(f^p(a_n))_{n \in \mathbb{N}}$ cannot converge to $f^p(a) \in \mathcal{O}_f(a)$ for any $p \in \mathbb{N}^*$. Thus $f^p$ is not continuous at $a$ for any $p \in \mathbb{N}^*$.

For the proof of the theorem we consider two cases: (i) Suppose $b$ is isolated. Then $b \in \mathcal{O}_f(a_n)$ for every $n \in \mathbb{N}$ and we are done from the result we proved above.

(ii) Assume that $b \in X' \setminus \bigcup_{n \in \mathbb{N}} \mathcal{O}_f(a_n))$. From the result proved above, we can assume that $\mathcal{O}_f(a_n)$ is infinite for every $n \in \mathbb{N}$. Then, we must have that $b \in \omega_f(a_n)$ for every $n \in \mathbb{N}$. Now, in virtue of Lemma 3.2 for every $n \in \mathbb{N}$ there is a periodic point $y_n \in X$ such that $\omega_f(a_n) = \mathcal{O}_f(y_n)$. Since $b$ is periodic and $b \in \mathcal{O}_f(y_n)$, then $\mathcal{O}_f(b) = \mathcal{O}_f(y_n)$ for all $n \in \mathbb{N}$. Thus $f^p(a_n) \in \mathcal{O}_f(b)$ for all $n$ and all $p \in \mathbb{N}^*$. Since $\mathcal{O}_f(a) \cap \mathcal{O}_f(b) = \emptyset$, we conclude as before that $f^p$ is not continuous at $a$ for any $p \in \mathbb{N}^*$.

In the next result we slightly modify the proof of the previous theorem to get an interesting statement.

**Theorem 3.10.** Let $(X, f)$ be a dynamical system such that $X$ is a compact metric countable space and every accumulation point of $X$ is periodic. Let $a \in X'$ and $(a_n)_{n \in \mathbb{N}}$ be a sequence in $X$ such that $f^p(a_n) \to f^p(a)$, for some $p \in \mathbb{N}^*$. Suppose $b \in X$ is a periodic point and $b \in \bigcap_{n \in \mathbb{N}} \overline{\mathcal{O}_f(a_n)}$, then $b \in \mathcal{O}_f(a)$.\[\square\]

**Proof.** Let $a \in X'$, $(a_n)_n$ in $X$ and $p \in \mathbb{N}^*$ as in the hypothesis. First, suppose that $b$ is isolated. Then, $b \in \bigcap_{n \in \mathbb{N}} \mathcal{O}_f(a_n)$ and so $\mathcal{O}_f(b) = \omega_f(b) = \omega_f(a_n)$ for every $n \in \mathbb{N}$. Since $f^p(a_n) \to f^p(a) \in \mathcal{O}_f(a)$ and $f^p(a_n) \in \omega_f(a_n) = \mathcal{O}_f(b)$ for each $n \in \mathbb{N}$, we must have that $\mathcal{O}_f(a) \cap \mathcal{O}_f(b) \neq \emptyset$ and so $b \in \mathcal{O}_f(a)$. Now, suppose that $b \in X'$. Notice that if $b \in \mathcal{O}_f(a_n)$ for some $n \in \mathbb{N}$, then $\mathcal{O}_f(b) = \omega_f(b) = \omega_f(a_n)$. Thus we have that $b \in \omega_f(a_n)$ for all $n \in \mathbb{N}$. By Lemma 3.2 there exists a periodic point $y_n \in X$ such that $\omega_f(a_n) = \mathcal{O}_f(y_n)$. Since $b \in \omega_f(a_n)$, then $\mathcal{O}_f(a_n) = \mathcal{O}_f(b)$ for all $n \in \mathbb{N}$. Thus, we have shown that $f^p(a_n) \in \mathcal{O}_f(b)$ for every $n \in \mathbb{N}$. Then, as before, we have $\mathcal{O}_f(a) \cap \mathcal{O}_f(b) \neq \emptyset$ and thus $b \in \mathcal{O}_f(a)$. \[\square\]

Concerning the last theorem we have the following example.

**Example 3.11.** We consider again the countable ordinal space $2\omega + 1$ identified with the subspace $X$ of $\mathbb{R}$ from above. Define the function $f : X \to X$ as follows:

- a) $f(a) = b$ and $f(b) = a$,
- b) $f(a_0) = b$,
- c) $f(a_n) = b_{n-1}$ for each $n > 0$, and
- d) $f(b_n) = a_n$ for each $n \in \mathbb{N}$.

The function $f$ is evidently continuous. From the definition we can see that $b_n \to a_n \to b_{n-1} \to a_{n-1} \to b_{n-2} \to a_{n-2} \to \cdots b_2 \to a_2 \to b_1 \to a_1 \to b_0 \to a_0 \to b$.

Hence, all points are eventually periodic. Besides, we have the following properties:

- i) For every $x \in X$ there is $n \in \mathbb{N}$ such that $f^n(x) = b$.
- ii) $f^p(x) = b$ for each $x \in X \setminus \{a, b\}$ and for each $p \in \mathbb{N}^*$.
- iii) $f^p(a) = a$ for all $p \in (2\mathbb{N})^*$. 

6
Thus, we have that \( f^p \) is discontinuous at \( a \) for all \( p \in (2\mathbb{N} + 1)^* \).

Therefore, in both cases, \( h \) is a homeomorphism between \( E(X, f) \) and \( X \).

Question 4.8 is related to the second condition of the previous theorem.

Corollary 4.3. Let \( (X, f) \) be a transitive dynamical system where \( X \) is a compact metrizable countable space. If \( f^p \) is continuous for each \( p \in \mathbb{N}^* \), then the set \( P_f \) is finite.

Proof. By Theorem 4.2, we know that \( E(X, f) \) is countable. If \( P_f \) were infinite, by Theorem 2.7 of [8], then \( E(X, f) \) would be homeomorphic to the Cantor set \( 2^{\mathbb{N}} \). So, \( P_f \) is finite. \( \square \)
As we have seen in the proof of the previous corollary, if $X$ is a compact metrizable space and $E(X, f)$ is countable, then $P_f$ must be finite. Next we shall estimate the cardinality of the Ellis semigroup under some restriction on the $\omega$-sets.

**Theorem 4.4.** Let $(X, f)$ be a transitive dynamical system such that $X$ is a compact metric countable space. If there is $m \in \mathbb{N}$ such that $|\omega_f(x)| \leq m$ for every $x \in X'$, then $E(X, f)$ is countable.

**Proof.** Let $E^* = E(X, f) \setminus \{f^n : n \in \mathbb{N}\}$. It suffices to show that $E^*$ is countable. First notice that $E^*$ is equal to $\{f^p : p \in \mathbb{N}^*\}$ by Lemma 2.4. Since $X'$ is $f$-invariant (by Lemma 4.1(ii)), then $(X', f \mid X')$ is a well defined dynamical system. By Lemma 4.1(i), $E(X', f \mid X')$ is finite. Let $w \in X$ with a dense orbit. Consider the function $\varphi : E^* \rightarrow E(X', f \mid X') \times X'$ given by $\varphi(g) = (g \mid X', g(w))$. It suffices to show that $\varphi$ is injective. In fact, let $g \in E^*$, then $g = f^p$ for some $p \in \mathbb{N}^*$. Notice that every isolated point is of the form $f^l(w)$ for some $l \in \mathbb{N}$. Thus $g(f^l(w)) = f^p(f^l(w)) = f^l(f^p(w)) = f^l(g(w))$. Therefore $g$ is completely determined by $g \mid X'$ and $g(w)$. Hence $\varphi$ is injective. □

Our next example satisfies the second conditions of Theorem 4.2 and all the $p$-iterates are discontinuous, for $p \in \mathbb{N}^*$.

The phase space of the next two examples is going to be $\omega^3 + 1$ which, for our convenience, will be identified with the following subspace of $\mathbb{R}$:

$$X = \{d_{i,j,k} : i, j, k \in \mathbb{N}\} \cup \{d_{j,k} : j, k \in \mathbb{N}\} \cup \{d_k : k \in \mathbb{N}\} \cup \{d\},$$

where $(d_k)_{k \in \mathbb{N}}$ is a strictly increasing sequence such that $d_k \xrightarrow[k \to \infty]{} d$; $(d_{j,0})_{j \in \mathbb{N}}$ is a strictly increasing sequence contained in $(-\infty, d_0)$ such that $d_{j,0} \xrightarrow[j \to \infty]{} d_0$; for each positive $k \in \mathbb{N}$, the sequence $(d_{j,k})_{j \in \mathbb{N}}$ is strictly increasing, it is contained in $(d_{k-1,0}, d_k)$ and $d_{j,k} \xrightarrow[j \to \infty]{} d_k$; $D_{0,0} := \{d_{i,0,0} : i \in \mathbb{N}\}$ is a strictly increasing sequence such that $d_{i,0,0} \xrightarrow[i \to \infty]{} d_{0,0}$ and it is contained in $(-\infty, d_{0,0})$; $D_{0,k} = \{d_{i,0,k} : i \in \mathbb{N}\}$ is a strictly increasing sequence with $d_{i,0,k} \xrightarrow[i \to \infty]{} d_{0,k}$ and contained in $(d_{k-1,0}, d_{0,k})$ for each $k \in \mathbb{N} \setminus \{0\}$ $D_{j,k} := \{d_{i,j,k} : i \in \mathbb{N}\}$ is a strictly increasing sequence with $d_{i,j,k} \xrightarrow[i \to \infty]{} d_{j,k}$ and contained in $(d_{j-1,k}, d_{j,k})$ for every $j \in \mathbb{N} \setminus \{0\}$ and for every $k \in \mathbb{N}$.

We are ready to describe our first example.

**Example 4.5.** There is a continuous function $f : \omega^3 + 1 \to \omega^3 + 1$ such that:

1. $\mathcal{O}_f(d_{0,0,0})$ is dense.
2. The points $d_{c_n-1,0}$ and $d_{c_n+1,0}$ have infinite orbits, where $c_n = 2 + 3n$ for every $n \in \mathbb{N}$.
3. $|\omega_f(x)| = 1$ for every $x \in (\omega^3 + 1)'$.
4. $E(\omega^3 + 1, f)$ is homeomorphic to $\omega^3 + 1$.
5. $f^p$ is discontinuous for all $p \in \mathbb{N}^*$.

Our function $f$ is defined as follows:

- $f(d_n) = d$ and $f(d_{n+1}) = d_n$ for each $n \in \mathbb{N}$.
- $f(d_{0,0}) = d$, $f(d_{1,0}) = d_{3,0}$, $f(d_{2,0}) = d_{0,0}$ and $f(d_{0,1}) = d_0$.
- $f(d_{c_n-1,0}) = d_{c_n-1,1,0}$ for each $n > 0$.
- $f(d_{c_n,0}) = d_{c_n-1,0}$ for each $n > 0$.
- $f(d_{c_n+1,0}) = d_{c_n+1,1,0}$ for each $n \in \mathbb{N}$.
- $f(d_{j,k}) = d_{j-1,k}$ for each $j > 0$ and $k > 0$.
- $f(d_{0,k}) = d_{k-1}$ for each $k > 0$.
- $f(d_{i,j,k}) = d_{i+1,j-1,k}$ for each $i \in \mathbb{N}$ and $j, k > 0$.
- $f(d_{i,0,1}) = d_{0,i+1}$ for each $i \in \mathbb{N}$.
- $f(d_{i,0,k}) = d_{0,i+1,k-1}$ for each $i \in \mathbb{N}$ and $k > 2$. 

8
k) \( f(d_{i,0}) = d_{0,c_i+1-1,0} \) for each \( i \in \mathbb{N} \).
l) \( f(d_{i,0}) = d_{i+1,0} \) for each \( i \in \mathbb{N} \).
m) \( f(d_{i,n}) = d_{i+1,c_{n-1},0} \) for each \( i \in \mathbb{N} \) and \( n > 0 \).

In the next diagram, we can see the behavior of the orbits on the isolated points.

\[
d_0,0 \rightarrow d_0,0,2 \rightarrow d_0,0,1 \rightarrow d_0,4,0 \rightarrow d_0,1,0 \rightarrow d_0,3,0 \rightarrow d_0,2,0 \rightarrow d_1,0,0
\]

\[
d_1,0,0 \rightarrow d_1,0,3 \rightarrow d_1,1,2 \rightarrow d_1,0,2 \rightarrow d_1,0,1 \rightarrow d_1,7,0 \rightarrow d_1,4,0
\]

\[
d_2,0,0 \rightarrow d_2,0,4 \rightarrow d_2,0,3 \rightarrow d_2,0,2 \rightarrow d_2,1,2 \rightarrow d_2,0,2 \rightarrow d_2,0,1 \rightarrow d_2,0,0
\]

\[
d_3,0,0 \rightarrow d_3,0,5 \rightarrow d_3,0,4 \rightarrow d_3,0,3 \rightarrow d_3,0,2 \rightarrow d_3,0,1 \rightarrow d_3,0,0
\]

\[
d_4,0,0 \rightarrow d_4,0,0 \rightarrow d_4,0,1 \rightarrow d_4,0,2 \rightarrow d_4,0,3 \rightarrow d_4,0,4 \rightarrow d_4,0,5
\]

The following properties are satisfied.

i) \( f(D_{j,k}) = D_{j-1,k} \) for each \( j > 0 \) and \( k > 0 \).

Observe that clauses a) and i) imply that \( f \) is continuous at \( d_i \) for each \( i > 0 \) and at \( d_{ij} \) for every \( i,j > 0 \). For \( j > 1 \), \( f \) is continuous at \( d_{0j} \) by clauses g) and viii). By d), e), ii), iii) and iv), we have that \( f \) is continuous at \( d_0 \) and at \( d_{ij} \) for every \( i > 2 \). By b), v), vi) and viii), \( f \) is continuous at the points \( d_{0,0}, d_{10}, d_{20} \) and \( d_{0,1} \). Therefore, \( f \) is continuous.

It is evident that the orbit \( O_f(d_{0,0,0}) \) is dense. Also it is evident that the points \( d_{c_{n-1},0} \) and \( d_{c_n+1,0} \) have infinite orbits, for every \( n \in \mathbb{N} \). The following relationships follows directly from the definition:
I) \( f^p(d) = d \) and \( f^p(d_n) = d_n \) for each \( n \in \mathbb{N} \) and \( p \in \mathbb{N}^* \).

II) \( f^p(d_{0,0}) = d \), \( f^p(d_{2,0}) = d \) and \( f^p(d_{0,1}) = d_0 \).

III) \( f^p(d_{c_n,0}) = d \) for each \( n > 0 \).

IV) \( f^p(d_{c_n+1,0}) = d_0 = f^p(d_{c_n-1,0}) \) for each \( n \in \mathbb{N} \).

V) \( f^p(d_{j,k}) = d_{k-1} \) for each \( j > 0 \) and \( k > 0 \).

All these properties imply clause (3), condition (4) follows from Theorem 4.2 and the last condition (5) follows from clauses III) and IV).

In the next example, we show that there exists a continuous function \( f \) such that the dynamical system \( (\omega^3 + 1, f) \) is transitive and has a sequence of accumulation points with arbitrarily large period. This example differs from Example 4.1 of [7] since this dynamical system is transitive and in the other one all points have finite orbit. Notice also that, in the example below, all \( p \)-iterates are discontinuous.

**Example 4.6.** There is a function \( f : \omega^3 + 1 \rightarrow \omega^3 + 1 \) such that

1. \( \mathcal{O}(f(d_{0,0,0})) \) is dense.
2. All points of \((\omega^3 + 1)'\) have finite orbit.
3. The accumulation point \( d_{a_n} \) has period \( n+2 \), where \( a_0 = 0 \) and \( a_n = a_{n-1} + n + 1 \), for every \( n \in \mathbb{N} \).
4. \( E(\omega^3 + 1, f) \) is homeomorphic to \( 2^\mathbb{N} \).
5. \( f^p \) is discontinuous for all \( p \in \mathbb{N}^* \).

The function \( f \) is defined as follows:

a) \( f(d) = d \).

b) \( f(d_{a_n}) = d_{a_n+n+1} = d_{a_n+1-1} \) for each \( n \in \mathbb{N} \).

c) \( f(d_{a_n+k}) = d_{a_n+k-1} \) for each \( n \in \mathbb{N} \) and \( 0 < k \leq n + 1 \).

d) \( f(d_{0,0}) = d \) and \( f(d_{0,a_n}) = d_{a_{n-1}} \) for each \( n > 0 \).

e) \( f(d_{i,a_n}) = d_{i-1,a_n+n+1} = d_{i-1,a_{n+1}-1} \) for each \( n \in \mathbb{N} \) and \( i > 0 \).

f) \( f(d_{i,a_n+k}) = d_{i,a_n+k-1} \) for each \( i \in \mathbb{N} \), \( n \in \mathbb{N} \) and \( 0 < k \leq n + 1 \).

g) \( f(d_{0,0,0}) = d_{0,0,1} \) and \( f(d_{0,0,0}) = d_{0,0,a_{n}} \) for each \( n > 0 \).

h) \( f(d_{i,j,0}) = d_{i+1,j-1} \) for each \( i \in \mathbb{N} \) and \( j > 0 \).

i) \( f(d_{i,0,1}) = d_{i+1,0,1} \) for each \( i \in \mathbb{N} \).

j) \( f(d_{i,j,1}) = d_{i,j,0} \) for each \( i \in \mathbb{N} \) and \( j > 0 \).

k) \( f(d_{i,j,a_n}) = d_{i-1,j-1,a_n+n+1} \) for each \( i \in \mathbb{N} \) and \( j,n > 0 \).

l) \( f(d_{i,0,a_n}) = d_{i+1,0,a_n-1} \) for each \( i \in \mathbb{N} \) and \( n > 0 \).

m) \( f(d_{i,j,k}) = d_{i,j,k-1} \) for each \( i,j \in \mathbb{N} \) and \( k \notin H \) and \( k \notin \{a_n + 1 : n \in \mathbb{N}\} \).

n) \( f(d_{i,j,k}) = d_{i,j,k-1} \) for each \( i \in \mathbb{N} \), \( j > 0 \) and \( k \in \{a_n + 1 : n > 0\} \).

o) \( f(d_{i,0,k}) = d_{i+1,0,k-1} \) for each \( i \in \mathbb{N} \) and \( k \in \{a_n + 1 : n > 0\} \).

To have some idea about the orbits we describe some of them in the next diagram:

\[
\begin{align*}
&d_{0,0,0} \rightarrow d_{0,0,1} \rightarrow d_{1,0,0} \rightarrow d_{0,0,2} \rightarrow d_{0,1,0} \rightarrow d_{0,0,3} \rightarrow d_{0,1,0} \rightarrow d_{2,0,0} \rightarrow d_{0,0,5} \rightarrow d_{0,1,4} \rightarrow d_{0,1,3} \rightarrow d_{0,2,1} \rightarrow d_{2,0,4} \rightarrow d_{0,0,3} \rightarrow d_{0,0,2} \rightarrow d_{1,0,2} \rightarrow d_{0,2,1} \rightarrow d_{0,0,2} \rightarrow d_{1,1,1} \rightarrow d_{1,1,0} \rightarrow d_{0,2,1} \rightarrow d_{3,0,0} \rightarrow \ldots \\
&d_{0,0,9} \rightarrow d_{0,1,1} \rightarrow d_{0,0,2} \rightarrow d_{0,1,6} \rightarrow d_{0,0,8} \rightarrow d_{0,1,7} \rightarrow d_{0,1,5} \rightarrow d_{0,1,5} \rightarrow d_{0,2,4} \rightarrow d_{0,2,3} \rightarrow d_{0,2,2} \rightarrow d_{1,1,4} \rightarrow d_{2,1,3} \rightarrow d_{1,1,2} \rightarrow d_{1,0,4} \rightarrow d_{2,0,3} \rightarrow d_{2,0,2} \rightarrow d_{3,0,1} \rightarrow d_{0,0,0} \rightarrow d_{0,0,0,1} \rightarrow d_{1,0,0,1} \rightarrow d_{2,0,0,1} \rightarrow d_{3,0,0,1} \rightarrow \ldots \\
&d_{0,2,a_{n-2}} \rightarrow d_{n,0,1} \rightarrow d_{n+1,0,0} \rightarrow \ldots \\
&d_{n,0,0,0} \rightarrow d_{0,0,0} \rightarrow d_{0,1,0,0} \rightarrow d_{0,0,1} \rightarrow d_{0,0,2} \rightarrow d_{0,0,3} \rightarrow d_{0,0,4} \rightarrow \ldots \\
&\vdots \quad \vdots \quad \vdots \\
&d_{n,0,0,0} \rightarrow d_{0,0,0,0} \rightarrow d_{0,0,0,1} \rightarrow d_{0,0,0,2} \rightarrow d_{0,0,0,3} \rightarrow d_{0,0,0,4} \rightarrow \ldots \\
&\vdots \quad \vdots \quad \vdots \\
&d_{n,0,0,0} \rightarrow d_{0,0,0,0} \rightarrow d_{0,0,0,1} \rightarrow d_{0,0,0,2} \rightarrow d_{0,0,0,3} \rightarrow d_{0,0,0,4} \rightarrow \ldots \\
&\vdots \quad \vdots \quad \vdots 
\end{align*}
\]
Notice that:

i. \( f(D_{0,0}) = \{d_{0,0,n} : n \in \mathbb{N}\} \).

ii. \( f(D_{j,0}) = D_{j-1,1} \setminus \{d_{0,j-1,1}\} \) for each \( j > 0 \).

iii. \( f(D_{0,1}) = D_{0,0} \setminus \{d_{0,0,0}\} \) and \( f(D_{ij}) = D_{(i-1)j} \) for each \( i, j > 0 \).

iv. \( f(D_{j,a_n}) = \{d_{0,j+1,a_n-1} : j \in \mathbb{N}\} \) for each \( n > 0 \).

v. \( f(D_{j,a_n}) = D_{j-1,a_n+n+1} \setminus \{d_{0,j-1,a_n+n+1}\} \) for each \( j, n > 0 \).

vi. \( f(D_{j,k}) = D_{j,k-1} \) for each \( j \in \mathbb{N} \) and \( k \notin H \cup \{a_n + 1 : n \in \mathbb{N}\} \).

vii. \( f(D_{j,k}) = D_{j,k-1} \) for each \( j > 0 \) and \( k \in \{a_n + 1 : n \in \mathbb{N}\} \).

viii. \( f(D_{0,k}) = D_{0,k-1} \setminus \{d_{0,0,k-1}\} \) for each \( k \in \{a_n + 1 : n \in \mathbb{N}\} \).

By conditions (a), (b), (c), (iv), (v), (vi), (vii) and (viii), we have that \( f \) is continuous at \( d \), \( d_k \) for every \( k > 0 \); \( f \) is continuous at \( d_0 \) by conditions (b) and (ii); and \( f \) is continuous at \( d_{ij} \), by conditions (d), (e), (f) and identities from (i) to (viii) for each \( i, j \in \mathbb{N} \). Consider the sequence \( (d_{0i}) \) that converges to \( d_0 \). By conditions (d), (e) and (f), for every \( i \in \mathbb{N} \) there exist \( l_i \in \mathbb{N} \) such that \( f^{l_i}(d_{0i}) = d_0 \). Then, for each \( i \in \mathbb{N} \), \( p \in \mathbb{N}^* \) \( f^p(d_{0i}) = d \) and \( f^p(d_0) = d_1 \). So, we conclude that \( f^p \) is discontinuous at \( d_0 \) for every \( p \in \mathbb{N}^* \). Since there are periodic points of arbitrarily large period, the Ellis semigroup \( E(\omega^3 + 1, f) \) is homeomorphic to \( 2^\mathbb{N} \) (by Theorem 2.7 of [5]).

Concerning the previous example we formulate the following question.

**Question 4.7.** Is there a continuous function \( f : \omega^3 + 1 \to \omega^3 + 1 \) such \( (\omega^3 + 1, f) \) is transitive and \( E(\omega^3 + 1, f)^* \) contains both continuous and discontinuous functions?

With respect to Theorem 4.2, it is natural to ask the following.

**Question 4.8.** Let \((\omega^\alpha + 1, f)\) be a transitive dynamical systems where \( \alpha \geq 1 \) is a countable ordinal. If \( 1 < \sup\{|\omega f(x)| : x \in (\omega^\alpha + 1)^\prime\} < \omega \), is \( E(\omega^\alpha + 1, f) \) homeomorphic to \( \omega^3 + 1 \) for some countable ordinal \( \beta \geq 1 \)?
