PROJECTIONS AND UNCONDITIONAL BASES IN DIRECT SUMS OF \( \ell_p \) SPACES, \( 0 < p \leq \infty \).

F. ALBIAC AND J. L. ANSORENA

Abstract. We show that every unconditional basis in a finite direct sum \( \bigoplus_{p \in A} \ell_p \), with \( A \subset (0, \infty] \), splits into unconditional bases of each summand. This settles a 40 year old question raised in [A. Ortyński, Unconditional bases in \( \ell_p \oplus \ell_q \), \( 0 < p < q < 1 \), Math. Nachr. 103 (1981), 109-116]. As an application we obtain that for any \( A \subset (0, 1] \) finite, the spaces \( Z = \bigoplus_{p \in A} \ell_p \), \( Z \oplus \ell_2 \), and \( Z \oplus c_0 \) have a unique unconditional basis up to permutation.

1. Introduction

From a structural point of view, an important topic in vintage Banach space theory is the description of the unconditional bases in a given space. This note is devoted to advance the state of art of this subject by proving the following result.

**Theorem 1.1** (Main Theorem). Let \( A \) be a finite set of indexes contained in \( (0, \infty] \). If \( (x_j)_{j \in J} \) is an unconditional basis of \( \bigoplus_{p \in A} \ell_p \) (with the convention that \( \ell_\infty \) means \( c_0 \) if \( \infty \in A \)) then there is a partition \( (J_p)_{p \in A} \) of \( J \) in such a way that \( (x_j)_{j \in J_p} \) is a basis of \( \ell_p \) for each \( p \in A \).

Theorem 1.1 builds on previous work on the subject initiated by Edelstein and Wojtaszczyk in 1976, and continued by Ortyński in 1981. In [12] the authors described unconditional bases in finite direct sums of \( \ell_p \) spaces for values of \( p \) in the locally convex range, i.e., when the set \( A \) in the statement of the theorem is contained in \( [1, \infty] \). Five years later, Ortyński ventured himself across the nonlocally convex border and extended Edelstein and Wojtaszczyk’s result to the case when \( A \subset (0, 1] \cup (1, \infty] \). However, Ortyński’s methods break down...
precisely when the set $A$ contains the index $p = 1$, which led him to raise the question whether his theorem remained valid without any restriction on $p$ (see Remark 2 in [22, p. 115]). Our goal is to fill this gap in the literature. With the help of fresh techniques derived from the theory of anti-Euclidean spaces developed by Casazza and Kalton in the late 1990’s (hence not yet available when [22] was written) we are able to prove Theorem 1.1 in its whole generality, thus providing a positive answer to Ortyński’s question.

2. Preliminaries

Throughout this article we employ the notation commonly used in Banach space theory as can be found in [2]. The only exception is that, for convenience in writing our results in a unified way, unless otherwise stated the symbol $\ell_\infty$ denotes the space of sequences tending to zero equipped with the supremum norm, usually denoted by $c_0$. Next we single out the notation that it is more heavily used. We denote by $F$ the real or complex scalar field and by $c_{00}(J)$ the set of all $(a_j)_{j \in J} \in F^J$ such that $|\{j \in J : a_j \neq 0\}| < \infty$. We write by $E_J := (e_j)_{i \in J}$ for the canonical unit vector system of $F^J$, i.e., $e_j = (\delta_{j,i})_{i \in J}$ for each $j \in J$, where $\delta_{j,j} = 1$ if $i = j$ and $\delta_{i,j} = 0$ otherwise. The symbol $\alpha_i \lesssim \beta_i$ for $i \in I$ means that the families of positive real numbers $(\alpha_i)_{i \in I}$ and $(\beta_i)_{i \in I}$ verify $\sup_{i \in I} \alpha_i / \beta_i < \infty$. If $\alpha_i \lesssim \beta_i$ and $\beta_i \lesssim \alpha_i$ for $i \in I$ we say $(\alpha_i)_{i \in I}$ and $(\beta_i)_{i \in I}$ are equivalent, and we write $\alpha_i \approx \beta_i$ for $i \in I$. The closed linear span of a set of vectors $A$ in a quasi-Banach space $X$ is denoted by $[A]$. If we have a finite family $(X_i)_{i \in F}$ of quasi-Banach spaces, the Cartesian product $\bigoplus_{i \in F} X_i$ of $X_i$’s with coordinatewise algebraic operations is a quasi-Banach space with the quasi-norm

$$\| (x_i)_i \| = \sup_{i \in F} \| x_i \|, \quad x_i \in X_i.$$ 

If $F = \{i, \ldots, N\}$ and $X_i = X$ for $i \in F$ we simply write $X^N$ and call the resulting direct sum the $N$-fold product of $X$. A 2-fold product will be called a square.

For expository ease and to fix the notation, below we gather well-known concepts scattered through the literature and the basic facts about them that we will need later on, both in Sections 3 and 4.

**Quasi-Banach spaces and envelopes.** Quasi-Banach spaces provide the natural framework for our work. Recall that a quasi-Banach space $X$ is a locally bounded topological vector space. This is equivalent to saying that the topology on $X$ is induced by a quasi-norm, i.e., a map $\| \cdot \| : X \to [0, \infty)$ with the following properties:
(i) \( \|x\| = 0 \) if and only if \( x = 0 \);
(ii) \( \|\alpha x\| = |\alpha|\|x\| \) for \( \alpha \in \mathbb{F} \) and, \( x \in \mathbb{X} \),
(iii) there is a constant \( \kappa \geq 1 \) so that for all \( x \) and \( y \) in \( \mathbb{X} \) we have
\[
\|x + y\| \leq \kappa (\|x\| + \|y\|).
\]
If it is possible to take \( \kappa = 1 \) we obtain a norm. A quasi-norm \( \| \cdot \| \) is
called \( p \)-norm \( (0 < p \leq 1) \) if it is \( p \)-subadditive, that is,
\[
\|x + y\|^p \leq \|x\|^p + \|y\|^p, \quad \forall x, y \in \mathbb{X}.
\]
In this case the unit ball of \( \mathbb{X} \) is an absolutely \( p \)-convex set and \( \mathbb{X} \) is
said to be \( p \)-convex. A quasi-norm clearly defines a metrizable vector
topology on \( \mathbb{X} \) whose base of neighborhoods of zero is given by sets of
the form \( \{ x \in \mathbb{X} : \|x\| < 1/n \} \), \( n \in \mathbb{N} \). If such topology is complete
we say that \( (\mathbb{X}, \| \cdot \|) \) is a quasi-Banach space. If the quasi-norm is \( p \)-subadditive for some \( 0 < p \leq 1 \), \( \mathbb{X} \) is said to be a \( p \)-convex quasi-Banach
space (\( p \)-Banach space for short). Let us notice that a \( p \)-subadditive
quasi-norm \( \| \cdot \| \) induces an invariant metric topology on \( \mathbb{X} \) by the
formula \( d(x, y) = \|x - y\|^p \).
All Banach spaces are locally convex thanks to the triangle law of
the norm, which translates geometrically in the spaces having a convex
set as unit ball. In contrast, a quasi-Banach space \( (\mathbb{X}, \| \cdot \|) \) need not be
\( p \)-convex for any \( p \leq 1 \). The Aoki-Rolewicz theorem \([8, 23]\) guarantees
that, at least, \( \mathbb{X} \) is \( p \)-normable for some \( 0 < p \leq 1 \), i.e., \( \mathbb{X} \) can be
endowed with an equivalent quasi-norm which is \( p \)-subadditive.
When dealing with a quasi-Banach space \( \mathbb{X} \) it is often convenient to
know which is, the “smallest” Banach space containing \( \mathbb{X} \). Formally,
the Banach envelope of a quasi-Banach space \( \mathbb{X} \) consists of a Banach
space \( \hat{\mathbb{X}} \) together with a linear contraction \( J_\mathbb{X} : \mathbb{X} \to \hat{\mathbb{X}} \) satisfying the
following universal property: for every Banach space \( \mathbb{Y} \) and every linear
contraction \( T : \mathbb{X} \to \mathbb{Y} \) there is a unique linear contraction \( \hat{T} : \hat{\mathbb{X}} \to \mathbb{Y} \)
such that \( \hat{T} \circ J_\mathbb{X} = T \). Given a family of vectors (usually a basis)
\( \mathcal{B} \) in \( \mathbb{X} \) we put \( \hat{\mathcal{B}} := J_\mathbb{X}(\mathcal{B}) \). A map \( J \) from \( \mathbb{X} \) into a Banach space
\( \mathbb{Y} \) is said to be an envelope map if the associated map \( \hat{J} : \hat{\mathbb{X}} \to \mathbb{Y} \) is
an isomorphic embedding. If \( J : \mathbb{X} \to \mathbb{Y} \) is an envelope map there
is a natural identification of \( (J_\mathbb{X}, \hat{\mathbb{X}}) \) with \( (J_\mathbb{Y}(\mathcal{X}), \hat{\mathcal{Y}}) \). For instance, the
Banach envelope of \( \ell_p \) for \( p < 1 \) is (naturally identified with) \( \ell_1 \), whereas
the Banach envelope of \( L_p([0, 1]) \) is \( \{0\} \). The unfamiliar reader will find
general information about quasi-Banach spaces in \([17]\).

**Unconditionality of bases and basic sequences.** Let \( \mathbb{X} \) be a quasi-
Banach space and \( J \) be a (finite or infinite) countable set. Given a
sequence \( (f_j)_{j \in J} \), a series \( \sum_{j \in J} f_j \) converges unconditionally to \( f \in \mathbb{X} \).
and write $f = \sum_{j \in J} f_j$ unconditionally, if either $J$ is finite and $f = \sum_{j \in J} f_j$ or $J$ is infinite and $f = \sum_{n=1}^{\infty} f_{\pi(n)}$ for every bijection $\pi: \mathbb{N} \to J$.

A sequence $B = (x_j)_{j \in J}$ in $X$ is an unconditional basic sequence if for every $f \in [x_j: j \in J]$ there is a unique family $(a_j)_{j \in J}$ in $F$ such that the series $\sum_{j \in J} a_j x_j$ converges unconditionally to $f$. Given $1 \leq C < \infty$ we say that $B$ is a $C$-unconditional basic sequence if $x_j \neq 0$ for every $j \in J$ and there is a constant $C$ such that

$$\left\| \sum_{j \in J} a_j x_j \right\| \leq C \left\| \sum_{j \in J} b_j x_j \right\|$$

for every $(a_j)_{j \in J}$ and $(b_j)_{j \in J}$ in $c_00(J)$ such that $|a_j| \leq |b_j|$ for all $j \in J$. It is well-known that $B$ is an unconditional basic sequence if and only it is a $C$-unconditional basic sequence for some $C$. The smallest constant $C \geq 1$ for which an unconditional basic sequence is $C$-unconditional will be called the unconditional constant of $B$. Of course, a finite unconditional basis is nothing but a finite linearly independent family. All unconditional basic sequences are assumed to be infinite, unless otherwise stated. It is customary to index basic sequences with the set $\mathbb{N}$ of natural numbers, and to index finite basic sequences with subsets $\{1, \ldots, m\}$ of $\mathbb{N}$. We prefer to use an arbitrary countable set $J$ to emphasize that, when dealing with unconditional basic sequences, it is unnecessary to arrange the sequences in a particular way.

The following lemmas just follow from the universal property of Banach envelopes (see, e.g., [1, Proposition 9.9]). We write them down for further reference.

**Lemma 2.1.** If $B$ is a semi-normalized complemented unconditional basic sequence of a quasi-Banach space $X$ then $\hat{B}$ is a semi-normalized complemented unconditional basic sequence of $\hat{X}$.

**Lemma 2.2.** If $Y$ is a complemented subspace of a quasi-Banach space $X$, then $J_{X|Y}: Y \to \hat{X}$ is an envelope map.

**Lemma 2.3.** If $X_1$ and $X_2$ are quasi-Banach spaces, then

$$(J_{X_1}, J_{X_2}): X_1 \oplus X_2 \to \hat{X}_1 \oplus \hat{X}_2$$

is an envelope map.

An unconditional basis of a quasi-Banach space $X$ is an unconditional basic sequence whose closed linear span is $X$. Given a basis $B = (x_j)_{j \in J}$ of $\hat{X}$ there is unique sequence $B^* = (x_j^*)_{j \in J}$ in $X^*$ such that $f = \sum_{j \in J} x_j^*(f) x_j$ for every $f \in X$. The support of $f = \sum_{j \in J} a_j x_j \in X$
with respect to $B$ is the set $\text{supp}(f) = \{ j \in J : a_j \neq 0 \}$, and the support of $f^* \in X^*$ with respect to $B$ is the set $\text{supp}(f^*) = \{ j \in J : f^*(x_j) \neq 0 \}$.

Associated to an unconditional basis $B$ of $X$, for each $\gamma = (\gamma_j)_{j \in J} \in \ell_\infty(J)$ there is a bounded linear map $S_\gamma : X \to X$ given by

$$S_\gamma(f) = \sum_{j \in J} \gamma_j x^*_j(f) x_j, \quad f \in X.$$ 

In case that $\gamma$ is the indicator function of a set $A \subseteq J$ we put $S_A := S_\gamma$ and say that the operator $S_A$ is the coordinate projection on $A$.

Suppose that $F$ is a finite set of indices and that $B_i = (x_{i,j})_{j \in J_i}$ is an unconditional basis of a quasi-Banach space $X_i$ for $i \in F$. Then the sequence

$$\bigoplus_{i \in F} B_i := (x_{i,j})_{(i,j) \in \cup_{i \in F} \{i\} \times J_i} \subseteq \bigoplus_{i \in F} X_i$$

defined by

$$x_{i,j} = (x_{i,j,k})_{k \in F}, \quad \text{where } x_{i,j,k} = \begin{cases} x_j & \text{if } k = i, \\ 0 & \text{otherwise,} \end{cases}$$

is an unconditional basis of $\bigoplus_{i \in F} X_i$. If $F = \{1, \ldots, N\}$ and $X_i = X$ and $B_i = B$ for all $i \in F$, we put $B^N = \bigoplus_{i \in F} B_i$ and say that $B^N$ is the $N$-fold product of $B$.

A subbasis of a basis $B = (x_j)_{j \in J}$ of a quasi-Banach space $X$ is a sequence of the form $(x_{i,j})_{j \in J}$ for some $I \subseteq J$. A block basic sequence with respect to $B$ is a sequence $(u_i)_{i \in G}$ in $X$ such that $(\text{supp}(u_i))_{i \in G}$ is a family of pairwise disjoint finite sets. A block basic sequence of an unconditional basic sequence, and the subbases of $B$ are in particular block basic sequences.

**Domination and equivalence of sequences.** Let $B_0 = (x_j)_{j \in J}$ and $B_1 = (y_i)_{i \in I}$ be two sequences in quasi-Banach spaces $X$ and $Y$ respectively. We say that $B_0$ dominates a permutation of $B_1$ if there is a bounded linear map $T : [B_0] \to [B_1]$ and a bijection $\pi : J \to I$ such that $T(x_j) = y_{\pi(j)}$ for all $j \in J$. In the case when $\pi$ is the identity map we say that $B_0$ dominates $B_1$. If $T$ is an isomorphism from $[B_0]$ onto $[B_1]$ we say $B_0$ and $B_1$ are permutatively equivalent (equivalent if, moreover, $\pi$ is the identity map), and we write $B_0 \sim B_1$. Note that if $B_0$ and $B_1$ are permutatively equivalent and $B_0$ is an unconditional basic sequence, then $B_1$ is an unconditional basic sequence.

An unconditional basis $B = (x_j)_{j=1}^\infty$ of a quasi-Banach space $X$ is said to be subsymmetric if it is equivalent to $(x_{\phi(j)})_{j=1}^\infty$ for every increasing map $\phi : \mathbb{N} \to \mathbb{N}$. For example, the canonical basis of $\ell_p$, which we
denote by $E_\ell^p$ from now on, is subsymmetric (in fact it is symmetric, see [13, 24]).

Let us record a very simple, yet useful, property.

**Lemma 2.4.** Suppose that $|F| < \infty$ and that for each $i \in F$, $B_i$ is a subsymmetric basis in a quasi-Banach space $X_i$. Then every subbasis of $\bigoplus_{i \in F} B_i$ is permutatively equivalent to $\bigoplus_{i \in G} B_i$ for some $G \subseteq F$.

**Proof.** Let $B_0$ be a subbasis of $\bigoplus_{i \in I} B_i$ and write $B_0 = \bigoplus_{i \in F} B_{i,0}$, where $B_{i,0}$ is a (finite or infinite) subbasis of $B_i$, $i \in F$. The set $G = \{i \in F : B_{i,0} \text{ is infinite}\}$ is clearly nonempty, and $B_0 \sim B' \oplus (\bigoplus_{i \in G} B_i)$ for some finite basis $B'$. Pick $g \in G$. Dropping a finite number of elements from $B_g$, we infer that $B_g \sim B' \oplus B_g$. Therefore, $B_0 \sim \bigoplus_{i \in G} B_i$. $\Box$

**Lattice structure and convexity conditions.** We are interested in quasi-Banach lattices of functions defined on a countable set $J$, i.e., a quasi-Banach space $L \subseteq E^J$ such that $e_j = (\delta_{i,j})_{i \in J} \in L$ for every $j \in J$, and whenever $f \in L$ and $g \in E^J$ satisfy $|g| \leq |f|$ we have $g \in L$ and $\|g\| \leq \|f\|$. In this case, the unit vector system $E_J = (e_j)_{j \in J}$ is a 1-unconditional basic sequence for $L$. If, additionally, $E_J$ is normalized we will say that $L$ is a sequence space. Recall that a quasi-Banach lattice $L$ is said to be $p$-convex (resp., $q$-concave), where $0 < p \leq \infty$ (resp. $0 < q \leq \infty$) if there is a constant $M > 0$ such that for any $x_1, \ldots, x_m \in L$ and $m \in \mathbb{N}$ we have

$$\left\| \left( \sum_{n=1}^{m} |x_n|^p \right)^{1/p} \right\| \leq M \left( \sum_{n=1}^{m} \|x_n\|^p \right)^{1/p}$$

(2.1)

(resp.,

$$\left( \sum_{n=1}^{m} \|x_n\|^q \right)^{1/q} \leq M \left\| \left( \sum_{n=1}^{m} |x_n|^q \right)^{1/q} \right\| .$$

(2.2)

The general procedure to define the element $(\sum_{n=1}^{m} |x_n|^p)^{1/p} \in L$ is described in [21, pp. 40-41]. However, when our lattice $L$ is a sequence space, so that $x_n = (a_{j,n})_{j \in J}$ for $n = 1, \ldots, m$, we have

$$\left( \sum_{n=1}^{m} |x_n|^p \right)^{1/p} = \left( \sum_{n=1}^{m} |a_{j,n}|^p \right)^{1/p}_{j \in J},$$

and so (2.1) and (2.2) take a more workable form.
Every semi-normalized unconditional basis $B$ of a quasi-Banach space $X$ becomes normalized and 1-unconditional after a suitable renorming of $X$, so that we can associate a sequence space to $B$. An unconditional basis $B$ will be said to be $p$-convex if its associated sequence space is. In general, we say that a semi-normalized unconditional basis has a property about lattices if its associated sequence space has it. And the other way around, i.e., we will say that a sequence space enjoys a certain property relevant to bases if its unit vector system does. A family of semi-normalized unconditional bases will be said to have a certain property if every basis in the family has it and all the constants involved (including the semi-normalization and the unconditionality ones) are uniformly bounded.

If a quasi-Banach lattice is locally convex as a quasi-Banach space, then it is 1-convex as a quasi-Banach lattice. However, despite the fact that every quasi-Banach space is $p$-convex for some $0 < p < 1$, there exist quasi-Banach lattices that are not $p$-convex for any $p$. Kalton introduced in [15] the concept of $L$-convex lattice and showed that a quasi-Banach lattice is $L$-convex if and only if it is $p$-convex for some $p > 0$.

**Lemma 2.5.** Let $A$ be a finite subset of $(0, \infty]$. Then the sequence space $\bigoplus_{p \in A} \ell_p$ is $q$-convex and $r$-concave, where $q = \min A$ and $r = \max A$.

**Proof.** Minkowski’s inequality yields that for any measure $\mu$, the lattice $L_p(\mu)$ is $r$-convex and $q$-concave for $0 < q \leq p \leq r \leq \infty$. Now we just need to use that $q$-convexity and $r$-concavity are preserved under direct sums. □

Recall that two quasi-Banach spaces $X_1$ and $X_2$ are **totally incomparable** if they have no infinite-dimensional subspaces in common (up to isomorphism). It is known [20, 25] that $\ell_p$ and $\ell_q$ are totally incomparable spaces if $0 < p < q \leq \infty$. Let us see what happens with the direct sums of $\ell_p$ spaces.

**Proposition 2.6.** Suppose that $\bigoplus_{p \in A} \ell_p \approx \bigoplus_{p \in B} \ell_p$ for some finite subsets $A, B$ of $(0, \infty]$. Then $A = B$.

**Proof.** Let $p \in A$. Applying [22] Proposition 1.3] yields $(X_q)_{q \in B}$ such that $X_q$ is a complemented subspace of $\ell_q$ for every $q \in B$ and $\ell_p \approx \bigoplus_{q \in B} X_q$. Pick $q \in B$ such that $X_q$ is infinite-dimensional. Then $\ell_q$ and $\ell_p$ are not totally incomparable, and so $p = q$. We have proved that $A \subseteq B$. Switching the roles of $A$ and $B$ we obtain $B \subseteq A$. □

We will take advantage of the lattice structure to delve a bit deeper into the concept of totally incomparable quasi-Banach spaces.
Lemma 2.7. Let $L_1$ and $L_2$ be sequence spaces. Suppose that $L_1$ is $r$-convex, that $L_2$ is $q$-convex and that $q < r$. Then $L_1$ and $L_2$ are totally incomparable.

To prove this we need an auxiliary result.

Lemma 2.8. Let $X$ be an infinite dimensional quasi-Banach space. For any $0 < \delta < 1$ there is $(f_n)_{n=1}^\infty$ in the open unit ball $B_X$ of $X$ with $\|f_n - f_m\| > \delta$ for all $n \neq m$ in $\mathbb{N}$.

Proof. We construct the sequence $(f_n)_{n=1}^\infty$ recursively. Fix $0 < \delta < 1$ and assume that for a given $k \in \mathbb{N}$ we have chosen vectors $(f_n)_{n=1}^{k-1}$ in $B_X$ satisfying our claim. Set $Y_n = \{ x_n : 1 \leq n \leq k-1 \}$ and $X_n = X/Y_{n-1}$. Since $X_n \neq \{ 0 \}$, there is $f \in X$ such that $\| f + Y_{n-1} \| < 1$ and $\| f + Y_{n-1} \| > \delta$. The mere definition of the norm in $X/Y_{n-1}$ yields $f_n \in X$ such that $f + f_n \in Y_{n-1}$ and $\| f_n \| < 1$. Let $k \leq n - 1$. Since $f_k - (f + f_n) \in Y_{n-1}$, $\| f_k - f_n \| = \| f + f_k - f_n - f \| \geq \| f + Y_{n-1} \| > \delta$. □

Proof of Lemma 2.7. Let $Y$ be a quasi-Banach space isomorphic to a subspace of both $L_1$ and $L_2$, and let $T_i : Y \to L_i$ be an isomorphic embedding, $i = 1, 2$. By Lemma 2.8 we can pick a sequence $(f_n)_{n=1}^\infty$ in $B_Y$ such that $\inf_{n \neq m} \| f_n - f_m \| > 0$. Using a Cantor diagonal argument, passing to a subsequence we obtain that $(T_i(f_n))_{n=1}^\infty$ is pointwise convergent in $L_i$, $i = 1, 2$. Then, if $y_n = f_{2n-1} - f_{2n}$, $(T_i(y_n))_{n=1}^\infty$ is pointwise convergent to zero in $L_i$, $i = 1, 2$. Since $\inf_{n} \| y_n \| > 0$ and $\sup_{n} \| y_n \| < \infty$, applying a standard “gliding hump” argument (see [9]) we may pass to a further subsequence and obtain that $(y_n)_{n=1}^\infty$ is equivalent to a block basic sequence with respect to the canonical basis of both $L_1$ and $L_2$. Then for any $(a_n)_{n=1}^\infty \in c_{00}$ we have

$$\left( \sum_{n=1}^{\infty} |a_n|^q \right)^{1/q} \leq \left( \sum_{n=1}^{\infty} a_n T_2(y_n) \right) \approx \left( \sum_{n=1}^{\infty} a_n T_1(y_n) \right) \leq \left( \sum_{n=1}^{\infty} |a_n|^r \right)^{1/r}.$$ 

This absurdity proves that $L_1$ and $L_2$ are totally incomparable. □

A quasi-Banach space (respectively, a quasi-Banach lattice) $X$ is said to be sufficiently Euclidean if $\ell_2$ is crudely finitely representable in $X$ as a complemented subspace (respectively, complemented sublattice), i.e., there is a positive constant $C$ such that for every $n \in \mathbb{N}$ there are bounded linear maps (respectively, lattice homomorphisms) $I_n : \ell_2^n \to X$ and $P_n : X \to \ell_2^n$ with $P_n \circ I_n = \text{Id}_{\ell_2^n}$ and $\| I_n \| \| P_n \| \leq C$. We say that $X$ is anti-Euclidean (resp. lattice anti-Euclidean) if it is not sufficiently Euclidean.
The theory of anti-Euclidean (locally convex) spaces goes back to [10]. As for nonlocally spaces, we point out that if the Banach envelope of a quasi-Banach space $X$ is anti-Euclidean, then $X$ is anti-Euclidean. However, no examples are known of anti-Euclidean quasi-Banach spaces whose Banach envelope is sufficiently Euclidean. Perhaps this gap is at the root of the lack of motivation for developing a theory of sufficiently Euclidean spaces in the setting of quasi-Banach spaces. In practice, the only thing we will use in this paper is that $\ell_1$ (the Banach envelope of $\ell_p$ for $0 < p < 1$) is anti-Euclidean. The most natural way to see this relies on Grothendick’s theorem. Indeed, if $\ell_1$ were sufficiently Euclidean, by [19, Theorem 4.1] the identity map on $\ell_2^n$ would be absolutely summing uniformly in $n$, which is absurd.

Remark 2.9. If a quasi-Banach space $X$ is anti-Euclidean then every complemented subspace $Y$ of $X$ is lattice anti-Euclidean with respect to any lattice structure on $Y$.

Proposition 2.10. Suppose $X$ is a quasi-Banach space with a semi-normalized unconditional basis $B$ which dominates the unit vector basis of $\ell_1$. Then the coefficient transform regarded as a map from $X$ into $\ell_1$ is an envelope map, hence $\hat{X} \approx \ell_1$ is anti-Euclidean.

Proof. Lemma 2.1 yields that $\hat{B}$ is a semi-normalized unconditional basis of $\hat{X}$. By the universal property of $\hat{X}$, the basis $\hat{B}$ dominates the unit vector system of $\ell_1$ and, by the local convexity of $\hat{X}$, the converse also holds. We conclude that those two bases are equivalent, therefore $\hat{X} \approx \ell_1$. □

3. Complemented sequences in quasi-Banach spaces

This section is geared towards Theorem 3.5, which tells us that, under three straightforwardly verified conditions regarding a space and a basis, the complemented unconditional basic sequences of certain quasi-Banach spaces with unconditional basis are rather easy to classify. The techniques used in the proof of this theorem are a development of the methods introduced by Casazza and Kalton in [10,11] to investigate the problem of uniqueness of unconditional basis in a class of Banach lattices that they called anti-Euclidean. The subtle but crucial role played by the lattice structure of the space in the proof of Theorem 3.5 has to be seen in that it will permit to simplify the untangled way in which complemented basic sequences can be written in terms of the basis. These techniques have been extended to the nonlocally convex setting and efficiently used in the literature to establish the uniqueness
of unconditional bases of complemented subspaces of infinite products such as \( \ell_p(\ell_q) = (\ell_q \oplus \ell_{q_2} \oplus \cdots \oplus \ell_{q_n}) \) for \( p \in (0, 1] \cup \{ \infty \} \) and \( q \in (0, 1] \cup \{ 2, \infty \} \). However, the spaces \( \bigoplus_{p \in A} \ell_p \) with \( 2 < |A| < \infty \) are not complemented in any space \( \ell_p(\ell_q) \), and so the known results on the subject do not shed direct information about them.

Before moving on, recall that a basic sequence \((u_i)_{i \in I}\) in a quasi-Banach space \( X \) (with nontrivial dual) is said to be complemented if its closed linear span \( U = \{ u_i : i \in I \} \) is a complemented subspace of \( X \), i.e., there is a bounded linear map \( P : X \to U \) with \( P|_U = \text{Id}_U \). Thus, a basic sequence \( B_u = (u_i)_{i \in I} \) is complemented in \( X \) if and only if there is a sequence \((u^*_i)_{i \in I}\) in \( X^* \) such that \( u^*_i(u) = \delta_{i,j} \) for every \( i, k \in I \) and the linear map \( P_u : X \to X \) given by

\[
P_u(f) = \sum_{i \in I} u^*_i(f) u_i, \quad f \in X,
\]

is well-defined (hence bounded by Closed Graph Theorem). We will refer to \((u^*_i)_{i \in I}\) as a sequence of projecting functionals for \( B_u \). Notice that the sequence \((u^*_i)_{i \in I}\) thus defined need not be unique unless, of course, \( B_u = (u_i)_{i \in I} \) spans the whole space \( X \). A complemented basic sequence \( B_u = (u_i)_{i \in I} \) in \( X \) with mutually disjoint supports with respect to a basis \( B \) will be said to be well complemented if we can choose a sequence of projecting functionals \( B^*_u = (u^*_i)_{i \in I} \) with \( \text{supp}(u^*_i) \subseteq \text{supp}(u_i) \) for \( i \in I \). In this case \( B^*_u \) is called a sequence of good projecting functionals for \( B_u \). For instance, since the coordinate projections of an unconditional basis \( B \) are bounded, the subbases of \( B \) are trivially well complemented basic sequences with respect to \( B \).

Let us get started with a reduction lemma.

**Lemma 3.1 (cf. [3] Lemma 3.8).** Let \( B_u = (u_i)_{i \in I} \) be a well complemented block basic sequence with respect to an unconditional basis \( B = (x_j)_{j \in J} \) of a quasi-Banach space \( X \), and let \((u^*_i)_{i \in I}\) be a sequence of good projecting functionals for \( B_u \). Suppose \( B_v = (v_i)_{i \in I} \) and \((v^*_i)_{i \in I}\) are sequences in \( X \) and \( X^* \) respectively such that for some positive constant \( C \) we have

\[
\begin{align*}
(i) \quad |x^*_i(v_j)| & \leq C|x^*_j(u_i)| \quad \text{for all } (i, j) \in I \times J, \\
(ii) \quad |v^*_i(x_j)| & \leq C|u^*_i(x_j)| \quad \text{for all } (i, j) \in I \times J, \quad \text{and} \\
(iii) \quad \inf_{i \in I} |v^*_i(v_i)| & > 0 \quad \text{for all } i \in I.
\end{align*}
\]

Then \( B_v \) is a well complemented block basic sequence equivalent to \( B_u \). Moreover, if \( v^*_i(v_i) = 1 \) and \( \text{supp}(v^*_i) \subseteq \text{supp}(v_i) \) for all \( i \in I \), then \((v^*_i)_{i \in I}\) is a sequence of good projecting functionals for \( B_v \).
Proof. Without loss of generality, by dilation we assume that \( v_i^*(v_j) = 1 \) for all \( i \in I \). Replacing \( v_i^* \) with \( S_{\text{supp}(v_i)}^*(v_i^*) \) we can also assume that \( \text{supp}(v_i^*) \subseteq \text{supp}(v_i) \) for all \( i \in I \). Since \( \text{supp}(v_i) \subseteq \text{supp}(u_i) \) for every \( i \in I \), there are \( \beta \) and \( \gamma \in \ell_\infty \) such that \( S_\gamma(u_i) = v_i \) and \( S_\beta^*(u_i^*) = v_i^* \) for every \( i \in I \). It follows that \( B_v \) is a block basic sequence, thus \( v_i^*(v_k) = 0 \) whenever \( i \neq k \).

Let \( P_u \) be defined as in (3.1). The bounded linear map \( T = P_u \circ S_\beta \) satisfies

\[
T(f) = \sum_{i \in I} u_i^*(S_\beta(f)) u_i = \sum_{i \in I} S_\beta^*(u_i^*) (f) u_i = \sum_{i \in I} v_i^*(f) v_i
\]

for all \( f \in X \). In particular, \( T(v_i) = u_i \) for all \( i \in I \). Therefore \( B_u \) and \( B_v \) are equivalent.

Finally, the bounded linear map \( P_v = S_\gamma \circ T \) satisfies

\[
P_v(f) = \sum_{i \in I} v_i^*(f) v_i, \quad f \in X.
\]

We deduce that \( B_v \) is well complemented and that \( (v_i^*)_{i \in I} \) is a sequence of (good) projecting functionals for \( B_v \). \( \Box \)

The following definition identifies and gives relief to an unstated feature shared by some unconditional bases. Examples of such bases can be found e.g. in [1][10][11], where the property naturally arises in connection with the problem of uniqueness of unconditional basis.

Definition 3.2. A semi-normalized unconditional basis \( B = (x_j)_{j \in J} \) of a quasi-Banach space \( X \) is said to be universal for well complemented block basic sequences if for every semi-normalized well complemented block basic sequence \( B_u = (u_i)_{i \in I} \) of \( B \) there is a one-to-one map \( \pi : I \to J \) such that \( \pi(i) \in \text{supp}(u_i) \) for all \( i \in I \), and \( B_u \) is equivalent to the rearranged subbasis \( (x_{\pi(i)})_{i \in I} \) of \( B \).

Remark 3.3. The fact that the canonical basis \( E_{\ell_p} \) of \( \ell_p \), \( 0 < p \leq \infty \), is perfectly homogeneous (see [2] Chapter 9) implies that \( E_{\ell_p} \) is universal for well complemented block basic sequences.

This observation in combination with our next result gives ground to the fact that for any \( A \subset (0, \infty) \) finite, the basis \( \bigoplus_{p \in A} E_{\ell_p} \) of \( \bigoplus_{p \in A} \ell_p \) is universal for well complemented block basic sequences.

Proposition 3.4. Let \( (X_i)_{i \in F} \) be a finite collection of quasi-Banach spaces. For each \( i \in F \) suppose that \( B_i \) is a basis of \( X_i \) which is universal for well complemented block basic sequences. Then the basis \( B = \bigoplus_{i \in F} B_i \) of \( X = \bigoplus_{i \in F} X_i \) is universal for well complemented block basic sequences.
Proof. Let \((u_j)_{j \in J}\) be a well complemented block basic sequence in \(X\) with respect to \(B\) with good projecting functionals \((u^*_j)_{j \in J}\). Write \(u_j = (u_{j,i})_{i \in I}\) and \(u^*_j = (u^*_{j,i})_{i \in I}\). By hypothesis we have \(\text{supp}(u^*_{j,i}) \subseteq \text{supp}(u_{j,i})\) for every \((j, i) \in J \times F\). Since \(\sum_{i \in F} u^*_{j,i}(u_{j,i}) = 1\), there is \(\iota: J \to F\) such that 

\[
|u^*_{j,\iota(j)}(u_{j,\iota(j)})| \geq |F|^{-1}, \quad j \in J.
\]

For \(i \in F\) let \(S_i: X_i \to X\) be the inclusion map. By Lemma 3.1, the family 

\[
B' = (S_i)(u_{j,\iota(j)}))_{j \in J}
\]

is a well complemented block basic sequence in \(X\) equivalent to \(B\). We infer that \(B'_i := (u_{j,i})_{j \in F} \iota^{-1}(i)\) is is a well complemented block basic sequence in \(X_i\) for every \(i \in F\). By hypothesis, \(B'_i\) is permutatively equivalent to a subbasis \(B''_i\) of \(B_i\). Hence, \(B'\) is permutatively equivalent to the subbasis \(\bigoplus_{i \in F} B''_i\) of \(B\). □

**Theorem 3.5.** Let \(X\) be a quasi-Banach space whose Banach envelope is anti-Euclidean. Suppose \(B\) is an unconditional basis for \(X\) such that:

1. The lattice structure induced by \(B\) in \(X\) is \(L\)-convex;
2. \(B\) is universal for well complemented block basic sequences; and
3. \(B \sim B^2\).

Then every complemented unconditional basic sequence of \(X\) is permutatively equivalent to a subbasis of \(B\).

Proof. Let \(B_0\) be a semi-normalized complemented unconditional basic sequence in \(X\). The unconditional basic sequence \(\widehat{B}_0\) spans a complemented subspace of \(\widehat{X}\) and hence, by Remark 2.9, \(\widehat{B}_0\) is lattice anti-Euclidean. Theorem 3.4 from [3] gives that \(B_0\) is permutatively equivalent to a well complemented block basic sequence of \(B^s\) for some \(s \in \mathbb{N}\). Since, by the hypothesis (iii), \(B^s \sim B\) and \(B\) is universal for well complemented block basic sequences, we are done. □

This result applied to finite direct sums \(\bigoplus_{p \in A} \ell_p\) gives the following.

**Theorem 3.6.** Let \(A\) be a finite subset of \((0, 1]\). Then every complemented unconditional basic sequence of the sequence space \(\bigoplus_{p \in A} \ell_p\) is permutatively equivalent to the unit vector basis of \(\bigoplus_{p \in B} \ell_p\) for some \(B \subseteq A\).

Proof. We have that \(\bigoplus_{p \in A} \ell_p \subseteq \ell_{|A|}^1 \equiv \ell_1\) (as quasi-Banach lattices). Then, the result follows by combining Lemma 2.4, Lemma 2.5, Proposition 2.10, Remark 3.3, Proposition 3.3, and Theorem 3.5. □
4. The Proof of the Main Theorem

With the all groundwork of the previous sections we may proceed directly to proof of our Main Theorem.

Completion of the proof of Theorem 1.1. Without loss of generality we assume that the basis $B = (x_j)_{j \in J}$ is normalized. Assume also that the set of indexes $A_K = \{ p \in A : p \leq 1 \}$ is nonempty, otherwise the result would follow from the afore-mentioned result by Edelstein and Wojtaszczyk’s [12, Theorem 4.11].

Put $A_C = A \setminus A_K$, $X_K = \bigoplus_{p \in A_K} \ell_p$, $X_C = \bigoplus_{p \in A_C} \ell_p$ and $X = \bigoplus_{p \in A} \ell_p$, so that $X = X_K \oplus X_C$.

Since $X_K$ is contained in the $|A_K|$-fold product $\ell_1^{A_K}$ we have $\tilde{X}_K \approx \ell_1$ and so $\tilde{X} \approx \ell_1 \oplus X_C$. By Edelstein-Wojtaszczyk’s theorem there is a partition $(J_p)_{p \in \{1\} \cup A_C}$ of $J$ such that for each $p \in \{1\} \cup A_C$, the sequence $(J_p(x_j))_{j \in J_p}$ generates a space isomorphic to $\ell_p$. By Lemma 2.2, if we put $Y_p = [x_j : j \in J_p]$ for $p \in \{1\} \cup A_C$, the restriction of $J_p$ to $Y_p$ is an envelope map. Therefore

$$\tilde{Y}_p \approx [J_p(x_j) : j \in J_p] \approx \ell_p, \quad p \in \{1\} \cup A_C.$$  

Since, by Lemmas 2.5 and 2.7, the spaces $X_K$ and $X_C$ are totally incomparable, there exist complemented subspaces $Y_K$ of $X_K$ and $Y_C$ of $X_C$ such that $Y_1 \simeq Y_K \oplus Y_C$. Taking Banach envelopes, in light of Lemma 2.3 we obtain

$$\ell_1 \approx \tilde{Y}_K \oplus \tilde{Y}_C = \tilde{Y}_K \oplus \tilde{Y}_C.$$  

Hence $X_K \oplus Y_C \approx \tilde{X}_K$. We infer that $Y_1$ is isomorphic to a complemented subspace of $X_K$. Then, by Theorem 3.6 there is $B \subseteq A_K$ such that $(x_j)_{j \in J}$ is permutatively equivalent to the unit vector system of $\bigoplus_{p \in B} \ell_p$. That is, there is a partition $(J_p')_{p \in B}$ of $J_1$ such that $(x_j)_{j \in J_p'}$ is (permutatively) equivalent to the unit vector system of $\ell_p$ for every $p \in B$.

If $p \in A_C$, the dual space of $\tilde{Y}_p$ has a finite cotype. Moreover, by [15, Theorem 4.2], $Y_p$ is an $L$-convex quasi-Banach lattice. Therefore, by [16, Theorem 3.4], $J_p|_{Y_p}$ is an isomorphism and so $(x_j)_{j \in J_p}$ generates a space isomorphic to $\ell_p$.

Summing up, if we put $A' = B \cup A_C$ and $J_p' = J_p$ for $p \in A_C$, we have that $(J_p')_{p \in A'}$ is a partition of $J$ such that $(x_j)_{j \in J_p'}$ generates a space isomorphic to $\ell_p$. Consequently, $X \approx \bigoplus_{p \in A'} \ell_p$. By Proposition 2.6 $A = A'$.

$\square$
As an application we obtain new additions to the list of spaces with a unique unconditional basis. Recall that a quasi-Banach space $X$ with an unconditional basis $B$ is said to have a unique unconditional basis up to a permutation if every normalized unconditional basis of $X$ is permutatively equivalent to $B$.

**Theorem 4.1.** Let $A$ be a finite subset of indexes of $(0, 1] \cup \{2, \infty\}$. Then the quasi-Banach space $\bigoplus_{p \in A} \ell_p$ has a unique unconditional basis, up to permutation.

**Proof.** It just follows by combining Theorem 1.1 and the uniqueness of unconditional basis of $\ell_p$ for $p \in A$ (14, 18, 19).

**Remark 4.2.** Observe that Theorem 3.5 provides a proof of the uniqueness of unconditional basis of $\ell_p$ for $p \in (0, 1] \cup \{\infty\}$.
