Decomposition of random walk measures on
the one-dimensional torus

Tom Gilat

Abstract

The main result of this paper is a decomposition theorem for a
measure on the one-dimensional torus. Given a "sufficiently large" subset $S$ of the positive integers, an arbitrary measure on the torus is decomposed as the sum of two measures. The first one $\mu_1$ has the property that the random walk with initial distribution $\mu_1$ evolved by the action of $S$ equidistributes very fast. The second measure $\mu_2$ in the decomposition is concentrated on very small neighborhoods of a small number of points.

1 Introduction

This paper is concerned with the dynamics of subsemigroups of the positive integers acting on the one-dimensional torus $\mathbb{R}/\mathbb{Z}$. This extensive line of research goes back to Furstenberg, who described the minimal sets of the action of the semigroup generated by two multiplicatively independent integers. They are finite periodic orbits and the whole torus.
Furstenberg also made several conjectures about such actions, which had an enormous impact on the field. Perhaps the most prominent of these asks for a classification of invariant measures on the torus under the action of the semigroup generated by 2 and 3 (or any other pair of multiplicatively independent integers). There has been some remarkable progress on this problem, but the conjecture is still wide open.

These problems become more manageable if one considers the action of "larger" semigroups. For example, Einsiedler and Fish gave a classification of invariant measure under the action of a semigroup with positive logarithmic density.

The main result of this paper is a decomposition theorem for a measure on the torus. Given a "sufficiently large" subset $S$ of the positive integers, an arbitrary measure on the torus is decomposed as the sum of two measures. The first one $\mu_1$ has the property that the random walk with initial distribution $\mu_1$ evolved by the action of $S$ equidistributes very fast. The second measure $\mu_2$ in the decomposition is concentrated on very small neighborhoods of a small number of points.

The proof of the main result uses tools from additive combinatorics and builds on the work of Bourgain, Furman, Lindenstrauss and Mozes on the classification of stationary measures under the action of non-commuting toral automorphisms.

We define the general setting as follows: for $L > 0$, let $S \subset [L, 2L]$ be a set of natural numbers, $|S| > L^\beta$ for $0 < \beta < 1$, with $S$ being $(\tilde{C}, \lambda)$-regular (definition follows). The variables $L, \beta$ and $\tilde{C}, \lambda$ should be considered as global parameters and are referred to in the different theorems, propositions
and lemmas. Typically, by giving thresholds on their values in the conditions of the statements.

For a set $S$ we define the following measure,

$$
\nu_S = \frac{1}{|S|} \sum_{s \in S} \delta_s.
$$

(1.1)

$S$ acts on the torus in the following standard way: $s.x = sx \pmod{1}$ for $s \in S$. For $s \in S$, let $T_s : \mathbb{T} \to \mathbb{T}$ be the mapping: $T_s(x) : x \mapsto s.x$.

For $\mu \in \mathcal{P}(\mathbb{T}), \nu \in \mathcal{P}(S)$ define the measure $\nu \ast \mu \in \mathcal{P}(\mathbb{T})$ as follows:

$$
\nu \ast \mu = \sum_{s \in S} \nu(s) T_s \ast \mu,
$$

(1.2)

where $T_s \ast \mu(E) = \mu(T_s^{-1}(E))$ for a Borel set $E \subset \mathbb{T}$.

The following definition says what it means for a set $S$ to be $(\tilde{C}, \lambda)$-regular.

**Definition 1.** We say that a set $S \subset [L, 2L] \subset \mathbb{N}$ is $(\tilde{C}, \lambda)$-regular at scale $r$ if the following holds

$$
|I \cap S| \leq \tilde{C} \cdot \left(\frac{|I|}{L}\right)^\lambda |S|
$$

(1.3)

for any interval $I \subset [L, 2L] \subset \mathbb{R}$ with $|I| \geq r$. By $|\cdot|$, we denote cardinality or the Lebesgue measure according to context.

If we say that a set is $(\tilde{C}, \lambda)$-regular, we mean that it is $(\tilde{C}, \lambda)$-regular at scale $1$.

We state the main theorem of this work, which is a decomposition theorem for a measure on the torus.
Theorem 2. Let $\mu$ be a probability measure on $\mathbb{T}$. For $\lambda, \beta$ there exist $L_1, k, \kappa, C, U, \tau_0 > 0$, such that if $L > L_1$, $S \subset [L, 2L]$ a $(\tilde{C}, \lambda)$-regular set for some $\tilde{C} < L^{\tau_0}$ and $\tau < \tau_0$ with $|S| > L^\beta$, then there is a decomposition $\mu = \mu_1 + \mu_2$ such that

$$|\nu_S^k \ast \mu_1(n)| \leq L^{-\tau} \quad \forall |n| < L^\tau, \quad (1.4)$$

and there are $l$ subsets of $\mathbb{T}$: $X_1, X_2, \ldots, X_l$, where $l < L^{C\tau}$, such that each $X_i$ is $\frac{1}{M}$-separated, and $\mu_2$ is supported on $\bigcup_{i=1}^l \bigcup_{x \in X_i} B_{x, \frac{1}{M}}$, where $M = N^{1-\kappa}$, $N = L^U$.

In a followup paper we intend to show how Theorem 2 can be used to prove effective equidistribution results in this context.

2 Preliminaries from additive combinatorics

The following is a triangle inequality which is due to Ruzsa. It is a classical result with a very simple proof.

Lemma 3 ([14], Lemma 2.6 - Ruzsa triangle inequality). Let $A, B, C \subset G$ with $G$ any additive group. Then

$$|A - B| \leq \frac{|A - C||B - C|}{|C|}$$

We will need the following graph-theoretic result, closely connected to the Balog-Szemerédi-Gowers Theorem, due to Sudakov B., Szemerédi, E. and Vu V. H.

Theorem 4 ([15], Lemma 4.2). Let $n$ and $K$ be positive numbers, and let $G = G(A, B, E)$ be a (finite) bipartite graph, where $|B| \leq |A| = n$ and $|E| = n^2/K$. Then one can find $A' \subset A$ and $B' \subset B$ such that
1. $|A'| \geq n/(16K^2)$ and $|B'| \geq n/(4K)$,

2. $|(A' \times B') \cap E| \geq |A'||B'|/(4K)$

3. for each $a \in A'$ and $b \in B'$, there are $n^2/(2^{12}K^5)$ paths of length 3 whose two endpoints are $a$ and $b$.

We need to present two notations for the statement of the next Lemma. These notations are used throughout the work.

**Definition 5.** Let $\mathcal{N}(A; M)$ for a set $A \subset \mathbb{R}$ and $M \in \mathbb{R}$, be the minimal number of open balls with radius $M$ (the center of a ball is any point in $\mathbb{R}$) that cover the set $A$.

**Definition 6.** Let $\mathcal{F}(\mu, \delta)$ for $\mu \in \mathcal{P}(\mathbb{T})$ and a real number $\delta \geq 0$, be the following,

$$\mathcal{F}(\mu, \delta) = \{a \in \mathbb{Z}\backslash\{0\} : |\widehat{\mu}(a)| > \delta\} \quad (2.1)$$

The following lemma allows us to extract a set of relatively large Fourier coefficients, which is stable with respect to subtraction, out of an initial set of high Fourier coefficients. The sets are in a window around 0 and are regarded at some resolution $M$. The uses a counting argument which involves the graph-theoretic Lemma 4 with the algebraic nature of the ring of integers.

**Lemma 7.** For positive integer numbers $N, M$ and a probability measure $\mu$ on $\mathbb{T}$; let $A_0$ be an $M$-separated subset of $\mathcal{F}(\mu, \delta) \cap [-N, N]$. Assume that the following holds for a positive real number $R$

$$\mathcal{N}(\mathcal{F}(\mu, \delta^2/8) \cap [-2N, 2N]; M) \leq R|A_0|,$$

then there exist a subset $A_1 \subset A_0$ such that
1. \[ \left| \frac{1}{|A_1|} \sum_{a \in A_1} \hat{\mu}(a) \right| \geq \delta \]

2. \[ |A_1| \gg |A_0| \delta^2 \]

3. \[ \mathcal{N}(A_1 - A_1; M) \ll |A_0| R^8 \delta^{-8} \]

**Proof.** By passing to a subset \( A \subset A_0 \) of size \( |A| \geq \frac{|A_0|}{4} \) we may assume that for some fixed \( \theta \in [0, 2\pi) \), for all \( a \in A \): \( \text{Re}(e^{i\theta} \cdot \hat{\mu}(a)) > \frac{\delta}{2} \). Therefore

\[ \left| \frac{1}{|A|} \sum_{a \in A} \hat{\mu}(a) \right| > \frac{\delta}{2}. \quad (2.2) \]

Let

\[ \phi(x) = \sum_{a \in A} e_a(x). \quad (2.3) \]

Where \( e_a(x) = e^{-2\pi axi} \). Note that

\[ |\phi(x)|^2 = (\sum_{a \in A} e_a(x)) \cdot (\sum_{b \in A} e_b(x)) = \sum_{a,b \in A} e_{a-b}(x). \quad (2.4) \]

We have that

\[
\sum_{a,b \in A} \hat{\mu}(a - b) = \int_{\mathbb{T}} \sum_{a,b \in A} e((a - b)x)d\mu(x)
= \int_{\mathbb{T}} |\phi(x)|^2 d\mu(x)
\geq \left| \int_{\mathbb{T}} \phi(x)d\mu(x) \right|^2
= \left| \sum_{a \in A} \hat{\mu}(a) \right|^2
\]

where the inequality is due to the Cauchy-Schwarz inequality. Therefore

\[ \frac{1}{|A|^2} \sum_{a,b \in A} \hat{\mu}(a - b) \geq \left| \frac{1}{|A|} \sum_{a \in A} \hat{\mu}(a) \right|^2 \geq \frac{\delta^2}{4} \quad (2.6) \]
Let
\[ E = \left\{ (a, b) \in A \times A : \tilde{\mu}(a - b) > \frac{\delta^2}{8} \right\} \]
\[ = \left\{ (a, b) \in A \times A : a - b \in \mathcal{F}(\mu, \frac{\delta^2}{8}) \cap [-2N, 2N] \right\} \quad (2.7) \]

By Lemma [14] we have that
\[ |E| \geq \frac{\delta^2}{8}|A|^2 \quad (2.8) \]

Define
\[ \bar{A} = \left\{ \left\lfloor \frac{a}{M} \right\rfloor \cdot M : a \in A \right\} + \{0, M\} \quad (2.9) \]

Note that (recall that \( A \) is \( M \)-separated)
\[ |A| \leq |\bar{A}| \leq 2|A| \quad (2.10) \]

Define
\[ H = \left\{ \left\lfloor \frac{h}{M} \right\rfloor \cdot M : h \in \mathcal{F}(\mu, \frac{\delta^2}{8}) \cap [-2N, 2N] \right\} + \{0, M\} \quad (2.11) \]

Note that
\[ |H| \leq 4N(\mathcal{F}(\mu, \delta^2/8) \cap [-2N, 2N]; M) \leq 4R|A_0| \leq 16R|\bar{A}| \quad (2.12) \]

Next, we define
\[ \bar{E} = \left\{ (a, b) \in \bar{A} \times \bar{A} : a - b \in H \right\} \quad (2.13) \]

Note that
\[ |\bar{E}| \geq |E| \quad (2.14) \]

By \(2.8,2.10,2.14\) we have that
\[ |\bar{E}| \geq \frac{\delta^2}{32}|\bar{A}|^2 \quad (2.15) \]
We choose subsets $A', B' \subset \bar{A}$ according to Theorem 4, such that

$$|A'| \geq \frac{\delta^2}{2^7}|\bar{A}|, \quad |B'| \geq \frac{\delta^4}{2^{14}}|\bar{A}|$$

(2.16)

Let $a \in A', b \in B'$. Then $a - b$ can be written as

$$a - b = (a - b_1) + (b_1 - a_1) + (a_1 - b)$$

(2.17)

in at least $\frac{|\bar{A}|^2 \delta^2}{2^{25}}$ ways with all $a - b_1, a_1 - b_1, a_1 - b \in H$, and so by (2.12)

$$\frac{|\bar{A}|^2 \delta^2}{2^{25}}|A' - B'| \leq (16R|\bar{A}|)^3$$

(2.18)

or

$$|A' - B'| \leq 2^{49}R^3\delta^{-2}|\bar{A}|$$

(2.19)

By Lemma 3 we have that

$$|A' - A'| \leq 2^{102}R^6\delta^{-8}|\bar{A}|$$

(2.20)

Define

$$A_1 = \left\{ a \in A : \exists a' \in A' \text{ s.t. } \left\lfloor \frac{a}{M} \right\rfloor \cdot M = a' \right\}$$

(2.21)

And so (using 2.10)

$$\mathcal{N}(A_1 - A_1; M) < 2^{105}R^6\delta^{-8}|A_0|$$

(2.22)

\[ \square \]

**Definition 8.** For any integer $n$, we denote by $V(y, \rho)$ the $\rho$-neighborhood of $y \in \mathbb{P}^n$ (the dependence on $n$ is implicit in the notation, most of the time we will take $n = 1$). Formally it is:

$$V(y, \rho) = \left\{ x \in \mathbb{P}^n : \frac{|\langle x, y \rangle|}{||x|| ||y||} < \rho \right\}.$$
The following theorem is a projection theorem by Bourgain which can be found in [3].

**Theorem 9** ([3], Thm. 5). For any $\alpha_0, \kappa > 0$ there are $\alpha_\Delta, \epsilon_0, r_0, \tau_0 > 0$ such that the following holds for $0 < r < r_0$ and $\alpha_0 < \alpha < 2 - \alpha_0$: let $\eta$ be a probability measure on $\mathbb{P}^1$ s.t.

$$\max_{y} \eta \left( V \left( y^\perp, \rho \right) \right) < \rho^\kappa \quad \text{if} \quad r < \rho < r^{\tau_0}. \quad (2.24)$$

Let $E \subset [0,1]^2$ be an $r$-separated set with $|E| > r^{-\alpha}$ and a nonconcentration property

$$\max_x |E \cap B_{x,\rho}| < \rho^\kappa |E| \quad \text{if} \quad r < \rho < r^{\tau_0}. \quad (2.25)$$

Then there exist $D \subset \mathbb{P}^1$ and $E' \subset E$ with

$$\eta(D) > 1 - r^{\epsilon_0}, \quad |E'| > r^{\epsilon_0}|E|$$

so that

$$\mathcal{N} \left( \pi_\theta(E''); r \right) > r^{-(\alpha + \alpha_\Delta)/2}$$

whenever $\theta \in D$ and $E'' \subset E'$ satisfies $|E''| > r^{2\epsilon_0}|E|$.

## 3 Regularity of sets

**Definition 10** ([4], Def. 5.1). A measure $\rho$ on a set $B \subset \mathbb{R}^d$ is said to be $(C, \alpha)$-regular at scale $r$ on $B$ if for any $x \in B$, $s \geq r$

$$\rho(B_{x,s}) < C \left( \frac{s}{\text{diam } B} \right)^\alpha. \quad (3.1)$$

A set $B$ is said to be $(C, \alpha)$-regular at scale $r$ if the corresponding uniform measure $\rho = \frac{1}{|B|} \sum_{x \in B} \delta_x$ is $(C, \alpha)$-regular at scale $r$. 

9
The following lemma (Lemma 5.2, [4]) relates the defined notion of a regularity of a set by expressing the dimension via a covering number.

**Lemma 11** ([4], Lemma 5.2). For any $\epsilon > 0$ there are constants $C_\epsilon, C'_\epsilon > 0$ such that for every $s, \alpha$ with $2\epsilon < s < \alpha$ and $r < 1$, if $\tilde{A} \subset B_{0,1} \subset \mathbb{R}^d$ satisfies

$$N(\tilde{A}; r) \geq r^{-\alpha},$$

then there is a point $x \in B_{0,1}$ and a probability measure $\rho$ supported on $\tilde{A} \cap B_{x,r^\beta}$ which is $(C_\epsilon, \alpha - s)$-regular on $B_{x,C'_\epsilon r^\beta}$ at scale $r$ for $\beta = \frac{1-\alpha+\epsilon}{1-\alpha+s-\epsilon}$.

**Lemma 5.3** in [4] is the following

**Lemma 12.** Let $\rho$ be a $(C, \alpha)$-regular probability measure at scale $r$ on $B \subset \mathbb{R}^d$. Then for any $\epsilon > 0$ there is an $r$-separated subset $A \subset \text{supp}(\rho)$ so that the uniform measure on $A$ is $(C_\epsilon, \alpha - \epsilon)$-regular at scale $r$ on $B$.

We will be using the following lemma. Lemmas 11, 12 are used in its proof.

**Lemma 13** (Lemma 6.7 in [4], one dimensional torus). For any $\epsilon > 0$, there is a $C_\epsilon$ so that the following holds. Let $\mu$ be a probability measure on $\mathbb{T}$. Assume that for some $N > M, t, \alpha$

$$N(\mathcal{F}(\mu, t) \cap [-N, N]; M) \geq \left(\frac{N}{M}\right)^\alpha.$$  \hspace{1cm} (3.3)

Then there is an $M < N_1 < N$ with

$$\log \frac{N_1}{M} > \left(\frac{1-\alpha+\epsilon}{1-\alpha+8\epsilon}\right) \log \frac{N}{M}$$  \hspace{1cm} (3.4)

so that $\mathcal{F}(\mu, t^2/4) \cap [-N_1, N_1]$ contains a subset which is $(C_\epsilon t^{-2}, \alpha - 10\epsilon)$-regular at scale $M$.  

10
4 Main Bootstrapping Lemma

The following lemma is very simple but it is employed over and over in the main lemmas, making its explicit statement and proof worthwhile.

**Lemma 14.** Let \( \{a_i\}_{i=1}^n \) be a set of real numbers in \([0, 1]\) for which
\[
\sum_{i=1}^n a_i \geq \alpha n.
\] (4.1)
for \( \alpha \in [0, 1] \). Then
\[
|\{i : a_i \geq \alpha/2\}| \geq \frac{\alpha}{2} n
\] (4.2)

*Proof.* Assume for contradiction that
\[
|\{i : a_i \geq \alpha/2\}| < \frac{\alpha}{2} n
\] (4.3)
Since each \( a_i \) can be at most 1, we have that
\[
\sum_{i=1}^n a_i < \frac{\alpha}{2} n \cdot 1 + \frac{2 - \alpha}{2} n \cdot \frac{\alpha}{2} < \alpha n
\] (4.4)
Contradiction. \( \Box \)

We prove the following lemma which is the extraction of the initial set of large Fourier coefficients, using the information of having one single large Fourier coefficient of the random walk measure.

**Lemma 15 (Initial dimension).** For any probability measure \( \mu \) on \( \mathbb{T} \) for \( n \geq 1 \), if for some \( a \in \mathbb{Z} \)
\[
|\hat{\mu}_n(a)| > \delta_0
\] (4.5)
for \( \delta_0 \in (0, 1) \), then
\[
\mathcal{N} \left( \mathcal{F}(\mu_{n-1}, \frac{\delta_0}{2}) \cap [-N, N]; M \right) \geq \frac{\delta_0}{2} \left( \frac{N}{M} \right)^{\alpha_{ini}}
\] (4.6)
where \( N = L|a|, M = |a|, \alpha_{ini} = \beta (|S| = L^\beta) \).
Proof. Note the equality:
\[
\hat{\mu}_n(\xi) = \frac{1}{|S|} \sum_{s \in S} \hat{\mu}_{n-1}(s\xi).
\] (4.7)

By the above, we have the following,
\[
\delta_0 < |\hat{\mu}(a)| = \left| \frac{1}{|S|} \sum_{s \in S} \hat{\mu}_{n-1}(sa) \right| \leq \frac{1}{|S|} \sum_{s \in S} |\hat{\mu}_{n-1}(sa)|.
\] (4.8)

By Lemma 14
\[
\left| \left\{ s \in S : |\hat{\mu}_{n-1}(sa)| > \frac{\delta_0}{2} \right\} \right| \geq \frac{|S|\delta_0}{2}
\] (4.9)

And so
\[
\mathcal{N} \left( \mathcal{F}(\mu_{n-1}, \frac{\delta_0}{2}) \cap [-L|a|, L|a|] ; |a| \right) \geq \frac{|S|\delta_0}{2}
\] (4.10)

For the next lemma we need the following simple definition.

**Definition 16.** For a set \( A \subset \mathbb{Z} \) and \( M \in \mathbb{R} \), let \( B_M(A) = \bigcup_{a \in A} B_{a,M} \).

The following is the main technical tool of the proof of our main decomposition theorem, Theorem 2. We either find a large set of Fourier coefficients by regarding a smaller value of the threshold on the coefficients, as being "large", or - we look at the previous generation random walk measure; the assumption of non-existence of a set that meets our terms, is employed with the additive structure of the Fourier coefficients to show two contradicting inequalities.

**Lemma 17** (Bootstrap lemma). Given \( \lambda, \tau > 0 \) and \( \alpha_{\text{ini}}, \alpha_{\text{high}} \), there exist \( C^*, \alpha_{\text{inc}} > 0 \) and \( L_1 \) such that if \( L > L_1 \), \( \alpha_{\text{high}} \geq \alpha \geq \alpha_{\text{ini}} \), \( S \subset [L, 2L] \) a \((\tilde{C}, \lambda)\)-regular set for some \( \tilde{C} < L^{C^*} \), and \( N, M, \delta \) satisfying
\[
L^\tau < \frac{N}{M} < L \text{ and } L^{-C^*} < \delta,
\] (4.11)
and if the following holds for some \( n \geq 1 \)
\[
\mathcal{N}(F(\mu_n, \delta) \cap [-N, N]; M) \geq \left( \frac{N}{M} \right)^{\alpha}
\]
then
\[
\mathcal{N}(F(\mu_{n-1}, \delta^3/256) \cap [-N', N']; M') \geq \left( \frac{N'}{M'} \right)^{\alpha+\alpha_{\text{inc}}}
\]
where \( N' = LN_0, M' = LM, \) and \( N_0 \) is such that \( M < N_0 \leq 2N \) with
\[
\log \frac{N_0}{M} > \frac{1}{8} \cdot \log \frac{N}{M}.
\]

**Proof.** Let \( \alpha_\Delta \) be as in Theorem 9 for \( \alpha_0 = \min(\alpha_{\text{ini}}, 1 - \alpha_{\text{high}})/2 \), and for \( \kappa = \frac{\lambda}{10} \).

Let
\[
E_0 \subset F(\mu_n, \delta) \cap [-N, N]
\]
be an \( M \)-separated set of maximal cardinality. Let \( \epsilon < \frac{\alpha_\Delta}{640 \cdot 20} \) to be determined later when we explain how to apply the projection theorem (Theorem 17) later in this proof. Note that the proof may end without actually applying the projection theorem. Apply Lemma 13 with respect to \( \mu_n, \delta \) (in the roles of \( \mu, t \)) to obtain
\[
E'_0 \subset F(\mu_n, \delta^2/4) \cap [-N_1, N_1],
\]
an \( M \)-separated set which is \((C\delta^{-2}, \alpha - 10\epsilon)\)-regular at scale \( M \) (\( C \) depends on \( \epsilon \)). \( N_1 \) is as obtained in the conclusion of Lemma 13. Let
\[
E_1 \subset F(\mu_n, \delta^4/32) \cap [-2N_1, 2N_1]
\]
be an \( M \)-separated set of maximal cardinality. And let
\[
\rho = \frac{|E_1|}{|E'_0|}.
\]
We first deal with the case that the following holds:

$$\rho \geq 1024C \left( \frac{N_1}{M} \right)^{\frac{\alpha \Delta / 640}{\delta^6}}. \tag{4.17}$$

We will use the following relation,

$$\hat{\mu}_n(\xi) = \frac{1}{|S|} \sum_{s \in S} \hat{\mu}_{n-1}(s\xi). \tag{4.18}$$

By passing to a subset $E_1' \subset E_1$ of size $|E_1'| > \frac{|E_1|}{4}$ we may assume that for some fixed $\theta \in [0, 2\pi)$, for all $\xi \in E_1'$, $\text{Re}(e^{i\theta} \cdot \hat{\mu}(\xi)) > \frac{\delta^4}{128}$. Therefore,

$$\left| \frac{1}{|E_1'|} \sum_{\xi \in E_1'} \hat{\mu}_n(\xi) \right| \geq \frac{\delta^4}{128}. \tag{4.19}$$

Then by the relation (4.18) we have the following,

$$\frac{1}{|S||E_1'|} \sum_{s \in S} \sum_{\xi \in E_1'} |\hat{\mu}_{n-1}(s\xi)| \geq \frac{\delta^4}{128}. \tag{4.20}$$

In particular there exists $s_0 \in S$ such that

$$\frac{1}{|E_1'|} \sum_{\xi \in E_1'} |\hat{\mu}_{n-1}(s_0\xi)| \geq \frac{\delta^4}{128}. \tag{4.21}$$

Let

$$E_2 \subset \mathcal{F}(\mu_{n-1}, \frac{\delta^4}{256}) \cap [-2LN_1, 2LN_1] \tag{4.22}$$

be an $(LM)$-separated set of maximal cardinality. By Lemma 14 we have that

$$|E_2| \geq \left| \left\{ \xi \in E_1' : |\hat{\mu}_{n-1}(s_0\xi)| \geq \frac{\delta^4}{256} \right\} \right| \geq \frac{\delta^4}{256} |E_1'| \geq \rho \frac{\delta^4}{1024} |E_0'|. \tag{4.23}$$
If the inequality (4.17) holds then we are done (as long as we choose $\alpha_{inc} \leq \frac{\alpha \Delta}{1280}$, and for $N_0 = 2N_1$) as

$$|E_2| \leq N\left( F(\mu_{n-1}, \delta^4/256) \cap [-2LN_1, 2LN_1]; LM \right)$$

and $\epsilon < \frac{\alpha \Delta}{640 \cdot 20}$.

We now turn to the harder case where (4.17) fails. Define $\delta' = \frac{\delta^2}{4}$. By Lemma 7 there exists a set $E \subset E'_0$ such that

(E.1) $\left| \frac{1}{|E|} \sum_{e \in E} \hat{\mu}_n(e) \right| \geq \frac{\delta'}{2}$.

(E.2) $|E| > c'|E'_0|\delta'^2$.

(E.3) $\mathcal{N}(E - E; M) < |E'_0|c\rho^6\delta'^{-8}$.

Where $c, c'$ are absolute constants. Set $\rho' = 1024C \left( \frac{N}{M} \right)^{\alpha \Delta/640} \delta^{-6}$ (this is the value in the bound in (4.17)). By (4.18) we have the following

$$\left| \frac{1}{|S|} \sum_{s \in S} \sum_{e \in E} \hat{\mu}_{n-1}(se) \right| \geq \frac{\delta'}{2}. \tag{4.24}$$

By Lemma 14 we have that

$$\# \left\{ (s, e) \in S \times E : |\hat{\mu}_{n-1}(se)| \geq \frac{\delta'}{4} \right\} \geq \frac{\delta'}{4}|S||E| \tag{4.25}$$

Assume that for $\alpha_{inc}$ small to be determined later (but certainly $\leq \frac{\alpha \Delta}{1280}$), the following holds:

$$\mathcal{N}\left( F(\mu_{n-1}, \frac{\delta'}{4}) \cap [-LN_1, LN_1]; LM \right) < \left( \frac{N_1}{M} \right)^{\alpha + \alpha_{inc}}. \tag{4.26}$$

Let

$$M' = LM, \quad N' = LN_1. \tag{4.27}$$
Let
\[ E_3 \subset \mathcal{F}(\mu_{n-1}, \frac{\delta'}{4}) \cap [-N', N'] \]  
(4.28)
be an \( M' \)-separated set of maximal cardinality. By inequality (4.25) we have that
\[ \frac{2}{M'} \sum_{s \in S} m(B_{M'}(sE) \cap B_{M'}(E_3)) \geq \frac{\delta'}{4} |S||E|. \]  
(4.29)
Therefore,
\[ \int_{B_{M'}(E_3)} \sum_{s \in S} 1_{B_{M'}(sE) \cap B_{M'}(E_3)}(x) dm(x) \geq \frac{\delta'}{8} M'|S||E|. \]  
(4.30)
By the Cauchy-Schwarz inequality we have that
\[ 2M'|E_3| \int_{B_{M'}(E_3)} \left( \sum_{s \in S} 1_{B_{M'}(sE) \cap B_{M'}(E_3)}(x) \right)^2 dm(x) \geq \frac{\delta'^2}{64} M^2 |S|^2 |E|^2. \]  
(4.31)
Writing inequality (4.31) in the following way
\[ \frac{1}{|S|^2} \sum_{(s_1, s_2) \in S \times S} \frac{m(B_{M'}(s_1 E) \cap B_{M'}(s_2 E))}{M'|E|} \geq \frac{\delta'^2 |E|}{128 |E_3|}. \]  
(4.32)
We see that (using Lemma 14),
\# \left\{ (s_1, s_2) \in S \times S : m(B_{M'}(s_1 E) \cap B_{M'}(s_2 E)) \geq \frac{M' \delta'^2 |E|^2}{256 |E_3|} \right\} \geq \frac{\delta'^2 |E|}{256 |E_3|} |S|^2. \]  
(4.33)
For a specific \( s_1 \in S \) we define the set \( B \) as follows:
\[ B = \left\{ s_2 \in S : m(B_{M'}(s_1 E) \cap B_{M'}(s_2 E)) \geq \frac{M' \delta'^2 |E|^2}{256 |E_3|} \right\}. \]  
(4.34)
By the pigeonhole principle there exists \( s_1 \in S \) so that
\[ |B| \geq \frac{\delta'^2 |E|}{512 |E_3|} |S|. \]  
(4.35)
By assumption $S$ is $(\bar{C}, \lambda)$-regular, and $|E_3| < \left( \frac{N}{M} \right)^{\alpha + \alpha_{\text{inc}}}$. By (E.2) and the $(C\delta^{-2}, \alpha - 10\epsilon)$ regularity of $E'_0$ we have
\[
|E| > C^{-1} \delta^4 \left( \frac{N}{M} \right)^{\alpha - 10\epsilon} \tag{4.36}
\]
(recall that $\delta' = \delta^2/4$) hence we may conclude that
\[
\frac{|E|}{|E_3|} \geq \frac{c'' \delta^6 (N_1/M)^{\alpha - 10\epsilon}}{(N_1/M)^{\alpha + \alpha_{\text{inc}}}}.
\]
and hence we may conclude that $B$ is $(\bar{C}_1, \lambda)$-regular, where
\[
\bar{C}_1 = C'' L^{10C_1}(N_1/M)^{\alpha_{\text{inc}} + 10\epsilon} \bar{C}
\]
for some $c'', C''$ independent of $N, M, L$.

Using Rusza’s triangle inequality (Lemma 3) we have the following, for the fixed $s_1$ and for all $s_2 \in B$:
\[
|B_{M'}(s_1 E) - B_{M'}(s_2 E)| \leq \frac{|B_{M'}(s_1 E) - B_{M'}(s_1 E) \cap B_{M'}(s_2 E)|}{|B_{M'}(s_1 E) \cap B_{M'}(s_2 E)|} |B_{M'}(s_2 E) - B_{M'}(s_1 E) \cap B_{M'}(s_2 E)|
\]
\[
\leq \frac{25N(E - E; M)^2 M^2}{|B_{M'}(s_1 E) \cap B_{M'}(s_2 E)|}.
\]
Which can be summarized as follows
\[
|B_{M'}(s_1 E) - B_{M'}(s_2 E)| \leq \frac{25N(E - E; M)^2 M^2}{|B_{M'}(s_1 E) \cap B_{M'}(s_2 E)|} \tag{4.37}
\]
By (E.2), (E.3) and by (4.31), (4.26), for $s_2 \in B$ (s_1 fixed before), we have
\[
|B_{M'}(s_1 E) - B_{M'}(s_2 E)| \leq c\rho^{12} \delta^{\prime - 22} M'|E_3|
\]
\[
< c_1 \rho^{12} \delta^{\prime - 44} M' \left( \frac{N_1}{M} \right)^{\alpha + \alpha_{\text{inc}}} \tag{4.38}
\]
\[
< c_2 \delta^{\prime - 116} M' \left( \frac{N_1}{M} \right)^{\alpha + \alpha_{\text{inc}} + 3\Delta / 16}.
\]

17
Define the set \( \tilde{E} = N_1^{-1}E \times N_1^{-1}E \). By (4.36),
\[
|\tilde{E}| > C^{-2}\delta^8 \left( \frac{N_1}{M} \right)^{2\alpha-20\epsilon} > \left( \frac{N_1}{M} \right)^{2\alpha-21\epsilon}
\]
by (4.11) and (4.12), the second inequality holds if \( C^* < 2^{-6}\tau\epsilon \) and \( L_1 \) is large enough.

The set \( \tilde{E} \) is \( \frac{M}{N_1} \)-separated and \( (C^2\delta^8, 2\alpha - 20\epsilon) \)-regular at scale \( M/N_1 \).

We apply the projection theorem, Theorem 9, to the set \( \tilde{E} \subset \left[-1, 1\right]^2 \) with respect to the measure \( \eta \) on the set of directions in \( \mathbb{P}^1 \) corresponding to uniform choice of direction from the projection of the set \( \left\{-s_1\right\} \times B \) to \( \mathbb{P}^1 \). This measure \( \eta \) will satisfy (2.24) for any \( \kappa < \lambda \) as long as the \( \tau_0 \) from Theorem 9 satisfies that \( \left( \frac{N_1}{M} \right)^{\tau_0(\lambda-\kappa)} > \tilde{C}_1 \), which holds for suitable choice of \( C^*, \epsilon, \alpha_{\text{ini}} \) once \( L_1 \) is large enough. Similarly, \( \tilde{E} \) will satisfy (2.25) once \( \kappa < \alpha_{\text{ini}} \) if \( C^*, \epsilon \) are small enough and \( L_1 \) large enough.

Theorem 9 gives us a set \( \Theta \subset \mathbb{P}^1 \) with \( \eta(\Theta) > 1 - \left( \frac{M}{N_1} \right)^{\epsilon_0} \) so that for \((-s_1, s_2) \in \Theta:\)
\[
N \left( \frac{s_2E/N_1 - s_1E/N_1}{\sqrt{s_1^2 + s_2^2}} ; \frac{M}{N_1} \right) \geq \left( \frac{N_1}{M} \right)^{\alpha + \alpha\Delta - 11\epsilon}
\]
(4.40)
Since \( \eta(\Theta) \) is positive, there is at least one \( s_2 \in B \subset S \), for which the inequality (4.40) holds. Let \( s_2 \) be any such number.

Using the fact that \( \sqrt{s_1^2 + s_2^2} \geq L \) and by \( M' = LM \), we have (if \( \epsilon \) is < \( \alpha_{\Delta}/100 \)),
\[
N \left( s_2E - s_1E ; M' \right) \geq \left( \frac{N_1}{M} \right)^{\alpha + \alpha\Delta/2}.
\]
(4.41)
Therefore we have the following,
\[
|B_{M'}(s_1E) - B_{M'}(s_2E)| \geq 25N \left( s_2E - s_1E ; M' \right) M' \geq M' \left( \frac{N_1}{M} \right)^{\alpha + \alpha\Delta/2}.
\]
(4.42)
Recalling that $\alpha_{\text{inc}}$ was chosen to be $\leq \alpha_\Delta/1280$, we get a contradiction in (4.38) compared to (4.42) if $C^*$ is small enough and $L_1$ large enough. This completes the proof (with $N_0 = N_1$).

\[\square\]

5 Dimensions of Projections

This section contains background material for a final bootstrapping lemma, which is stated and proved in its end. The following part is adapted from [4]. Closely related to the notion of $(C, \alpha)$-regular measure introduced in Definition 10 is the notion of $\alpha$-energy of a measure $\rho$, denoted by $E_\alpha(\rho)$, which we define for a compactly supported measure $\rho$ on $\mathbb{R}^d$ and $\alpha < d$.

**Definition 18.** The $\alpha$-energy of a compactly supported measure $\rho$ on $\mathbb{R}^d$ and $\alpha < d$ is denoted by $E_\alpha(\rho)$ and is defined by

\[
E_\alpha(\rho) = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{d\rho(x)d\rho(y)}{|x-y|^\alpha}.
\]  

(5.1)

If $\rho$ is $(C, \alpha + \epsilon)$-regular on a set $B$ at all scales, then

\[
E_\alpha(\rho) = \alpha \int \int \frac{\rho(B_{x,r})}{r^{\alpha+1}}d\rho(x)dr \leq C(\text{diam } B)^{-\alpha}\alpha\epsilon^{-1}.
\]  

(5.2)

The energy $E_\alpha(\rho)$ can also be given in terms of the Fourier transform of $\rho$, up to an implicit constant that tends to $\infty$ as $\alpha \to 1$ (see [11], Lemma 12.12):

\[
E_\alpha(\rho) \asymp \int_{\mathbb{R}^d} |\hat{\rho}(\xi)|^2(1+|\xi|)^{\alpha-d}d\xi.
\]  

(5.3)

If $E_\alpha(\rho) < \infty$, then any set of positive $\rho$ measure has Hausdorff dimension $\geq \alpha$ (for this and further information about $\alpha$-energy, see [11]).
A simple way to adapt this notion to our "coarse" setup, where we do not care about the details of how $\rho$ behaves at scales smaller than $r$, is to smoothen it by convolving with an appropriate kernel. Let $\Phi$ be a fixed radially symmetric nonnegative smooth function on $\mathbb{R}^d$ with $\|\Phi\|_1 = 1$ supported on $B_{0,1}$ and set for $r > 0$

$$\Phi_r(x) = r^{-d}\Phi(r^{-1}x). \quad (5.4)$$

Then instead of using the possibly atomic measure $\rho$, we can consider its smoothed version $\rho' = \rho \ast \Phi_r$. In particular, if $\rho$ is $(C, \alpha + \epsilon)$-regular at scale $r$ on a subset $B \subset \mathbb{R}^d$, then

$$\mathcal{E}_\alpha(\rho \ast \Phi_r) \ll C(\text{diam } B)^{-\alpha}\alpha\epsilon^{-1} \quad (5.5)$$

with the implicit parameter depending only on $d$ and the choice of $\Phi$.

See [4], subsection 6.C. for more details. Let $\Psi : \mathbb{R} \to \mathbb{R}^+$ be the smooth compactly supported function

$$\Psi(x_1) = \int dx_2 \ldots \int dx_d \Phi(x_1, x_2, \ldots, x_d), \quad (5.6)$$

and define $\Psi_r$ analoguously to (5.4)

**Lemma 19** ([4], Lemma 6.10). Let $\rho$ be a probability measure on $\mathbb{R}$, and let $\phi$ be the Radon-Nykodym derivative $\phi = \frac{d(\rho \ast \Psi_r)}{dx}$. Then for every $r < r_1 < 1$

$$\mathcal{N}(\text{supp } \rho; r_1) \geq (4r_1\|\phi\|_2^2)^{-1}. \quad (5.7)$$

Moreover, for any subset $X \subset \text{supp } \rho$,

$$\mathcal{N}(X; r_1) \geq \frac{\rho(X)^2}{4r_1\|\phi\|_2^2}. \quad (5.8)$$
For the following proposition we need this definition

**Definition 20.** Let $\rho$ be a probability measure supported on the unit ball $B_{0,1}$ of $\mathbb{R}^d$. $\rho_\theta$ is the orthogonal projection of the measure $\rho$ in the direction $\theta \in \mathbb{S}^{d-1}$.

$\hat{\rho}_\theta(t)$ is defined to be

$$
\hat{\rho}_\theta(t) = \int_{-\infty}^{\infty} e^{-2\pi i tz} d\rho_\theta(z).
$$

(5.9)

**Proposition 21** ([4], Prop. 6.11). Let $\rho$ be a probability measure supported on the unit ball $B_{0,1}$ of $\mathbb{R}^d$ so that $\mathcal{E}_\alpha(\rho) < \infty$ for some $0 < \alpha < d$, $0 < r < 1$, and let $\eta$ be a measure on $\mathbb{S}^{d-1}$ such that for some $c_\eta, \beta > 0$

$$
\eta(B_{\theta,\epsilon}) \leq c_\eta \epsilon^\beta \quad \text{for every } \epsilon > r \text{ and } \theta \in \mathbb{S}^{d-1}.
$$

(5.10)

Then for any $\beta' < \beta$

$$
\int_\theta \int_t |\hat{\rho}_\theta(t)|^2 \left| \hat{\Psi}_r(t) \right|^2 (1 + |t|)^{\beta' + \alpha - d} dt d\eta(\theta)
\leq c_\eta C_d \int_{\mathbb{R}^d} |\hat{\rho}(x)|^2 \left| \hat{\Phi}_r(x) \right|^2 (1 + |x|)^{\alpha - d} dx + c_\eta C(\alpha, \beta, \beta', d).
$$

(5.11)

We will use Proposition 21 for $d = 2$. Almost quoting from [4]: note that if $\alpha + \beta' > d$ and $\rho$ is $(C, \alpha')$-regular at scale $r$ for $\alpha' > \alpha$, then by (5.2) the right-hand side of (5.11) is bounded from above by a constant (depending on $\alpha, \alpha', \beta, \beta', C, \ldots$) while the left hand side dominates

$$
\int_\theta \left\| d(\rho_\theta * \Psi_r) \right\|_2^2 d\eta(\theta).
$$

(5.12)

In view of Lemma 19 this in particular implies that for $\eta$-many choices of $\theta$, the covering number of supp$(\rho_\theta)$ by $r$-intervals is large.

We prove the following lemma, which will be used as a final step after the application of a number of iterations of Lemma 17.
Lemma 22 (High dimension to positive density). For any \( \lambda > 0 \) there exists \( \epsilon_0 > 0 \) and there are \( L_1, C^* > 0 \), so that if \( L > L_1, \delta > L^{-C^*} \), \( S \subset [L, 2L] \) is \((\tilde{C}, \lambda)\)-regular, \( N \leq LM \) and

\[
N(F(\mu_n, \delta) \cap [-N, N]; M) > \left( \frac{N}{M} \right)^{1-\epsilon_0},
\]

then there exists \( N_1 \) so that

\[
N(F(\mu_{n-1}, \frac{\delta^4}{128}) \cap [-N_1, N_1]; M) > \frac{c\delta^{10} N_1}{C^{*} M},
\]

where \( c \) is a constant, and \( N_1 \) is such that,

\[
\log \frac{N_1}{M} > \frac{1}{2} \log \frac{N}{M}.
\]

Proof. (Parts of this Lemma are adapted from [4], Lemma 6.12). Set \( \epsilon_0 = \lambda/60 \). Assume that for \( N, M, n, \delta \) the inequality 5.13 holds. Let

\[
E_0 \subset F(\mu_n, \delta) \cap [-N, N]
\]

be an \( M \)-separated set of maximal cardinality.

Set \( \delta' = \delta^2/4 \). By Lemma 13 applied with \( \epsilon = \lambda/6 \), there is an \( N_1 \in (M, N) \) with \( \log(N_1/M) > \frac{1}{2} \log(N/M) \) so that \( F(\mu_n, \delta') \cap [-N_1, N_1] \) contains a subset \( E \) which is \((C\delta'^{-2}, 1 - 2\lambda/6)\)-regular at scale \( M \) and \( C \) depends only on \( \lambda \). We may assume,

\[
\frac{1}{E} \left| \sum_{b \in E} \hat{\mu}_n(b) \right| \geq \frac{\delta'}{2},
\]

since we may always choose a subset \( E_1 \subset E \) of cardinality \( \geq |E|/4 \) on which the above inequality holds which is \((C\delta'^{-2}, 1 - 2\lambda/6)\)-regular (possibly for a slightly different \( C \)).
Set $\phi(x) = \sum_{s \in S} \sum_{\xi \in E} e_{s\xi}(x)$. Then we have, using the Cauchy-Schwarz inequality,

\[
\sum_{s_1, s_2 \in S} \sum_{\xi_1, \xi_2 \in E} \hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2) = \int_T \sum_{s_1, s_2 \in S} \sum_{\xi_1, \xi_2 \in E} e_{s_1 \xi_1 - s_2 \xi_2}(x) d\mu_{n-1}(x) \\
= \int_T |\phi(x)|^2 d\mu_{n-1}(x) \\
\geq \left| \int_T \phi(x) d\mu_{n-1}(x) \right|^2 \\
= \left| \sum_{s \in S} \sum_{\xi \in E} \hat{\mu}_{n-1}(s \xi) \right|^2 \\
= \left| |S| \sum_{\xi \in E} \hat{\mu}_n(\xi) \right|^2.
\]

(5.18)

We then obtain,

\[
\frac{1}{|S|^2} \sum_{s_1, s_2 \in S} \sum_{\xi_1, \xi_2 \in E} \hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2) \geq \left| \sum_{\xi \in E} \hat{\mu}_n(\xi) \right|^2.
\]

(5.19)

And so,

\[
\frac{1}{|E|^2} \frac{1}{|S|^2} \sum_{s_1, s_2 \in S} \sum_{\xi_1, \xi_2 \in E} \hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2) \geq \frac{1}{|E|} \sum_{\xi \in E} \hat{\mu}_n(\xi) \geq \frac{\delta^2}{4}.
\]

(5.20)

Fix $s_2$ to be an element in $S$ such that the term corresponding to it in the above sum, is the largest. Then,

\[
\frac{1}{|S|} \frac{1}{|E|^2} \sum_{s_1, s_2 \in S} \sum_{\xi_1, \xi_2 \in E} \hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2) \geq \frac{\delta^2}{4}.
\]

(5.21)
By Lemma 14 we have that,

\[
\# \left\{ (s_1, \xi_1, \xi_2) \in S \times E \times E : |\hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2)| \geq \frac{\delta^2}{8} \right\} \geq \frac{\delta^2}{8} |S||E|^2.
\]  
(5.22)

Let \( Q \) be

\[
Q = \left\{ (s_1, \xi_1, \xi_2) \in S \times E \times E : |\hat{\mu}_{n-1}(s_1 \xi_1 - s_2 \xi_2)| \geq \frac{\delta^2}{8} \right\}.
\]  
(5.23)

Next, we define the following set:

\[
S' = \left\{ s_1 \in S : |Q \cap \{s_1\} \times E \times E| \geq \frac{\delta^2|E|^2}{16} \right\}.
\]  
(5.24)

By Lemma 14 we have that \( |S'| \geq \frac{\delta^2}{16} |S| \).

Let \( \eta \) be the uniform measure on the set of directions in \( \mathbb{P}^1 \) corresponding to the set \( \{-s_2\} \times S' \). The \( (\tilde{C}, \lambda) \)-regularity of \( S \) ensures that for any \( \xi \in \text{supp}(\eta) \subset \mathbb{P}^1 \) we have the following,

\[
\eta(V(\xi, r)) \leq u\tilde{C} \delta^{r-2} r^\lambda,
\]  
(5.25)

for any positive real number \( r \geq M/N \) and \( u \) some absolute constant. Applying Proposition 21 with \( \beta = \lambda, \beta' = \frac{5\lambda}{6}, \alpha = 1 - \frac{5\lambda}{6} \) and

\[
\rho = \frac{1}{|E|^2} \sum_{b \in E' \times E'} \delta_{b/N_1},
\]

we get that

\[
\int_{\xi} \left\| \frac{d(\rho \ast \Phi_r)}{dx} \right\|^2_2 d\eta \leq \tilde{C} \delta^{r-2} \left[ C_2 \int_{\mathbb{R}^2} |\bar{\rho}(x)|^2 |\bar{\Phi}_r(x)|^2 (1 + |x|)^{\alpha-2} dx + C(\alpha, \beta, \beta') \right],
\]  
(5.26)

for \( r = M/N_1 \). Recall that \( \rho \) is \((C\delta^{-2}, 2 - 2\lambda/3)\)-regular at scale \( M/N_1 \) (by
adjusting $C$ if needed). It follows that
\[
\int_{\mathbb{R}^2} |\tilde{\rho}(x)|^2 \left|\tilde{\Phi}_{r}(x)\right|^2 (1 + |x|)^{\alpha-2} dx \asymp \mathcal{E}_\alpha(\rho * \Phi_r) \leq c'' \delta^{-2} = 8c'' \delta^{-1} \quad \text{(since } \alpha < 2 - 2\lambda/3) \tag{5.27}
\]
with $C', c''$ depending on $\lambda$. Substituting into 5.26 we get
\[
\int_\xi \left\| \frac{d(\rho_\xi \Phi_r)}{dx} \right\|^2 d\eta(\xi) \leq \tilde{C}_c \delta^{-3}. \tag{5.28}
\]
We conclude that there is a subset $S'' \subset S'$ with $|S'| > (1 - \frac{\delta^2}{16})|S|$ for which if $s_1 \in S''$ and $\xi_0 = (-s_2, s_1) \in \mathbb{P}^1$
\[
\left\| \frac{d(\rho_{\xi_0} \Phi_r)}{dx} \right\|^2 \leq \tilde{C}_c \delta^{-3} \cdot \frac{16}{\delta^2}. \tag{5.29}
\]
Let $\pi_{\xi_0}$ denote the orthogonal projection to any such direction $\xi_0 \in \mathbb{P}^1$ (considered as a map $\mathbb{R}^2 \to \mathbb{R}$). By Lemma 19 and 5.29 it follows that
\[
\mathcal{N}(\pi_{\xi_0} \left( E'' \times E' \frac{M}{N_1} \right) : \frac{M}{N_1} ) \geq 4\delta^3 \cdot \frac{\delta^2}{16\tilde{C}_c} \cdot \frac{N_1}{M}. \tag{5.30}
\]
This yields the conclusion of our lemma.

6 The Main Granulation Estimate

We state and prove two key propositions. The first is a general statement which is stated and proved in [4]. The second is the main granulation estimate, which is used in the proof of the main theorem, Theorem 2.

The following proposition and its proof are adopted from Bourgain, Furman, Lindenstrauss and Mozes, [4]. The statement and its proof are harmonic analytic in nature.
Proposition 23 ([4], Prop. 7.5). There exists \( c > 0 \) so that if a probability measure \( \mu \) on \( \mathbb{T}^d \) satisfies
\[
\mathcal{N} \left( \{ a \in \mathbb{Z}^d \cap B_{0,N} : |\hat{\mu}(a)| > t \} ; M \right) > s \cdot \left( \frac{N}{M} \right)^d
\] (6.1)
with \( M < \text{const}_d \cdot N \) then there exists an \( \frac{1}{M} \)-separated set \( X \subset \mathbb{T} \) with
\[
\mu \left( \bigcup_{x \in X} B_{x,N} \right) > c \cdot (ts)^3.
\] (6.2)

Proof. We shall need an auxiliary smooth function \( F \) on the torus such that
\[
0 \leq F \leq C_1 \cdot N^d, \quad \text{supp}(F) \subset B_{0,\frac{1}{N}}, \quad \int_{\mathbb{T}^d} F \, dx = 1 \quad (6.3)
\]
and the Fourier coefficients
\[
\hat{F}(a) \geq 0, \quad \hat{F}(a) \geq \frac{1}{2} \quad \text{for} \quad a \in \mathbb{Z}^d \cap B_{0,N}
\] (6.4)
where \( C_1 \) is a constant depending on \( d \) only. To construct such a function, consider the step function \( F_1(x) = m \left( B_{0,r}^{-1} \right) \cdot 1_{B_{0,r}}(x) \) where \( r = \epsilon/N \) for some fixed small \( \epsilon > 0 \). Then \( \hat{F_1}(a) \) is close to 1 for \( a \in \mathbb{Z}^d \cap B_{0,N} \). If \( F_2 \) is a smooth symmetric approximation of \( F_1 \), then the convolution \( F = F_2 \ast \hat{F}_2 \) has the desired properties.

Let \( \tilde{A} \) be an \( M \)-separated set of size \( |\tilde{A}| > s(N/M)^d \) consisting of coefficients \( a \in \mathbb{Z}^d \cap B_{0,N} \) with \( |\hat{\mu}(a)| > t \). Upon passing to a subset \( A \subset \tilde{A} \) of size
\[
|A| \geq \frac{|\tilde{A}|}{4} > \frac{s}{4} \left( \frac{N}{M} \right)^d,
\] (6.5)
we may assume that \( \text{Re}(e^{i\theta} \cdot \hat{\mu}(a)) > \frac{t}{2} \) for some fixed \( \theta \in [0, 2\pi] \). Let
\[
\phi(x) = \sum_{a \in A} e_a(x).
\] (6.6)
As usual, $e_a = e^{-2\pi i x a}$. Note that

$$|\phi(x)|^2 = \left( \sum_{a \in A} e_a(x) \right) \cdot \left( \sum_{b \in A} e_b(x) \right) = \sum_{a, b \in A} e_{a-b}(x). \quad (6.7)$$

The probability measure $\lambda = \mu \ast F$ has a smooth density $g : \mathbb{T}^d \to [0, \infty)$ with $\hat{g}(b) = \hat{\mu}(b) \cdot \hat{F}(b)$. On $A$ we have $\hat{F} \geq 1/2$ and $\text{Re}(e^{i\theta} \hat{\mu}(a)) > t/2$.

Therefore

$$\left| \int_{\mathbb{T}^d} \phi d\lambda \right| \geq \sum_{a \in A} \text{Re}(e^{i\theta} \cdot \hat{g}(a)) > \frac{t}{4} \cdot |A| > \frac{ts}{2^d} \cdot \left( \frac{N}{M} \right)^d. \quad (6.8)$$

We shall see that the right-hand side is close to an a priori upper estimate for the left-hand side. Partition $\mathbb{T}^d$ into $M^d$ ”cubes” $Q_i$ with side length $\frac{1}{M}$ and centers $c_i \in \mathbb{T}^d$. By the Cauchy-Schwarz inequality

$$\left| \int_{\mathbb{T}^d} \phi d\lambda \right| \leq \sum_i \left| \int_{Q_i} \mathbf{1}_{Q_i} \cdot \phi d\lambda \right| \leq \sum_i \lambda(Q_i)^{1/2} \cdot \left( \int_{Q_i} |\phi|^2 d\lambda \right)^{1/2} \quad (6.9)$$

Let $r = \frac{1}{M}$ which is assumed to dominate $\frac{1}{N}$. Then $Q_i \subset B_{c_i, r/2}$ and $y + Q_i \subset B_{c_i, r}$ for any $y \in \text{supp}(F) \subset B_{0, \frac{1}{N}}$, thus

$$\lambda(Q_i) = \int_{\mathbb{T}^d} F(y) \cdot \mu(y + Q_i) dy \leq \mu(B_{c_i, r}). \quad (6.10)$$

Since $d\lambda(x) = g(x) dx$, we have

$$\int_{Q_i} |\phi|^2 d\lambda \leq G_i \cdot \int_{Q_i} |\phi|^2 dx, \quad \text{where} \quad G_i = \max_{x \in Q_i} g(x). \quad (6.11)$$

We shall estimate $\int_{Q_i} |\phi|^2 dx$ using an auxiliary function $f$ on $\mathbb{T}^d$; we take $f$ to be the product $f(x) = \prod_{i=1}^d h_M(x_i)$ of one-dimensional Fejér kernels

$$h_n(u) = \frac{1}{n} \sum_{k=1}^n \sum_{j=-k}^k e^{2\pi j u i} = \frac{1}{n} \left( \frac{\sin \frac{nu}{2}}{\sin \frac{u}{2}} \right)^2. \quad (6.12)$$

27
Note that $f$ is a nonnegative function, with $f(x) > 10^{-d} \cdot M^d$ on the $\frac{1}{M}$-cube $Q_0 = \left[ -\frac{1}{2M}, \frac{1}{2M} \right]^d + \mathbb{Z}^d$ around $0 \in \mathbb{T}^d$. The Fourier coefficients $\hat{f}$ take values in $[0, 1]$ and vanish outside the $[-M, M]^d \cap \mathbb{Z}^d$ cube. Thus

$$\int_{Q_i} |\phi(x)|^2 dx = \int_{Q_0} |\phi(x + y)|^2 dy \leq \frac{10^d}{M^d} \int_{Q_0} |\phi(c + y)|^2 f(y) dy$$

$$\leq \frac{10^d}{M^d} \int_{\mathbb{T}^d} |\phi(c + y)|^2 f(y) dy = \frac{10^d}{M^d} \int_{\mathbb{T}^d} \sum_{a, b \in A} e_{a-b}(c + y) \cdot f(y) dy$$

$$= \frac{10^d}{M^d} \left( \sum_{a, b \in A} e_{a-b}(c) \hat{f}(a-b) \right) \leq \frac{10^d}{M^d} \sum_{a, b \in A} |\hat{f}(a-b)|.$$  \hspace{1cm} (6.13)

Let $C_2$ denote the constant which is $10^d$ times the maximal cardinality of a 1-separated set in $[-1, 1]^d$. Since $A$ is $M$-separated and $0 \leq \hat{f} \leq 1$, we have

$$\frac{10^d}{M^d} \sum_{a, b \in A} |\hat{f}(a-b)| \leq \frac{C_2 \cdot |A|}{M^d} \leq \frac{C_2 \cdot N^d}{M^{2d}}. \hspace{1cm} (6.14)$$

The density $g$ of $\lambda = \mu * F$ has the following upper bound:

$$g(x) = \int_{\mathbb{T}^d} F(x - y) d\mu(y) \leq C_1 \cdot N^d \cdot \mu(B_{x, \frac{1}{N}}). \hspace{1cm} (6.15)$$

Since $\text{Nbd}_{\frac{1}{N}}(Q_i) \subset B_{c_i, r}$, it follows that

$$G_i = \max_{x \in Q_i} g(x) \leq C_1 N^d \mu(B_{c_i, r}). \hspace{1cm} (6.16)$$

Let $0 \leq H_i \leq 1$ denote the ratio, so $G_i = H_i \cdot C_1 N^d \mu(B_{c_i, r})$. By (6.8) and (6.9)

$$\frac{ts}{2^d} \left( \frac{N}{M} \right)^d \leq \sum_i \mu(B_{c_i, r}) \frac{1}{2} \cdot G_i \frac{1}{2} \cdot \sqrt{C_2 N^d} \frac{1}{M^d}$$

$$\leq \sum_i \mu(B_{c_i, r}) \cdot H_i \frac{1}{2} \cdot \sqrt{C_1 \cdot C_2} \cdot \left( \frac{N}{M} \right)^d. \hspace{1cm} (6.17)$$
Let $C_3 = \sqrt{C_1 \cdot C_2}$. We have

$$\sum_i \mu(B_{c,r}) \cdot H_i^{1/2} > \frac{ts}{2^{3} C_3}. \quad (6.18)$$

Therefore

$$\sum_{i \in I} \mu(B_{c,r}) > \frac{ts}{2^{5} C_3} \quad \text{where} \quad I = \left\{ i : H_i^{1/2} > \frac{ts}{2^{3} C_3} \right\}. \quad (6.19)$$

For each $i \in I$ choose $x_i \in Q_i$ so that

$$g(x_i) > \left( \frac{ts}{2^{5} C_3} \right)^2 \cdot C_1 N^d \cdot \mu(B_{c,r}). \quad (6.20)$$

Then [6.15] gives

$$\mu(B_{x_i, \frac{1}{N}}) > \frac{g(x_i)}{C_1 N^d} > \frac{(ts)^2}{2^{10} C_3^2} \cdot \mu(B_{c,r}), \quad (6.21)$$

and using [6.19]

$$\sum_{i \in I} \mu(B_{x_i, \frac{1}{N}}) > \frac{(ts)^3}{2^{15} C_3^3}. \quad (6.22)$$

The set $\tilde{X} = x_i : i \in I$ visits each of the cubes $Q_j$ at most once. Thus it may be separated into $2^d$ subsets each of which never visits neighboring $Q_j$-s and is therefore $\frac{1}{N}$-separated. At least one of the $2^d$ subsets $X \subset \tilde{X}$ has

$$\mu(\bigcup_{x \in X} B_{x,r}) = \sum_{x \in X} \mu(B_{x,\frac{1}{N}}) > 2^{-d} \sum_{i \in I} \mu(B_{x_i, \frac{1}{N}}) > \frac{(ts)^3}{2^{6+15} C_3^3}. \quad (6.23)$$

This completes the proof of the proposition. \qed

**Proposition 24.** For $\lambda, \beta > 0$ there exist $k, C_1, C', L_0$, such that if $L > L_0$, $n \geq k$, $S \subset [L, 2L]$ a $(\tilde{C}, \lambda)$-regular set for some $\tilde{C} < L^{C_1}$ with $|S| > L^\beta$, and if the measure $\mu_n = \nu_s^n * \mu$ satisfies that for some $a \in \mathbb{Z}\backslash\{0\}$ and $t > L^{-C_1}$ that

$$|\hat{\mu}_n(a)| > t > 0, \quad (6.24)$$
then there exists a $\frac{1}{M}$-separated set $X \subset \mathbb{T}$ with

$$\mu_{n-k} \left( \bigcup_{x \in X} B_x, \frac{1}{N} \right) > C' \cdot t^{33 \cdot 2^k},$$

(6.25)

where $M = L^k|a|$ and $N = L^{k+\frac{1}{N^2}}|a|$.

**Proof.** Let $\epsilon_0$ be as in Lemma 22. Set $\alpha_{ini} = 0.99\beta$ and $\alpha_{high} = 1 - \epsilon_0$. Let $L_{lb}$ be the maximum of the value $L_1$ as in Lemma 17 and the value $L_1$ as in Lemma 22. Let $C^*$ be such that the conditions of both lemmas, Lemma 17 and Lemma 22, hold. We will determine $C_1$ later in the proof.

By Lemma 15 we have that for $\mu_n$

$$\mathcal{N} \left( \mathcal{F}(\mu_{n-1}, \frac{t}{2}) \cap [-N, N]; M \right) \geq \frac{t}{2} \left( \frac{N}{M} \right)^{0.99\beta}$$

(6.26)

where $N = L|a|, M = |a|$. Since $t$ is bounded from below by $L^{-C_1}$ which will depend only on $\alpha_{ini}$ (and formally also on $\alpha_{high}$) then we can modify, if needed, $L_{lb}$ to be large enough, such that the following holds,

$$\mathcal{N} \left( \mathcal{F}(\mu_{n-1}, \frac{t}{2}) \cap [-N, N]; M \right) \geq \left( \frac{N}{M} \right)^{0.99\beta}.$$  

(6.27)

We now use our bootstrapping lemma, Lemma 17, to obtain denser and denser sets of large Fourier coefficients. We finalize by applying the Final Bootstrapping Lemma, 22. The first step is actually checking if we can reach the conclusion of this lemma by applying once Lemma 22.

If $\alpha_{ini} > 1 - \epsilon_0$ then apply Lemma 22 and Proposition 23 to complete the proof. If $\alpha_{ini} \leq 1 - \epsilon_0$ then we do the following. Let $\alpha_{inc}$ be as in Lemma 17 for the chosen values of $\alpha_{ini}, \alpha_{high}$. Let $k' = \left\lfloor (1 - \epsilon_0 - \alpha_{ini})/\alpha_{inc} \right\rfloor$ and $k = k' + 1$. Let $C_1$ be such that if $L_{lb}^{-C^*} < t$ then $L_{lb}^{-C_1} < \left( t^{2k}/4^{6k} \right)^4/128$. 

Apply Lemma 17 \( k' \) times to obtain
\[
\mathcal{N} \left( \mathcal{F}(\mu_{n-k'}, t^{2^k/4^{6^k}}) \cap [-N', N']; M' \right) > \left( \frac{N'}{M'} \right)^{1-\epsilon_0}. \tag{6.28}
\]

Apply Lemma 22 to obtain
\[
\mathcal{N} \left( \mathcal{F}(\mu_{n-k'}, (t^{2^k/4^{6^k}})^4/128) \cap [-N'', N'']; M' \right) > c \cdot \left( \frac{t^{2^k}}{4^{6^k}} \right)^{10} \left( \frac{N'}{M'} \right), \tag{6.29}
\]
where \( c \) is the constant in the conclusion of Lemma 22. Apply Proposition 23 to complete the proof. \( \square \)

7 Proof of Theorem 2

Proof of Theorem 2. For \( \lambda, \beta \), let \( k, L_{lb}, C_1, C' \) be as in the conclusion of Proposition 24; we will set \( L_1 \) later to be \( > L_{lb} \). Let \( \tau_0 = \min \{C_1, \frac{1}{10^8 \epsilon} \} \).

For \( \tau < \tau_0 \), let \( a \in \mathbb{Z}\setminus\{0\} \) be such that \(|a| < L' \) and such that \(|\hat{\nu}^k_x * \mu(a)| > L^{-\tau} \). Apply Proposition 24 to the measure \( \nu^k_x * \mu \) to obtain a set \( X_1 \) which is \( \frac{1}{M} \)-separated and \( \mu(\bigcup_{x \in X_1} B_{x, \frac{1}{M^2}}) > C' \cdot L^{-33-2^k} \) for some constant \( C' \), where \( M = L^{k+\frac{1}{10^8 \epsilon}}, N = L^{k+\frac{1}{10^8 \epsilon}} \) (the proposition gives the slightly stronger statement that \( X_1 \) is \( \frac{1}{L^{|a|}} \)-separated and that \( \mu(\bigcup_{x \in X_1} B_{x, \frac{1}{M^2}}) > C' \cdot L^{-33-2^k} \) for \( N' = L^{k+\frac{1}{10^8 \epsilon}} |a| \); this clearly implies what we use here). Let \( X_1 = \bigcup_{x \in X_1} B_{x, \frac{1}{M^2}} \).

Set
\[
\mu_1^{(1)} = \mu|_{T \setminus X_1} \quad \text{and} \quad \mu_2^{(1)} = \mu|_{X_1}.
\]
As long as there are large Fourier coefficients of the measure \( \mu_1^{(1)} \) in the relevant range, we continue in a similar manner: for \( a \in \mathbb{Z}\setminus\{0\} \) in the range \(|a| < L' \) such that \(|\nu^k_x * \mu_1^{(1)}(a)| > L^{-\tau} \) obtain \( X_2 \) using Proposition 24.
in order to apply Proposition 24, the measure $\mu_1^{(1)}$ is normalized so that the input is a probability measure $\overline{\mu}_1^{(1)}$, which only increases the Fourier coefficient, hence
\[ |\widehat{\nu_1^{(1)} * \overline{\mu}_1^{(1)}}(a)| > |\widehat{\nu_1^{(1)} * \mu_1^{(1)}}(a)| > L^{-\tau}. \]

We obtain a set $X_2$ which is $\frac{1}{M}$-separated and
\[ \mu_1^{(1)}\left( \bigcup_{x \in X_2} B_x \right) > C' \cdot L^{-33 \cdot 2^{k^*} \tau} \mu_1^{(1)}(\mathbb{T}). \]

Let $\overline{X}_2 = \bigcup_{x \in X_2} B_x \downarrow$. Set $\mu_1^{(2)}, \mu_2^{(2)}$ to be these new measures:
\[ \mu_1^{(2)} = \mu\big|_{\mathbb{T} \setminus (\overline{X}_1 \cup \overline{X}_2)} \]
\[ \mu_2^{(2)} = \mu\big|_{\overline{X}_1 \cup \overline{X}_2}. \]

We repeat this step in an analogous manner, as long there is an $|a| < L^\tau$ for which $|\widehat{\mu_1^{(\ell)}}(a)| > L^{-\tau}$, obtaining a (as we will soon see finite) sequence of measures $\mu_1^{(\ell)}, \mu_2^{(\ell)}$ for $\ell = 0, \ldots, \ell_{\text{max}}$. Note that for every $\ell \leq \ell_{\text{max}}$
\[ \mu_1^{(\ell)}(\mathbb{T}) \leq (1 - C' \cdot L^{-33 \cdot 2^{k^*} \tau})^\ell \leq e^{-C' \cdot L^{-33 \cdot 2^{k^*} \tau} \ell} \]
which in particular shows that $\ell_{\text{max}} < \infty$ as $|\widehat{\mu_1^{(\ell)}}(a)| \leq \mu_1^{(\ell)}(\mathbb{T})$ for all $\ell$.

Indeed, this shows that
\[ e^{-C' \cdot L^{-33 \cdot 2^{k^*} \tau} \ell_{\text{max}}} \geq L^{-\tau} \]

hence $\ell_{\text{max}} < C^{-1}(\log L) \cdot L^{33 \cdot 2^{k^*} \tau} < L^{34 \cdot 2^{k^*} \tau}$ if $L_1$ is large enough. \qed

8 Acknowledgments

The work presented in this paper comprises most of my PhD dissertation written at the Hebrew University. I wish to thank my advisor, Prof. Elon
Lindenstrauss, for having me as a student, acquainting me with the techniques and ideas which consist of this work, guiding me and more. I am deeply grateful for that.

I would also like to thank Prof. Barak Weiss and Prof. Tamar Ziegler, who served on my PhD committee, for following the process of the work and asking important questions. I would like to thank Prof. Mike Hochman for his remarks and help. In addition, I wish to thank the Hebrew University and the Einstein Institute for being such a pleasant home. Lastly, I wish to thank the anonymous referees who meticulously read my thesis. One of the referees summarized the work so well, and I could not avoid using his descriptions in the introduction of this paper.
