SPECTRAL STABILITY OF MONOTONE TRAVELING FRONTS
FOR REACTION DIFFUSION-DEGENERATE NAGUMO
EQUATIONS

J. FRANCISCO LEYVA, LUIS F. LÓPEZ RÍOS, AND RAMÓN G. PLAZA

ABSTRACT. This paper establishes the spectral stability of monotone traveling front solutions for reaction-diffusion equations where the reaction function is of Nagumo (or bistable) type and with diffusivities which are density dependent and degenerate at zero (one of the equilibrium points of the reaction). Spectral stability is understood as the property that the spectrum of the linearized operator around the wave, acting on an exponentially weighted space, is contained in the complex half plane with non-positive real part. Three different types of monotone waves are studied: (i) stationary diffusion-degenerate fronts, connecting the two stable equilibria of the reaction; (ii) traveling diffusion-degenerate fronts connecting zero with the unstable equilibrium; and, (iii) non-degenerate fronts. In the first two cases, the degeneracy is responsible of the loss of hyperbolicity of the asymptotic coefficient matrices of the spectral problem at one of the end points, precluding the application of standard techniques to locate the essential spectrum. This difficulty is overcome with a suitable partition of the spectrum, a generalized convergence of operators technique, the analysis of singular (or Weyl) sequences and the use of energy estimates. The monotonicity of the fronts, as well as detailed descriptions of the decay structure of eigenfunctions on a case by case basis, are key ingredients to show that all traveling fronts under consideration are spectrally stable in a suitably chosen exponentially weighted $L^2$ energy space.

1. Introduction

This paper studies the stability of monotone traveling fronts for diffusion-degenerate Nagumo equations of the form

\[ u_t = (D(u)u_x)_x + f(u), \]  

where \( u = u(x,t) \in \mathbb{R}, x \in \mathbb{R}, t > 0 \), the reaction function is of Nagumo (or bistable) type \([52, 45]\) and the diffusion coefficient is degenerate at \( u = 0 \), that is, \( D(0) = 0 \). More precisely, we assume that

\[
\begin{align*}
D(0) &= 0, \quad D(u) > 0 \text{ for all } u \in (0,1], \\
D &\in C^4([0,1]; \mathbb{R}) \text{ with } D'(u) > 0 \text{ for all } u \in [0,1].
\end{align*}
\]

As an example we have the quadratic function

\[ D(u) = u^2 + bu, \]  

for some constant \( b > 0 \), proposed by Shigesada \([70, 71]\) to model dispersive forces due to mutual interferences between individuals of an animal population.

The reaction function \( f : \mathbb{R} \rightarrow \mathbb{R} \) is supposed to be smooth enough and to have two stable equilibria at \( u = 0, u = 1 \), and one unstable equilibrium point at \( u = \alpha \in (0,1) \), that is,

\[
\begin{align*}
f &\in C^3([0,1]; \mathbb{R}), \\
f(0) = f(\alpha) = f(1) = 0, \\
f'(0), f'(1) < 0, \quad f'(\alpha) > 0, \\
f(u) > 0 \text{ for all } u \in (\alpha,1), \\
f(u) < 0 \text{ for all } u \in (0,\alpha),
\end{align*}
\]

for a certain \( \alpha \in (0,1) \). A well-known example is the widely used cubic polynomial

\[ f(u) = u(1-u)(u-\alpha), \]  

with \( \alpha \in (0,1) \).

Scalar reaction-diffusion equations with a bistable reaction function appear in many different contexts and the nomenclature is not uniform. It is known as the bistable reaction-diffusion equation \([16]\), the Nagumo equation in neurophysiological modeling \([45, 52]\), the real Ginzburg–Landau for the variational description of phase transitions \([47]\), the parabolic Allen-Cahn equation \([2]\), as well as the Chafee-Infante equation \([9]\). For simplicity, in this work we call it the Nagumo reaction diffusion equation. In terms of continuous models of the spread of biological populations, reaction functions of Nagumo type often describe kinetics exhibiting positive growth rate for population densities over a threshold value (\( u > \alpha \)), and decay for densities below such value (\( u < \alpha \)). The former is often described as the Allee effect, in which aggregation can improve the survival rate of individuals, resulting in the correlation of population density and its growth rate (cf. Murray \([49]\)). The function \( f \), which underlies two competing stable states, \( u = 0 \) and \( u = 1 \), can also be interpreted as the derivative of a double-well potential, \( F(u) = -\int_0^u f(s) \, ds, \) \( F(0) = 0 \), with wells centered at those states (see Figure 1). This interpretation is the fundamental idea behind the parabolic Allen-Cahn equation as a model for the motion of phase boundaries in alloys \([2]\).
Figure 1. Typical cubic reaction function of Nagumo of the form (1.5) with $\alpha = 0.4$ (panel (a), graph in orange), and its potential (panel (b), graph in blue), with two wells at $u = 0$ and $u = 1$ (color online).

1.1. Density-dependent diffusion models. Since the seminal works by Fisher [17] and by Kolmogorov, Petrovsky and Piskunov [34], reaction-diffusion equations of the form (1.1) have constituted prototypical models of multiple phenomena such as chemical reactions with diffusion, fluid mechanics, porous media, population dynamics and action potential propagation, among others. In all these contexts, traveling front solutions play a prominent role. There is a vast literature on the analysis of reaction-diffusion equations which we will not review. In early works the diffusion coefficient (or motility) was considered as a positive constant. Since the work of Skellam [72, 73] (see also [4, 57]), who stressed out the role of the underlying random process prior to the diffusion approximation, it is now clear that in many situations in physics and biology the diffusion coefficient must be a function of the density. For instance, density-dependent diffusion coefficients often appear in descriptions in spatial ecology [70, 71], motility of eukaryotic cells [68] and, in
In continuous population models \([3, 21, 51]\). In all these models, the form of the diffusion as a function of the density is based on phenomenological considerations; from a modeling viewpoint, this dependence might as well be mathematically derived by taking parabolic scalings and mean field limits of stochastic processes (see, e.g., \([24, 25, 58, 59]\) for further information).

The nonlinear diffusion coefficient is called **degenerate** if it approaches zero when the density tends to certain equilibrium points of the reaction (typically zero). In terms of population dynamics, zero diffusion for zero densities is tantamount to requiring no motility in regions of space where the population is very scarce or near absent (this is an experimentally observed feature that appears, for example, in models of bacterial dynamics \([33, 37, 66]\)). In this paper, under hypotheses (1.2), we assume that the nonlinear diffusion function \(D = D(u)\) vanishes only at \(u = 0\); in particular, the condition that \(D > 0\) for \(u > 0\) means that populations tend to “avoid crowds” (cf. \([4]\)). Models with degenerate diffusivities are also endowed with interesting mathematical properties. Among the new features one finds the emergence of traveling waves of “sharp” type (see, for example, \([61, 63, 69]\)) and, notably, that solutions may exhibit finite speed of propagation of initial disturbances, in contrast with the strictly parabolic case (see, e.g., \([19]\)). Clearly, not all models with degenerate diffusions are related to biology. In chemical engineering, the very well-known choice \(D(u) = mu^m - 1, m \geq 1\), is often used to model diffusion in porous media (see \([50, 76]\) and the references therein).

**1.2. Diffusion-degenerate traveling fronts.** The existence of fronts for reaction-diffusion equations with degenerate diffusion was first studied for very specific forms of the nonlinear diffusion function (for an abridged list of references see \([4, 5, 55, 56]\)), particularly in the case of a “porous medium” type of diffusion function. In the case of generic degenerate diffusion functions satisfying hypotheses (1.2), Sanchez-Garduño and Maini proved the existence of traveling fronts for kinetics of Fisher-KPP (also known as monostable) type \([61, 62]\) and of Nagumo (bistable) type \([63]\). The authors apply a dynamical systems approach to establish the existence of heteroclinic connections. In the Fisher-KPP model with degenerate diffusion, for example, the degeneracy is responsible for the emergence of sharp traveling solutions for a particular value of the speed and a whole family of smooth traveling fronts for any larger speed (for details, see \([62]\)). These orbits connect the only two equilibrium points of the Fisher-KPP reaction (namely, \(u = 0\) and \(u = 1\)). In the Nagumo case, the dynamics is much richer, mainly due to the presence of a third (unstable) equilibrium point \(u = \alpha\). This leads to a wider range of possible homoclinic and heteroclinic connections compared to those of the Fisher-KPP case. The authors in \([63]\) prove the existence of a unique positive wave speed, \(c_* > 0\), associated to fronts of sharp type. Depending on conditions relating \(D\) with \(f\), there exists a continuum of monotone fronts, pulses and oscillatory waves. The present stability analysis considers only **monotone and smooth** (non-sharp) traveling fronts which can be classified into three types (see Theorem 1 in \([63]\) or Proposition 2.1 below):

(i) stationary diffusion-degenerate fronts (case \([sN]\)): if \(\int_0^1 D(u)f(u)\,du = 0\) then there exists a unique stationary monotone increasing front (with speed \(c = 0\)) connecting \(u = 0\) with \(u = 1\) (the two stable equilibria of the reaction), and a unique stationary, monotone decreasing front connecting \(u = 1\) with \(u = 0\);
(ii) diffusion-degenerate traveling fronts (case [Nd]): for each speed value above a threshold speed, \( c \geq \tau(\alpha) > c_* \) (see (2.5) below), there exists a diffusion-degenerate, monotone increasing front connecting \( u = 0 \) with \( u = \alpha \), traveling with speed \( c \); and,

(iii) non-degenerate traveling fronts (case [Nn]): for each value \( c > c(\alpha) \) there exists a non-degenerate, monotone decreasing front connecting \( u = 1 \) with \( u = \alpha \), traveling with speed \( c \).

This paper addresses the stability properties of the three types of waves described above and whose existence was proved by Sanchez-Garduño and Maini [63].

As a final remark on the existence theory, let us mention that there is another approach which applies the Conley index and can be found in [13, 64]; for front existence results in a more general class of equations with advection terms, the reader is referred to [20]; the case of a doubly degenerate diffusion has also been considered in the literature (see references [41, 42]); and, finally, even in the case of systems of equations with degenerate diffusions some existence results are available (see, for example, [15]).

1.3. Previous front stability results and the contributions of this paper.

The stability of reaction-diffusion fronts with uniformly positive diffusion coefficients has been the subject of intense research in the last fifty years and the literature is exhaustive. From a methodological viewpoint we mention here the seminal works by Fife and McLeod [16], which applies comparison principles for super- and sub-solutions, and those by Sattinger [67] and Henry [22], more in the spirit of dynamical systems techniques for PDEs. The stability of degenerate-diffusion fronts has been significantly less studied. An early work by Hosono [26] establishes the stability of the sharp traveling front with speed \( c = c_* \) for reaction diffusion equations in the “porous medium” form, \( u_t = (u^m)_{xx} + f(u) \), with \( m \geq 1 \) (that is, for \( D(u) = mu^{m-1} \)) and reaction function \( f \) of Nagumo (or bistable type). Hosono’s analysis is based on comparison principles and on the construction of super- and sub-solutions to the degenerate parabolic problem. Notice that this diffusion coefficient does not satisfy assumptions (1.2) except in the case \( m = 2 \); in addition, the method of proof is based on particular properties of solutions to the porous medium equation, more precisely, on the maximum principle. Up to our knowledge, Hosono’s paper is the only rigorous work on the stability of diffusion-degenerate Nagumo fronts in the literature. Slightly more attention has been devoted to the Fisher-KPP reaction function with degenerate diffusivities (see, e.g., [7, 11, 23, 28, 29, 46]) but most of these works pertain to the role of sharp waves \((c = c_*)\) as attractors of compactly supported initial data (or exponentially decaying, for that matter) for equation (1.1), but not on the stability of the latter.

It is to be observed that compactly supported initial data cannot be considered as perturbations of the monotone fronts because the former have non-zero asymptotic limits: any small perturbation \( u_0 \) of the wave \( \varphi \) stays in the neighborhood of non-zero equilibrium states as \( x \to \infty \) or \( x \to -\infty \) and, therefore, the initial data \( u_0 + \varphi \) cannot be compactly supported (not even asymptotically decaying). As far as we know there is no work on the stability of monotone traveling diffusion-degenerate Nagumo fronts available in the literature.

In this paper, we study the stability of both diffusion-degenerate and non-degenerate monotone Nagumo fronts. Our work establishes the first step of a general stability program: the property of spectral stability, which is based on the
analysis of the spectrum of the linearized differential operator around the wave. Our approach is linked to the modern stability theory of nonlinear waves based on Evans function methods and the relation between spectral stability properties with the (orbital) nonlinear stability of the wave as a solution to the evolution equation under small perturbations. We refer the reader to the works by Alexander, Gardner and Jones [1], Sandstede [65] and the book by Kapitula and Promislow [30] (see also the multiple references therein). Spectral stability can be formally defined as the “well-behavior” of the linearized operator around the traveling front, in the sense that there are no eigenvalues with positive real part which could render exponentially growing-in-time solutions to the linear problem (for the precise statement, see Definition 3.2 below). The degeneracy of the diffusion coefficient, however, is responsible of some technical difficulties even at the spectral level. The stability of diffusion-degenerate Fisher-KPP fronts is studied in a companion paper [38]. There are new aspects, however, which are particular to the Nagumo cases. Here we summarize the contributions of this work. Due to the degeneracy of the diffusion coefficient at \( u = 0 \), one of the end points of the front, the corresponding asymptotic coefficient matrix (when the spectral problem is written as a first order system) ceases to be hyperbolic. This prevents us to apply standard results (basically, the relation between hyperbolicity, exponential dichotomies and the Fredholm borders location) to locate the essential spectrum. For that purpose, we use the particular partition of spectrum proposed in [38] to deal with degenerate problems. We generalize the method in [38] and show that there is convergence in the generalized sense of a family of operators (parabolic regularizations of the linearized operator around the front) when the regularization parameter tends to zero. The new partition of spectrum sorts out the complex values \( \lambda \) for which the operator \( \mathcal{L} - \lambda \) has closed range or not. Thus, this technique only allows to control a subset of the essential spectrum characterized by this closed range property. To deal with points in the compressed spectrum (the range is no longer closed) we analyze the behavior of singular (or Weyl) sequences. Appropriately chosen exponential weights allow to control both the “closed range” points of the essential spectrum and the singular sequences associated to complex values in the subset of the compressed spectrum. These exponential weights allow us, in turn, to perform energy estimates on spectral equations that help to locate the point spectrum. The estimates are possible thanks to the monotonicity of the fronts and to the fact that the exponential weights imply that a certain transformation remains in the space domain of the operator. All these assumptions have to be verified on a case by case basis for each of the monotone Nagumo fronts under consideration.

1.4. Main results. Let us now state the main results of this paper. The first theorem pertains to the spectral stability of non-degenerate fronts (the diffusion coefficient is uniformly bounded below and the problem is non-degenerate).

**Theorem 1.1** (spectral stability of non-degenerate monotone Nagumo fronts). Under hypotheses (1.2) and (1.4), there exists a positive wave speed \( c_0(\alpha) \geq \bar{c}(\alpha) \) such that the family of all non-degenerate monotone Nagumo fronts connecting the equilibrium states \( u = 1 \) with \( u = \alpha \) and traveling with speed \( c > c_0(\alpha) \) are spectrally stable with spectral gap in an exponentially weighted energy space \( L^2_a \).

More precisely, there exists \( a > 0 \) such that

\[
\sigma(\mathcal{L})_{L^2_a} \subset \{ \lambda \in \mathbb{C} : \Re \lambda \leq -\mu < 0 \} \cup \{ 0 \},
\]
for some $\mu > 0$ and where $\mathcal{L} : L^2_a \to L^2_a$ denotes the linearized operator around the traveling front and $\sigma(\mathcal{L})|_{L^2_a}$ denotes the spectrum with respect to the energy space $L^2_a$.

It is to be observed that, notably, only those fronts traveling with a speed greater than a certain threshold value are spectrally stable in a certain exponentially weighted energy space. In this non-degenerate case we are able to show the existence of a “spectral gap” (a positive distance between the spectrum and the imaginary axis, except to the eigenvalue zero which is isolated and simple).

The second theorem establishes the spectral stability in $L^2$ of stationary Nagumo diffusion-degenerate fronts. Notice that this result does not provide information on the spectral gap.

**Theorem 1.2** (spectral stability of degenerate monotone stationary Nagumo fronts). Under hypotheses (1.2) and (1.4), all monotone stationary diffusion-degenerate Nagumo fronts connecting the equilibrium states $u = 0$ and $u = 1$ are spectrally stable in the energy space $L^2$. More precisely,

$$\sigma(\mathcal{L})|_{L^2} \subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq 0 \}.$$

The third and final theorem guarantees the spectral stability in a suitably chosen exponentially weighted energy $L^2$-space of all fronts in the family of degenerate fronts connecting $u = 0$ with the unstable equilibrium $u = \alpha$. Once again, no information on the spectral gap is provided.

**Theorem 1.3** (spectral stability of degenerate non-stationary monotone Nagumo fronts). Under hypotheses (1.2) and (1.4), the family of all monotone diffusion-degenerate Nagumo fronts connecting the equilibrium states $u = \alpha$ with $u = 0$ and traveling with speed $c > c(\alpha)$ are spectrally stable in an exponentially weighted energy space $L^2_a$. More precisely, there exists $a > 0$ such that

$$\sigma(\mathcal{L})|_{L^2_a} \subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq 0 \},$$

where $\mathcal{L} : L^2_a \to L^2_a$ denotes the linearized operator around the traveling front.

**Plan of the paper.** This article is organized as follows. In Section 2 we review the existence results due to Sánchez-Garduño and Maini [63]. As a by-product of their analysis we establish the asymptotic decay of the waves and some structural properties that are needed in the stability study. In Section 3 we pose the spectral stability problem. In particular, we recall Weyl’s partition of spectrum and the partition introduced in [38] to deal with degenerate diffusions. Section 4 contains a generalization to conjugated operators of the parabolic regularization technique and the convergence of operators in the generalized sense that is needed to locate a subset of the essential spectrum. In Section 5, we establish energy estimates on the solutions to the spectral equation for conjugated operators under particular hypotheses on the decaying properties of such solutions (see Assumption 5.1 below). The basic energy estimate (see Lemma 5.2) is the main tool to locate the point spectrum. Sections 6, 7 and 8 are devoted to prove the Main Theorems 1.1, 1.2 and 1.3, respectively.

**On notation.** We denote the real and imaginary parts of a complex number $\lambda$ by $\text{Re} \lambda$ and $\text{Im} \lambda$, respectively, as well as complex conjugation by $\lambda^*$. We use lowercase boldface roman font to indicate column vectors (e.g., $w$), and with the
exception of the identity matrix $I$, we use upper case boldface roman font to indicate square matrices (e.g., $A$). Linear operators acting on infinite-dimensional spaces are indicated with calligraphic letters (e.g., $L$ and $T$), except for the identity operator which is indicated by $\text{Id}$. In the sequel, $L^2$ and $H^m$, $m \in \mathbb{Z}$, will denote the standard Sobolev spaces of complex-valued functions on the real line, $L^2(\mathbb{R}; \mathbb{C})$ and $H^m(\mathbb{R}; \mathbb{C})$, respectively, except when it is explicitly stated otherwise. They are endowed with the standard inner products,

$$
\langle u, v \rangle_{L^2} = \int_{\mathbb{R}} uv^* \, dx,
$$

$$
\langle u, v \rangle_{H^m} = \sum_{k=1}^{m} \langle \partial^k_x u, \partial^k_x v \rangle_{L^2}.
$$

Let $M(\mathbb{R}; \mathbb{C})$ denote the set of Lebesgue measurable complex-valued functions in $\mathbb{R}$. For any $a \in \mathbb{R}$, the exponentially weighted Sobolev spaces, defined as

$$
H^m_a(\mathbb{R}; \mathbb{C}) = \{ v \in M(\mathbb{R}; \mathbb{C}) : e^{ax} v \in H^m(\mathbb{R}; \mathbb{C}) \},
$$

for $m \in \mathbb{Z}$, $m \geq 0$, are Hilbert spaces endowed with the inner product and norm,

$$
\langle u, v \rangle_{H^m_a} := \langle e^{ax} u, e^{ax} v \rangle_{H^m}, \quad \|v\|_{H^m_a}^2 := \|e^{ax} v\|_{H^m}^2 = \langle v, v \rangle_{H^m_a}.
$$

According to custom we denote $L^2_a = H^0_a$. We use the standard notation in asymptotic analysis [14], in which the symbol $\sim$ means “behaves asymptotically like” as $x \to x^*$, more precisely, $f \sim g$ as $x \to x^*$ if $f - g = o(|g|)$ as $x \to x^*$ (or equivalently, $f/g \to 1$ as $x \to x^*$ if both functions are positive).

## 2. Structure of monotone diffusion-degenerate Nagumo fronts

In this section we recall the existence theory of diffusion-degenerate Nagumo fronts and prove some structural properties which will be useful later on.

### 2.1. Monotone diffusion-degenerate Nagumo fronts

The existence of diffusion-degenerate Nagumo fronts for equations of the form (1.1), under assumptions (1.2) and (1.4), was proved by Sánchez-Garduño and Maini [63]. The authors analyze the local and global phase portraits of the associated ODE system and prove the emergence of heteroclinic connections. Since the Nagumo reaction function has another equilibrium point at $u = \alpha \in (0, 1)$, the structure of the fronts is richer than that of the Fisher-KPP case [61, 62]. Sánchez-Garduño and Maini [63] show, for instance, the existence of monotone, oscillating and sharp fronts. We specialize our observations, however, to monotone fronts only.

If we suppose that $u(x, t) = \varphi(x - ct)$ is a traveling wave solution to (1.1) with speed $c \in \mathbb{R}$, then the profile function $\varphi : \mathbb{R} \to \mathbb{R}$ is a solution to

$$
(D(\varphi)\varphi_{\xi})_{\xi} + c\varphi_{\xi} + f(\varphi) = 0,
$$

where $\xi = x - ct$ denotes the translation variable. We write the asymptotic limits of the traveling wave as

$$
u_\pm := \varphi(\pm \infty) = \lim_{\xi \to \pm \infty} \varphi(\xi).$$

It is assumed that $u_+$ and $u_-$ are equilibrium points of the reaction function, that is, $u_\pm \in \{1, 0, \alpha\}$ in the Nagumo case. Written as a first order system, equation
(2.1) is recast as
\[
\frac{d\varphi}{d\xi} = v,
\]
\[
D(\varphi)\frac{dv}{d\xi} = -cv - D'(\varphi)v^2 - f(\varphi). \tag{2.2}
\]

Aronson [3] (see also [63]) overcomes the singularity at \( \varphi = 0 \) by introducing the parameter \( \tau = \tau(\xi) \), such that
\[
\frac{d\tau}{d\xi} = 1 - D'\left(\varphi(\xi)\right),
\]
and the system is transformed into
\[
\frac{d\varphi}{d\tau} = D(\varphi)v, \tag{2.3}
\]
\[
\frac{dv}{d\tau} = -cv - D'(\varphi)v^2 - f(\varphi).
\]

Heteroclinic trajectories of both systems are equivalent, so the analysis focuses on the study of the topological properties of equilibria for system (2.3), which depend upon the reaction function \( f \).

Let us suppose that \( f = f(u) \) is of Nagumo type, satisfying (1.4). In [63], the authors define the function \( D : [0, 1] \to \mathbb{R} \) as
\[
D(\phi) := \int_0^\phi D(u)f(u)du. \tag{2.4}
\]
Likewise, let us define the following threshold speed
\[
\overline{c}(\alpha) := 2\sqrt{D(\alpha)f''(\alpha)} > 0. \tag{2.5}
\]

The existence of monotone fronts can be summarized as follows.

**Proposition 2.1 (monotone Nagumo fronts [63])**. If the function \( D = D(u) \) satisfies (1.2) and \( f = f(u) \) is of Nagumo (or bistable) type satisfying (1.4), then there exist monotone traveling wave solutions to equation (1.1) which can be classified as follows:

**[sN]** Stationary, monotone increasing front: when \( c = 0 \) and \( D(1) = 0 \) there exists a unique monotone increasing front \( \varphi = \varphi(x) \) with
\[
u_+ = \varphi(+\infty) = 1, \quad \nu_- = \varphi(-\infty) = 0,
\]
and \( \varphi_x > 0 \) for all \( x \in \mathbb{R} \). It is diffusion degenerate at \( \nu_- = 0 \) as \( x \to -\infty \).

**[sN]** Stationary, monotone decreasing front: when \( c = 0 \) and \( D(1) = 0 \) there exists a unique monotone decreasing front \( \varphi = \varphi(x) \) with
\[
u_+ = \varphi(+\infty) = 0, \quad \nu_- = \varphi(-\infty) = 1,
\]
and \( \varphi_x < 0 \) for all \( x \in \mathbb{R} \). It is diffusion degenerate at \( \nu_+ = 0 \) as \( x \to +\infty \).

**[Nn]** Non-degenerate, monotone decreasing fronts: for each speed value \( c > \overline{c}(\alpha) \), there exists a traveling wave solution \( \varphi = \varphi(x - ct) \) with
\[
u_+ = \varphi(+\infty) = \alpha, \quad \nu_- = \varphi(-\infty) = 1,
\]
and \( \varphi_\xi < 0 \) for all \( \xi \in \mathbb{R} \). These fronts are non-degenerate in the sense that \( D(\nu_\pm) > 0 \) and \( D(\varphi) \geq \delta_0 > 0 \) for all values of \( \varphi \).
Degenerate, monotone increasing fronts: for each speed value \( c > \overline{c}(\alpha) \), there exists a traveling wave solution \( \varphi = \varphi(x-ct) \) with
\[
    u_+ = \varphi(+\infty) = \alpha, \quad u_- = \varphi(-\infty) = 0,
\]
and \( \varphi_\xi > 0 \) for all \( \xi \in \mathbb{R} \). These fronts are diffusion degenerate at \( u_- = 0 \) as \( \xi \to -\infty \).

Remark 2.2. The main Theorem 1 in [63] also establishes the existence of sharp traveling waves, as well as that of pulses and oscillatory (non-monotone) fronts, which are not considered in the present analysis.

A summary of the diffusion degenerate monotone traveling Nagumo fronts can be found in Table 1. An illustration of the three different types of monotone fronts can be observed in Figure 2 as well. Stationary fronts are depicted in Figure 2(a), whereas traveling fronts with speed \( c > c \), either degenerate or not, are illustrated in Figure 2(b).

2.2. Asymptotic decay. In this section we examine the asymptotic behavior of the traveling fronts as \( \xi \to \pm \infty \), which can be deduced from the existence analysis of [63]. We shall use this information in the course of the stability study.

The first result shows that monotone stationary Nagumo fronts decay algebraically on the degenerate side and exponentially on the non-degenerate side.

Lemma 2.3 (asymptotic decay; cases \([\text{sN}]\geq\)). Let \( \varphi = \varphi(x) \) be the stationary monotone decreasing (resp. increasing) Nagumo front, with \( c = 0 \), and \( u_+ = 0 \) (resp. \( u_- = 1 \)). Then, \( \varphi \) decays when \( x \to \pm \infty \) as
\[
\begin{align*}
    |\partial^j_x(\varphi - 1)| &= O(e^{-\eta|x|}), \quad \text{as } x \to -\infty \ (\text{resp. } x \to +\infty), \ j = 0, 1; \\
    |\partial^j_x\varphi| &= O(x^{-(2+j)}), \quad \text{as } x \to +\infty \ (\text{resp. } x \to -\infty), \ j = 0, 1,
\end{align*}
\]
with \( \eta = \sqrt{-f'(1)/D(1)} > 0 \). Moreover, \( \varphi \) and \( \varphi_x \) behave asymptotically as
\[
\begin{align*}
    \varphi &\sim C_0 + O(x^{-4}), \quad \varphi_x \sim C_1 x^{-1}, \quad \text{as } x \to +\infty \ (\text{resp. } x \to -\infty), \\
    \varphi &\sim C_2 e^{-\eta|x|}, \quad \varphi_x \sim C_3 e^{-\eta|x|}, \quad \text{as } x \to -\infty \ (\text{resp. } x \to +\infty),
\end{align*}
\]
for some uniform \( C_j, \eta > 0 \).

Proof. Without loss of generality we consider the monotone decreasing front only (case \([\text{sN}]<\), with \( c = 0, u_+ = 0, u_- = 1 \)). The front corresponds to an heteroclinic
orbit from the equilibrium point $P_1 = (1, 0)$ to the point $P_0 = (0, 0)$ in the phase plane for system (2.3). Following [63], we can write the former in Hamiltonian form, 

$$ \dot{\varphi} = \frac{\partial H}{\partial v}, \quad \dot{v} = -\frac{\partial H}{\partial \varphi}, $$

where

$$ H(\varphi, v) = \frac{1}{2}(D(\varphi)v)^2 + \int_0^{\varphi} D(u)f(u)\, du, \quad (2.8) $$
that is,
\[ \dot{\varphi} = D(\varphi)^2 v, \]
\[ \dot{v} = -D'(\varphi) D(\varphi) v^2 - D(\varphi) f(\varphi). \]  

(2.9)

This is accomplished by making the change of variables \( d\tau/dx = D(\varphi)^{-2}, \) = \( d/d\tau, \) in the original system (2.2). Therefore, the trajectories of (2.9), and hence those of (2.2), coincide with the level curves of \( H(\varphi, v) = \text{constant}. \) In particular, the heteroclinic trajectory between \( P_0 \) and \( P_1 \) corresponds to the level set \( H(0, 0) = H(1, 0) = \mathcal{D}(1) = 0. \) Solving \( H(\varphi, v) = 0 \) for \( v \) and taking the negative root in view of \( \varphi_x < 0, \) we obtain
\[ \varphi_x = v = -\frac{\sqrt{2}}{D(\varphi)} (-\mathcal{D}(\varphi))^{1/2}, \]
for \( \varphi \in (0, 1). \) Since \( \varphi \to 0, \varphi_x \to 0, \) as \( x \to +\infty, \) in order to find the rate of decay we make asymptotic expansions around \( \varphi = 0: \)
\[ D(\varphi) = D'(0) \varphi + \frac{1}{2} D''(0) \varphi^2 + O(\varphi^3), \]
\[ \mathcal{D}(\varphi) = \frac{1}{4} D'(0) f'(0) \varphi^3 + O(\varphi^4). \]

Upon substitution,
\[ \varphi_x = -\frac{\sqrt{2}}{\varphi} \left( D'(0) + \frac{1}{2} D''(0) \varphi + O(\varphi^2) \right)^{-1} \left( \frac{1}{4} D'(0) f'(0) \varphi^3 + O(\varphi^4) \right)^{1/2} \]
\[ = -a_0 \varphi^{1/2} + b_0 \varphi^{3/2} + O(\varphi^{5/2}), \]
with \( a_0 = \sqrt{-\frac{2}{3} f'(0)/D'(0)} > 0 \) and some \( b_0 > 0. \) Normalizing \( \varphi \to \varphi/a_0^2 \) we obtain
\[ \varphi_x = -\varphi^{1/2} + b \varphi^{3/2} + O(\varphi^{5/2}), \]
as \( \varphi \to 0^+ \) with \( b = a_0 b_0 > 0. \) By standard results of asymptotic analysis (cf. Bender and Orzag [6]) we conclude that \( \varphi \) behaves asymptotically like the solution \( \tilde{\varphi} \) to the equation
\[ \tilde{\varphi}_x = -\tilde{\varphi}^{1/2} + b \tilde{\varphi}^{3/2}, \]
as \( x \to +\infty. \) Integrating this equation by separation of variables one obtains
\[ \log \left( \frac{1/b + \tilde{\varphi}^{1/2}}{1/b - \tilde{\varphi}^{1/2}} \right) = \frac{1}{2x}. \]
Solving for \( \tilde{\varphi} \) we get,
\[ \tilde{\varphi}^{1/2} = \frac{1}{b} \left( e^{1/2x} - 1 \right) e^{1/2x} + 1 \rightarrow 0^+, \quad \text{as} \quad x \to +\infty. \]
Thus,
\[ \varphi \sim \tilde{\varphi} = \frac{1}{b^2} \tanh^2 \left( \frac{1}{4x} \right) = \frac{1}{4b^2} x^{-2} + O(x^{-4}), \]
as \( x \to +\infty. \) We then deduce the asymptotic behavior (2.7) when \( x \to +\infty \) (use L'Hôpital's rule, for instance, to show that \( \varphi_x \sim x^{-3} \)). This yields the desired algebraic decay rate on the degenerate side in (2.6).
To verify the exponential decay on the non-degenerate side, note that the equilibrium point \( P_1 = (1, 0) \) is hyperbolic because the diffusion coefficient is not degenerate at \( u = 1 \). The linearization of system (2.2) around \( P_1 \), written as

\[
\frac{d}{dx} \begin{pmatrix} \varphi \\ v \end{pmatrix} = \mathbf{g}(\varphi, v) = \begin{pmatrix} -D(\varphi)^{-1}(D'(\varphi)v^2 + f(\varphi)) \\ v \end{pmatrix},
\]

where \( c = 0 \), is given by

\[
(D_{(\varphi,v)}\mathbf{g})|_{(1,0)} = \begin{pmatrix} 0 & 1 \\ -f'(1)/D(1) & 1 \end{pmatrix},
\]

with positive eigenvalue \( \eta = \sqrt{-f'(1)/D(1)} \) (decaying mode as \( x \to -\infty \)). By standard ODE estimates we deduce that \( \varphi \) and \( \varphi_x \) behave asymptotically as

\[
\varphi \sim C_0 e^{-\eta|x|}, \quad \varphi_x \sim -C_1 e^{-\eta|x|},
\]

as \( x \to -\infty \) for some uniform constants \( C_0, C_1 > 0 \). This shows (2.7) at \( x = -\infty \) and the exponential decay rate (2.6) on the non-degenerate side, as well. The lemma is now proved.

Lemma 2.4 (asymptotic decay; case [Nd]). Let \( \varphi = \varphi(\xi) \) be a monotone increasing degenerate Nagumo front, for which \( u_+ = \alpha, u_- = 0, \varphi_0 > 0 \), traveling with speed \( c > \bar{\tau}(\alpha) \). Then \( \varphi \) behaves asymptotically as

\[
|\partial_\xi^j(\varphi - u_+)| = |\partial_\xi^j(\varphi - \alpha)| = O(e^{-\eta \xi}), \quad \text{as} \quad \xi \to +\infty, \quad j = 0, 1, \tag{2.10}
\]

for \( \eta = (2D(\alpha))^{-1}(c + \sqrt{c^2 - 4D(\alpha)f'(\alpha)}) > 0 \); and as,

\[
|\partial_\xi^j(\varphi - u_-)| = |\partial_\xi^j \varphi| = O(e^{|f'(0)|\xi/c}), \quad \text{as} \quad \xi \to -\infty, \quad j = 0, 1, \tag{2.11}
\]

on the degenerate side. Moreover, \( \varphi \) and \( \varphi_\xi \) behave asymptotically like

\[
\varphi \sim C_0 e^{-\eta \xi}, \quad \varphi_\xi \sim C_1 e^{-\eta \xi}, \tag{2.12}
\]

when \( \xi \to +\infty \), and like

\[
\varphi \sim C_2 e^{|f'(0)|\xi/c}, \quad \varphi_\xi \sim C_3 e^{|f'(0)|\xi/c}, \tag{2.13}
\]

when \( \xi \to -\infty \), for appropriate positive uniform constants \( C_j > 0 \).

Proof. Let us first examine the asymptotic behavior on the non-degenerate side as \( \xi \to +\infty \). The linearization of system (2.2) around the equilibrium point \( P_\alpha = (\alpha, 0) \) is given by

\[
(D_{(\varphi,v)}\mathbf{g})|_{(\alpha,0)} = \begin{pmatrix} 0 & 1 \\ -f'(\alpha)/D(\alpha) & -c/D(\alpha) \end{pmatrix},
\]

having only one negative eigenvalue,

\[
\mu = -\frac{1}{2D(\alpha)}(c + \sqrt{c^2 - \bar{\tau}(\alpha)^2}) =: -\eta,
\]

with \( \eta > 0 \). By standard ODE estimates around a hyperbolic end point the trajectory behaves asymptotically as

\[
\varphi \sim C_0 e^{-\eta \xi}, \quad \varphi_\xi \sim C_1 e^{-\eta \xi},
\]

when \( \xi \to +\infty \) for some uniform constants \( C_0, C_1 > 0 \).
To verify the exponential decay on the degenerate side, notice that \( P_0 = (0,0) \) is a non-hyperbolic point for system (2.3) for all admissible values of the speed \( c \geq \tau(\alpha) = \sqrt{4D(\alpha)f''(\alpha)} > 0 \), and we need higher order terms to approximate the trajectory along a center manifold. Let us denote the former as \( v = h(\varphi) \). After an application of the center manifold theorem, we find that \( P_0 \) is locally a saddle-node, and the center manifold has the form

\[
h(\varphi) = -\frac{J'(0)}{c} \varphi - \frac{1}{2c^3} \left( f''(0) c^2 + 4D(0) f'(0)^2 \right) \varphi^2 + O(\varphi^3),
\]
as \( \varphi \to 0^+ \) (see Sánchez-Garduño and Maini [63] for details). The trajectory leaves the saddle-node along the center manifold for \( \varphi \to 0^+ \). Therefore, for \( \xi \to -\infty \), the trajectory behaves as

\[
\varphi = h(\varphi) \sim -\frac{J'(0)}{c} \varphi \geq 0,
\]
as \( \varphi \to 0^+ \), yielding

\[
\varphi = O(e^{\vert J'(0) \vert \xi / c}), \quad \text{as} \quad \xi \to -\infty.
\]
This proves the result.

Finally, since non-degenerate Nagumo fronts (case \([Nn]\)), for which \( u_+ = \alpha \) and \( u_- = 1 \), correspond to heteroclinic orbits joining hyperbolic rest points (none of the end points is diffusion degenerate), the linearization is sufficient to conclude exponential asymptotic decay. This behavior is summarized in the following lemma; we omit its proof.

**Lemma 2.5** (asymptotic decay; case \([Nn]\)). Let \( \varphi = \varphi(\xi) \) be a monotone decreasing non-degenerate Nagumo front, for which \( u_+ = \alpha \), \( U_- = 1 \) and \( \varphi_\xi < 0 \), traveling with speed \( c > \tau(\alpha) \). Then \( \varphi \) decays as

\[
|\partial_\xi^j(\varphi - u_+) - |\partial_\xi^j(\varphi - \alpha)| = O(e^{-\eta_j \xi}), \quad \text{as} \quad \xi \to +\infty,
\]

\[
|\partial_\xi^j(\varphi - u_-)| - |\partial_\xi^j(\varphi - 1)| = O(e^{\eta_j \xi}), \quad \text{as} \quad \xi \to -\infty,
\]
for \( j = 0, 1 \), and with

\[
\eta_1 = (2D(\alpha))^{-1} \left( c + \sqrt{c^2 - 4D(\alpha)f'(\alpha)} \right) > 0,
\]

\[
\eta_2 = (2D(1))^{-1} \left( c + \sqrt{c^2 - 4D(1)f'(1)} \right) > 0.
\]
Moreover, the trajectory behaves asymptotically like

\[
\varphi \sim C_0 e^{-\eta_1 \xi}, \quad \varphi_\xi \sim C_1 e^{-\eta_2 \xi}, \quad (2.14)
\]
as \( \xi \to \pm \infty \) for appropriate constants \( C_0, C_1 > 0 \) and \( \eta > 0 \).

### 2.3. Further properties

We finish this section by proving that the fronts have the required regularity for the spectral analysis that follows. For later use, we also prove an auxiliary lemma that guarantees the boundedness of a particular coefficient. We use the asymptotic decay of the fronts in a key way.

**Lemma 2.6** (\( C^4 \)-regularity). Under assumptions (1.2) and (1.4), all the monotone Nagumo fronts in Table 1 are of class \( C^4(\mathbb{R}) \).

**Proof.** Since \( D \in C^4 \), \( f \in C^4 \) and \( (\varphi, v) = (\varphi, \varphi_\xi) \) is a solution to a nonlinear autonomous system of the form

\[
\frac{d}{d\xi} \begin{pmatrix} \varphi \\ \varphi_\xi \end{pmatrix} = g(\varphi, \varphi_\xi),
\]
with \( g = g(\varphi, v) \) of class \( C^3 \) in \((\varphi, v)\), then \( \varphi \) is at least of class \( C^4 \) for \( \xi \in \mathbb{R} \). \( \square \)

**Lemma 2.7** \((H^2\text{-regularity})\). All the monotone Nagumo fronts in Table 1 satisfy \( \varphi_\xi \in H^2 \).

**Proof.** Since each profile is at least of class \( C^4 \) as a function of \( \xi \in \mathbb{R} \), in order to show that \( \varphi_\xi \in H^2(\mathbb{R}) \) it suffices to verify that \( \varphi_\xi \) and its derivatives decay sufficiently fast as \( \xi \to \pm \infty \).

Let us first examine the case of stationary fronts. Without loss of generality we consider only the monotone decreasing case \([sN<] \) with \( u_+ = 0, u_- = 1 \) and \( \varphi_x < 0 \). Notice that on the degenerate side we have

\[
|\varphi_x| \leq C x^{-3}, \quad \text{as} \quad x \to +\infty.
\]

Since \( x^{-3} \) is square integrable in \((x_0, +\infty)\) for any fixed (but arbitrary) \( x_0 > 1 \), we deduce that \( \varphi_x \in L^2(x_0, +\infty) \). On the non-degenerate side the decay is exponential,

\[
|\varphi_x| \leq C e^{-\eta|x|}, \quad \text{as} \quad x \to -\infty,
\]

with \( C, \eta > 0 \). This yields \( \varphi_x \in L^2(-\infty, -x_0) \) for any \( x_0 > 1 \). Since \( \varphi_x \in C^3 \) then it is bounded in any compact interval and we have \( \varphi_x \in L^2(-x_0, x_0) \) as well. We conclude that \( \varphi_x \in L^2(\mathbb{R}) \).

Now since \( \varphi_x \sim x^{-3} \) as \( x \to +\infty \) and \( \varphi_x < 0 \) then we have

\[
-x^3 \varphi_x \to C_0, \quad \text{as} \quad x \to +\infty,
\]

for some \( C_0 > 0 \). Then by L'Hôpital's rule we obtain

\[
C_0 = -\lim_{x \to +\infty} x^3 \varphi_x = \lim_{x \to +\infty} \frac{x^4 \varphi_{xx}}{3} = -\lim_{x \to +\infty} \frac{x^5 \varphi_{xxx}}{12},
\]

yielding

\[
|\varphi_{xx}| \leq C_1 \frac{1}{x^4}, \quad |\varphi_{xxx}| \leq C_2 \frac{1}{x^5},
\]

as \( x \to +\infty \) for some \( C_j > 0 \). Consequently, \( \varphi_{xx}, \varphi_{xxx} \in L^2(x_0, +\infty) \) for any \( x_0 > 1 \). On the non-degenerate side the decay is exponential, more precisely,

\[
|\varphi_x| \sim C e^{\eta x}, \quad \text{as} \quad x \to -\infty.
\]

By the same arguments this behavior yields

\[
|\varphi_{xx}|, |\varphi_{xxx}| \leq C e^{\eta x}, \quad \text{as} \quad x \to -\infty,
\]

for some \( \bar{C} > 0 \). Thus, \( \varphi_{xx}, \varphi_{xxx} \in L^2(-\infty, -x_0) \) for any \( x_0 > 1 \). We conclude that \( \varphi_x \in H^2(\mathbb{R}) \).

The same argument applies to the degenerate [Nd] and the non-degenerate [Nn] cases, inasmuch as the decay is exponential in both cases (Lemmata 2.4 and 2.5), even on the degenerate side. Details are omitted. We conclude that \( \varphi_\xi \in H^2(\mathbb{R}) \) and the lemma is proved. \( \square \)

**Lemma 2.8.** For all monotone Nagumo fronts under consideration, there exists a uniform constant \( C > 0 \) such that

\[
\sup_{\xi \in \mathbb{R}} \left| D(\varphi) \frac{\varphi_\xi}{\varphi_\xi} \right| \leq C.
\]
Proof. Follows directly from the asymptotic behavior (2.7) of stationary fronts, (2.12) of monotone degenerate fronts, and (2.14) in the non-degenerate case. For example, in the stationary monotone decreasing case $[sN<]$ one has

$$\varphi \sim \frac{C_0}{x^2}, \quad \varphi_x \sim -\frac{C_1}{x^3}, \quad \varphi_{xx} \sim \frac{C_2}{x^4},$$

as $x \to +\infty$, with $C_j > 0$ and $D(\varphi) = D'(0)\varphi + O(\varphi^2)$ as $\varphi \to 0^+$. Therefore, it is easy to verify that $D(\varphi)\varphi_{xx}/\varphi_x$ behaves asymptotically as

$$D(\varphi)\frac{\varphi_{xx}}{\varphi_x} \sim CD'(0)x^{-3} \to 0,$$

as $x \to +\infty$ for some uniform $C > 0$. On the non-degenerate side the decay of the profile and its derivatives is exponential, yielding

$$D(\varphi)\frac{\varphi_{xx}}{\varphi_x} \sim \bar{C}e^{\eta x} \to 0,$$

as $x \to -\infty$, for some $\bar{C}, \eta > 0$. Since the coefficient is continuous in $[-R,R]$ for any $R > 0$ and tends to zero as $x \to \pm \infty$ the conclusion follows. The cases $[Nd]$ and $[Nn]$ can be treated similarly. We omit the details. □

3. The spectral stability problem

3.1. Perturbation equations. Suppose that $u(x,t) = \varphi(x - ct)$ is one of the monotone diffusion-degenerate Nagumo traveling fronts of Table 1, traveling with speed $c \in \mathbb{R}$. In all the cases under consideration, the speed is non-negative, so we assume from this point on that $c \geq 0$. With a slight abuse of notation we make the change of variables $x \to x - ct$, where now $x$ denotes the translation variable. We shall keep this notation for the rest of the paper. In the new coordinates, equation (1.1) is recast as

$$u_t = (D(u)u_x)_x + cu_x + f(u), \quad (3.1)$$

for which traveling fronts are stationary solutions, $u(x,t) = \varphi(x)$, satisfying the profile equation,

$$(D(\varphi)\varphi_x)_x + c\varphi_x + f(\varphi) = 0. \quad (3.2)$$

The front connects asymptotic equilibrium points of the reaction: $\varphi(x) \to u_\pm$ as $x \to \pm \infty$, where $u_\pm \in \{0, 1, \alpha\}$, depending on the case (see Table 1). The wave can be either monotone increasing, $\varphi_x > 0$, or monotone decreasing, $\varphi_x < 0$.

Let us consider solutions to (3.1) of the form $\varphi(x) + u(x,t)$, where, from now on, $u$ denotes a perturbation. Substituting we obtain the nonlinear perturbation equation

$$u_t = (D(\varphi + u)(\varphi + u)_x)_x + cu_x + c\varphi_x + f(u + \varphi).$$

Linearizing around the front and using the profile equation (3.2) we get

$$u_t = (D(\varphi)u)_x + cu_x + f'(\varphi)u. \quad (3.3)$$

The right hand side of equation (3.3), regarded as a linear operator acting on an appropriate Banach space $X$, naturally defines the following spectral problem

$$\lambda u = \mathcal{L}u, \quad (3.4)$$

where $\lambda \in \mathbb{C}$ is the spectral parameter, and

$$\mathcal{L} : D(\mathcal{L}) \subset X \to X,$$

$$\mathcal{L}u = (D(\varphi)u)_x + cu_x + f'(\varphi)u. \quad (3.5)$$
Loosely speaking, by spectral stability we understand the absence of solutions \( u \in X \) to equation (3.4) for \( \Re \lambda > 0 \), that is, the situation in which the spectrum of the operator \( \mathcal{L} \) belongs to the stable half plane with \( \Re \lambda \leq 0 \). Clearly, the spectrum of the operator depends upon the choice of the Banach space \( X \). In the stability analysis of nonlinear waves, it is customary to consider energy spaces \( X = L^2 \) and \( \mathcal{D}(\mathcal{L}) = H^2 \), so that \( \mathcal{L} \) can be regarded as a closed, densely defined operator acting on \( L^2 \) (see Appendix A). In this fashion, the stability analysis of the operator \( \mathcal{L} \) pertains to localized perturbations.

3.2. Partitions of spectra. In this section we define the resolvent and spectra of a linearized operator and what we understand as spectral stability. More importantly, we introduce two different partitions of the spectrum, which will be used in the stability analysis.

Let \( X \) and \( Y \) be Banach spaces, and let \( \mathcal{C}(X,Y) \) and \( \mathcal{B}(X,Y) \) denote the sets of all closed and bounded linear operators from \( X \) to \( Y \), respectively. For any \( L \in \mathcal{C}(X,Y) \) we denote its domain as \( \mathcal{D}(L) \subseteq X \) and its range as \( R(L) := L(\mathcal{D}(L)) \subseteq Y \). We say \( L \) is densely defined if \( \mathcal{D}(L) = X \).

**Definition 3.1** (resolvent and spectrum). Let \( L \in \mathcal{C}(X,Y) \) be a closed, densely defined operator. Its **resolvent** \( \rho(L) \) is defined as the set of all complex numbers \( \lambda \in \mathbb{C} \) such that \( L - \lambda \) is injective, \( R(L - \lambda) = Y \) and \( (L - \lambda)^{-1} \) is bounded. Its **spectrum** is defined as \( \sigma(L) := \mathbb{C} \setminus \rho(L) \).

**Definition 3.2** (X-spectral stability). We say the traveling front \( \varphi \) is **X-spectrally stable** if

\[
\sigma(L) \subset \{ \lambda \in \mathbb{C} : \Re \lambda \leq 0 \}.
\]

In the analysis of stability of nonlinear waves (cf. [30, 65]) the spectrum is often partitioned into essential and isolated point spectrum. This definition is originally due to Weyl [79] (see also [12, 32]).

**Definition 3.3** (Weyl’s partition of spectrum). Let \( L \in \mathcal{C}(X,Y) \) be a closed, densely defined linear operator. We define its **isolated point spectrum** and its **essential spectrum**, as the sets

\[
\tilde{\sigma}_{pt}(L) := \{ \lambda \in \mathbb{C} : L - \lambda \text{ is Fredholm with index zero and non-trivial kernel} \},
\]

and,

\[
\sigma_{ess}(L) := \{ \lambda \in \mathbb{C} : L - \lambda \text{ is either not Fredholm, or has index different from zero} \},
\]

respectively.

We remind the reader that an operator \( L \in \mathcal{C}(X,Y) \) is said to be Fredholm if its range \( R(L) \) is closed, and both its nullity, \( \text{null} L = \dim \ker L \), and its deficiency, \( \text{def} L = \dim \ker R(L) \), are finite. \( L \) is said to be semi-Fredholm if \( R(L) \) is closed and at least one of \( \text{null} L \) and \( \text{def} L \) is finite. In both cases the index of \( L \) is defined as \( \text{ind} L = \text{null} L - \text{def} L \) (cf. [32]).

**Remark 3.4.** Notice that since \( L \) is a closed operator, then \( \sigma(L) = \tilde{\sigma}_{pt}(L) \cup \sigma_{ess}(L) \) (cf. Kato [32], p. 167). There are many definitions of essential spectrum in the literature. Weyl’s definition makes it easy to compute and has the advantage that the remaining point spectrum, \( \tilde{\sigma}_{pt} \), is a discrete set of isolated eigenvalues (see Remark 2.2.4 in [30]).
In the present context with degenerate diffusion, however, this partition is not particularly useful when analyzing fronts that connect a degenerate point for the diffusion due to the loss of hyperbolicity of the asymptotic coefficients of the operator when the spectral problem is written as a first order system. Consequently, in this paper we shall also employ the following partition of the spectrum (see also [38]).

**Definition 3.5.** Let \(L \in \mathcal{C}(X,Y)\) be a closed, densely defined operator. We define the following subsets of the complex plane:
- \(\sigma_{pt}(L) := \{\lambda \in \mathbb{C} : L - \lambda \text{ is not injective}\}\),
- \(\sigma_{\delta}(L) := \{\lambda \in \mathbb{C} : L - \lambda \text{ is injective, } \mathcal{R}(L - \lambda) \text{ is closed and } \mathcal{R}(L - \lambda) \neq Y\}\),
- \(\sigma_{\pi}(L) := \{\lambda \in \mathbb{C} : L - \lambda \text{ is injective and } \mathcal{R}(L - \lambda) \text{ is not closed}\}\).

**Remark 3.6.** Observe that the sets \(\sigma_{pt}(L)\), \(\sigma_{\pi}(L)\) and \(\sigma_{\delta}(L)\) are clearly disjoint and, since \(L\) is closed, we know that if \(L\) is invertible then \(L^{-1} \in \mathcal{B}(Y,X)\). Consequently,
\[
\sigma(L) = \sigma_{pt}(L) \cup \sigma_{\pi}(L) \cup \sigma_{\delta}(L).
\]
Also note that the set of isolated eigenvalues with finite multiplicity (see Definition 3.3) is contained in \(\sigma_{pt}\), that is, \(\bar{\sigma}_{pt}(L) \subset \sigma_{pt}(L)\), and that \(\lambda \in \sigma_{pt}(L)\) if and only if there exists \(u \in \mathcal{D}(L)\), \(u \neq 0\) such that \(Lu = \lambda u\).

**Remark 3.7.** Note that the set \(\sigma_{\delta}(L)\) is clearly contained in what is known as the *compression spectrum* (see, e.g., [27], p. 196):
\[
\sigma_{\delta}(L) \subset \sigma_{\text{com}}(L) := \{\lambda \in \mathbb{C} : L - \lambda \text{ is injective, and } \mathcal{R}(L - \lambda) \neq Y\},
\]
whereas the set \(\sigma_{\pi}(L)\) is contained in the *approximate spectrum* [12], defined as
\[
\sigma_{\pi}(L) \subset \sigma_{\text{app}}(L) := \{\lambda \in \mathbb{C} : \text{there exists } u_n \in \mathcal{D}(L) \text{ with } \|u_n\| = 1 \text{ such that } (L - \lambda)u_n \to 0 \text{ in } Y \text{ as } n \to +\infty\}.
\]
The last inclusion follows from the fact that, for any \(\lambda \in \sigma_{\pi}(L)\), the range of \(L - \lambda\) is not closed and, therefore, there exists a singular sequence, \(u_n \in \mathcal{D}(L)\), \(\|u_n\| = 1\) such that \((L - \lambda)u_n \to 0\), which contains no convergent subsequence (see Theorems 5.10 and 5.11 in Kato [32], p. 233). Moreover, since the space \(L^2\) is reflexive, this sequence can be chosen so that \(u_n \to 0\) in \(L^2\) (see [12], p. 415). On the other hand, it is clear that \(\sigma_{pt}(L) \subset \sigma_{\text{app}}(L)\), as well.

In the sequel, \(\sigma(L)|X\) will denote the \(X\)-spectrum of the linearized operator (3.5) with dense domain \(\mathcal{D}(L) \subset X\). For example, when it is computed with respect to a local energy weighted space \(L^2_{a}\) for some \(a \in \mathbb{R}\), its spectrum is denoted by \(\sigma(L)|L^2_{a}\). This notation applies to any subset of the spectrum.

**Remark 3.8** (translation eigenvalue). We recall that \(\lambda = 0\) always belongs to the \(L^2\)-point spectrum because
\[
L\varphi = \partial_x ((D(\varphi)\varphi_x)_x + c\varphi_x + f(\varphi)) = 0,
\]
in view of the profile equation (3.2) and the fact that \(\varphi_x \in H^2 = \mathcal{D}(L)\) (see Lemma 2.7). Thus, \(\varphi_x\) is the eigenfunction associated to the eigenvalue \(\lambda = 0\).
4. Generalized convergence of parabolic regularizations

In this section we extend the technique introduced in [38] (see Section 5 in that reference) to locate the subset $\sigma_\delta$ of the spectrum, to the case of exponentially weighted Sobolev spaces. The method consists of performing a parabolic regularization of the linearized operator around the wave and on establishing the convergence (in the generalized sense) of the family of regularized operators to the degenerate operator as the regularization parameter tends to zero.

4.1. The regularized operator on exponentially weighted energy spaces.

Let $\varphi = \varphi(x)$ be any of the monotone Nagumo fronts of Table 1 and consider the following regularization of the diffusion coefficient: for any $\epsilon > 0$, let us define

\[ D'(\varphi) := D(\varphi) + \epsilon. \]

Note that, for fixed $\epsilon > 0$, $D'(\varphi)$ is positive and uniformly bounded below, including the asymptotic limits, $D'(u_{\pm}) = D(u_{\pm}) + \epsilon > 0$.

Let us consider now the following family of linearized, regularized operators defined on weighted energy spaces,

\[ \mathcal{L}' u := (D'(\varphi)u)_{xx} + cu_x + f'(\varphi)u, \]

\[ \mathcal{L}' : \mathcal{D}_a(\mathcal{L}') \subset L^2_a \rightarrow L^2_a, \tag{4.2} \]

for some $a \in \mathbb{R}$ and any $\epsilon \geq 0$. Its domain $\mathcal{D}_a(\mathcal{L}')$ is a dense subset of $L^2_a$. For instance, we can take

\[ \mathcal{D}_a(\mathcal{L}') := H^1_a. \]

In this fashion, for any $\epsilon > 0$, $\mathcal{L}'$ is a densely defined, closed operator in $L^2_a$, with domain $\mathcal{D}_a(\mathcal{L}') = H^1_a$. For $\epsilon = 0$, $\mathcal{L}' = \mathcal{L}$ is a densely defined, closable operator in $L^2_a$. In this case we work with the closed extension of $\mathcal{L}$ and, without loss of generality, we regard $\mathcal{L}' : L^2_a \rightarrow L^2_a$ as a closed, densely defined operator for any $\epsilon \geq 0$ with dense domain $\mathcal{D}_a(\mathcal{L}') = H^1_a$ (see Section A.1 in the Appendix).

We are interested in computing the spectrum of $\mathcal{L}'$ with respect to the weighted energy space $L^2_a$. It is well known that the location of the essential spectrum depends upon the weight function under consideration (see, e.g., Kapitula and Promislow [30], chapter 3), whereas the point spectrum is unmoved (cf. [30], or Proposition 3 in [38]). It is also known [30] that the spectrum of $\mathcal{L}'$ on $L^2_a$ is equivalent to that of the conjugated operator $\mathcal{L}'_a$ acting on the original $L^2$ space, where

\[ \mathcal{L}'_a := e^{ax} \mathcal{L}' e^{-ax} : \mathcal{D}(\mathcal{L}'_a) \subset L^2 \rightarrow L^2, \]

\[ \mathcal{D}(\mathcal{L}'_a) := \{ u \in L^2(\mathbb{R}) : e^{-ax}u \in H^1_a \} \subset L^2. \]

From its definition it is clear that $\mathcal{D}(\mathcal{L}'_a) = H^2(\mathbb{R}) \subset L^2(\mathbb{R})$ and, therefore, $\mathcal{L}'_a$ is a densely defined operator in $L^2$. Once again, if $\epsilon > 0$ then $\mathcal{L}'_a$ is a closed operator in $L^2$, whereas if $\epsilon = 0$ the operator is closable and we work with the closed extension of $\mathcal{L}'_a$ on $L^2$. Hence, without loss of generality, we regard $\mathcal{L}'_a : \mathcal{D}(\mathcal{L}'_a) = H^2 \subset L^2 \rightarrow L^2$, as a family of closed, densely defined operators for each $\epsilon \geq 0$.

If $\varphi$ is any of the monotone traveling fronts in Table 1 and $\mathcal{L}'$ is the linear operator defined in (4.2), then after straightforward calculations we find that the associated conjugated operator $\mathcal{L}'_a$ is given by

\[ \mathcal{L}'_a u = D'(\varphi)\partial^2_x + b'_{1,a}(x)\partial_x + b'_{0,a}(x)\Id, \tag{4.3} \]
with coefficients
\[
\begin{align*}
\beta_{1,a}(x) & := 2D'(\varphi)x + c - 2aD'(\varphi), \\
\beta_{0,a}(x) & := a^2D'(\varphi) - 2aD'(\varphi)x - ac + D'(\varphi)xx + f'(\varphi).
\end{align*}
\] (4.4)

Set \( \epsilon = 0 \) in (4.3) and (4.4) to obtain the expression of the conjugated operator of the original (non-regularized) operator \( L \),
\[
\begin{align*}
\mathcal{L}_a : & \mathcal{D}(\mathcal{L}_a) = H^2 \subset L^2 \rightarrow L^2, \\
& \mathcal{L}_a u = D(\varphi)\partial_x^2 + b_{1,a}(x)\partial_x + b_{0,a}(x)\text{Id},
\end{align*}
\] (4.5)
where
\[
\begin{align*}
b_{1,a}(x) & := 2D(\varphi)x + c - 2aD(\varphi), \\
b_{0,a}(x) & := a^2D(\varphi) - 2aD(\varphi)x - ac + D(\varphi)xx + f'(\varphi).
\end{align*}
\] (4.6)

Observe that \( \mathcal{L}_a \) and \( \mathcal{L}_{a'} \) have the same domain, \( \mathcal{D} = H^2 \).

Notice as well that for every \( \epsilon > 0 \), \( \mathcal{L}_{a,\epsilon} \) is a \textit{strongly elliptic} operator acting on \( L^2 \) and that multiplication by \( D'(\varphi)^{-1} \) is an isomorphism (recall that \( 0 < \epsilon \leq D'(\varphi) \leq C_\epsilon \) for all \( x \in \mathbb{R} \) and some uniform \( C_\epsilon > 0 \)). Henceforth, the Fredholm properties of \( \mathcal{L}_{a,\epsilon} - \lambda \) and those of the operator \( \mathcal{J}_{a,\epsilon}(\lambda) : L^2 \rightarrow L^2 \), densely defined as
\[
\begin{align*}
\mathcal{J}_{a,\epsilon}(\lambda) := & D'(\varphi)^{-1}(\mathcal{L}_{a,\epsilon} - \lambda) = \partial_x^2 + D'(\varphi)^{-1}b_{1,a}(x)\partial_x + D'(\varphi)^{-1}(b_{0,a}(x) - \lambda)\text{Id},
\end{align*}
\] (4.7)
are the same (see Lemma A.3 in the Appendix).

Following a procedure which is customary in the literature on nonlinear waves (cf. [1, 65, 30]), let us recast the spectral problem (4.7) as a first order system of the form
\[
w_x = A_{\epsilon}^a(x,\lambda)w,
\] (4.8)
where
\[
w = \begin{pmatrix} u \\ u_x \end{pmatrix} \in H^1 \times H^1,
\]
and,
\[
A_{\epsilon}^a(x,\lambda) = \begin{pmatrix} 0 & 1 \\ D'(\varphi)^{-1}(\lambda - b_{0,a}(x)) & -D'(\varphi)^{-1}b_{1,a}(x) \end{pmatrix}.
\] (4.9)

It is a well-known fact (see, e.g., Theorem 3.2 in [48], as well as the references [30] and [65]) that the associated first order operators
\[
\mathcal{T}_{a,\epsilon}(\lambda) = \partial_x - A_{\epsilon}^a(\cdot,\lambda), \quad \mathcal{T}_{a}^\pm(\lambda) : L^2 \times L^2 \rightarrow L^2 \times L^2,
\]
with domain \( \mathcal{D}(\mathcal{T}_{a}^\pm(\lambda)) = H^1 \times H^1 \) (and hence, densely defined in \( L^2 \times L^2 \)), are endowed with the same Fredholm properties as \( \mathcal{J}_{a,\epsilon}(\lambda) \) and, consequently, as \( \mathcal{L}_{a,\epsilon} - \lambda \). Moreover, these Fredholm properties depend upon the hyperbolicity of the asymptotic coefficient matrices (cf. [65])
\[
A_{a,\epsilon}^{\pm} = \lim_{x \rightarrow \pm \infty} A_{a,\epsilon}^a(x,\lambda).
\]

Denoting
\[
\begin{align*}
\beta_{0,a}^{\pm} & := \lim_{x \rightarrow \pm \infty} b_{0,a}(x) = a^2D'(u_{\pm}) - ac + f'(u_{\pm}), \\
\beta_{1,a}^{\pm} & := \lim_{x \rightarrow \pm \infty} b_{1,a}(x) = c - 2aD'(u_{\pm}),
\end{align*}
\]
then the constant coefficients of the asymptotic systems are given by
\[
A_{a,\epsilon}^{\pm}(\lambda) = \begin{pmatrix} 0 & 1 \\ D'(u_{\pm})^{-1}(\lambda - \beta_{0,a}^{\pm}) & -D'(u_{\pm})^{-1}\beta_{1,a}^{\pm} \end{pmatrix}.
\] (4.10)
Lemma 4.1 (consistent splitting) coefficient matrices. Follows by elementary facts: thanks to connectedness of $\Omega(\lambda, \epsilon)$ and one negative root: $\pi a, \epsilon$-ity of $a, \epsilon$ as the set of points in the complex plane in which there is a center eigenspace, we conclude that the asymptotic matrices are strictly hyperbolic in $\Omega(\lambda, \epsilon)$.

Therefore, we define the region of consistent splitting for each $a \in \mathbb{R}$ and each $\epsilon \geq 0$ as

$$\Omega(a, \epsilon) := \{ \lambda \in \mathbb{C} : \Re \lambda > \max \{ D'(u_+) a^2 - ac + f'(u_+), D'(u_-) a^2 - ac + f'(u_-) \} \}. \quad (4.12)$$

Now, for each fixed $\lambda \in \mathbb{C}$, $a \in \mathbb{R}$ and $\epsilon > 0$, let us denote $S^a_{\epsilon, \pm}(\lambda)$ and $U^a_{\epsilon, \pm}(\lambda)$ as the stable and unstable eigenspaces of $A^a_{\epsilon, \pm}(\lambda)$ in $\mathbb{C}^2$, respectively.

**Lemma 4.1** (consistent splitting). For each $\lambda \in \Omega(a, \epsilon)$, $a \in \mathbb{R}$ and all $\epsilon > 0$, the coefficient matrices $A^a_{\epsilon, \pm}(\lambda)$ have no center eigenspace and

$$\dim S^a_{\epsilon, \pm}(\lambda) = \dim U^a_{\epsilon, \pm}(\lambda) = 1.$$

**Proof.** Follows by elementary facts: thanks to connectedness of $\Omega(a, \epsilon)$ and continuity of $\lambda$, it is clear that the dimensions of the stable and unstable eigenspaces do not change for $\lambda \in \Omega(a, \epsilon)$. Moreover, since the Fredholm curves are defined precisely as the set of points in the complex plane in which there is a center eigenspace, we conclude that the asymptotic matrices are strictly hyperbolic in $\Omega(a, \epsilon)$. To compute the dimensions of the eigenspaces it suffices to take $\lambda \in \mathbb{R}$, $\lambda \gg 1$, sufficiently large. Thus, we find that the characteristic equation $\pi^a_{\epsilon, \pm}(\lambda, z) = 0$ has one positive and one negative root:

$$z_1 = -\frac{1}{2}(D'(u_\pm))^{-1}b^a_{1, \pm} - \frac{1}{2}\sqrt{(D'(u_\pm))^{-1}b^a_{1, \pm})^2 + 4(D'(u_\pm))^{-1}(\lambda - b^a_{0, \pm})} < 0,$$

$$z_2 = -\frac{1}{2}(D'(u_\pm))^{-1}b^a_{1, \pm} + \frac{1}{2}\sqrt{(D'(u_\pm))^{-1}b^a_{1, \pm})^2 + 4(D'(u_\pm))^{-1}(\lambda - b^a_{0, \pm})} > 0,$$

for $\lambda > 0$ large. The conclusion follows. \hfill \Box

4.2. Fredholm properties and generalized convergence. Next, we characterise the Fredholm properties of the operators $\mathcal{L}_a - \lambda$ for $\lambda$ in the region of consistent splitting.

**Lemma 4.2.** For all $\epsilon > 0$, $a \in \mathbb{R}$, and for each $\lambda \in \Omega(a, \epsilon)$, the operator $\mathcal{L}_a^\epsilon - \lambda$ is Fredholm with index zero.

**Proof.** If we fix $\lambda \in \Omega(a, \epsilon)$ then the matrices $A^a_{\epsilon, \pm}(\lambda)$ are hyperbolic. Therefore, by standard exponential dichotomies theory [10] (see also Theorem 3.3 in [65]), system (4.8) is endowed with exponential dichotomies on both rays $[0, +\infty)$ and $(-\infty, 0]$, with Morse indices $i^a_{\epsilon, +}(\lambda) = \dim U^a_{\epsilon, +}(\lambda) = 1$ and $i^a_{\epsilon, -}(\lambda) = \dim S^a_{\epsilon, -}(\lambda) = 1$, respectively. Apply Theorem 3.2 in [65] to conclude that the operators $\mathcal{T}_a^\epsilon(\lambda)$ are Fredholm with index $\text{ind } \mathcal{T}_a^\epsilon(\lambda) = i^a_{\epsilon, +}(\lambda) - i^a_{\epsilon, -}(\lambda) = 0$, showing that $\mathcal{J}_a^\epsilon(\lambda)$ and $\mathcal{L}_a^\epsilon - \lambda$ are Fredholm with index zero, as claimed. \hfill \Box
Remark 4.3. When the front is diffusion-degenerate (that is, when $D(u_+) = 0$ or $D(u_-) = 0$), the parabolic regularization ensures that $D'(u_{\pm}) > 0$ for all $\epsilon > 0$ and hence the hyperbolicity of the asymptotic coefficients $A_{\nu, \pm}(\lambda)$ is assured. In the non-degenerate case, however, we no longer need to regularize the operator and the asymptotic matrices remain hyperbolic even with $\epsilon = 0$. Therefore, by the same arguments of Lemma 4.2 and defining
\[
\Omega(\alpha) := \Omega(\alpha, 0)
\]
we obtain the following immediate corollary.

Corollary 4.4. In the case of a non-degenerate front (case [Nn] in Table 1), for which $D(u_+) > 0$, we have that for all $\alpha \in \mathbb{R}$ and each $\lambda \in \Omega(\alpha)$ the operator $L_\alpha - \lambda$ is Fredholm with $\text{ind}(L_\alpha - \lambda) = 0$.

We now prove that in the generalized limit when $\epsilon \to 0^+$, the regularized operators conserve their Fredholm properties. First, let us remind the reader the following standard definitions from Functional Analysis (cf. Kato [32]): Let $Z$ be a Banach space, and let $M$ and $N$ be any two nontrivial closed subspaces of $Z$. Let $S_M$ be the unitary sphere in $M$. Then one defines
\[
d(M, N) := \sup_{u \in S_M} \text{dist}(u, S_N),
\]
\[
\hat{d}(M, N) := \max\{d(M, N), d(N, M)\}.
\]
$\hat{d}(M, N)$ is called the distance between $M$ and $N$ and satisfies the triangle inequality. (Here the function $\text{dist}(u, M)$ is the usual distance function from $u$ to any closed manifold $M$.)

Definition 4.5. Let $X, Y$ be Banach spaces. If $\mathcal{T}, \mathcal{S} \in \mathcal{G}(X, Y)$, then the graphs $G(\mathcal{T}), G(\mathcal{S})$ are closed subspaces of $X \times Y$, and we set
\[
d(\mathcal{T}, \mathcal{S}) = d(G(\mathcal{T}), G(\mathcal{S})),
\]
\[
\hat{d}(\mathcal{T}, \mathcal{S}) = \max\{d(\mathcal{T}, \mathcal{S}), d(\mathcal{S}, \mathcal{T})\}.
\]
It is said that a sequence $\mathcal{T}_n \in \mathcal{G}(X, Y)$ converges in generalized sense to $\mathcal{T} \in \mathcal{G}(X, Y)$ provided that $\hat{d}(\mathcal{T}_n, \mathcal{T}) \to 0$ as $n \to +\infty$.

Lemma 4.6. For each fixed $\lambda \in \mathbb{C}$ and each $\alpha \in \mathbb{R}$, the operators $L_\alpha^\epsilon - \lambda$ converge in generalized sense to $L_\alpha - \lambda$ as $\epsilon \to 0^+$.

Proof. It is to be observed that, from the definition of $d(\cdot, \cdot)$, we have
\[
d(L_\alpha^\epsilon - \lambda, L_\alpha - \lambda) = d(G(L_\alpha^\epsilon - \lambda), G(L_\alpha - \lambda)) = \sup_{u \in S_G(L_\alpha^\epsilon - \lambda)} \left( \inf_{v \in S_G(L_\alpha - \lambda)} \|v - w\| \right),
\]
where $S_{G(L_\alpha - \lambda)}$ (respectively, $S_{G(L_\alpha^\epsilon - \lambda)}$) is the unit sphere in the graph $G(S_{G(L_\alpha - \lambda)})$ (respectively, $G(S_{G(L_\alpha^\epsilon - \lambda)})$). Now let $v \in S_{G(L_\alpha - \lambda)}$ be such that $v = (p, (L_\alpha - \lambda)p) \in L^2 \times L^2$ for some $p \in D(L_\alpha - \lambda) = H^2$ and with
\[
\|v\|^2_{L^2 \times L^2} = \|p\|^2_{L^2} + \|(L_\alpha - \lambda)p\|^2_{L^2} = 1.
\]
Likewise, let $w \in S_{G(L_\alpha - \lambda)}$ be such that $w = (u, (L_\alpha - \lambda)u)$ for some $u \in D(L_\alpha - \lambda) = H^2$ and
\[
\|w\|^2_{L^2 \times L^2} = \|u\|^2_{L^2} + \|(L_\alpha - \lambda)u\|^2_{L^2} = 1.
\]
Let us find an upper bound for $\|v - w\|_{L^2 \times L^2}$ so that the set consisting of the infima taken over $S_{G(\mathcal{L}_a - \lambda)}$ is bounded and therefore the supremum over $S_{G(\mathcal{L}_a - \lambda)}$ is bounded too. Let us write

$$\|v - w\|_{L^2 \times L^2}^2 = \|p - u\|_{L^2}^2 + ((\mathcal{L}_a^\epsilon - \lambda)p - (\mathcal{L}_a - \lambda)u)^2.$$  

(4.14)

If we keep $v \in S_{G(\mathcal{L}_a - \lambda)}$ fixed then it suffices to take $w = (p, (\mathcal{L}_a - \lambda)p)$ because $p \in H^2 = D(\mathcal{L}_a) = D(\mathcal{L}_a^\epsilon)$. Note that $(\mathcal{L}_a - \lambda)p = (\mathcal{L}_a^\epsilon - \lambda)p - \epsilon p_{xx}$. Therefore expression (4.14) gets simplified to

$$\|v - w\|_{L^2 \times L^2}^2 = \|\mathcal{L}_a^\epsilon - \lambda\|p - (\mathcal{L}_a - \lambda)p\|_{L^2}^2 = \|\epsilon p_{xx}\|_{L^2}^2.$$  

If we regard $\partial_x^2$ as a closed, densely defined operator on $L^2$, with domain $\mathcal{D} = H^2$, then it follows from Remark 1.5 in [32, p. 191], that $\partial_x^2$ is $(\mathcal{L}_a^\epsilon - \lambda)$–bounded, i.e., there exist a constant $C_\lambda > 0$ such that

$$\|p_{xx}\|_{L^2} \leq C_\lambda(\|p\|_{L^2} + \|\mathcal{L}_a^\epsilon - \lambda\|p\|_{L^2}),$$

for all $p \in H^2$. Observe that the constant $C_\lambda$ may depend on $\lambda \in \mathbb{C}$, fixed. Consequently,

$$\|p_{xx}\|_{L^2}^2 \leq C_\lambda(\|p\|_{L^2}^2 + \|\mathcal{L}_a^\epsilon - \lambda\|p\|_{L^2}^2) = C_\lambda,$$

for some other $C_\lambda > 0$ and for $v = (p, (\mathcal{L}_a^\epsilon - \lambda)p) \in S_{G(\mathcal{L}_a - \lambda)}$. This estimate implies, in turn, that

$$\|v - w\|_{L^2 \times L^2}^2 = \epsilon^2\|p_{xx}\|_{L^2}^2 \leq C_\lambda \epsilon^2,$$

yielding

$$\bar{d}(\mathcal{L}_a^\epsilon - \lambda, \mathcal{L}_a - \lambda) \leq C_\lambda \epsilon^2.$$  

In a similar fashion it can be proved that $d(\mathcal{L}_a - \lambda, \mathcal{L}_a^\epsilon - \lambda) = O(\epsilon^2)$. This shows that $\bar{d}(\mathcal{L}_a - \lambda, \mathcal{L}_a^\epsilon - \lambda) \to 0$ as $\epsilon \to 0^+$ and the lemma is proved. \hfill \Box

Now, let us recall the definition of the reduced minimum modulus of a closed operator: for any $S \in \mathcal{C}(X, Y)$ we define $\gamma = \gamma(S)$ as the greatest number $\gamma \in \mathbb{R}$ such that

$$\|Su\| \geq \gamma \text{dist}(u, \text{ker} S),$$

for all $u \in D(S)$. It is well-known that $R(S)$ is closed if and only if $\gamma(S) > 0$ (cf. [12, 32]). The following classical result of functional analysis due to Kato, known as the general stability theorem, is the main tool to relate the Fredholm properties of $\mathcal{L}_a - \lambda$ to those of $\mathcal{L}_a^\epsilon - \lambda$ (see [32], p. 235).

**Theorem 4.7** (Kato’s stability theorem). Let $\mathcal{T}, S \in \mathcal{C}(X, Y)$ and let $\mathcal{T}$ be Fredholm (semi-Fredholm). If

$$\bar{d}(S, \mathcal{T}) < \gamma(1 + \gamma^2)^{-1/2},$$

where $\gamma = \gamma(\mathcal{T})$, then $S$ is Fredholm (semi-Fredholm) and $\text{nul} S \leq \text{nul} \mathcal{T}$, $\text{def} S \leq \text{def} \mathcal{T}$. Furthermore, there exists $\delta > 0$ such that $\bar{d}(S, \mathcal{T}) < \delta$ implies

$$\text{ind} S = \text{ind} \mathcal{T}.$$  

If $X, Y$ are Hilbert spaces then we can take $\delta = \gamma(1 + \gamma^2)^{-1/2}$.

**Remark 4.8.** The original statement of Kato’s theorem is expressed in terms of the gap between the graphs; the distance and the gap are, however, equivalent (see Kato [32], p. 202).
We apply Kato’s theorem in order to obtain the following result, which is the main tool to locate the subset of the compression spectrum, $\sigma_\delta(\mathcal{L}_a)$, in the degenerate front case.

**Lemma 4.9.** Suppose that $\mathcal{L}_a - \lambda$ is semi-Fredholm, for $a \in \mathbb{R}$, $\lambda \in \mathbb{C}$. Then for each $0 < \epsilon \ll 1$ sufficiently small $\mathcal{L}^\epsilon_a - \lambda$ is semi-Fredholm and $\text{ind}(\mathcal{L}^\epsilon_a - \lambda) = \text{ind}(\mathcal{L}_a - \lambda)$.

**Proof.** If $\mathcal{L}_a - \lambda$ is semi-Fredholm then $\mathcal{R}(\mathcal{L}_a - \lambda)$ is closed and, consequently, $\gamma := \gamma(\mathcal{L}_a - \lambda) > 0$ and is independent of $\epsilon > 0$. Since $\mathcal{L}^\epsilon_a - \lambda \to \mathcal{L}_a - \lambda$ in the generalized sense as $\epsilon \to 0^+$, then we have that for all $0 < \epsilon \ll 1$ sufficiently small, $\hat{\lambda}(\mathcal{L}^\epsilon_a - \lambda, \mathcal{L}_a - \lambda) < \gamma(1 + \gamma^2)^{-1/2}$.

From a direct application of Kato’s theorem 4.7 we conclude that $\mathcal{L}^\epsilon_a - \lambda$ is semi-Fredholm and $\text{ind}(\mathcal{L}^\epsilon_a - \lambda) = \text{ind}(\mathcal{L}_a - \lambda)$, for all $\epsilon > 0$ small enough. \hfill $\square$

5. Energy estimates on spectral equations

In this section we establish the basic energy estimate for solutions to the spectral equation. The monotonicity of the fronts plays a crucial role in the analysis.

Let $\varphi = \varphi(x)$ be any of the monotone fronts in Table 1 traveling with speed $c \geq 0$, and let $\mathcal{L}_a : \mathcal{D}(\mathcal{L}_a) = H^2 \subset L^2 \rightarrow L^2$ be the conjugated linearized operator around the front (4.5) for a certain fixed $a \in \mathbb{R}$. Take any fixed $\lambda \in \mathbb{C}$ and suppose that there exists a solution $u \in \mathcal{D}(\mathcal{L}_a) = H^2$ to the spectral equation

$$0 = (\mathcal{L}_a - \lambda)u = D(\varphi)u + \left(2D(\varphi)x - 2aD(\varphi) + c\right)u + \left(a^2D(\varphi) - 2aD(\varphi)x + ac + D(\varphi)xx + f'(\varphi) - \lambda\right)u. \quad (5.1)$$

Consider the change of variables

$$u(x) = w(x)e^{\theta(x)}, \quad (5.2)$$

where $\theta = \theta(x)$ is a function to be chosen later. Upon substitution into the spectral equation (5.1) we obtain the following equation for $w$,

$$D(\varphi)w + \left(2D(\varphi)x + 2\theta_x D(\varphi) - 2aD(\varphi) + c\right)w + \tilde{G}(x, a)w - \lambda w = 0, \quad (5.3)$$

where the coefficient

$$\tilde{G}(x, a) := D(\varphi)(\theta_{xx} + \theta_x^2) + (2D(\varphi)x - aD(\varphi) + c)\theta_x + a^2D(\varphi) - 2aD(\varphi)x + ac + D(\varphi)xx + f'(\varphi),$$

is a function of $x \in \mathbb{R}$, parametrized by $a \in \mathbb{R}$ and $c \geq 0$. Let us choose $\theta = \theta(x)$ such that

$$2\theta_x D(\varphi) - 2aD(\varphi) + c = 0,$$

for all $x \in \mathbb{R}$. In view that $D(\varphi) > 0$ for all $x \in \mathbb{R}$ and that it may vanish only in the limit when $x \to \pm \infty$, we obtain

$$\theta(x) = -c \int_{x_0}^x \frac{dy}{D(\varphi(y))} + a(x - x_0), \quad x \in \mathbb{R}, \quad (5.4)$$

for any fixed (but arbitrary) $x_0 \in \mathbb{R}$. With this choice of $\theta = \theta(x)$, and upon substitution into (5.3), one gets

$$D(\varphi)w + 2D(\varphi)xw + \tilde{G}(x)w - \lambda w = 0, \quad (5.5)$$
where
\[ G(x) := \tilde{G}(x, a) = \frac{c}{2} \frac{D(\varphi)_x}{D(\varphi)} - \frac{c^2}{4D(\varphi)} + D(\varphi)_{xx} + f'(\varphi). \]

In other words, with this particular form of \( \theta \), the function \( \tilde{G}(x, a) \) becomes independent of the parameter \( a \in \mathbb{R} \). Notice that \( \theta = \theta(x) \) is well defined for all \( x \in \mathbb{R} \); depending on the case under consideration, though, it may diverge (and consequently, so may \( e^{-\theta(x)} \)) as \( x \to \pm \infty \).

In the analysis that follows, we are going to suppose that \( u \in H^2 \) decays sufficiently fast as \( x \to \pm \infty \) so that \( w \) defined in (5.2) belongs to \( H^2 \) as well. More precisely, we make the following

**Assumption 5.1.** Given \( a \in \mathbb{R} \), for any \( \lambda \in \Omega(a) \) and any solution \( u \in H^2 \) of the spectral equation \((\mathcal{L}_a - \lambda)u = 0\), the function
\[ w(x) = \exp \left( \frac{c}{2} \int_{x_0}^{x} \frac{dy}{D(\varphi(y))} - a(x - x_0) \right) u(x), \quad x \in \mathbb{R}, \tag{5.6} \]
belongs to \( H^2 \) as well. The set \( \Omega(a) \) is defined in (4.13).

**Lemma 5.2** (basic energy estimate). For \( a \in \mathbb{R} \) fixed let \( \mathcal{L}_a : \mathcal{D} = H^2 \subset L^2 \to L^2 \) be the conjugated linearized operator around any monotone traveling Nagumo front of Table 1. Let \( \lambda \in \Omega(a) \) be fixed and let \( u \in H^2 \) be any solution to the spectral equation \((\mathcal{L}_a - \lambda)u = 0\). Let us suppose that \( a \in \mathbb{R} \) is such that \( 0 \in \Omega(a) \) and \( e^{ax} \varphi_x \in H^2 \). Then, under Assumption 5.1 there holds the energy estimate
\[ \lambda(D(\varphi)w, w)_{L^2} = -\|D(\varphi)\psi(w/\psi)_x\|_{L^2}^2, \tag{5.7} \]
where \( w := e^{-\theta(x)}u \in H^2 \), \( \psi := e^{-\theta(x)}e^{ax} \varphi_x \in H^2 \) and \( \theta = \theta(x) \) is defined in (5.4).

**Proof.** By hypothesis, \( a \in \mathbb{R} \) is such that \( \lambda = 0 \in \Omega(a) \) and \( e^{ax} \varphi_x \in H^2 \). Hence, since \( \varphi_x \in H^2 \) is an \( L^2 \)-eigenfunction of the linearized operator \( \mathcal{L} \) around the wave associated to the zero eigenvalue, as \( \mathcal{L} \varphi_x = 0 \) (see Remark 3.8), we obtain that \( e^{ax} \varphi_x \in H^2 \) is an \( L^2 \)-eigenfunction of the conjugated operator associated to the zero eigenvalue as well, because
\[ \mathcal{L}_a e^{ax} \varphi_x = e^{ax} \mathcal{L} e^{-ax} e^{ax} \varphi_x = e^{ax} \mathcal{L} \varphi_x = 0. \]

Thanks to Assumption 5.1, the solution \( u = e^{ax} \varphi_x \) to the spectral equation \( \mathcal{L}_a u = 0 \) is such that \( \psi = e^{-\theta(x)}e^{ax} \varphi_x \in H^2 \), in view that \( \lambda = 0 \in \Omega(a) \). Hence, we can repeat the procedure leading to equation (5.5) on \( \psi \) to arrive at the equation
\[ D(\varphi)\psi_{xx} + 2D(\varphi)_x \psi_x + G(x)\psi = 0. \tag{5.8} \]

Now take any \( \lambda \in \Omega(a) \) and any solution \( u \in H^2 \) to the spectral equation \((\mathcal{L}_a - \lambda)u = 0\). Defining \( w = e^{-\theta(x)}u \in H^2 \) (by Assumption 5.1) we arrive at the spectral equation (5.5). Multiply equations (5.5) and (5.8) by \( D(\varphi) \) and rearrange the terms appropriately. The result is
\[ (D(\varphi)^2 w)_x + D(\varphi)G(x)w - \lambda D(\varphi)w = 0, \]
\[ (D(\varphi)^2 \psi)_x + D(\varphi)G(x)\psi = 0. \tag{5.9} \]

Since the fronts is monotone \( (\varphi_x \geq 0) \) we have that \( \psi \neq 0 \) for all \( x \in \mathbb{R} \) and we can substitute
\[ D(\varphi)G(x) = \frac{(D(\varphi)^2 \psi)_x}{\psi}. \]
into the first equation in (5.9) to obtain
\[
(D(\phi)^2 w_x)_x - \frac{(D(\phi)^2 \psi_x)_x}{\psi} w - \lambda D(\phi) w = 0. \tag{5.10}
\]

Take the complex $L^2$-product of $w$ with last equation and integrate by parts. This yields,
\[
\lambda \int_{\mathbb{R}} D(\phi) \frac{|w|^2}{\psi} dx = - \int_{\mathbb{R}} D(\phi)^2 |w_x|^2 dx + \int_{\mathbb{R}} D(\phi)^2 \psi_x \left( \frac{|w|^2}{\psi} \right)_x dx
\]
\[
= \int_{\mathbb{R}} D(\phi)^2 \left( \psi_x \left( \frac{|w|^2}{\psi} \right)_x - |w_x|^2 \right) dx.
\]

Use the identity
\[
\psi^2 \left( \frac{w}{\psi} \right)_x \right|^2 = - \left( \psi_x \left( \frac{|w|^2}{\psi} \right)_x - |w_x|^2 \right),
\]
to obtain
\[
\lambda \int_{\mathbb{R}} D(\phi) |w|^2 dx = - \int_{\mathbb{R}} D(\phi)^2 \psi^2 \left( \frac{w}{\psi} \right)_x^2 dx,
\]
as claimed. Finally, we need to verify that $D(\phi) \psi(w/\psi)_x \in L^2$. But this is a straightforward consequence of Assumption 5.1. Indeed, use the expression for $\theta$ and substitute $\psi = e^{-\theta(x)e^{ax} \phi_x}$ to obtain
\[
D(\phi) \psi \left( \frac{w}{\psi} \right)_x = \frac{c}{2} w + D(\phi) \frac{\phi_{xx}}{\phi_x} w,
\]
yielding
\[
\|D(\phi) \psi(w/\psi)_x\|_{L^2} \leq C \|w\|_{L^2} < \infty,
\]
for some uniform $C > 0$ because the coefficient $D(\phi) \phi_{xx}/\phi_x$ is uniformly bounded for all $x \in \mathbb{R}$ (see Lemma 2.8) and $w \in H^2$ by Assumption 5.1. Thus the integral on the right hand side of (5.7) exists and the conclusion follows.

**Remark 5.3.** A few observations are in order. First, notice that we need to find $a \in \mathbb{R}$ such that Assumption 5.1 holds in order to obtain the energy estimate. Hence, the search for such $a \in \mathbb{R}$ will be done on a case by case basis. Second, observe that the monotonicity of the front is important to conclude. Not only is it crucial to eliminate one of the spectral equations and to perform the energy estimate, but it is a fundamental property of the trajectory: it is well-known, in the particular case of constant diffusion coefficients, for instance, that the traveling pulse solutions to bistable reaction-diffusion equations are spectrally unstable precisely because of the lack of monotonicity of the trajectory, which renders positive eigenvalues of second order differential operators of Sturm type (see Section 2.3.3 and Theorem 2.3.3 in [30]).

**Remark 5.4.** The transformation (5.2) of the eigenfunction and the corresponding energy estimate that leads to the conclusion of Lemma 5.2 has been also adapted.
to the spectral stability of planar fronts with degenerate diffusions in a multidimensional setting [8] and to traveling fronts for hyperbolic models of diffusion [35].

Let us first study the spectral stability of the family of monotone non-degenerate Nagumo fronts, for which

\[ u_+ = \alpha, \quad u_- = 1, \]
\[ f'(u_+) = f'(\alpha) > 0, \quad f'(u_-) = f'(1) < 0; \]
each front \( \varphi = \varphi(x) \) is monotone decreasing, \( \varphi_x < 0 \), traveling with positive constant velocity \( c > \bar{c}(\alpha) \) (see Table 1 and Figure 2(b)). The fronts are non-degenerate in the sense that the diffusion coefficient is strictly positive along the trajectory, with positive limits \( D(u_{\pm}) \) when \( x \to \pm \infty \). More precisely we have,

\[ \sup_{x \in \mathbb{R}} D(\varphi(x)) = \max_{u \in [\alpha, 1]} D(u) = D(1) > 0, \]
\[ \inf_{x \in \mathbb{R}} D(\varphi(x)) = \min_{u \in [\alpha, 1]} D(u) = D(\alpha) > 0. \]

The spectral stability analysis in the present, non-degenerate case is quite standard. In view that \( \inf_{\mathbb{R}} D(\varphi) \geq \delta > 0 \) for some \( \delta > 0 \), the coefficient of the highest (second) order of differentiation is uniformly positive and makes the operator \( -\mathcal{L} \) uniformly elliptic. As a result, we are able to apply standard results on operators of Sturm type (cf. [30, 36, 78]). The essential spectrum, for example, is easy to locate and we only need to choose and appropriate weight to stabilize it.

6.1. Choice of the exponential weight. In the present non-degenerate case [Nu], we have \( f'(u_+) = f'(\alpha) > 0 \), and therefore the Fredholm borders bounding \( \sigma_{ess}(\mathcal{L})_{|L^2} \) from the right invade the unstable half plane (making the essential spectrum unstable; see Section 4). Thus, in this section we choose an appropriate \( a \in \mathbb{R} \) to stabilize the essential spectrum of \( \mathcal{L} \) in a suitable local energy space \( L^2_{\sigma} \).

More precisely, we find the conditions under which it is possible to choose \( a \in \mathbb{R} \) such that

\[ \sigma_{ess}(\mathcal{L})_{|L^2} = \sigma_{ess}(\mathcal{L}_a)_{|L^2} \subset \{ \text{Re} \lambda < 0 \}. \]

The front is non-degenerate. Therefore, we do not need to regularize the diffusion coefficient (the operator \( \partial_x - \mathcal{L} \) is strictly parabolic). Thus, the set \( \Omega(a) = \Omega(a, 0) \) defined in (4.12), is given by

\[ \Omega(a) = \{ \lambda \in \mathbb{C} : \text{Re} \lambda > \max\{D(\alpha)a^2 - ac + f'(\alpha), D(1)a^2 - ac + f'(1)\} \}, \]

for each \( a \in \mathbb{R} \). We have the following immediate

Lemma 6.1. \( \sigma_{ess}(\mathcal{L}_a)_{|L^2} \subset \mathbb{C} \setminus \Omega(a) \) for each \( a \in \mathbb{R} \).

Proof. Follows directly from Corollary 4.4 and the definition of \( \sigma_{ess} \). \( \square \)

Whence, we need to find \( a \in \mathbb{R} \) such that \( \sigma_{ess}(\mathcal{L}_a)_{|L^2} \subset \{ \text{Re} \lambda < 0 \} \). For any fixed \( u \in [\alpha, 1] \) (for which \( D(u) > 0 \)), let \( a_1(u) \) and \( a_2(u) \) be the roots of

\[ p(a; u) := D(u)a^2 - ac + f'(u) = 0, \]

namely,

\[ a_1(u) = (2D(u))^{-1} \left( c - \sqrt{c^2 - 4D(u)f'(u)} \right), \]
\[ a_2(u) = (2D(u))^{-1} \left( c + \sqrt{c^2 - 4D(u)f'(u)} \right). \]
Let us define the function $u : \mathbb{R} \to \mathbb{R}$, and consider the waveprofile $u(x, t)$ in the set $\Omega = \mathbb{R}$. To have stability of the essential spectrum, we need to find $\hat{c}$ such that $p(\hat{c}; 1) > 0$ and $p(\hat{c}; 0) < 0$ simultaneously. Since $a_1(1) < 0$, we have that $p(\alpha; 0) < 0$ for all $\alpha \in (a_1(1), a_2(1))$. To have stability of $\sigma_{ess}$, it is then sufficient that

$$a_1(\alpha) < a < \min\{a_2(\alpha), a_2(1)\}.$$  \hfill (6.3)

This can be achieved only when $a_2(1) > a_1(\alpha)$. Let us define

$$\vartheta_\alpha := \varpi(\alpha) = \sqrt{4D(\alpha)f'(\alpha)} > 0,$$

$$\vartheta_1 := \sqrt{-4D(1)f'(1)} > 0,$$

$$\varphi := D(\alpha)/D(1).$$

By monotonicity of $D = D(\cdot)$, see (1.2), we have $\varphi \in (0, 1)$. After straightforward calculations we have that $a_2(1) > a_1(\alpha)$ if and only if

$$h(c) := \varphi(1 + \vartheta_1^2/c^2)^{1/2} + (1 - \vartheta_1^2/c^2)^{1/2} > 1 - \varphi.$$

Clearly, $h(c) > 0$ for all $c > \vartheta_\alpha > 0$. Moreover, $\lim_{c \to \vartheta_\alpha} h(c) = 1 + \varphi > 1 - \varphi > 0$, $\lim_{c \to \vartheta_\alpha} h'(c) = +\infty$, as well as $h(\vartheta_\alpha) = \varphi(1 + \vartheta_1^2/\vartheta_\alpha^2)^{1/2} > 0$. Thus, we have two cases: either (i) $h(\vartheta_\alpha) > 1 - \varphi$; or (ii) $h(\vartheta_\alpha) < 1 - \varphi$. By analyzing the behaviour of the function $c \mapsto h(c)$ for $c \in [\vartheta_\alpha, +\infty)$, one can verify that either $h'(c) > 0$ for all $c \in [\vartheta_\alpha, +\infty)$, or it has at most, one local maximum in $c \in (\vartheta_\alpha, +\infty)$. Therefore, in the first case (i) we have that $h(c) > 1 - \varphi$ for all $c \in [\vartheta_\alpha, +\infty)$. In case (ii) there exists a unique value $\hat{c} > \vartheta_\alpha$ such that $h(c) > 1 - \varphi$ for all $c \in (\hat{c}, +\infty)$. The value of $\hat{c}$ is given implicitly by the positive solution $c$ to

$$\varphi(1 + \vartheta_1^2/c^2)^{1/2} + (1 - \vartheta_1^2/c^2)^{1/2} = 1 - \varphi.$$

To sum up, in case (i), $h = h(c)$ stays above $1 - \varphi$ for all $c > \vartheta_\alpha$. In case (ii), where $0 < h(\vartheta_\alpha) \leq 1 - \varphi$, then there exists a unique value $\hat{c} > \vartheta_\alpha$ such that $h(\hat{c}) > 1 - \varphi$ for all $c > \hat{c}$. Thus, the condition of stability of $\sigma_{ess}$ in a certain weighted space (that is, the possibility of finding a suitable $\alpha \in \mathbb{R}$ that stabilizes the essential spectrum) depends upon the value of the speed $c$ and the model parameter $\alpha \in (0, 1)$. Suppose, for instance, that for a certain front traveling with speed $c$, we have $a_1(\alpha) < \min\{a_2(\alpha), a_2(1)\}$ and let us choose $\alpha \in \mathbb{R}$ such that (6.3) holds. This implies that

$$\max\{D(\alpha)a^2 - ac + f'(\alpha), D(1)a^2 - ac + f'(1)\} = \max\{p(\alpha; 1), p(\alpha; 0)\} < -\mu_0 < 0,$$

for some $\mu_0 = \mu_0(\alpha) > 0$ (for example, one may take $\mu_0(\alpha) = \frac{1}{2} \min\{|p(\alpha; 1)|, |p(\alpha; 0)|\}$). Consequently,

$$\sigma_{ess}(\mathcal{L}_\alpha) \subset \mathbb{C} \setminus \Omega(\alpha) \subset \{\Re \lambda < -\mu_0 < 0\}.$$

We have proved the following

**Theorem 6.2** (essential spectral stability; case [Nn]). Under assumptions (1.2) and (1.4), consider the family of non-degenerate monotone Nagumo fronts, for which $u_+ = \alpha$, $u_- = 1$, $f'(\alpha) > 0$, $f'(1) < 0$, traveling with speed $c > \varpi(\alpha) > 0$. Let us define the function

$$h(c) := \frac{D(\alpha)}{D(1)} \left(1 - \frac{4D(1)f'(1)}{c^2}\right)^{1/2} + \left(1 - \frac{4D(\alpha)f'(\alpha)}{c^2}\right)^{1/2}, \quad c \in [\varpi(\alpha), +\infty).$$  \hfill (6.4)
(i) If \( h(\varpi(\alpha)) > 1 - D(\alpha)/D(1) \) then for all non-degenerate monotone Nagumo fronts traveling with speed \( c > \varpi(\alpha) \), we can find \( a \in \mathbb{R} \) satisfying
\[
0 < \frac{c - \sqrt{c^2 - 4D(\alpha)f'(\alpha)}}{2D(\alpha)} < a < m(\alpha),
\]
where
\[
m(\alpha) := \min \left\{ \frac{c + \sqrt{c^2 - 4D(1)f'(1)}}{2D(1)}, \frac{c + \sqrt{c^2 - 4D(\alpha)f'(\alpha)}}{2D(\alpha)} \right\},
\]
and such that all the fronts satisfy
\[
\sigma_{ess}(\mathcal{L})|_{L^2_\alpha} = \sigma_{ess}(\mathcal{L}_\alpha)|_{L^2} \subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq -\mu_0 < 0 \}
\]
for some \( \mu_0 = \mu_0(\alpha) > 0 \).

(ii) If \( h(\sqrt{4D(\alpha)f'(\alpha)}) \leq 1 - D(\alpha)/D(1) \) then there exists a unique value \( \hat{c} = \hat{c}(\alpha) \geq \varpi(\alpha) \), determined by the positive solution \( c \) to
\[
h(c) = 1 - \frac{D(\alpha)}{D(1)},
\]
such that every monotone non-degenerate front traveling with speed \( c > \hat{c}(\alpha) \) satisfies the essential spectral stability condition (6.6) for any \( a \in \mathbb{R} \) satisfying (6.5).

**Remark 6.3.** The cases (i) and (ii) in Theorem 6.2 depend upon the choices of both the reaction function and the diffusion coefficient. For example, let us consider the cubic polynomial (1.5) with \( \alpha \in (0, 1) \), and the Shigesada function (1.3) with any \( b > 0 \). One can easily verify that
\[
\varrho = \frac{D(\alpha)}{D(1)} = \frac{\alpha^2 + ab}{1 + b}, \quad \vartheta_1^2 = 4(1 + b)(1 - \alpha), \quad \vartheta_\alpha^2 = 4\alpha^2(\alpha + b)(1 - \alpha),
\]
and the condition \( h(\vartheta_\alpha) > 1 - \varrho \) reduces to \( (\alpha + b)(1 + 2\alpha) > 1 + b \).

If we choose \( \alpha = \frac{1}{2} \) and \( b = 1 \), then we clearly have \( h(\vartheta_\alpha) > 1 - \varrho \) (case (i)), and all monotone non-degenerate Nagumo fronts are spectrally stable in some local energy space \( L^2_\alpha \); see Figure 3. However, if we choose \( \alpha = \frac{1}{2} \) and \( b = 1 \), then it is easy to verify that \( h(\vartheta_\alpha) < 1 - \varrho \) (case (ii)), and only sufficiently fast non-degenerate Nagumo fronts, namely, those traveling with speed \( c > \hat{c} \), underlie an essential spectrum which is stable in some exponentially weighted space \( L^2_\alpha \). See Figure 4.

From Theorem 6.2 we deduce the existence of a positive speed \( c_0(\alpha) \geq \varpi(\alpha) \), defined explicitly by
\[
c_0(\alpha) := \begin{cases} \varpi(\alpha), & h(\varpi(\alpha)) > 1 - D(\alpha)/D(1), \\ \hat{c}(\alpha), & \text{otherwise}, \end{cases}
\]
such that all fronts traveling with speed \( c > c_0(\alpha) \) satisfy \( \sigma_{ess}(\mathcal{L})|_{L^2_\alpha} \subset \{ \text{Re} \lambda \leq -\mu_0 < 0 \} \).

**Definition 6.4.** In the non-degenerate Nagumo front case [Nu], we call the front \( \varphi \) *essentially spectrally stable* provided that its speed satisfies \( c > c_0(\alpha) \). In such a case condition (6.5) holds for some \( a \in \mathbb{R} \).
Figure 3. Plot of the function \( h = h(c) \) (panel (a)) defined in (6.4) in the case of the Shigesada diffusion function (1.3) with \( b = 1, \ D(u) = u^2 + u \), and cubic reaction of the form (1.5) with \( \alpha = 0.5 \), for values \( c \in [\tau(\alpha), \infty) \). The numerical value of \( \tau(\alpha) \) is indicated on the axis. Observe that case (i) holds as \( h(c) > 1-\rho \). As a consequence if we plot (see panel (b)) the polynomials \( p = p(a; \alpha) \) and \( p = p(a; 1) \) for values \( c \approx \tau(\alpha) \) in red for values \( c \approx \tau(\alpha)^+ \), then we can always find values of \( a \) such that condition (6.5) holds (color online).

6.2. Point spectral stability in the non-degenerate case. In view of Theorem 6.2, we only need to control the point spectrum of \( L \) on the appropriate energy space \( L^2_a \) to conclude spectral stability of such fronts. More precisely, we need to prove that

\[ \overline{\sigma}_{pt}(L)|_{L^2_a} \subset \{ \text{Re} \lambda \leq 0 \}. \]

First, it is to be observed that \( D(\varphi) \) is a function bounded from above and from below, that is,

\[ 0 < C_0 \leq D(\varphi(x)) \leq C_1, \quad x \in \mathbb{R}, \]

for some uniform \( C_j > 0 \) and by strict ellipticity of the operator \(-L\) (actually, from the monotonicity of \( D \) we have that \( C_0 = D(\alpha) \) and \( C_1 = D(1) \)).

Given that \( \overline{\sigma}_{pt}(L)|_{L^2_a} = \overline{\sigma}_{pt}(L_a)|_{L^2} \), let us then consider the conjugated operator \( L_a : D(L_a) = H^2 \subset L^2 \to L^2 \) defined as

\[ L_a = b_2(x) \partial_x^2 + b_1(x) \partial_x + b_0(x) \text{Id}, \]

where

\[
\begin{align*}
b_2(x) &= D(\varphi), \\
b_1(x) &= 2D(\varphi)x - 2aD(\varphi) + c, \\
b_0(x) &= \alpha^2 D(\varphi) - 2aD(\varphi)x - ac + D(\varphi)_{xx} + f'(\varphi).
\end{align*}
\]

Notice that from hypotheses (1.2), (1.4) and Lemma 2.6, \( b_j \in C^2(\mathbb{R}) \cap L^\infty(\mathbb{R}) \) (smooth enough and bounded coefficients). Let us denote their asymptotic limits as

\[ b_j^\pm := \lim_{x \to \pm \infty} b_j(x), \quad j = 0, 1, 2, \]
Figure 4. Plot of the function $h = h(c)$ (panel (a)) defined in (6.4) in the case of the Shigesada diffusion function (1.3) with $b = 1$, $D(u) = u^2 + u$, and cubic reaction of the form (1.5) with $\alpha = 0.25$, for values $c \in [\bar{c}(\alpha), \infty)$. The numerical value of $\bar{c}(\alpha)$ is indicated on the axis. Observe that case (ii) holds as $h(c) \leq 1 - \rho$ for $c$ near $\bar{c}$. As a consequence if we plot (see panel (b)) the polynomials $p = p(a; \alpha)$ (in orange) and $p = p(a; 1)$ (in red) for values $c \approx \bar{c}(\alpha)$ then condition (6.5) does not hold. Notice, however, that $h(c)$ grows fast near $\bar{c}$ and only for very small positive perturbations of $c$ we do not have stability of the essential spectrum (color online).

or, more precisely,

$$
\begin{align*}
  b_2^+ &= D(\alpha), & b_2^- &= D(1), \\
  b_1^+ &= c - 2aD(\alpha), & b_1^- &= c - 2aD(1), \\
  b_0^+ &= a^2D(\alpha) - ac + f'(\alpha), & b_0^- &= a^2D(1) - ac + f'(1).
\end{align*}
$$

Thanks to the exponential decay of the profile and its derivatives (see Lemma 2.5) the coefficients decay exponentially to their limits and there exist uniform constants $C, \nu > 0$ such that

$$
|b_j(x) - b_j^\pm| \leq Ce^{-\nu|x|}, \quad x \to \pm\infty.
$$

First we verify that, for a suitable exponential weight, the eigenfunction of the linearized operator around the wave associated to the zero eigenvalue transforms into an eigenfunction for the conjugated operator with same eigenvalue.

**Lemma 6.5.** Let $\varphi$ be a non-degenerate, monotone, essentially spectrally stable Nagumo front and let $a \in \mathbb{R}$ be such that condition (6.5) holds. Then $\phi \in H^2$, where

$$
\phi(x) := e^{ax}\varphi_x(x), \quad x \in \mathbb{R}.
$$

Moreover, $\lambda = 0 \in \sigma_{pt}(L_a)_{L^2}$ with associated eigenfunction $\phi \in \ker(L_a) \subset H^2$.

**Proof.** Since $a > 0$ and $\varphi_x \in H^2$ then it is clear that $\phi \in L^2(-\infty, x_0)$ for any fixed $x_0 \in \mathbb{R}$. Likewise, $\phi_x = e^{ax}(\varphi_{xx} + a\varphi_x)$ and $\phi_{xx} = e^{ax}(\varphi_{xxx} + 2a\varphi_{xx} + a^2\varphi_x)$ belong to $L^2(-\infty, x_0)$ as well. We conclude that $\phi \in H^2(-\infty, x_0)$. 
Whence, we only need to verify that $\phi \in H^2(x_0, \infty)$ for some $x_0$. By Lemma 2.5, $\varphi_x$ decays exponentially as $|\varphi_x| \leq C e^{-\eta x}$ when $x \to \infty$, where

$$\eta_1 = (2D(\alpha))^{-1} \left( c + \sqrt{c^2 - 4D(\alpha)f'(\alpha)} \right) = a_2(\alpha) > 0.$$  

Since the end point is a hyperbolic point for the dynamical system and by a bootstrapping argument, it can be shown that $\varphi_x$ and its derivatives decay to zero with the same exponential rate $|\partial_x^j \varphi_x| \leq C e^{-\eta x}$, $j = 0, 1, 2$ as $x \to \infty$. Therefore,

$$\phi(x) \leq e^{ax}|\varphi_x| \leq C e^{(a-\eta)x} \leq C e^{-\eta x},$$

for some $\eta > 0$, inasmuch as $a_1(\alpha) < a < \min\{a_2(\alpha), a_2(1)\}$ by condition (6.5). Therefore, $\phi \in L^2(x_0, \infty)$. In the same fashion,

$$|\varphi_x(x)| = e^{ax}|\varphi_{xx} + a\varphi_x| \leq C e^{-\eta x},$$

as $x \to \infty$ with $C, \eta > 0$. This yields $\phi_x, \phi_{xx} \in L^2(x_0, \infty)$. We conclude that $\phi \in H^2$.

Finally, it is straightforward to verify that $\lambda = 0 \in \widehat{\sigma}_\text{pt}(\mathcal{L}_a)|_{L^2}$ with eigenfunction $\phi \in H^2$ because $\mathcal{L}_a \phi = e^{ax}L e^{-ax} \phi = e^{ax}L \varphi_x = 0$ (see Remark 3.8). This proves the lemma.

Finally, we profit from the boundedness from above and from below of the leading coefficient of the linearized conjugated operator and the regularity assumptions, in order to apply the standard Sturm-Liouville theory and to characterize the isolated point spectrum.

**Theorem 6.6 (point spectral stability; case $[\text{Nn}]$).** Let $\varphi$ be a non-degenerate, monotone, essentially spectrally stable Nagumo front and let $a \in \mathbb{R}$ be such that condition (6.5) holds. Then the isolated point spectrum of the conjugated linearized operator around the front, namely $\widehat{\sigma}_\text{pt}(\mathcal{L}_a)|_{L^2}$, is real, stable and consists of a finite number of simple, isolated eigenvalues which can be enumerated in descending order as

$$0 = \lambda_0 > \lambda_1 > \ldots > \lambda_N.$$

The eigenfunctions can be normalized such that the eigenfunction $\phi_j$ associated to the eigenvalue $\lambda_j$ has exactly $j$ zeros, $j = 0, 1, 2, \ldots$.

**Proof.** From the regularity assumptions on the coefficients, uniform boundedness of $0 \leq c_0 \leq b_2(x) = D(\varphi) \leq C_1$, $C_j > 0$, and exponential decay to finite asymptotic limits, it is then clear that the linearized operator $\mathcal{L}_a$ satisfies hypotheses (i) - (iv) of Theorem A.8 (see section A.2 in the Appendix). In view that $a \in \mathbb{R}$ is such that condition (6.5) holds, by Lemma 6.5 we conclude that the ground state, or first eigenvalue $\lambda_0$, is associated to the eigenfunction $\phi = e^{ax}\varphi_x$, which has no zeros. Hence $\lambda_0 = 0$ and the remaining point spectrum is real and strictly negative. \qed  

6.3. **Proof of Main Theorem 1.1.** Under the hypotheses of Theorem 1.1, consider a traveling front traveling with speed $c$ such that $c > c_0(\alpha)$, where $c_0$ is the threshold speed defined in (6.7). Then apply Theorems 6.2 and 6.6 to conclude the existence of $a \in \mathbb{R}$ satisfying condition (6.5) and for which

$$\sigma(\mathcal{L})|_{L^2} = \sigma_{\text{ess}}(\mathcal{L})|_{L^2} \cup \widehat{\sigma}_\text{pt}(\mathcal{L})|_{L^2} = \sigma_{\text{ess}}(\mathcal{L}_a)|_{L^2} \cup \widehat{\sigma}_\text{pt}(\mathcal{L}_a)|_{L^2}$$

$$\subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq -\mu \} \cup \{ 0 \},$$
with $\mu = \min\{\mu_0(\alpha), |\lambda_1|\} > 0$; $\mu_0(\alpha) > 0$ is the constant of Theorem 6.2 and $\lambda_1 < 0$ is the first non-zero isolated eigenvalue as in Theorem 6.6. The theorem is proved. \qed

7. Stability in the stationary degenerate cases $[sN]$

Let us now consider the case of stationary Nagumo fronts (cases $[sN]$ in Table 1), for which $c = 0$, and either $u_+ = 0$ or $u_- = 0$, that is, they are diffusion degenerate at one of the end points (see Figure 2(a)). In addition, notice that the two end points are stable equilibria of the reaction: $f'(u_\pm) < 0$.

Stationary fronts are special. First, as they connect the two stable states of the reaction, the Fredholm curves of the associated asymptotic operator $L^\pm$, namely,

$$S_{\pm} = \{-D(u_\pm)\xi^2 + f'(u_\pm) : \xi \in \mathbb{R}\} \subset (-\infty, 0),$$

are located in the stable half plane and there is no need to consider a weighted $L^2$ space (i.e. we can set $a = 0$). Since the diffusion is degenerate at one of the end points, however, we cannot immediately conclude the stability of the essential spectrum and we need to use the partition of the spectrum in Definition 3.5. The stability of the end points (as equilibria of the dynamical system) allows us to control the set $\sigma_\delta(L)|_{L^2}$, as we shall see below in Section 7.1. Second, stationary fronts do not decay exponentially on the degenerate side. Yet, due to the fact that the fronts are stationary, it is possible to apply the analysis of Section 5 to obtain energy estimates for solutions to the spectral equation and to conclude the stability of the $L^2$-point spectrum, that is, the set $\sigma_{pr}(L)|_{L^2}$. In other words, the decay properties of these solutions play no role because $c = 0$ and $a = 0$ (Assumption 5.1 is trivially satisfied). Finally, the decay properties of the fronts, although algebraic (see Lemma 2.3), are enough to control the remaining subset of the spectrum, namely $\sigma_{\tau}(L)|_{L^2}$, by showing that the singular sequence in Remark 3.7 disperses its $L^2$-mass to infinity, where the sign of the coefficients of $L$ is known.

7.1. Stability of $\sigma_\delta(L)|_{L^2}$. In view that $f'(u_\pm) < 0$, we do not need to choose any exponential weight, that is, we set $a = 0$. Consider the regularized operator $L^\epsilon$ defined in Section 4.1 with $a = 0$ and $c = 0$, namely

$$L^\epsilon u = (D(\varphi) u)_{xx} + f(\varphi) u,$$

$$L^\epsilon : D(L^\epsilon) = H^2 \subset L^2 \rightarrow L^2.$$

Since $a = 0$ and from the definition of the region of consistent splitting (4.12), we observe that the set

$$\Omega(0, \epsilon) = \{\lambda \in \mathbb{C} : \Re \lambda > \max\{f'(0), f'(1)\}\} = \Omega(0, 0) =: \Omega,$$

is independent of $\epsilon > 0$. Therefore from Lemma 4.2 we know that for every $\lambda \in \Omega$ and all $\epsilon > 0$, the operator $L^\epsilon - \lambda$ is Fredholm with $\text{ind}(L^\epsilon - \lambda) = 0$.

With this information at hand, let us now locate the subset $\sigma_\delta(L)|_{L^2}$ of the compression spectrum.

**Lemma 7.1.** Let $\varphi = \varphi(x)$ be any stationary diffusion-degenerate Nagumo front (cases $[sN]$ in Table 1), and let $L : D(L) = H^2 \subset L^2 \rightarrow L^2$ be the linearized operator around the front. Then

$$\sigma_\delta(L)|_{L^2} \subset \mathbb{C}\setminus\Omega = \{\lambda \in \mathbb{C} : \Re \lambda \leq \max\{f'(0), f'(1)\} < 0\}.$$

That is, $\sigma_\delta(L)|_{L^2}$ is stable.
Proof. First it is to be observed that
\[ \sigma_\delta(\mathcal{L})|_{L^2} \subset \{ \lambda \in \mathbb{C} : \mathcal{L} - \lambda \text{ is semi-Fredholm with } \text{ind}(\mathcal{L} - \lambda) \neq 0 \}. \]
Indeed, if \( \lambda \in \sigma_\delta(\mathcal{L})|_{L^2} \) then from Definition 3.5 we know that \( \mathcal{L} - \lambda : L^2 \to L^2 \) is injective, \( \mathcal{R}(\mathcal{L} - \lambda) \) is closed in \( L^2 \) and \( \mathcal{R}(\mathcal{L} - \lambda) \subseteq \mathcal{R}^\perp \). This implies that \( \text{nul}(\mathcal{L} - \lambda) = 0 \) and consequently \( \mathcal{L} - \lambda \) is semi-Fredholm. Moreover, since \( \text{def}(\mathcal{L} - \lambda) = \text{codim}(\mathcal{L} - \lambda) > 0 \) we have that \( \text{ind}(\mathcal{L} - \lambda) \neq 0 \).

Now suppose that \( \lambda \in \sigma_\delta(\mathcal{L})|_{L^2} \). Then from Lemma 4.9 we conclude that for every \( 0 < \epsilon \ll 1 \) sufficiently small, \( \mathcal{L}^\epsilon - \lambda \) is semi-Fredholm with \( \text{ind}(\mathcal{L}^\epsilon - \lambda) = \text{ind}(\mathcal{L} - \lambda) \neq 0 \). This implies that \( \lambda \not\in \Omega \). The lemma is proved. \( \square \)

7.2. Point spectral stability. In this Section we show that the point spectrum is stable by a direct application of the energy estimate of Section 5. Notice that in the present stationary cases \([s\mathbb{N}_2]\), \( c = 0 \) and by stability of the Fredholm curves (7.1) we work directly with the energy space \( L^2 \) with \( a = 0 \). As a result, Assumption 5.1 is trivially satisfied for any \( \lambda \in \Omega \). Notice that \( \lambda = 0 \in \Omega \) and the hypotheses of Lemma 5.2 hold in our case. Hence we have the following immediate

Corollary 7.2. Let \( \varphi = \varphi(x) \) be any stationary diffusion-degenerate Nagumo front (cases \([s\mathbb{N}_2]\) in Table 1), and let \( \mathcal{L} : \mathcal{D}(\mathcal{L}) = H^2 \subset L^2 \to L^2 \) be the linearized operator around the front. Then for any \( \lambda \in \Omega \) and any solution \( u \in H^2 \) of the spectral equation \( (\mathcal{L} - \lambda)u = 0 \) there holds
\[ \lambda\langle D(\varphi)u, u \rangle_{L^2} = -\|D(\varphi)\varphi_x(u/\varphi_x)\|_{L^2}^2. \] (7.2)

Immediately from equation (7.2) we deduce the following

Corollary 7.3. The \( L^2 \)-point spectrum of the linearized operator around a stationary degenerate Nagumo front is real and non-positive:
\[ \sigma_{\text{pt}}(\mathcal{L})|_{L^2} \subset (-\infty, 0]. \]

7.3. Location of \( \sigma(\mathcal{L})|_{L^2} \). In this section we control the remaining subset of the spectrum, namely, \( \sigma(\mathcal{L})|_{L^2} \).

Lemma 7.4. The \( \sigma(\mathcal{L})|_{L^2} \) spectrum of the linearized operator around a stationary degenerated Nagumo front (cases \([s\mathbb{N}_2]\)) is stable:
\[ \sigma(\mathcal{L})|_{L^2} \subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq 0 \}. \]

Proof. Fix \( \lambda \in \sigma(\mathcal{L})|_{L^2} \). Then from Definition 3.5 the range of \( \mathcal{L} - \lambda \) is not closed and there exists a singular sequence \( u_n \in \mathcal{D}(\mathcal{L}) = H^2 \) with \( \|u_n\|_{L^2} = 1 \), for all \( n \in \mathbb{N} \), such that \( (\mathcal{L} - \lambda)u_n \to 0 \) in \( L^2 \) as \( n \to \infty \) and which has no convergent subsequence. Since \( L^2 \) is a reflexive space, this sequence can be chosen so that \( u_n \to 0 \) in \( L^2 \) (see Remark 3.7).

We claim that there exists a subsequence, still denoted by \( u_n \), such that \( u_n \to 0 \) in \( L^2_{\text{loc}} \) as \( n \to \infty \). Indeed, fix an open bounded interval \( I \) and let \( f_n := (\mathcal{L} - \lambda)u_n \). Then
\[ (b_2(x)\partial_x u_n)_x + b_1(x)\partial_x u_n + (b_0(x) - \lambda)u_n = f_n, \] (7.3)
where
\[ b_2(x) = D(\varphi), \quad b_1(x) = D(\varphi)_x \quad \text{and} \quad b_0(x) = D(\varphi)_{xx} + f'(\varphi). \]
After taking the complex $L^2$-product of last equation with $u_n$, integrating by parts and taking the real part, we obtain

\[
\Re \lambda = -\Re \langle f_n, u_n \rangle_{L^2} - \langle b_2(x) \partial_x u_n, \partial_x u_n \rangle_{L^2} + \langle \langle b_0(x) - \frac{1}{2} \partial_x b_1(x) \rangle u_n, u_n \rangle_{L^2}. \tag{7.4}
\]

This equation together with the hypothesis on $u_n$, $f_n$, $\lambda$ fixed and the strict positivity of $b_2 = D(\varphi)$ on $I$, imply that $u_n$ is bounded in the space $H^1(I)$. Therefore, by the Rellich-Kondrachov theorem there exists a subsequence, still denoted by $u_n$, such that $u_n \to 0$ in $L^2(I)$. By using a standard diagonal argument in increasing intervals, we arrive at a subsequence $u_n$ such that $u_n \to 0$ in $L^2_{loc}$ as $n \to +\infty$.

To prove that $\Re \lambda \leq 0$, observe that, as $f'(0), f'(1) < 0$, we can choose $R > 0$ big enough such that

\[
b_0(x) - \frac{1}{2} \partial_x b_1(x) = \frac{1}{2} D(\varphi)_{xx} + f'(\varphi) < 0 \quad \text{for } |x| \geq R.
\]

Therefore, from $b_2(x) = D(\varphi) \geq 0$ and (7.4) we obtain

\[
\Re \lambda = -\Re \langle f_n, u_n \rangle_{L^2} - \int_R b_2(x) |\partial_x u_n|^2 \, dx + \int_R \langle b_0(x) - \frac{1}{2} \partial_x b_1(x) \rangle |u_n|^2 \, dx
\]

\[
\leq \langle (L - \lambda) u_n \rangle_{L^2} + C \int_{-R}^R (b_0(x) - \frac{1}{2} \partial_x b_1(x)) |u_n|^2 \, dx + \int_{|x| \geq R} (b_0(x) - \frac{1}{2} \partial_x b_1(x)) |u_n|^2 \, dx
\]

\[
\leq \| (L - \lambda) u_n \|_{L^2} + C \| u_n \|_{L^2(-R,R)} \to 0,
\]

as $n \to \infty$, thanks to boundedness of the coefficients, $\| u_n \|_{L^2} = 1$, $(L - \lambda) u_n \to 0$ in $L^2$ and convergence of $u_n$ to zero in $L^2_{loc}$. This shows the lemma. \hfill $\square$

7.4. **Proof of Main Theorem 1.2.** Under the hypotheses of Theorem 1.2, consider a stationary diffusion-degenerate front (case $[sN\geq]$ in Table 1). Then from Lemmata 7.1 and 7.4, as well as from Corollary 7.3, we immediately conclude that

\[
\sigma(L)_{L^2} = \sigma_\delta(L)_{L^2} \cup \sigma_{pt}(L)_{L^2} \cup \sigma_\pi(L)_{L^2} \subset \{ \lambda \in \mathbb{C} : \Re \lambda \leq 0 \}.
\]

The theorem is proved. \hfill $\square$

**Remark 7.5.** Notice that, in cases $[sN\geq]$, we have not proved the existence of a positive spectral gap, which is an important feature when studying the nonlinear stability of the fronts with semigroup methods. This is a limitation of the technique we have used. We conjecture, however, that due to degeneracy there is accumulation of the continuous spectrum near zero. The nonlinear stability of stationary fronts will be addressed in a companion paper [40].

8. **Stability in the monotone degenerate case $[Nd]$**

As a final case, in this section we analyze the spectral stability of the family of monotone, non-stationary, diffusion-degenerate Nagumo fronts (case $[Nd]$ in Table 1), for which

\[
u_+ = \alpha, \quad v_- = 0,
\]

\[
f'(u_+) = f'(\alpha) > 0, \quad f'(v_-) = f'(0) < 0.
\]

Each front $\varphi = \varphi(x)$ is monotone increasing, $\varphi_x > 0$, traveling with positive constant speed

\[
c > \varphi(\alpha) = 2D(\alpha) f'(\alpha) > 0.
\]

The fronts are diffusion degenerate in view that $D(u_-) = D(0) = 0$ and the underlying spectral problem is degenerate. Consequently, we use the partition of spectrum of Definition 3.5. In addition, note that $f'(u_+) = f'(\alpha) > 0$, $f'(u_-) = f'(0) < 0$.\]
proving the stability of the subset of spectrum $\sigma$ around the front is unstable. Therefore, it is necessary to locate the subset of the compression spectrum, $\sigma_\delta$, under both conjugation and parabolic regularization. Section 8.1 is devoted to find the sufficient conditions on the exponential weight so that $\sigma_\delta(L)_{L^2_a}$ gets stabilized. These conditions on $a \in \mathbb{R}$ are crucial in order to verify Assumption 5.1. For that purpose, Section 8.2 establishes the detailed decay structure of solutions to the spectral equation on both the degenerate and the non-degenerate sides. On the non-degenerate side, as $x \to \infty$, the asymptotic coefficient is hyperbolic and we are able to apply the Gap Lemma (cf. [18, 31]) to obtain the exact decay rate of the eigenfunctions. Due to the degeneracy in the asymptotic limit as $x \to -\infty$ and after a detailed description of the eigenfunctions’ decay structure, we find the necessity to impose a further condition on the exponential weight in order to verify Assumption 5.1. In this fashion, under the appropriate exponential weight compatible with the hypotheses of Lemma 5.2, we prove that the point spectrum of the conjugated operator is stable (Section 8.3).

Finally, thanks also to the choice of the proper energy space $L^2_\delta$, in Section 8.4 we prove the stability of the subset of spectrum $\sigma_x$ by showing that singular sequences disperse their $L^2$-mass asymptotically to $\pm \infty$ where the sign of the coefficients of the operator is known. An energy estimate closes the argument.

8.1. Choice of the exponential weight. First, we choose the weight $a \in \mathbb{R}$ that defines the conjugated operator $L_a$ and stabilizes $\sigma_\delta(L)_{L^2_a} = \sigma_\delta(L_a)_{L^2_a}$. In this case the region of consistent splitting is

$$\Omega(a) = \{ \lambda \in \mathbb{C} : \Re \lambda > \max\{D(\alpha)a^2 - ac + f'(\alpha), -ac + f'(0)\} \},$$

for each $a \in \mathbb{R}$.

**Lemma 8.1.** For any $a > 0$, there holds

$$\sigma_\delta(L_a)_{L^2} \subset \mathbb{C} \setminus \Omega(a).$$

**Proof.** Consider the regularized operator $L^*_a : D(L^*_a) = H^2 \subset L^2 \to L^2$ defined in (4.3) (Section 4.1) for some $\epsilon > 0$ and $a > 0$. Let us suppose, by contradiction, that there exists $\lambda_0 \in \sigma_\delta(a) \cap \Omega(a)$. First, observe that $L_a - \lambda_0$ is semi-Fredholm with $\text{ind}(L_a - \lambda_0) \neq 0$. Indeed, if $\lambda_0 \in \sigma_\delta(L_a)$ then, by definition, $L_a - \lambda_0$ is injective, $\mathcal{R}(L_a - \lambda_0)$ is closed and $\mathcal{R}(L_a - \lambda_0) \not\subset L^2$ (see Definition 3.5). This implies that $\text{null}(L_a - \lambda_0) = 0$ and $L_a - \lambda_0$ is semi-Fredholm. Moreover, since $\text{def}(L_a - \lambda_0) = \text{codim}\mathcal{R}(L_a - \lambda_0) > 0$ we conclude that $\text{ind}(L_a - \lambda_0) \neq 0$.

Now, thanks to Lemma 4.6, we deduce the existence of $\epsilon_0 > 0$ sufficiently small such that $L^*_a - \lambda_0$ is semi-Fredholm with $\text{ind}(L^*_a - \lambda_0) = \text{ind}(L_a - \lambda_0) \neq 0$ for each $0 < \epsilon < \epsilon_0$. Now, since $\lambda_0 \in \Omega(a)$ we have

$$\Re \lambda > q_0(\alpha, a) := \max\{D(\alpha)a^2 - ac + f'(\alpha), -ac + f'(0)\}.$$  

In view that $D'(u_\pm) - ac + f'(u_\pm) = ca^2 + D(u_\pm) - ac + f'(u_\pm)$ and $a > 0$, we can always choose $\bar{\epsilon} > 0$ sufficiently small such that

$$0 < \bar{\epsilon} < \frac{1}{2} \min \left\{ \epsilon_0, \frac{\Re \lambda_0 - q_0(\alpha, a)}{a^2} \right\}.$$  

This implies that $\lambda_0 \in \Omega(a, \bar{\epsilon})$ by definition (see (4.12)). Apply Lemma 4.2 to conclude that $L^*_a - \lambda_0$ is Fredholm with $\text{ind}(L^*_a - \lambda_0) = 0$, yielding a contradiction. This proves the lemma. \qed
Henceforth, in order to achieve stability of $\sigma_\delta(\mathcal{L}_a)_{L^2}$ we need to find values of $a > 0$ such that $q_0(a, \alpha) < 0$. In view that $f'(0) < 0$, this happens if and only if $a_1(\alpha) < a < a_2(\alpha)$, where $a_1(\alpha)$ and $a_2(\alpha)$ are the roots of
\[ p(a; \alpha) := D(\alpha)a^2 - ac + f'(\alpha) = 0, \] namely,
\[ a_1(\alpha) = \frac{1}{2D(\alpha)} \left( c - \sqrt{c^2 - 4D(\alpha)f'(\alpha)} \right), \]
\[ a_2(\alpha) = \frac{1}{2D(\alpha)} \left( c + \sqrt{c^2 - 4D(\alpha)f'(\alpha)} \right). \]
Observe that $0 < a_1(\alpha) < a_2(\alpha)$, inasmuch as $c > \bar{c}(\alpha)$. We conclude that it suffices to take $0 < a_1(\alpha) < a < a_2(\alpha)$ to stabilize $\sigma_\delta(\mathcal{L}_a)_{L^2}$. We have thus proved the following

**Lemma 8.2.** In the monotone degenerate case [Nd], for each value of $a \in \mathbb{R}$ such that
\[ 0 < a_1(\alpha) < a < a_2(\alpha), \] the set $\sigma_\delta(\mathcal{L}_a)_{L^2}$ is stable, more precisely,
\[ \sigma_\delta(\mathcal{L}_a)_{L^2} \subset \mathbb{C}\setminus\Omega(a) = \{ \lambda \in \mathbb{C} : \Re \lambda \leq -\mu_0 < 0 \}, \]
where $\mu_0 = -\max\{ D(\alpha)a^2 - ac + f'(\alpha), -ac + f'(0) \} > 0$.

### 8.2. Decay structure of solutions

In this section we show that there exists $a \in \mathbb{R}$ satisfying condition (8.2) for which, in addition, Assumption 5.1 holds. This implies, in turn, that the change of variables (5.6) satisfies the hypotheses of Lemma 5.2 in the present degenerate case [Nd]. For that purpose, we examine the decay properties of solutions to the spectral equation.

Let us suppose that for a given fixed $a \in \mathbb{R}$ and $\lambda \in \Omega(a)$ there exists a solution $u \in H^2$ to the spectral equation $(\mathcal{L}_a - \lambda)u = 0$. Let us write the change of variables (5.6) as
\[ w(x) = e^{-\theta(x)}u(x) = \Theta(x)u(x), \quad x \in \mathbb{R}, \]
where
\[ \Theta(x) := \exp \left( c \int_{x_0}^x \frac{ds}{D(\varphi(s))} - a(x - x_0) \right) u(x), \quad x \in \mathbb{R}, \] (8.3)
and $\theta = \theta(x)$ is defined in (5.4). Here $x_0 \in \mathbb{R}$ is fixed but arbitrary. Since $\Theta$ is smooth, it is clear that if $u \in H^2$ then $w \in H^2(-x_0, x_0)$ for any finite $x_0 \in \mathbb{R}$. Hence, in order to show that $w \in H^2$, it suffices to prove that $w$ decays sufficiently fast as $x \to \pm \infty$. We shall show that if we impose further conditions on $a$ then we can guarantee this behavior.

Let us first examine the decay on the non-degenerate side as $x \to +\infty$.

#### 8.2.1. Behavior at $+\infty$.

The asymptotic decay properties of $u \in H^2$ as a solution to $(\mathcal{L}_a - \lambda)u = 0$ are determined by those of $w \in H^1 \times H^1$, solution to
\[ w_x = A_a(x, \lambda)w, \quad w = \begin{pmatrix} u \\ u_x \end{pmatrix}, \] (8.4)
where the variable coefficient matrices are given by
\[ A_a(x, \lambda) = \begin{pmatrix} 0 & 1 \\ D(\varphi)^{-1}(\lambda - b_{0,a}(x)) & -D(\varphi)^{-1}b_{1,a}(x) \end{pmatrix}, \]
\[ b_{1,a}(x) = 2D(\varphi)_x + c - 2aD(\varphi), \]
\[ b_{0,a}(x) = a^2D(\varphi)_x - ac + D(\varphi)_{xx} + f'(\varphi) \]
(see expressions (4.8) - (4.9) with \( \epsilon = 0 \)). On the non-degenerate side the asymptotic constant coefficients are well-defined and hyperbolic,

\[
A_a^+(\lambda) = \lim_{x \to +\infty} A_a(x, \lambda) = \begin{pmatrix} 0 & 1 \\ \frac{\lambda - p(a; \alpha)}{D(\alpha)} & 2a - \frac{c}{D(\alpha)} \end{pmatrix},
\]
(8.5)

and the associated asymptotic system is

\[ v_x = A_a^+(\lambda)v. \]
(8.6)

To determine the decaying properties of \( w \) we invoke the Gap Lemma of Gardner and Zumbrun [18] and Kapitula and Sandstede [31] (see also [44, 43, 60, 80, 81] for its different versions, further information and direct applications), which relates the decay structure of solutions of the variable coefficient system (8.4) to those of the asymptotic constant coefficient system (8.6), provided that \( A_a(x, \lambda) \) approaches \( A_a^+(\lambda) \) exponentially fast as \( x \to +\infty \). For the precise statement of the Gap Lemma we refer the reader to Lemma A.11 in [80] or Appendix C in [43].

First we need to prove the following auxiliary result.

**Lemma 8.3.** Given \( a > 0 \) suppose that \( \lambda \in \Omega(a) \). Then the decaying eigenvalue of \( A_a^+(\lambda) \) is given by

\[ \mu_1^+(\lambda) = a - \frac{c}{2D(\alpha)} - \frac{1}{2} \zeta^+(\lambda)^{1/2}, \]
(8.7)

where the discriminant

\[ \zeta^+(\lambda) := \left( \frac{c}{D(\alpha)} - 2a \right)^2 + \frac{4(\lambda - p(a; \alpha))}{D(\alpha)}, \]
(8.8)

is an analytic function of \( \lambda \in \Omega(a) \) and \( p(a; \alpha) \) is defined in (8.1).

**Proof.** By a straightforward computation one easily finds that the eigenvalues of (8.5) are

\[ \mu_j^+(\lambda) = a - \frac{c}{2D(\alpha)} + z_j^+(\lambda), \quad j = 1, 2, \]

where

\[ z_1^+(\lambda) = -\frac{1}{2} \zeta^+(\lambda)^{1/2}, \quad z_2^+(\lambda) = \frac{1}{2} \zeta^+(\lambda)^{1/2}. \]

Clearly, the discriminant \( \zeta^+(\lambda) \) is linear in \( \lambda \) and, hence, analytic in \( \lambda \in \Omega(a) \). Therefore, here \( \zeta^+(\lambda)^{1/2} \) denotes the principal branch of the square root and it is analytic in \( \lambda \in \Omega(a) \) as well.

Now, we know from Lemma 4.1 that for \( \lambda \in \mathbb{R}, \lambda \gg 1 \) sufficiently large, the only eigenvalue with negative real part is \( \mu_1^+(\lambda) \). Since the set of sufficiently large real numbers is contained in the connected set \( \Omega(a) \) (this is evident by definition of \( \Omega(a) \)), and since the eigenvalues are continuous (actually, analytic) in \( \lambda \in \Omega(a) \), we conclude that \( \text{Re} \mu_1^+(\lambda) < 0 \) for all \( \lambda \in \Omega(a) \) and that \( \mu_1^+(\lambda) \) is the only decaying mode of \( A_a^+(\lambda) \). Otherwise the hyperbolicity (and consequently, the consistent splitting at \( +\infty \)) would be violated. This shows the result. \( \square \)
It is to be observed that, thanks to the exponential decay of the front at the non-degenerate side (see Lemma 2.4), one readily obtains

\[|A_a(x, \lambda) - A_{a0}^+(\lambda)| \leq Ce^{-\eta x},\]

as \(x \to +\infty\) for some \(C, \eta > 0\) and uniformly in \(\lambda \in \Omega(a)\) (due to hyperbolicity). Henceforth, we are able to apply the Gap Lemma and to conclude that the decaying solution to the variable coefficient equation (8.4) behaves as

\[w(x,\lambda) = e^{\mu_1^+(\lambda)x}(v_1^+(\lambda) + O(e^{-\eta|x|}|v_1^+(\lambda)|)), \quad x > 0,
\]

where \(v_1^+(\lambda)\) denotes the eigenvector of \(A_{a0}^+(\lambda)\) associated to the decaying eigenmode \(\mu_1^+(\lambda)\) with \(\Re \mu_1^+(\lambda) < 0\). This implies, in turn, that \(u\) and \(u_x\) decay at most as

\[|u|, |u_x| \leq C_1 e^{\Re \mu_1^+(\lambda)x} \to 0,
\]

for some \(C_1 > 0\) as \(x \to +\infty\), for \(\lambda \in \Omega(a)\). Use the spectral equation,

\[u_{xx} = \frac{1}{D(x)} (b_{1,a}(x)u_x + b_{0,a}(x)u) - \lambda u,
\]

and the boundedness of the coefficients on the non-degenerate side to observe that

\[|u_{xx}| \leq C(1 + |\lambda|)e^{\Re \mu_1^+(\lambda)x} = C_2(\lambda)e^{\Re \mu_1^+(\lambda)x} \to 0,
\]

as \(x \to +\infty\), for some \(C_2 = C_2(\lambda) > 0\). Thus, \(u_{xx}\) also decays exponentially fast. We use this information to prove the following

**Lemma 8.4.** Given \(a > 0\) and any fixed \(\lambda \in \Omega(a)\), if \(u \in H^2\) is a solution to the spectral equation \((L_a - \lambda)u = 0\) then the function \(w(x) = \Theta(x)u(x)\) belongs to \(H^2(\Omega_a, \infty)\) for \(x_0 \gg 1\) sufficiently large, where \(\Theta = \Theta(x)\) is defined in (8.3).

**Proof.** It suffices to show that \(w\) and its derivatives decay sufficiently fast as \(x \to \infty\). First denote

\[\Re \mu_1^+(\lambda) = a - \frac{c}{2D(\alpha)} - r^+(\lambda) < 0,
\]

where

\[r^+(\lambda) := \frac{1}{2} \Re \zeta^+(\lambda)^{1/2} = \frac{1}{2\sqrt{2}} \sqrt{\Re \zeta^+(\lambda) + |\zeta^+(\lambda)|} > 0.
\]

Now, we estimate

\[\Theta(x)e^{\Re \mu_1^+(\lambda)x} = e^{-\theta(x)}e^{\Re \mu_1^+(\lambda)x}
\]

\[= \exp\left(\frac{c}{2} \int_{x_0}^{x} \frac{ds}{D(\varphi(s))} - a(x-x_0)\right) \exp\left((a - \frac{c}{2D(\alpha)})x_0\right) \times
\]

\[\times \exp\left((a - \frac{c}{2D(\alpha)}) (x-x_0)\right) \exp\left(-r^+(\lambda)x_0\right) \times
\]

\[\times \exp\left(-r^+(\lambda)(x-x_0)\right)
\]

\[\leq C_0(\lambda) \exp\left(\frac{c}{2} \int_{x_0}^{x} \frac{ds}{D(\varphi(s))} - \frac{c}{2D(\alpha)} (x-x_0)\right) \exp\left(-r^+(\lambda)(x-x_0)\right),
\]

for some \(C_0 = C_0(\lambda) > 0\).

Let us define

\[\chi(x) := \frac{c}{2} \int_{x_0}^{x} \left(\frac{1}{D(\varphi(y))} - \frac{1}{D(\alpha)}\right) dy - r^+(\lambda)(x-x_0),
\]
so that
\[ \Theta(x)e^{\Re \mu^+(\lambda)x} = e^{-\theta(x)}e^{\Re \mu^+(\lambda)x} \leq C_0(\lambda)e^{\lambda(x)}, \]
for fixed \( \lambda \in \Omega(a) \). From Lemma 2.4 we have that
\[ \alpha - \varphi(x) = |\alpha - \varphi(x)| \leq Ce^{-\eta x}, \]
as \( x \to +\infty \). Thus, after a Taylor expansion that reads
\[ \frac{1}{D(\varphi)} - \frac{1}{D(\alpha)} = \frac{D'(\alpha)}{D^2(\alpha)}(\alpha - \varphi) + O(|\alpha - \varphi|^2) \leq C_1(\alpha - \varphi), \]
for \( \varphi \uparrow \alpha^- \), we arrive at
\[ \frac{c}{2} \int_{x_0}^{x} \left( \frac{1}{D^{(\varphi)(y)}} - \frac{1}{D^{(\alpha)}} \right) dy \leq \frac{cC_1}{2\eta} (e^{-\eta x_0} - e^{-\eta x}) = C_2(e^{-\eta x_0} - e^{-\eta x}), \]
for \( x > x_0 \gg 1 \), sufficiently large. Hence,
\[ \chi(x) \leq C_2(e^{-\eta x_0} - e^{-\eta x}) - r^+(\lambda)(x-x_0) \leq C_2e^{-\eta x_0} - r^+(\lambda)(x-x_0), \]
yielding
\[ e^{\lambda(x)} = \exp(C_2e^{-\eta x_0})e^{-r^+(\lambda)(x-x_0)} \leq C_3e^{-r^+(\lambda)(x-x_0)}. \]
Thus, we have proved the decay estimate
\[ \Theta(x)e^{\Re \mu^+(\lambda)x} = e^{-\theta(x)}e^{\Re \mu^+(\lambda)x} \leq C(\lambda)e^{-r^+(\lambda)(x-x_0)} \to 0, \]
as \( x \to +\infty \) for some \( C(\lambda) > 0 \) with \( \lambda \in \Omega(a) \) fixed.

Now, since
\[ w = e^{-\theta}u, \]
\[ w_x = e^{-\theta}(u_x - \theta_x u), \]
\[ w_{xx} = e^{-\theta}(u_{xx} - 2\theta_x u_x + (\theta_x^2 - \theta_{xx})u), \]
and noticing that
\[ \theta_x = \alpha - \frac{c}{2D(\varphi)}, \quad \theta_{xx} = \frac{cD'(\varphi)\varphi_x}{2D(\varphi)^2}, \]
are uniformly bounded on the non-degenerate side (as \( D(\varphi) \to D(\alpha) > 0 \)), we apply estimates (8.9) and (8.10) to arrive at
\[ |w|, |w_x|, |w_{xx}| \leq C(\lambda)e^{-r^+(\lambda)x} \to 0, \]
as \( x \to +\infty \). This shows that \( w \in H^2(x_0, +\infty) \), as claimed. \( \square \)

8.2.2. Behavior at \(-\infty\). On the degenerate side, however, we lose hyperbolicity of the asymptotic matrix coefficient and we are not able to apply the Gap Lemma. To guarantee that \( w \in H^2(-\infty, x_0) \) we need to impose a further condition on \( a \in \mathbb{R} \). This is the content of the following

**Lemma 8.5.** Let \( a \in \mathbb{R} \) satisfy the condition
\[ 0 < a_1(\alpha) < a < \frac{c}{2D(\alpha)} < a_2(\alpha). \] (8.11)

Then for any solution \( u \in H^2 \) to the spectral equation \( (\mathcal{L}_a - \lambda)u = 0 \) with \( \lambda \in \Omega(a) \) the function \( w(x) = \Theta(x)u(x) \) belongs to \( H^2(-\infty, x_0) \) for any \( x_0 < 0, |x_0| \gg 1 \) sufficiently large.
Proof. We know that $D(\alpha) > D(\varphi(x)) > 0$ for all $x \in \mathbb{R}$. Therefore, condition (8.11) clearly implies that
\[
\int_{x_0}^{x} \left( \frac{c}{2D(\varphi(y))} - a \right) dy < 0,
\]
if $x < 0$, inasmuch as $c/2D(\varphi) - a > 0$. This shows that $0 < \Theta(x) < 1$ if $x < x_0$ for $x_0$ fixed but arbitrary, which includes the case when $x \to -\infty$. Therefore,
\[
|w(x)|^2 = |\Theta(x)|^2|u(x)|^2 \leq |u(x)|^2,
\]
yielding $w \in L^2(-\infty, x_0)$. Now, $w_x = \Theta_x u + \Theta u_x$. Since $u \in H^2$ it is then clear that $\Theta u_x \in L^2(-\infty, x_0)$. Let us now compute
\[
\Theta_x = \left( \frac{c}{2D(\varphi(x))} - a \right) \Theta(x).
\]
On the degenerate side $D(\varphi)$ decays to zero as $\varphi \to 0^+$. Moreover, we have proved that $\varphi \to 0^+$ as $x \to -\infty$ at rate $O(\exp(|f'(0)|x/c))$ (see Lemma 2.4). Therefore, we make expansions around $\varphi = 0$ of the form
\[
\frac{1}{D(\varphi)} = \frac{1}{D'(0)\varphi} + O(1),
\]
as $\varphi \to 0^+$.

Hence, from $0 < \varphi(x) \leq C \exp(|f'(0)|x/c)$ when $x \to -\infty$ and some $C > 0$ we obtain the bound
\[
\int_{x_0}^{x} \frac{dy}{\varphi(y)} \leq C_1 \int_{x_0}^{x} \exp\left(-|f'(0)|y/c\right) dy,
\]
for $x < x_0 < 0$, $|x_0| \gg 1$ large enough and some uniform $C_1 > 0$. Substituting the expansion for $D(\varphi)^{-1}$ for $x < x_0 < 0$ with $|x_0| \gg 1$ we arrive at
\[
\frac{c}{2} \int_{x_0}^{x} \frac{dy}{D(\varphi(y))} - a(x - x_0) \leq \frac{c}{2} \int_{x_0}^{x} \left( \frac{1}{D'(0)\varphi(y)} + C_2 \right) dy - a(x - x_0)
\]
\[
\leq \frac{cC_1}{2D'(0)} \int_{x_0}^{x} \exp\left(-|f'(0)|y/c\right) dy + C_3(x - x_0)
\]
\[
= \frac{c^2C_1}{2D'(0)|f'(0)|} \left(e^{-|f'(0)|x_0/c} - e^{-|f'(0)|x/c} - C_3|x - x_0|\right),
\]
for all $x < x_0 \ll -1$ and with uniform constants $C_j > 0$. This implies that
\[
0 < \Theta(x) \leq \exp\left(-C_4e^{-|f'(0)|x_0/c} - C_5|x - x_0|\right) \leq \exp\left(-C_4e^{-|f'(0)|x_0/c}\right) \to 0,
\]
as $x \to -\infty$ for some $C_4 > 0$.

Now, in view that $\varphi \sim C_0 \exp(|f'(0)|x/c)$ asymptotically as $x \to -\infty$ (see (2.12)), use
\[
\frac{1}{C_0^2} \varphi(x) e^{-|f'(0)|x/c} \to 1, \quad \text{as} \quad x \to -\infty,
\]
and the expansion (8.12) to show that
\[
|\Theta_x| \leq \left| \frac{c}{2D'(0)\varphi(x)} + a \right| \exp\left(-C_4e^{-|f'(0)|x/c}\right) \leq \frac{C_6e^{-|f'(0)|x/c}}{\exp(C_4e^{-|f'(0)|x/c})} \to 0,
\]
as $x \to -\infty$. Therefore, we readily conclude that $w_x = \Theta_x u + \Theta u_x \in L^2(-\infty, x_0)$ for $x_0 \ll -1$. 
In a similar fashion it can be proved that \( \Theta_x D(\varphi)^{-1} \) and \( \varphi_x \Theta D(\varphi)^{-2} \) are bounded above as \( x \to -\infty \), due to the fast decay of \( \Theta = O(\exp(-Ce^{-kx})) \) as \( x \to -\infty \), with appropriate constants \( C, k > 0 \). Details are left to the reader. This analysis shows, in turn, that \( w_{xx} = \Theta_{xx} u + 2\Theta_x u_x + \Theta u_{xx} \in L^2(-\infty, x_0) \) as well. We conclude that \( w \in H^2(-\infty, x_0) \), as claimed. \( \square \)

8.3. Point spectral stability in the monotone degenerate case. The decay estimates of Section 8.2, as well as the establishment of inequality (8.11) for the exponential weight, are the key ingredients to show that the point spectrum of the conjugated operator is stable. First we verify that for any \( a \in \mathbb{R} \) satisfying (8.11) the eigenfunction of the linearized operator around the wave associated to the zero eigenvalue transforms, under multiplication by \( e^{ax} \), into an eigenfunction for the conjugated operator with same eigenvalue.

**Lemma 8.6.** Let \( \varphi \) be a degenerate, monotone Nagumo front traveling with speed \( c > \sigma(\alpha) \) (case [Nd]), and let \( a \in \mathbb{R} \) be such that condition (8.11) holds. Then the function
\[
\phi(x) := e^{ax} \varphi(x), \quad x \in \mathbb{R},
\]
belongs to \( H^2(\mathbb{R}) \). Moreover, \( \lambda = 0 \in \sigma_{pt}(\mathcal{L}_a|_{L^2}) \) with associated eigenfunction \( \phi \in \ker(\mathcal{L}_a) \subset H^2 \).

**Proof.** On the non-degenerate side as \( \varphi \to \alpha \) when \( x \to \infty \), the front and its derivatives decay asymptotically as (see Lemmata 2.4 and 2.6)
\[
|\partial_j^2 (\varphi - \alpha)| \leq Ce^{-a_2(\alpha)x},
\]
for \( j = 0, 1, 2, 3 \). By hypothesis, \( a \in \mathbb{R} \) satisfies (8.11). Thus, \( a > a(\alpha) \) and then it is clear that
\[
\begin{align*}
\phi &= e^{ax} \varphi, \\
\phi_x &= e^{ax} (a \varphi_x + \varphi_{xx}), \\
\phi_{xx} &= e^{ax} (a^2 \varphi_x + 2a \varphi_{xx} + \varphi_{xxx}),
\end{align*}
\]
decay exponentially to zero when \( x \to \infty \) with rate \( |\partial_j^2 \phi| \leq Ce^{-\nu x} \) for all \( j \) and where \( \nu := a_2(\alpha) - a > 0 \).

On the degenerate side as \( \varphi \to 0 \) when \( x \to -\infty \) the front and its derivatives decay exponentially as (see Lemma 2.4)
\[
|\partial_j^2 \varphi| \leq Ce^{(|f(0)|x/c)},
\]
for \( j = 0, 1, 2, 3 \). Thus, since \( a > 0 \) it is then straightforward to observe that \( \phi \) and its derivatives decay exponentially as well, in view that
\[
|e^{ax} \varphi_x|, |e^{ax} \varphi_{xx}|, \quad |e^{ax} \varphi_{xxx}| \leq Ce^{(|f(0)|x/c)} \rightarrow 0,
\]
as \( x \to -\infty \). Since the front is at least of class \( C^4 \), the exponential decay of \( \phi \) and its derivatives at \( x = \pm \infty \) is sufficient to conclude that \( \phi \in H^2(\mathbb{R}) \).

Finally, notice that \( \lambda = 0 \in \sigma_{pt}(\mathcal{L}_a) \) with associated eigenfunction \( \phi \in H^2 \) because \( \mathcal{L}_a \phi = e^{ax} \mathcal{L} e^{-ax} \phi = e^{ax} \mathcal{L} \varphi = 0 \). This proves the lemma. \( \square \)

**Theorem 8.7** (point spectral stability; case [Nd]). Let \( \varphi \) be a diffusion-degenerate monotone Nagumo front of Table 1 traveling with speed \( c > \sigma(\alpha) \) (case [Nd]). If \( a \in \mathbb{R} \) satisfies inequality (8.11) then the conjugated linearized operator around the wave is point spectrally stable in \( L^2 \). More precisely,
\[
\sigma_{pt}(\mathcal{L}_a|_{L^2}) \subset (-\infty, 0].
\]
Proof. By definition of \( \sigma_{pt} \) (see Definition 3.5), if \( \lambda \in \sigma_{pt}(L_a)_{L^2} \) then there exists \( u \in H^2 \) such that \( (L_a - \lambda)u = 0 \). Now let \( \lambda \in \sigma_{pt}(L_a)_{L^2} \cap \Omega(a) \). For each \( x \in \mathbb{R} \) let us define \( w = w(x) \) as in (5.6), where \( u \in H^2 \) is a solution to the spectral equation. Pick \( x_0 \in \mathbb{R} \), \( x_0 > 1 \) sufficiently large. Hence, if \( a \in \mathbb{R} \) satisfies condition (8.11) then we apply Lemmata 8.5 and 8.4 to reckon
\[
\begin{align*}
w(x) &= \exp \left( c \int_{x_0}^{x} \frac{dy}{D(\varphi(y))} - a(x - x_0) \right) u(x) \in H^2(x_0, \infty), \\
&= C_0 \exp \left( \int_{-x_0}^{x} \left( \frac{c}{2D(\varphi(y))} - a \right) dy \right) u(x) \in H^2(-\infty, -x_0).
\end{align*}
\]

Since for any finite \( x_0 \in \mathbb{R} \) we clearly have \( w \in H^2(-x_0, x_0) \), we conclude that \( w \in H^2(\mathbb{R}) \) and Assumption 5.1 holds. Moreover, it is to be observed that under condition (8.11) we have
\[
\Omega(a) \subset \{ \text{Re} \lambda > -\mu_0 \} \subset \{ \text{Re} \lambda \leq 0 \},
\]
where \( \mu_0 > 0 \) (see Lemma 8.2). Therefore, \( 0 \in \Omega(a) \). Also thanks to Lemma 8.6, \( \phi = e^t \varphi_x \) is the eigenfunction of \( L_a \) associated to the zero eigenvalue, and Assumption 5.1 is also valid for \( \psi = e^{-t} \phi \). Henceforth, all the hypotheses of Lemma 5.2 are satisfied. We conclude that for each \( \lambda \in \sigma_{pt}(L_a)_{L^2} \cap \Omega(a) \) the basic energy estimate (5.7) holds yielding \( \sigma_{pt}(L_a)_{L^2} \subset (-\infty, 0] \), as claimed. \( \square \)

8.4. Location of \( \sigma_\pi(L_a)_{L^2} \). In this section we locate the subset of the approximate spectrum, namely \( \sigma_\pi(L_a)_{L^2} \) in the stable half plane. The arguments are very similar to those of Section 7.3 in the stationary case. For a given \( a \in \mathbb{R} \) satisfying (8.11) let us write the conjugated operator (4.5), \( L_a : D(L_a) = H^2 \subset L^2 \rightarrow L^2 \), as
\[
L_a u = (b_2(x)u_x)_x + b_1(x)u_x + b_0(x)u, \quad u \in H^2,
\]
where
\[
\begin{align*}
b_2(x) &= D(\varphi), \\
b_1(x) &= D(\varphi)_x - 2aD(\varphi) + c, \\
b_0(x) &= a^2D(\varphi) - 2aD(\varphi)_x - ac + D(\varphi)_{xx} + f'(\varphi).
\end{align*}
\]

Let us denote,
\[
\begin{align*}
b_j^+ &:= \lim_{x \to \pm \infty} b_j(x), \quad j = 0, 1, 2, \\
b_2^- &:= 0, \\
b_1^+ &= c - 2aD(\alpha), \quad b_1^- = c, \\
b_0^+ &= a^2D(\alpha) - ac + f'(\alpha), \quad b_0^- = f'(1) - ac.
\end{align*}
\]

Lemma 8.8. Suppose that \( a \in \mathbb{R} \) satisfies condition (8.11). Then the \( \sigma_\pi(L_a)_{L^2} \) spectrum of the linearized operator around a degenerate Nagumo front (case [Nd]) is stable:
\[
\sigma_\pi(L_a)_{L^2} \subset \{ \lambda \in \mathbb{C} : \text{Re} \lambda \leq 0 \}.
\]

Proof. Let \( \lambda \in \sigma_\pi(L_a)_{L^2} \) be fixed. Then the range of \( L_a - \lambda \) is not closed and there exists a singular sequence \( u_n \in D(L) = H^2 \) with \( \|u_n\|_{L^2} = 1 \), for all \( n \in \mathbb{N} \), such that \( (L_a - \lambda)u_n \rightarrow 0 \) in \( L^2 \) and \( u_n \rightarrow 0 \) in \( L^2 \) as \( n \rightarrow \infty \) (see Remark 3.7). Set \( f_n := (L_a - \lambda)u_n \).
Take the complex $L^2$-product of $(\mathcal{L}_a - \lambda)u_n = f_n$ with $u_n$, integrate by parts and take the real part. The result is

$$\text{Re}\lambda = \text{Re}(f_n, u_n)_{L^2} - \langle b_2(x) \partial_x u_n, \partial_x u_n \rangle_{L^2} + \langle (b_0(x) - \frac{1}{2} \partial_x b_1(x))u_n, u_n \rangle_{L^2}.$$  

(8.13)

Like in the proof of Lemma 7.4, this equation together with the hypothesis on $u_n$, $f_n$, $\lambda$ fixed and the strict positivity of $b_2 = D(\varphi)$ on compact intervals, imply that there exists a subsequence, still denoted by $u_n$, such that $u_n \to 0$ in $L^2_{\text{loc}}$ as $n \to +\infty$.

Since

$$b_0(x) - \frac{1}{2} \partial_x b_1(x) = a^2 D(\varphi) - aD(\varphi)x - ac + \frac{1}{2} D(\varphi)_{xx} + f'(\varphi)$$

$$\to a^2 D(u_\pm) - ac + f'(u_\pm),$$

as $x \to \pm \infty$, thanks to the fact that $a \in \mathbb{R}$ satisfies (8.11) we can choose $R > 0$ sufficiently large such that

$$b_0(x) - \frac{1}{2} \partial_x b_1(x) = \frac{1}{2} D(\varphi)_{xx} + f'(\varphi) < 0 \quad \text{for } |x| \geq R.$$  

Hence, from $b_2(x) = D(\varphi)_x \geq 0$ and (8.13) we get

$$\text{Re}\lambda \leq (f_n, u_n)_{L^2} + \int_{-R}^{R} (b_0(x) - \frac{1}{2} \partial_x b_1(x))|u_n|^2 dx + \int_{|x| \geq R} (b_0(x) - \frac{1}{2} \partial_x b_1(x))|u_n|^2 dx$$

$$\leq ||(\mathcal{L} - \lambda)u_n||_{L^2} + C||u_n||_{L^2_{\text{loc}}} \to 0,$$

as $n \to \infty$, thanks to boundedness of the coefficients, $||u_n||_{L^2} = 1$, $(\mathcal{L} - \lambda)u_n \to 0$ in $L^2$ and convergence of $u_n$ to zero in $L^2_{\text{loc}}$. The lemma is proved.

\[\square\]

8.5. **Proof of Main Theorem 1.3.** Under the hypotheses of Theorem 1.3, choose any $a \in \mathbb{R}$ such that condition (8.11) holds. More precisely,

$$0 < a_1(\alpha) < a < \frac{c}{2D(\alpha)} < a_2(\alpha).$$

Then apply Theorem 8.7 and Lemmata 8.1 and 8.8 in order to obtain

$$\sigma(\mathcal{L})_{L^2} = \sigma_{\text{pt}}(\mathcal{L}_a)_{L^2} = \sigma_{\text{pt}}(\mathcal{L}_a)_{L^2} \cup \sigma_{\delta}(\mathcal{L}_a)_{L^2} \cup \sigma(\mathcal{L}_a)_{L^2} \subset \{\lambda \in \mathbb{C} : \text{Re } \lambda < 0\},$$

as claimed. This proves the Theorem.

\[\square\]

**Appendix A. Remarks on the Spectral Theory of Linear Differential Operators**

For convenience of the reader, in this section we gather some known facts of the spectral theory of linear differential operators. For more information the reader is referred to [12, 32, 53, 54, 74, 75, 77].
A.1. **Differential operators on the real line.** Consider a linear differential operator of the form
\[
\mathcal{L} : \mathcal{D}(\mathcal{L}) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R}),
\]
\[
\mathcal{L} = b_m(x)\partial_x^m + \ldots + b_1(x)\partial_x + b_0(x)\text{Id},
\]
(A.1)
where \( m \geq 1 \) denotes the order of the operator and \( x \in \mathbb{R} \) is the spatial variable. It is assumed that the coefficients are real, smooth enough and uniformly bounded, that they have finite asymptotic limits at \( x = \pm \infty \) and that \( b_m \) is non-negative; more precisely, that
\[
b_j \in C^m(\mathbb{R}) \cap L^\infty(\mathbb{R}), \quad 0 \leq j \leq m,
\]
\[
\partial^k b_j \in L^\infty(\mathbb{R}), \quad 1 \leq j, k \leq m,
\]
\[
b_j^\pm := \lim_{x \to \pm \infty} b_j(x) \in \mathbb{R}, \quad 0 \leq j \leq m,
\]
(A.2)
and \( b_m(x) \geq 0 \), for all \( x \in \mathbb{R} \).

The domain \( \mathcal{D}(\mathcal{L}) \) is supposed to be a dense subspace of \( L^2(\mathbb{R}) \) and, consequently, \( \mathcal{L} : L^2 \to L^2 \) is densely defined. For example, let us consider
\[
\mathcal{D}(\mathcal{L}) = H^m(\mathbb{R}),
\]
which is clearly dense in \( L^2(\mathbb{R}) \).

We remind the reader that if \( \mathcal{L} \) and \( \mathcal{T} \) are linear operators from \( X \) to \( Y \) (Banach spaces) such that \( \mathcal{D}(\mathcal{L}) \subset \mathcal{D}(\mathcal{T}) \) and \( \mathcal{L} u = \mathcal{T} u \) for all \( u \in \mathcal{D}(\mathcal{L}) \), then \( \mathcal{T} \) is called an extension of \( \mathcal{L} \) (denoted \( \mathcal{T} \supset \mathcal{L} \)) and \( \mathcal{L} \) is called a restriction of \( \mathcal{T} \) (denoted \( \mathcal{L} \subset \mathcal{T} \)); cf. [12, 32]. An operator \( \mathcal{T} \) from \( X \) to \( Y \) is closable if \( \mathcal{T} \) has a closed extension. \( \overline{\mathcal{T}} \) is the smallest closed extension of \( \mathcal{T} \) if any other closed extension of \( \mathcal{T} \) is also an extension of \( \overline{\mathcal{T}} \).

**Proposition A.1.** Under assumptions (A.2), \( \mathcal{L} : \mathcal{D}(\mathcal{L}) = H^m(\mathbb{R}) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R}) \) given in (A.1) is a closable operator.

**Proof.** Since \( L^2 \) is a reflexive Hilbert space we identify \( L^2 \) with its dual. Thus, the formal adjoint of \( \mathcal{L} \), given by
\[
\mathcal{L}^* : \mathcal{D}(\mathcal{L}^*) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R}),
\]
\[
\mathcal{L}^* v = \sum_{k=0}^{m} (-1)^k \partial^k_x (b_k(x)v(x)),
\]
has domain (cf. [32], p. 167)
\[
\mathcal{D}(\mathcal{L}^*) = \{ v \in L^2(\mathbb{R}) : \exists f \in L^2 \text{ such that } \langle v, \mathcal{L} u \rangle_{L^2} = \langle f, u \rangle_{L^2}, \text{ for all } u \in H^m \}.
\]

It suffices to show that \( H^m \subset \mathcal{D}(\mathcal{L}^*) \) to conclude that \( \mathcal{D}(\mathcal{L}^*) \) is dense in \( L^2 \). Let \( v \in H^m \). Then for any \( u \in \mathcal{D}(\mathcal{L}) = H^m \) we have, after integration by parts, that
\[
\langle v, \mathcal{L} u \rangle_{L^2} = \langle \mathcal{L}^* v, u \rangle_{L^2}.
\]
Since clearly \( f := \mathcal{L}^* v \in L^2 \) whenever \( v \in H^m \), we obtain that \( v \in \mathcal{D}(\mathcal{L}^*) \). Thus, \( \mathcal{D}(\mathcal{L}^*) \) is dense in \( L^2 \).

Now, since \( \mathcal{L} \) is densely defined, \( \mathcal{L}^* \) coincides with the proper adjoint of \( \mathcal{L} \) (see Kato [32], p. 167). As \( \mathcal{L}^* \) is densely defined, one applies Theorem 5.28 in [32] (p. 168) to conclude that \( \mathcal{L} \) is closable. Moreover, since \( L^2 \) is a reflexive space, by Theorem 5.29 in [32] we also have that \( \mathcal{L}^* \) is closed and \( \mathcal{L}^{**} = \overline{\mathcal{L}} \supset \mathcal{L} \), where \( \overline{\mathcal{L}} \) denotes the smallest closed extension of \( \mathcal{L} \). \( \square \)
If we further assume that the highest order coefficient is uniformly bounded above and below, that is,

\[ 0 < C_0 \leq b_m(x) \leq C_1, \quad x \in \mathbb{R}, \text{ uniform } C_j > 0, \tag{A.3} \]

then we have the following

**Proposition A.2.** Under hypotheses (A.2) and (A.3), \( \mathcal{L} : \mathcal{D}(\mathcal{L}) = H^m(\mathbb{R}) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R}) \) given in (A.1) is a closed operator.

**Proof.** Define \( a_k(x) := b_k(x)b_m(x)^{-1} \), for \( k = 0, \ldots, m-1 \). Then from (A.2) and (A.3) it is clear that \( a_k \in W^{1,\infty}(\mathbb{R}) \). Apply Lemma 3.1.2 in reference [30] (p. 40) to deduce that the operator \( \mathcal{A} : H^m \subset L^2 \to L^2, \mathcal{A} := \partial_x^m + a_{m-1}(x)\partial_x^{m-1} + \ldots + a_0 \text{Id} \) is closed. Now take any sequence \( u_j \in H^m \) such that \( u_j \to u \) and \( \mathcal{L}u_j \to v \) in \( L^2 \).

From (A.3) we have that \( \bar{v} = b_m(x)^{-1}v \in L^2 \) and that

\[ \|\mathcal{A}u_j - \bar{v}\|_{L^2} \leq C\|\mathcal{L}u_j - v\|_{L^2} \to 0, \]

as \( j \to \infty \). Since \( \mathcal{A} \) is closed we conclude that \( u \in H^m \) and \( \mathcal{A}u = \bar{v} \), which is tantamount to \( \mathcal{L}u = v \). Thus, \( \mathcal{L} \) is closed. \( \square \)

Being the highest order coefficient \( b_m \) bounded from above and from below, multiplication by \( b_m^{-1} \) is a diffeomorphism that does not affect the Fredholm properties of an operator.

**Lemma A.3.** Under assumptions (A.2) and (A.3), \( \mathcal{L} \) is a Fredholm operator with index \( \nu \) if and only if \( \mathcal{J} := b_m(x)^{-1}\mathcal{L} : H^m \subset L^2 \to L^2 \) is Fredholm with index \( \nu \).

**Proof.** Suppose \( \mathcal{L} \) is Fredholm with index \( \nu \). Take a sequence \( v_j \in \mathcal{R}(\mathcal{J}) \) such that \( v_j \to v \) in \( L^2 \). Then there exists \( u_j \in H^m \) such that \( \mathcal{J}u_j = b_m(x)^{-1}\mathcal{L}u_j = v_j \), that is, \( b_m(x)v_j \in \mathcal{R}(\mathcal{L}) \). Thanks to (A.3) we have that \( v_j \to v \) in \( L^2 \) if and only if \( b_m(x)v_j \to b_m(x)v \) in \( L^2 \). Since \( \mathcal{R}(\mathcal{L}) \) is closed we obtain \( b_m(x)v \in \mathcal{R}(\mathcal{L}) \) or, equivalently, \( v \in \mathcal{R}(\mathcal{J}) \). Thus, \( \mathcal{R}(\mathcal{J}) \) is closed. Moreover, the transformation \( \Phi : \mathcal{R}(\mathcal{J}) \to \mathcal{R}(\mathcal{L}) \) defined by \( \Phi v = b_m(x)v \) is injective and onto, yielding codim \( \mathcal{R}(\mathcal{J}) = \text{codim } \mathcal{R}(\mathcal{L}) \). Finally, observe that if \( v \in \ker \mathcal{J} \) then

\[ \|b_m(x)^{-1}\mathcal{L}v\|_{L^2} < C_1^{-1}\|\mathcal{L}v\|_{L^2}, \]

yielding \( v \in \ker \mathcal{L} \). Likewise, \( \ker \mathcal{L} \subset \mathcal{J} \). Hence \( \text{null } \mathcal{L} = \text{null } \mathcal{J} \) and \( \mathcal{J} \) is Fredholm with index \( \nu = \text{ind } \mathcal{L} \). \( \square \)

**Remark A.4.** In the present study of the spectral properties of linearized operators around diffusion-degenerate traveling fronts, the highest order coefficient is not uniformly bounded below. Nonetheless, we work with the smallest closed extension of the linearized operator and, without loss of generality, we regard it as a closed, densely defined operator in a suitable energy space.

### A.2. Second order Sturmian operators on the real line.

Consider a linear second order differential operator on the real line of the form

\[
\mathcal{L} : \mathcal{D}(\mathcal{L}) = H^2(\mathbb{R}) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R}),
\]

\[
\mathcal{L} := b_2(x)\partial_x^2 + b_1(x)\partial_x + b_0(x)\text{Id},
\tag{A.4}
\]

where the coefficients satisfy:

(i) \( b_j \in C^2(\mathbb{R}) \cap L^\infty(\mathbb{R}), j = 0, 1, 2; \)

(ii) there exist uniform constants \( C_0, C_1 > 0 \) such that

\[
0 < C_0 \leq b_2(x) \leq C_1, \quad \text{for all } x \in \mathbb{R};
\tag{A.5}
\]

(iii) \( \partial_x^k b_2 \in L^\infty(\mathbb{R}) \) for \( k = 0, 1, 2; \)
(iv) the coefficients decay exponentially to finite limits, that is, there exist uniform constants $C, \nu > 0$ such that

$$|b_j(x) - b_j^\pm| \leq Ce^{-\nu|x|}, \quad as \ x \to \pm \infty,$$

for some $b_j^\pm \in \mathbb{R}$.

By Proposition A.2, $L$ is a closed, densely defined operator in $L^2$ with domain $H^2$.

The main observation of this section is that under a Liouville-type transformation [39] (see also [36, 75, 82]) it is possible to write the spectral problem for operator (A.4) in Sturmian form [30]:

$$\tilde{\mathcal{L}} - \lambda = \partial_x^2 + \tilde{b}_1(x)\partial_x + (\tilde{b}_0(x) - \lambda)\text{Id},$$

for appropriate coefficients $\tilde{b}_j$. The Liouville transformation is given by (see [82], p. 88):

$$\xi(x) := \int_0^x \frac{ds}{b_2(s)^{1/2}}, \quad u(x) := b_2(x)^{-1/4}v(\xi(x)). \quad (A.6)$$

**Proposition A.5.** Under transformation (A.6) the spectral equation $$(\mathcal{L} - \lambda)u = 0,$$

with $u \in H^2$, can be recast as

$$(\tilde{\mathcal{L}} - \lambda)v := v_{\xi\xi} + \tilde{b}_1(\xi)v_\xi + (\tilde{b}_0(\xi) - \lambda)v = 0, \quad (A.7)$$

for some $v \in H^2$ where

$$\tilde{b}_1(\xi) := \left(\frac{b_1 - \partial_x b_2}{b_2^{1/2}}\right)_{|x=x(\xi)},$$

$$\tilde{b}_0(\xi) := \left(\frac{5}{16} \frac{|\partial_x b_2|^2}{b_2} - \frac{1}{4} \frac{\partial_x^2 b_2}{b_2} - \frac{1}{4} \frac{b_1 \partial_x b_2}{b_2} + b_0\right)_{|x=x(\xi)}.$$

Moreover, $u \in H^2$ if and only if $v \in H^2$.

**Proof.** Under transformation (A.6) we have

$$\frac{d\xi}{dx} = \frac{1}{b_2(x)^{1/2}} > 0,$$

for all $x \in \mathbb{R}$ and hence $\xi = \xi(x)$ is monotone increasing. Moreover, from (A.5) we obtain

$$\xi \geq \frac{x}{C_1^{1/2}} \to \infty \quad as \ x \to \infty, \quad \xi \leq \frac{x}{C_0^{1/2}} \to -\infty \quad as \ x \to -\infty.$$

Thus, it is clear that $\xi$ maps $\mathbb{R}$ onto $\mathbb{R}$ and it is invertible with unique inverse $x = x(\xi)$. Let us then define

$$v(\xi) := b_2(x(\xi))^{1/4}u(x(\xi)), \quad \xi \in \mathbb{R}.$$

By straightforward calculations, if $u \in C_0^2(\mathbb{R})$ (dense in $H^2(\mathbb{R})$) is a solution to $$(\mathcal{L} - \lambda)u = 0$$ then $v$ is also smooth (by assumptions (i) - (iv)) and satisfies

$$v_{\xi\xi} + \tilde{b}_1(\xi)v_\xi + (\tilde{b}_0(\xi) - \lambda)v = 0,$$

where $\tilde{b}_j = \tilde{b}_j(\xi)$, $j = 0, 1$, are given above.
Notice that, thanks to the assumptions on the coefficients (i) - (iv), we clearly have \( b_1, b_0 \in C(\mathbb{R}) \cap L^\infty(\mathbb{R}) \). In particular, by exponential decay to finite limits we have that \( \partial_x^2 b_2, \partial_x b_2 \to 0 \) as \( x \to \pm \infty \) and
\[
|b_j(x(\xi)) - b_j^\pm| \leq Ce^{-\nu x(\xi)} \leq Ce^{-\nu C_1^1/2 \xi}, \quad \text{as} \ \xi \to \infty,
\]
\[
|b_j(x(\xi)) - b_j^\pm| \leq Ce^{\nu x(\xi)} \leq Ce^{\nu C_0^1/2 \xi}, \quad \text{as} \ \xi \to -\infty,
\]
for each \( j = 0, 1, 2 \). Thus, we conclude that \( \tilde{b}_1, \tilde{b}_0 \) decay exponentially to constant states as \( \xi \to \pm \infty \),
\[
|\tilde{b}_j(\xi) - b_j^\pm| \leq Ce^{-\nu \xi},
\]
for some uniform \( C, \tilde{\nu} > 0 \) and with
\[
\tilde{b}_1^\pm = \frac{b_1^\pm}{(b_2^\pm)^{1/2}}, \quad \tilde{b}_0^\pm = b_0^\pm.
\]

From (A.6) it is clear that
\[
\|v\|^2_{L^2} = \int_{-\infty}^{\infty} |v(\xi)|^2 \, d\xi = \int_{-\infty}^{\infty} |u(x)|^2 \, dx = \|u\|^2_{L^2}, \quad (A.8)
\]
and, in addition, thanks to assumptions (i) - (iv), particularly to (A.5), it is easy to verify that
\[
\|u_x\|_{L^2} \leq C\|v\|_{H^1}, \quad \|u_{xx}\|_{L^2} \leq C\|v\|_{H^2},
\]
for some \( C > 0 \). Likewise, we can show that \( \|v\|_{H^2} \leq C\|u\|_{H^2} \). Hence we conclude that if \( u \in H^2 \) is a solution to the spectral equation then \( v \) is a solution to (A.7) and, moreover, that \( u \in H^2(-\infty < x < \infty) \) if and only if \( v \in H^2(-\infty < \xi < \infty) \). \( \Box \)

**Lemma A.6.** The \( L^2 \)-isolated point spectrum of the operators \( \mathcal{L} \) and \( \tilde{\mathcal{L}} \) (see Definition 3.3) are the same, that is \( \tilde{\sigma}_{pt}(\tilde{\mathcal{L}})|_{L^2} = \tilde{\sigma}_{pt}(\mathcal{L})|_{L^2} \). Moreover, the algebraic and geometric multiplicities of the eigenvalues coincide.

**Proof.** Suppose \( \lambda \in \tilde{\sigma}_{pt}(\tilde{\mathcal{L}})|_{L^2} \). Then there exists an eigenfunction \( u \in \mathcal{D}(\mathcal{L}) = H^2 \) such that \( (\mathcal{L} - \lambda)u = 0 \). From Proposition A.5 and its proof it is then clear that the mapping
\[
\mathcal{I} : \ker(\mathcal{L} - \lambda) \to \ker(\tilde{\mathcal{L}} - \lambda), \quad \mathcal{I}(u) := v, \quad u \in H^2,
\]
is one-to-one and onto, yielding \( \tilde{\sigma}_{pt}(\tilde{\mathcal{L}})|_{L^2} = \tilde{\sigma}_{pt}(\mathcal{L})|_{L^2} \) and \( \text{nul}(\tilde{\mathcal{L}} - \lambda) = \text{nul}(\mathcal{L} - \lambda) \) (that is, the geometric multiplicities of \( \lambda \) as an eigenvalue of both \( \mathcal{L} \) and \( \tilde{\mathcal{L}} \) coincide).

It is not hard to verify that the algebraic multiplicities coincide as well. This is a consequence of the one-to-one correspondence between solutions to \( (\mathcal{L} - \lambda)u = w \) for a given \( w \in L^2 \) and the solutions to \( (\tilde{\mathcal{L}} - \lambda)\tilde{u} = \tilde{w} \) for \( \tilde{w} \in L^2 \) under the transformation \( \mathcal{I} : H^2 \to H^2 \). Therefore, under the mapping \( \mathcal{I} \), a Jordan chain for the operator \( \mathcal{L} - \lambda \) induces a Jordan chain for \( \tilde{\mathcal{L}} - \lambda \) with the same block structure and length. The lemma is proved. \( \Box \)

**Remark A.7.** This spectral equivalence also follows from the fact that, if we define \( \mathcal{I} : L^2 \to L^2, \mathcal{I}(u) = v \), then from (A.8) we obtain \( \|\mathcal{I}\|^2_{L^2 \to L^2} = 1 \), and \( \mathcal{I} \) is a unitary isomorphism from \( L^2 \) to \( L^2 \); consequently \( \mathcal{L} \) and \( \tilde{\mathcal{L}} \) are \( L^2 \)-unitarily equivalent with the same \( L^2 \)-spectrum (cf. [12]).
It is now straightforward to verify that the operator (A.7) satisfies the standard assumptions of Sturm-Liouville theory on the real line (cf. section 2.3.2 in [30]; see also [75, 74]). Indeed, the operator $\tilde{L} : H^2 \subset L^2 \rightarrow L^2$ is a second order Sturmian operator in the sense that, first, the coefficients $\tilde{b}_1(\xi)$ and $\tilde{b}_0(\xi)$ are continuous and decay exponentially to constants at $\xi = \pm \infty$, that is,

$$\lim_{\xi \to \pm \infty} e^{\nu|\xi|} |\tilde{b}_1(\xi) - \tilde{b}_1^\pm| = 0, \quad \lim_{\xi \to \pm \infty} e^{\nu|\xi|} |\tilde{b}_0(\xi) - \tilde{b}_0^\pm| = 0,$$

for some $\nu > 0$ and constants $\tilde{b}_1^\pm, \tilde{b}_0^\pm \in \mathbb{R}$, and, second, the operator $\tilde{L}$ is self-adjoint with respect to the $\omega$-weighted inner product

$$\langle u, v \rangle_\omega = \int_{\mathbb{R}} u(\xi)v(\xi)^* \omega(\xi) d\xi,$$

where the weight function $\omega : \mathbb{R} \rightarrow (0, +\infty)$ is defined by $\omega(\xi) = \exp \left( \int_0^\xi b_1(s) ds \right)$ and has finite asymptotic limits

$$\omega_\pm := \lim_{\xi \to \pm \infty} e^{-\tilde{b}_1^\pm \xi} \omega(\xi) \in \mathbb{R}.$$

The first assertion follows by straightforward calculations; the second is a consequence of exponential decay of the coefficients (see [30], section 2.3.2).

Whence, we are able to apply standard results of Sturm-Liouville theory to completely characterize the point spectrum of the operator $L$ under assumptions (i) - (iv).

**Theorem A.8.** Under hypotheses (i) - (iv), the point spectrum of the second order differential operator (A.4) consists of a finite number of simple eigenvalues which can be enumerated in descending order as

$$\lambda_0 > \lambda_1 > \ldots > \lambda_N,$$

and for any $j = 0, \ldots, N$ the eigenfunction $\phi_j$ associated to the eigenvalue $\lambda_j$ can be normalized so that $\phi_j$ has exactly $j$ simple zeros. Moreover, the ground state eigenvalue $\lambda_0$ is given by

$$\lambda_0 = \sup_{\|u\|_\omega = 1} \langle Lu, u \rangle_\omega,$$

where the supremum is achieved at $u = \phi_0$, which has no zeros, and the weight function $\varpi : \mathbb{R} \rightarrow (0, \infty)$ is given by

$$\varpi(x) = \exp \left( \int_0^x b_1(y) - \frac{\partial_x b_2(y)}{b_2(y)^{3/4}} dy \right).$$

**Proof.** This is a direct application of Theorem 2.3.3 in [30] (see chapter 2, section 2.3.2) and Lemma A.6 above. The expression of the weight $\varpi(x)$ follows from a standard change of variables inside the $L^2$ weighted inner product. The supremum does not change due to the spectral equivalence, both in location and in multiplicity. \square
