On sets of commuting and anticommuting Paulis

Rahul Sarkar and Ewout van den Berg

September 19, 2019

Abstract

In this work we study the structure and cardinality of maximal sets of commuting and anticommuting Paulis in the setting of the abelian Pauli group. We provide necessary and sufficient conditions for anticommuting sets to be maximal, and present an efficient algorithm for generating anticommuting sets of maximum size. As a theoretical tool, we introduce commutativity maps, and study properties of maps associated with elements in the cosets with respect to anticommuting minimal generating sets. We also derive expressions for the number of distinct sets of commuting and anticommuting abelian Paulis of a given size.

1 Introduction

In this work we study properties of sets of Pauli operators such that the elements either all pairwise commute or all pairwise anticommute. Sets of mutually commuting Paulis arise in the theory of quantum error correction, for instance in stabilizer theory [1]. Anticommuting Paulis arise in the mapping of Majorana operators to qubits in fermionic quantum computation [2].

An n-Pauli operator \( P \) is formed as the Kronecker product \( \bigotimes_{i=1}^{n} T_i \) of \( n \) terms \( T_i \), where each term \( T_i \) is either the two-by-two identity matrix \( \sigma_i \), or one of the three Pauli matrices \( \sigma_x, \sigma_y, \) and \( \sigma_z \). Pauli operators have the property that any two operators, \( P \) and \( Q \), either commute (\( PQ = QP \)) or anticommute (\( PQ = -QP \)). Pauli operators can be represented as strings \( \{i, x, y, z\}^n \) and commutativity between two operators is conveniently determined by counting the number of positions in which the corresponding string elements differ and neither element is \( i \). If the total count is even, the operators commute, otherwise they anticommute. Given two Pauli operators \( P \) and \( Q \), and arbitrary non-zero coefficients \( \alpha, \beta \in \mathbb{C} \), it is easily verified that the commutativity of \( \alpha P \) and \( \beta Q \) is the same as that of \( P \) and \( Q \). In Section 2 we define the notion of the abelian Pauli group, thereby allowing us to ignore such coefficients, which may arise when multiplying Pauli operators. We then study sets of mutually commuting Paulis in Section 3 and sets of mutually anticommuting Paulis in Section 4. We study the number of distinct maximally commuting and anticommuting sets in Section 5. We conclude the paper with a discussion in Section 6.

2 Group structure

In this subsection we define the abelian Pauli group, which forms the foundation for the remainder of the paper. We can define the elements of the n-Pauli group \( \mathcal{P}_n \) as all possible products of n-Pauli operators. It is easily checked that \( \mathcal{P}_n \) is a non-abelian group of order \( 4^{n+1} \). The set \( K = \{I, -I, iI, -iI\} \) is a normal abelian subgroup of \( \mathcal{P}_n \), and we define the abelian n-Pauli group as the quotient group \( \mathcal{P}_n/K \).

The associated canonical quotient map will be denoted by \( \pi \), i.e., \( \pi : \mathcal{P}_n \to \mathcal{P}_n/K \), which is surjective and is given by \( \pi(g) = gK \). We will sometimes denote \( \pi(g) \) by the equivalence class \( [g] \), under the quotient map. \( \mathcal{P}_n/K \) is an abelian group of order \( 4^n \), and the order of each element of the group, other than \( I \), is 2. Given \( \mathcal{H} \subseteq \mathcal{P}_n/K \) and \( P \in \mathcal{P}_n/K \) we define multiplication of the element \( P \) with the set \( \mathcal{H} \) as \( P * \mathcal{H} = \{PQ : Q \in \mathcal{H}\} \). For two sets \( \mathcal{H}_1, \mathcal{H}_2 \subseteq \mathcal{P}_n/K \) we define \( \mathcal{H}_1 * \mathcal{H}_2 = \{P_1P_2 : P_1 \in \mathcal{H}_1, P_2 \in \mathcal{H}_2\} \).
Multiplications with empty sets give empty sets. We frequently need to take the product of all elements in a set \( H \), and write \( \prod H := \prod_{Q \in H} Q \). We define the product of the empty set to be the identity element \( I \). We denote subsets by \( \subseteq \) and proper subsets by \( \subset \).

### 2.1 Generators

Let \( H \) be a subset of \( \mathcal{P}_n/K \). A set \( G \subseteq H \) is a generating set of \( H \) whenever any element in \( H \) can be expressed as a product of the elements in \( G \). For any \( G \subseteq \mathcal{P}_n/K \), we denote by \( \langle G \rangle \) the generated set of \( G \); that is, all elements that can be generated by products of the elements in \( G \), and thus any subset is a generating set of a possibly larger subset of \( \mathcal{P}_n/K \). The set \( G \) is called a minimal generating set, if no proper subset of \( G \) generates \( \langle G \rangle \). We say that the elements in minimal generating sets are independent.

We begin by proving some elementary properties of generating sets of \( \mathcal{P}_n/K \), in particular minimal generating sets, which are used subsequently in this paper. The first lemma shows that generating sets always form a subgroup of \( \mathcal{P}_n/K \), and also characterizes the sizes of minimal generating sets in relation to the sizes of the sets generated by them.

**Lemma 2.1.** The abelian Pauli group \( \mathcal{P}_n/K \) satisfies the following properties.

(a) If \( G \subseteq \mathcal{P}_n/K \) is non-empty, then \( \langle G \rangle \) is a subgroup of \( \mathcal{P}_n/K \).

(b) If \( S \) is a subgroup of \( \mathcal{P}_n/K \), then \(|S| = 2^\ell\), for some \( 0 \leq \ell \leq 2n \). \( G \) is a generating set of \( S \) if and only if \( \langle G \rangle = S \). For minimal generating sets \( G \) it holds that \( I \in G \) if \( S = \{I\} \). If \( S \neq \{I\} \), then a minimal generating set \( G \) of \( S \) always exists, and satisfies \(|G| = \ell\), and \( \prod H \neq I \) for all non-empty \( H \subseteq G \).

(c) If \( G \subseteq \mathcal{P}_n/K \) is a minimal generating set, then \(|G| \leq 2n\). Moreover if \(|G| \geq 2\), and \( G' \subset G \), then \( P \in \langle G' \rangle \) implies \( P \notin \langle G \rangle \).

**Proof.** (a) Take any \( P \in G \) and notice that \( P^2 = I \), and so \( I \in \langle G \rangle \). Now if \( P, Q \in \langle G \rangle \), then both can be expressed as products of elements in \( G \), and hence \( PQ \) can also be expressed as products of elements in \( G \). This shows that \( \langle G \rangle \) is a subgroup of \( \mathcal{P}_n/K \), as the other group axioms hold automatically.

(b) The order of \( \mathcal{P}_n/K \) is \( 4^n \). Hence Lagrange's theorem implies that if \( S \) is a subgroup of \( \mathcal{P}_n/K \), then the order of \( S \) must divide \( 4^n \), so \(|S| = 2^\ell\), for some \( 0 \leq \ell \leq 2n \). If \( \langle G \rangle = S \), then \( G \) is clearly a generating set for \( S \). For the converse, let \( G \) be a generating set for \( S \). By definition of generating sets we have \( G \subseteq S \), and as \( S \) is a subgroup it follows that \( \langle G \rangle \subseteq S \). Since \( G \) generates \( S \), we also have \( S \subseteq \langle G \rangle \), and hence \( \langle G \rangle = S \). If \( G = \{I\} \), then the minimal generating set is \( G = \{I\} \). Given a minimal generating set \( G \neq \{I\} \) it holds that \( \langle G \rangle = \langle G \setminus \{I\} \rangle \), since any other element can be used to generate \( I \). We now show that for a generating set \( G \neq \{I\} \), we must have that \( \prod H \neq I \) for all non-empty subsets \( H \subseteq G \). The condition holds when \( H \) has size one because \( I \notin H \). Otherwise, suppose \( \prod H = I \), then for any \( P \in H \) it holds that \( P \in \prod (H \setminus \{P\}) \) and therefore \( \langle G \rangle = \langle G \setminus \{P\} \rangle \), which contradicts minimality of \( G \).

The minimal generating set of \( S \neq \{I\} \) always exists; we start with generator set \( G = \{Q\} \) for any \( Q \in S \setminus \{I\} \), and repeatedly update it with an element \( P \in (S \setminus \langle G \rangle) \) until \( G \) generates \( S \). So it only remains to show that \(|G| = \ell\), which is now equivalent to showing that \(|\langle G \rangle| = 2^\ell\) because \( \langle G \rangle = S \).

But this is immediate from the fact that \( \langle G \rangle = \prod H = H \subseteq G \) if we can show that non-empty distinct subsets \( H_1, H_2 \subseteq G \) give rise to distinct elements \( \prod H_1, \prod H_2 \). Suppose for the sake of contradiction that \( \prod H_1 = \prod H_2 \). This would imply that \( I = (\prod H_1)(\prod H_2) = \prod ((H_1 \cup H_2) \setminus (H_1 \cap H_2)) \), which contradicts the fact that no subset of \( G \) multiplies to \( I \).

(c) Suppose that \( G \) is a minimal generating set, and \(|G| \geq 2n + 1\). Then by (b), \(|\langle G \rangle| \geq 2^{2n+1} > 4^n \). This is a contradiction as \( \mathcal{P}_n/K \) is a generating set for itself, and its order is \( 4^n \). If \(|G| \geq 2\), then \( \langle G \setminus \{I\} \rangle \neq \langle G \rangle \), and as \( G \) is a minimal generating set we must have \( I \notin G \). Now for the sake of contradiction assume that for \( G' \subset G \) there exist a \( P \in \langle G' \rangle \) such that \( P \in \langle G \rangle \). Then \( P \) can be expressed as a product of elements in \( G' \), and thus \( \langle G \rangle = \langle G \setminus \{P\} \rangle \), which contradicts that \( G \) is a minimal generating set.

The next lemma characterizes what happens when we take the product of all the elements of a generated set. This lemma is used often in this paper; for instance, it will immediately imply that a maximally commuting subgroup, defined later, multiplies to \( I \).

**Lemma 2.2.** Let \( G \subseteq \mathcal{P}_n/K \) be a generating set. Then

\[
\prod \langle G \rangle = \begin{cases} 
Q & \text{if } G = \{Q\}, \\
I & \text{otherwise.}
\end{cases}
\]

Thus if \( S \) is a subgroup of \( \mathcal{P}_n/K \), and \(|S| \neq 2\), then \( \prod S = I \).
Proof. If \( \mathcal{G} = \{Q\} \), and \( Q \neq I \), then \( \langle \mathcal{G} \rangle = \{I, Q\} \) as \( Q^2 = I \), and the statement is true. If \( \mathcal{G} = \{I\} \), then \( \langle \mathcal{G} \rangle = \{I\} \) and the statement is true. For the general case, let \( \mathcal{G}' = \{P_i\}_{i=1}^\ell \) be a minimal generating set of \( \langle \mathcal{G} \rangle \) with cardinality \( \ell \geq 2 \). By Lemma 2.1(b), \( I \notin \mathcal{G}' \), and therefore \( P_i \neq I \) for all \( i \in [\ell] \). Denote \( I_k = \bigcup_{i=1}^\ell \{P_i\} \), then \( \langle I_k \rangle = \{I, P_i, P_j, P_iP_j\} \), where \( P_iP_j \) is distinct from \( I, P_i, P_j \), and the product is therefore \( I \). By induction, suppose the result holds for some \( 2 \leq k < \ell \), then by the fact that \( \langle I_k \rangle \) is an abelian subgroup, and \( |\langle I_k \rangle| \) is even, we have

\[
\prod_{k=1}^{\ell} (\langle I_k \rangle) = \prod_{k=1}^{\ell} (\langle I_k \rangle) \cdot \prod_{P = P_{k+1}} \ldots \cdot \prod_{P = P_{\ell}} = I.
\]

If \( |S| = 1 \), then \( S = \{I\} \) implying \( \prod S = I \). By Lemma 2.1(b), \( |S| \) is a power of 2, so assume that \( |S| \geq 4 \). As \( S \) is a generating set for itself, the result above implies that \( \prod S = I \).

\[\square\]

2.2 Commutativity

Each element of \( P_n/K \) is an equivalence class containing exactly four Pauli operators. In a slight deviation to standard terminology, we say that two elements \( P, Q \in P_n/K \) commute (anticommute) whenever any chosen representative of \( P \) commutes (anticommutes) with any chosen representative of \( Q \). It is easily verified that this is a well defined notion, that does not depend on the choice of the representatives. Throughout the remainder of the paper we exclusively use the terms ‘commute’ or ‘anticommutate’ to refer to this notion, rather than that of the group operation on \( P_n/K \). With this convention, we say that a subset \( H \subseteq P_n/K \) is commuting (anticommuting), if no two distinct elements \( P, Q \in H \) anticommute (commute). Given any \( P \in P_n/K \), we say that \( P \) commutes with \( H \) if it commutes with all elements in \( H \), and likewise for anticommutates.

Given \( P, Q \in P_n/K \) we define the commutativity function \( \text{comm}(P, Q) \) such that

\[\text{comm}(P, Q) = \begin{cases} 1 & \text{if } P \text{ and } Q \text{ commute}, \\ -1 & \text{otherwise}. \end{cases}\]

For any set \( H \subseteq P_n/K \) and element \( P \in P_n/K \), we define the commutativity map of \( P \) with respect to \( H \) as \( \Omega_{P, H} : H \to \{1, -1\} \), such that \( \Omega_{P, H}(Q) = \text{comm}(P, Q) \) for all \( Q \in H \). It is clear that if \( |H| = k \), then there are a maximum of \( 2^k \) distinct commutativity maps. We will say that the commutativity map is all commuting (all anticommuting), if \( P \) commutes (anticommutes) with all elements in \( H \).

We now provide an important lemma that states that, given a minimal generating set \( \mathcal{G} \), each commutativity map with respect to \( \mathcal{G} \) is equally likely. This key fact is used in several results proved later.

Lemma 2.3. Let \( \mathcal{G} \subseteq P_n/K \) be a minimal generating set with \( \mathcal{G} \neq \{I\} \) and \( |\mathcal{G}| = k \). Then each of the \( 2^k \) possible commutativity maps with respect to \( \mathcal{G} \) is generated by \( 4^k/2^k \) distinct elements \( P \in P_n/K \).

Proof. Let \( \mathcal{G}' \) be a minimal generating set for \( P_n/K \) such that \( \mathcal{G} \subseteq \mathcal{G}' \), which exists by the proof of Lemma 2.1(b). Given any distinct elements \( P, Q \in P_n/K \), then the commutativity maps with respect to \( \mathcal{G}' \) must differ, otherwise \( PQ \) commutes with all elements in \( \mathcal{G}' \), and therefore with \( \langle \mathcal{G}' \rangle = P_n/K \). But that would mean \( PQ = I \), and therefore \( P = Q \). It follows that \( \Omega_{P, \mathcal{G}'} = \Omega_{Q, \mathcal{G}'} \) whenever \( P \neq Q \), and shows that there are \( 4^k \) distinct maps \( \Omega_{\mathcal{G}', \mathcal{G}'} \). We can iteratively remove elements from \( \mathcal{G}' \) to arrive at \( \mathcal{G} \). Each time we remove an element we collapse maps that differ only in the commutativity with the removed element, which means that the number of different maps is halved, but their occurrence is doubled. The result then follows directly.

\[\square\]

2.3 Decomposition

We can decompose any set \( S \subseteq P_n/K \), with \( n \geq 2 \), as

\[S = (\langle \sigma_1 \rangle \cup \langle \sigma_x \rangle \cup \langle \sigma_y \rangle \cup \langle \sigma_z \rangle),\tag{2}\]

with possibly empty sets \( \langle \sigma_\ell \rangle \subseteq P_{n-1}/K \) for \( \ell \in \{x, y, z\} \). In the above we use the convention that \( \sigma_\ell \otimes C = \{\sigma_\ell \otimes P : P \in C\} \), where we define \( \sigma_\ell \otimes P \) to be the equivalence class \( [\sigma_\ell \otimes A] \subseteq P_{n-1}/K \) for any chosen representative \( A \in P \), the notion being well defined and independent of the choice of the representative \( A \). In many cases we are not concerned with the exact labels of the sets and instead work with the decomposition

\[S = (\langle \sigma \rangle \cup \langle \sigma_x \rangle \cup \langle \sigma_y \rangle \cup \langle \sigma_z \rangle),\tag{3}\]

where \((u, v, w)\) is an arbitrary permutation of \( (x, y, z)\) that satisfies the condition that \( C_u = \emptyset \) implies \( C_v = \emptyset \), and \( C_u = \emptyset \) implies \( C_w = \emptyset \).

3
3 Sets of commuting Paulis

In this section we study the structure and cardinality of maximally commuting sets of Paulis. One of the basic properties of these sets is that they from subgroups, which stated in the following lemma.

Lemma 3.1. If $S \subseteq \mathcal{P}_n/K$ is maximally commuting, then $S$ is a subgroup of $\mathcal{P}_n/K$.

Proof. Since $I$ commutes with all elements in $\mathcal{P}_n/K$, it follows that $I \in S$ by maximality. If $P, Q \in S$ are distinct elements, then $PQ$ commutes with all elements in $S$, and therefore by maximality $PQ \in S$. Hence $S$ is a subgroup of $\mathcal{P}_n/K$. □

From this result it immediately follows using Lemma 2.1(b), that $|S|$ is a power of two. From Lemma 2.2 it further follows that $\prod S = I$ whenever $\ell \geq 2$. The next lemma elaborates on the structure of maximally commuting subsets of abelian Paulis.

Lemma 3.2. (Commuting structure lemma) Let $S \subseteq \mathcal{P}_n/K$ be maximally commuting with $n \geq 2$ and decomposition of the form $[3]$. Then $I \in C_i$, and the following are true:

(a) For $\ell \in \{i, u, v, w\}$ the elements within $C_\ell$ commute with each other, as well as with all elements in $C_i$. The elements between any pair of sets $C_u, C_v, C_w$ anticommute.

(b) If $C_u = C_v = \emptyset$, then $C_i = C_u$, and $C_i$ is a maximally commuting set.

(c) If $C_u, C_v \neq \emptyset$, the sets $C_i, C_u, C_v, C_w$ satisfy the following properties:
   1. for any $P \in C_i$ we have $P \ast C_i = C_i \ast C_i = C_i$,
   2. for any $P \in C_u$ we have $P \ast C_u = C_u \ast C_u = C_i$,
   3. for any $P \in C_i$ and any $Q \in C_u$ we have $P \ast C_u = Q \ast C_i = C_i \ast C_u = C_u$,
   4. for any $P \in C_i$ and any $Q \in C_v$ we have $P \ast C_v = Q \ast C_i = C_i \ast C_v = C_v$,
   5. $|C_i| = |C_u| = |C_v| = |C_w|$, and the sets are non-empty and disjoint,
   6. sets $C_i, (C_i \cup C_u), (C_i \cup C_v), (C_i \cup C_w)$ are subgroups of $\mathcal{P}_{n-1}/K$.

Proof. If $I \notin C_i$, we can add it, so for maximally commuting sets we have $I \in C_i$.

(a) This follows directly from commutativity of the elements in $S$.

(b) If $C_i$ and $C_u, C_v$ are empty, we can add any element of $C_i$ to $C_u$ and vice versa, and for maximal sets they must therefore be equal. The set $C_i$ must also be maximally commuting, otherwise there exists an $R \in (\mathcal{P}_{n-1}/K) \setminus C_i$ that commutes with $C_i$ and could therefore be added to both $C_i$ and $C_u$, which contradicts maximality of $S$.

(c) Now assume that $C_u$ and $C_v$ are non-empty.

1. Given any $P, Q \in C_i$, $PQ$ commutes with all elements in the sets $C_i, C_u, C_v, C_w$, and by maximality must therefore be an element of $C_i$. For a fixed $P$, the products $PQ$ differ for all $Q \in C_i$, and $P \ast C_i$ must therefore coincide with $C_i$.

2. Given any $P, Q \in C_u$, it can be verified that $PQ$ commutes with the elements in all the sets. By maximality we must therefore have that $PQ \in C_i$ and $P \ast C_u \subseteq C_i$. Again for a fixed $P$, the products $PQ$ differ for all $Q \in C_u$, and so $|P \ast C_u| = |C_u| \leq |C_i|$.

3. Given $P \in C_i$ and $Q \in C_u$, $PQ$ commutes with all elements in $C_i$ and $C_u$, and anticommutes with all elements in $C_v$ and $C_w$. By maximality we must therefore have that $PQ \in C_u$. Using arguments similar to the proof of properties 1–2, we thus conclude that $P \ast C_u = C_u, Q \ast C_i \subseteq C_u$, and $|Q \ast C_i| = |C_i| \leq |C_u|$.

4. Given $P \in C_u$ and $Q \in C_v$, it can be verified that $PQ$ anticommutes with all elements in $C_u$ and $C_v$, and commutes with all elements in $C_i$ and $C_w$. It again follows from maximality that $PQ \in C_w$, and thus $P \ast C_v \subseteq C_w$. $Q \ast C_u \subseteq C_w$. $P \ast C_v \subseteq |C_v|$, and $|Q \ast C_u| = |C_u|$.

5. From the cardinality relations in the proof of properties 2–3 it follows that $|C_i| = |C_u|$. Since the choice of $u, v, w$ was arbitrary it follows that $|C_u| = |C_v| = |C_w|$. Given that the cardinality of all four sets are equal it follows that the $\subseteq$ and $\leq$ relations in items 2–4 can be replaced with equality. As $C_i$ contains $I$, we conclude that all the four subsets are non-empty. We know from (a) that all elements in $C_i$ commute with $C_i$, and anticommute with $C_u$, and it must therefore hold that $C_i \cap C_u = \emptyset$. A similar argument applies to $C_u \cap C_v$, and all other pairs of sets.

6. Property 2 shows that $C_i$ is closed under the group operation of $\mathcal{P}_{n-1}/K$, while properties 2–4 show that $C_i \cup C_u, C_i \cup C_v,$ and $C_i \cup C_w$ are also closed under the same group operation. □
For the cardinality of maximally commuting sets in $P_n/K$ we have the following result:

**Theorem 3.3.** A commuting set $S \subseteq P_n/K$ is maximally commuting if $|S| = 2^n$.

**Proof.** Let $G$ be a minimal generator set for $S$. Suppose by contradiction that $k := |G| > n$, then it follows from Lemma 2.3 and the fact that elements commute with themselves, that each commutativity map with $G$ is generated by $4^k/2^k < 2^n$ elements. For all $Q \in \langle G \rangle$, the commutativity map with respect to $G$ is the all-commuting map, but this gives a contradiction, since $|\langle G \rangle| = 2^k > 2^n$. Similarly, suppose that $|G| < n$. In this case it follows from Lemma 2.6 that there must exist a $P \in (P_n/K) \setminus \langle G \rangle$ that commutes with all elements in $G$, and therefore with all elements in $\langle G \rangle$. It follows that $P$ could be added to $S$, thus contradicting maximality.

A slight strengthening of the commuting structure lemma is now possible.

**Corollary 3.4.** Let $S \subseteq P_n/K$ be a maximally commuting set with $n \geq 2$ and decomposition $\mathcal{G}$ with $C_w \neq \emptyset$. Then $|C_i| = |C_u| = |C_v| = |C_w| = 2^{n-2}$. In addition, $(C_i \cup C_u)$, $(C_i \cup C_v)$, and $(C_i \cup C_w)$ are maximally commuting subgroups of $P_{n-1}/K$.

**Proof.** By Theorem 3.3, $|S| = 2^n$. Since each of the four sets $C$ have equal size by Lemma 3.2(c), it follows that each must have size $2^n/4 = 2^{n-2}$. The set $H := C_i \cup C_\ell$ is commuting for any $\ell \in \{u, v, w\}$. From property 5 of Lemma 3.2(c) we know that $C_i \cap C_\ell = \emptyset$, and it therefore follows that $|H| = 2^{n-1}$, which is maximal by Theorem 3.4.

The next two lemmas provide a converse to Lemma 3.4.

**Lemma 3.5.** Let $S \subseteq P_{n-1}/K$ be maximally commuting. Then the set $S' = (\sigma_i \otimes S) \cup (\sigma_i \otimes \sigma_j \otimes R)$ is a maximally commuting subgroup of $P_n/K$, for all $\ell \in \{x, y, z\}$.

**Proof.** Without loss of generality, assume that $\ell = x$. Next, for the sake of contradiction, suppose that $S'$ is not maximally commuting. As $S$ is maximally commuting, there exists no element of the form $S_i \otimes R$, or $S_i \otimes R$, with $R \notin S$, such that $S' \setminus (\sigma_i \otimes R)$ is still commuting. So there must exist an element of the form $S_i \otimes R$, $j \in \{y, z\}$, and $R \in P_{n-1}/K$, such that $S' \setminus (\sigma_i \otimes R)$ is maximally commuting. But then $R$ must commute and anticommute simultaneously with each element in $S$, which is a contradiction.

**Lemma 3.6.** Suppose we have four subsets $C_i$, $C_x$, $C_y$, and $C_z$ of $P_{n-1}/K$, that satisfy the property in Lemma 3.2(a), and also satisfy $|C_i| = |C_x| = |C_y| = |C_z| = 2^{n-2}$. Then the set $S = (\sigma_i \otimes C_i) \cup (\sigma_i \otimes C_z) \cup (\sigma_i \otimes C_y) \cup (\sigma_i \otimes C_z)$ is a maximally commuting subgroup of $P_n/K$, for all permutations $(u, v, w)$ of $(x, y, z)$. In particular this implies that $C_i$, $C_x$, $C_y$, and $C_z$ satisfy properties 1–6 of Lemma 3.2(c).

**Proof.** It is easily checked that $S \subseteq P_n/K$ is a commuting set. We also have that $|S| = 2^n$, and hence by Theorem 3.4, it is a maximally commuting subgroup. Hence the sets $C_i$, $C_x$, $C_y$, and $C_z$ satisfy all the properties 1–6 of Lemma 3.2(c).

## 4 Sets of anticommuting Paulis

In this section we study the structure of sets of maximally anticommuting abelian Paulis. After clarifying the basic structure in Section 4.1, we consider possible sizes of these sets and properties of sets that attain the maximum size in Sections 4.2 and 4.3. We provide an efficient algorithm for creating various types of maximally anticommuting sets in Section 4.4.

### 4.1 Structure of maximally anticommuting sets

We start with a number of basic facts on sets of anticommuting abelian Paulis.

**Theorem 4.1.** Let $G = \{P_1, \ldots, P_k\}$ be a set of anticommuting Paulis, then

(a) if $k$ is even, then $Q = \prod G$ anticommutes with $G$, and $G \cup \{Q\}$ is maximally anticommuting,

(b) $G$ is maximal implies that $k$ is odd,

(c) $\prod G = I$ implies that $G$ is maximal and $k$ is odd,

(d) for any proper non-empty subset $H \subseteq G$ it holds that $\prod H \neq I$,

(e) $\prod G \neq I$ implies that $G$ is a minimal generating set for a subgroup of order $2^k$,

(f) $\prod G = I$ implies that $G$ is a generating set for a subgroup of order $2^{k-1}$.
Proof. (a) To determine commutativity we can take any Pauli operator represented by the equivalence classes, which we shall indicate by a bar. For any \( i \in [k] \) it takes \( k \) pairwise matrix swaps to convert \( P_iQ \) to \( QP_i \). Each swap with a term other than \( P_i \) leads to a multiplication by \(-1\) due to anticommutativity. Given that only one of the \( k \) swaps is with \( P_i \) itself, it follows from \( k - 1 \) is odd, that \( P_iQ = -Q P_i \), and therefore that \( P_i \) and \( Q \) anticommute. The result that \( Q \) anticommutes with all \( G \) follows by observing that both \( i \) and the operator representation was arbitrary. Now, suppose there exists a \( P \in (\mathcal{P}_n/K \setminus \{G\}) \) that anticommutes with \( G \), then any corresponding operator \( P \) anticommutes with all even \( k \) terms that comprise \( Q \), and therefore commutes with \( Q \). It follows that \( G \cup \{Q\} \) cannot be extended, and is therefore maximally anticommuting.

(b) It follows from (a), that if \( k \) is even we can add \( Q \) to \( G \), which means that \( G \) is not maximal.

(c) If \( G = \{I\} \) then the result is clear, and we therefore assume that \( k \geq 2 \). Suppose \( k \) is even, then we have from (a) that \( \prod G \) anticommutes with every element in \( G \), the product could therefore not have been \( I \), and it follows that \( k \) must be odd. Define \( G' = \{P_1, \ldots, P_{k-1}\} \), then \( P_k = Q = \prod G' \). Applying (a) to \( G' \) then shows that \( G = G' \cup \{Q\} \) is maximally anticommuting.

(d) Suppose that \( \prod H = I \). Then from the previous result it follows that \( H \) is maximal. Consequently, \( G \setminus H \) cannot anticommute with \( H \), thereby contradicting the fact that \( G \) is anticommuting.

(e) For sake of contradiction suppose that \( G \) is not a minimal generating set (note that \( I \notin G \) since it is anticommuting). Then there exists \( i \in [k] \), such that \( G = \langle G \setminus \{P_i\} \rangle \). This implies that \( P_i = \prod H \) for some \( H \subseteq G \setminus \{P_i\} \), and thus \( P_i \langle H \rangle = I \). If \( H \subseteq G \setminus \{P_i\} \) is a proper subset, then we get a contradiction by (b), while if \( H = G \setminus \{P_i\} \) we also get a contradiction because that would imply \( \prod G = I \). Finally \(|G| = 2^k\) by Lemma 4.2 (b).

If \( G = \{I\} \) the statement is true. Otherwise \( I \notin G \), and \(|G| \geq 2 \). In this case \( I \neq P_1 = \prod (G \setminus \{P_i\}) \), and so \( G = \langle G \setminus \{P_i\} \rangle \), and by (a), \( G \setminus \{P_i\} \) is a minimal generating set for the subgroup \( \langle G \setminus \{P_i\} \rangle \) of order 2^{k-1}.

The above result also shows that if \( G \neq \{I\} \) is an anticommuting set with \( \prod G = I \), then we can create a minimum generating set by removing any single element. Next we prove an important structure theorem for any maximally anticommuting subset of \( \mathcal{P}_n/K \).

**Theorem 4.2.** (Anticommuting structure theorem) Let \( G \subseteq \mathcal{P}_n/K \) be maximally anticommuting with decomposition (4). Then the following statements are true.

(i) The elements within each of the sets anticommute, and elements in \( C_i \) anticommute with \( C_\ell \) for \( \ell \in \{u,v,w\} \). Elements between \( C_u, C_v, \) and \( C_w \) commute.

(ii) Decomposition (4) has exactly one of the following forms:

<table>
<thead>
<tr>
<th>Non-empty sets</th>
<th>Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) ( C_i )</td>
<td>( C_i ) is maximally anticommuting and (</td>
</tr>
<tr>
<td>(b) ( C_i, C_u )</td>
<td>(</td>
</tr>
<tr>
<td>(c) ( C_i, C_u, C_v )</td>
<td>(</td>
</tr>
<tr>
<td>(d) ( C_u, C_v, C_w )</td>
<td>(</td>
</tr>
<tr>
<td>(e) all ( C_u, C_v, ) and ( C_w ) are either all odd (even), and (</td>
<td>C_i</td>
</tr>
</tbody>
</table>

(iii) The sets \( C_u, C_v \) are disjoint and \( |C_i| \cup |C_\ell| \) is odd for all \( \ell \in \{u, v, w\} \). The sets \( C_u, C_v \) are disjoint whenever \(|C_u| \geq 1 \) or \(|C_v| \geq 1 \), for every distinct \( a, b \in \{u, v, w\} \).

Proof. (i) The commutativity relations are easily verified.

(ii) The decomposition has exactly one of the given forms (a)–(e). By contradiction, if only \( C_u \) is non-empty we can add \( \sigma_u \otimes \sigma_i \). Likewise, if only \( C_u \) and \( C_v \) are non-empty, then one of the sets, say \( \ell \), has even size. It follows that we can add \( \sigma_\ell \otimes P \) with \( P = \prod C_\ell \).

In cases (a) and (b) note that we can omit the first element of all Paulis without affecting the commutativity. It follows that \( C_i \cup C_u \) is a set of maximally anticommuting \((n - 1)\)-Paulis, and we must therefore have that \(|G| \geq 2(n - 1) + 1 < 2n \).

In cases (b) and (c), suppose that \( |C| \) is even. Then \( P = \prod C_i \) anticommutes with \( C_i \) and commutes with the other sets, and we can therefore add \( \sigma_w \otimes P \) to \( G \). It follows that \(|C_\ell| \) must be odd. For (c), we show that \(|C_u| \) must be even. Since \(|G| \) is odd, it follows that \(|C_u| \) is also even. Suppose by contradiction that \(|C_u| \) is odd. Then \( P = \prod (C_i \cup C_u) \) anticommutes with \( C_i, C_u, \) and \( C_v \). It follows that we can add \( \sigma_\ell \otimes P \).

In case (d), suppose that, without loss of generality, \(|C_u| \) is even. Then \( P = \prod C_u \) anticommutes with \( C_u \), but commutes with both \( C_v \) and \( C_w \), since \( C_u \) and \( C_w \) commute with all matrices in \( C_u \). It follows that we can add \( \sigma_u \otimes P \), which contradicts maximality. Since the choice of \( C_u \) was arbitrary it follows that all sets must have odd cardinality.
In case (e), suppose that $|C_i| + |C_u|$ is even. Then we can form $P = \prod \{C_i \cup C_u\}$, which anticommutes with $C_i$ and $C_u$ and either commutes or anticommutes with both $C_v$ and $C_w$. If it commutes with both we can add $\sigma_u \otimes P$, otherwise we can add $\sigma_v \otimes P$. It follows that $|C_i| + |C_u|$ is odd for all $\ell \in \{u, v, w\}$. If $|C_i|$ is even, then $|C_u|$, $|C_v|$, and $|C_w|$ are all odd, and vice versa.

(iii) First suppose that $P \in C_i \cap C\ell = \emptyset$, for $\ell \in \{u, v, w\}$. Then $\sigma_i \otimes P$ and $\sigma_\ell \otimes P$ are both in $G$ but commute, which is a contradiction. Now suppose, without loss of generality, that $\sigma_u \otimes R$ commutes with $\sigma_v \otimes Q$, which is again a contradiction. The fact that $|C_i \cup C\ell|$ is odd follows directly from the decompositions in (ii).

The following observation now follows, which is the most important result of this section.

**Corollary 4.3.** An anticommuting subset $G \subseteq \mathcal{P}_n/K$ is maximally anticommuting iff $\prod G = I$.

**Proof.** The "if" part was already proved in Theorem 4.1(c). For the other direction, assume that $G \subseteq \mathcal{P}_n/K$ is maximally anticommuting. Without loss of generality, choose any term index of the underlying Pauli operators and permute the term order such that the selected index is the first one. It suffices to show that the product of all the elements in $G$ can be written as $\sigma_i \otimes P$, since the result then holds for all terms due to the fact that the selected index was arbitrary. To complete the proof, consider the decomposition in (3). Theorem 4.2(ii) guarantees that only one of the cases (a)–(e) can occur, and in each case the product of the first term is $\sigma_i$, as desired.

Another interesting corollary is the following:

**Corollary 4.4.** Let $G \subseteq \mathcal{P}_n/K$ be maximally anticommuting, and suppose $|G| = 2m + 1 \geq 3$. Define $H_m = G$, and for $0 < k \leq m$, recursively define $H_{k-1} = (H_k \setminus \mathcal{J}_k) \cup \{\prod \mathcal{J}_k\}$, for any $\mathcal{J}_k \subseteq H_k$ with $|\mathcal{J}_k| = 3$. Then $H_k$ is maximally anticommuting for all $0 \leq k \leq m$, and $H_0 = \{I\}$.

**Proof.** We proceed by induction. $H_m$ is maximally anticommuting by definition. Now assume that $H_k$ is maximally anticommuting for some positive $k \leq m$. Then by Corollary 4.3 we have $\prod H_k = I$, and so by construction $\prod H_{k-1} = \prod H_k = I$. Moreover $H_{k-1}$ is anticommuting, and using Corollary 4.3 again, we conclude that $H_{k-1}$ is maximally anticommuting. This completes the induction step. Note that the final set satisfies $H_0 = \{\prod H_n\} = \{I\}$.

### 4.2 Size of maximally anticommuting sets

For 1-Paulis we find that $\{\sigma_i\}$ and $\{\sigma_x, \sigma_y, \sigma_z\}$ are maximally anticommuting sets. We can hierarchically generate sets of higher-dimensional anticommuting matrices from existing sets. For example, given a set $G_n$ of maximally anticommuting $n$-Paulis, we can:

1. Set $G_{n+1} = (\sigma_x \otimes G_n) \cup (\sigma_y \otimes I) \cup (\sigma_z \otimes I)$.
2. Set $G_{2n+1} = (\sigma_x \otimes I \otimes G_n) \cup (\sigma_y \otimes G_n \otimes I) \cup (\sigma_z \otimes I \otimes I)$.
3. Given an odd number of maximal sets $S_i$ of equal cardinality, then taking Kronecker products of corresponding elements in these sets gives a maximally anticommuting set, since the new elements anticommutate with $I$.

Repeated application of the first construction with the initial set $G_1 = \{\sigma_x, \sigma_y, \sigma_z\}$, gives a set $G_n$ with $|G_n| = 2n + 1$. The following results clarify possible sizes of maximally anticommuting sets, and show that the above $G_n$ attains the maximum size for sets of anticommuting elements in $\mathcal{P}_n/K$.

**Lemma 4.5.** If $G \subseteq \mathcal{P}_n/K$ is anticommuting, then $|G| \leq 2n + 1$.

**Proof.** We note that this lemma is well-known and follows for example from Proposition 9 in [4]. Here we give another elegant proof of this fact. For the sake of contradiction, suppose $|G| > 2n + 1$. If $\prod G \neq I$, then $G$ is a minimal generating set, while if $\prod G = I$, we can exclude any element $P \in G$ and then $G \setminus \{P\}$ is a minimal generating set by Theorem 4.1(c). In either case we have a minimal generating set of cardinality at least $2n + 1$. By Lemma 2.1(b), the set generates a subgroup of $\mathcal{P}_n/K$ of order at least $2^{2n+1} > 4^n$, which is a contradiction.

**Corollary 4.6.** For every odd integer $\ell$ up to and including $2n + 1$, there exists a maximally anticommuting subset of $\mathcal{P}_n/K$ of cardinality $\ell$.

**Proof.** We know from the example at the beginning of this section that maximally anticommuting subsets of size $2n + 1$ exist in $\mathcal{P}_n/K$, so take any such set $G$. The result then follows by applying the construction in Corollary 4.4. 

7
4.3 Anticommuting sets of maximum size

In the next theorem, we clarify the structure of maximally anticommuting subsets of $\mathcal{P}_n/K$ that attain the maximum size.

**Theorem 4.7.** Given a maximally anticommuting set $\mathcal{G} \subseteq \mathcal{P}_n/K$ of size $2n+1$, with decomposition (2). Then

(a) $\prod (C_\ell \cup C_\ell) = I$ for $\ell \in \{x, y, z\}$.
(b) $C_\ell \cup C_z$ is a maximally anticommuting set for $\ell \in \{x, y, z\}$.
(c) Sets $C_x$, $C_y$, and $C_z$ are non-empty.
(d) $\prod C_\ell = \prod C_x = \prod C_y = \prod C_z$. Moreover, $\prod C_x = \prod C_y = \prod C_z = I$ iff $C_\ell = \emptyset$.
(e) $\prod C_\ell \prod C_\ell = I$ for all $\ell, m \in \{x, y, z\}$.

*Proof.* (a) Let $(u, v, w)$ be an arbitrary permutation of $(x, y, z)$. By Theorem 4(ii), the set $T = C_u \cup C_v$ is anticommuting in $P_{n-1}/K$ and we therefore have $|T| \leq 2n-1$. If this holds with equality we have an anticommuting set of maximum size, which implies $\prod T = I$. Otherwise we have $|C_u| + |C_v| \geq 3$. Suppose that $\prod T \neq I$, then $T$ forms a minimal generator for a subgroup of $P_{n-1}/K$. Since $G$ generates $P_n/K$, it follows that we can find $D \subseteq (C_u \cup C_v)$ with $|D| = 3$, such that $G' := T \cup ((C_u \cup C_v) \setminus D)$ generates $P_{n-1}/K$. Because $|D| = 3$, it follows that $|D \cap C_\ell| \geq 2$ for exactly one $\ell \in \{u, v, w\}$, and we can therefore find distinct elements $P, Q \in (D \cap C_\ell)$. Both elements are generated by $G'$ and have the same commutativity map with the elements in $G'$. From Lemma 4.8 we know that each commutativity map with respect to $G'$ occurs exactly once, which gives a contradiction. It must therefore hold that $\prod T = I$, and the result follows by noting that the choice of $u$ was arbitrary.

(b) This follows from (a) because $C_u \cup C_v$ is an anticommuting set by Theorem 4(ii).

(c) Consider the decomposition (3). Then from Theorem 4(ii), we have that $|C_u|$ and $|C_v|$ must be non-empty, otherwise $|\mathcal{G}| < 2n$. By maximality of $\mathcal{G}$ it follows from Corollary 4.3 that $\prod \mathcal{G} = I$. Now suppose $C_w = \emptyset$, then $\prod (C_u \cup C_v) \cdot \prod C_\ell = I$. Using the fact $\prod (C_u \cup C_v) = I$ for (a), we conclude that $\prod C_\ell = I$, which means that $C_\ell$ is maximally anticommuting. From maximality of $C_\ell \cup C_v$, we must therefore have that $C_\ell = \emptyset$. However, Theorem 4(ii) shows that maximally anticommuting sets cannot have $C_\ell = C_v = \emptyset$. This contradiction shows that $C_w$ cannot be empty, and consequently all three sets $C_x$, $C_y$, and $C_z$ are non-empty.

(d) If $C_\ell \neq \emptyset$, then combining with (c) we have that all four sets $C_x, C_y, C_z$ are non-empty. The result then again follows from (a) because it implies that $\prod C_\ell = \prod C_\ell$ for $\ell \in \{x, y, z\}$. If $C_\ell = \emptyset$, the result is true from (a) by substituting $C_\ell = \emptyset$. Conversely, if $\prod C_\ell = I$ for any $\ell \in \{x, y, z\}$, then $C_\ell$ is maximally anticommuting, and because $C_\ell \cup C_\ell$ is also maximally anticommuting by (b), Theorem 4(iii) then implies that $C_\ell = \emptyset$.

(e) This follows from (d). \qed

4.4 Extending an anticommuting set to its maximum size

Given an anticommuting set $S \subseteq \mathcal{P}_n/K$, an interesting question is whether it can be extended to the maximum possible size of $2n+1$. By definition this cannot be done if $S$ is maximally anticommuting, or when $|S| = 2n+1$, in which case there is nothing to do. So the interesting case is when $\prod S \neq I$. We show that this is possible in the following lemma.

**Lemma 4.8.** Let $S \subseteq \mathcal{P}_n/K$ be an anticommuting set that is not maximally anticommuting. Then $S$ can be extended to a maximally anticommuting set of cardinality $2n+1$.

*Proof.* As $S$ is not maximally anticommuting, $S \neq \{I\}$ and $|S| < 2n+1$. We note that the lemma is proved if we can show that if $|S| < 2n$, then $S$ can be extended to an anticommuting set of cardinality $|S| + 1$ that is not maximally anticommuting. Repeating this process we can extend $S$ to a set of cardinality $2n$, after which the construction in Theorem 4.10 gives the desired result.

If $|S|$ is odd, there exists an element $P \notin S$, such that $S \cup \{P\}$ is anticommuting, and because $|S \cup \{P\}|$ is even, by Theorem 4(iii) $S \cup \{P\}$ is not maximally anticommuting. Now assume that $|S|$ is even, and $|S| < 2n$. Pick an element $Q \notin \langle S \rangle$, and partition $S = \mathcal{C} \cup A$ (one of the sets possibly empty), such that $Q$ commutes with all elements in $\mathcal{C}$, and $Q$ anticommutes with all elements in $A$. Choosing $R$ as

$$ R = \begin{cases} Q(\prod A) & \text{if } |\mathcal{C}| \text{ is odd,} \\ Q(\prod C) & \text{if } |\mathcal{C}| \text{ is even, } \mathcal{C} \neq \emptyset, \\ Q & \text{if } \mathcal{C} = \emptyset, \end{cases} $$

(4)
we find that $R$ anticommutes with all elements in $S$, and so $S \cup \{R\}$ is anticommuting. Moreover $R(\prod S) \neq I$, because otherwise we would have $Q \in \langle S \rangle$. This implies that $S \cup \{R\}$ is not maximally anticommuting, which finishes the proof.

Lemma 4.3 raises some interesting questions:
(1) Given an anticommuting set $S \subseteq P_n/K$ that is not maximally anticommuting, in how many distinct ways can we extend it to a bigger size?

(2) Is there an efficient algorithm to perform the extension?

In order to answer the above questions, we need to develop a better understanding of the cosets of $\langle S \rangle$. The first question is answered in Section 5.2. For the second question, it turns out that there exists an efficient randomized algorithm to extend $S$ to a bigger anticommuting set. We start by characterizing a simple function that is important in the proof of the following theorem.

**Lemma 4.9.** Let $S$ be a set with $|S| = m \geq 1$, and let $v : S \to \{1, -1\}$ be any arbitrary map. Define a map $F_v : 2^S \times S \to \{1, -1\}$ by

$$F_v(T, x) = \begin{cases} v(x)(-1)^{|T|} & \text{if } x \in T, \\ v(x)(-1)^{|T|} & \text{if } x \notin T, \end{cases}$$

and also define

$$f(v) := \left( \sum_{x \in S} (1 + v(x))/2 \right) = \sum_{x \in S} \mathbb{1}_{\{v(x)=-1\}}.$$  

If $m$ is even, then for every map $q : S \to \{1, -1\}$, there exists a unique subset $U \subseteq S$ (possibly empty), such that $F_v(U, \cdot) = q$. If $m$ is odd, then we have the following cases:

(a) If $q : S \to \{1, -1\}$ is a map such that $f(q) \equiv f(v) \mod 2$, then there exist exactly two subsets $V, S \setminus V \in 2^S$ (possibly with one empty), such that $F_v(V, \cdot) = F_v(S \setminus V, \cdot) = q$.

(b) If $q : S \to \{1, -1\}$ is a map such that $f(q) \not\equiv f(v) \mod 2$, then there does not exist any subset $V$ of $S$ such that $F_v(V, \cdot) = q$.

**Proof.** We need a fact that for arbitrary subsets $A, B \subseteq S$, the function in (3) satisfies

$$F_w(B, \cdot) = F_v((A \cup B) \setminus (A \cap B), \cdot), \text{ where } w = F_v(A, \cdot).$$

This is true because

$$F_w(B, x) = \begin{cases} v(x)(-1)^{|A|+|B|} & \text{if } x \in (A \cup B) \setminus (A \cap B), \\ v(x)(-1)^{|A|+|B|} & \text{if } x \notin (A \setminus B) \cup (B \setminus A), \end{cases}$$

from the definitions, and moreover $|A| + |B| = |A \setminus B| + |B \setminus A| + 2|A \cap B| = |(A \cup B) \setminus (A \cap B)| + 2|A \cap B|$.

We first assume that $m$ is even. Let $S = S_1 \cup S_2$, such that $v(x) = 1$ for all $x \in S_1$, and $v(x) = -1$ for all $x \in S_2$. If we define $T \subseteq S$ by

$$T = \begin{cases} S_1 & \text{if } |S_1| \text{ is odd,} \\ S_2 & \text{if } |S_1| \text{ is even,} \end{cases}$$

then $F_v(T, x) = 1$ for all $x \in S$. For any map $q : S \to \{1, -1\}$, let $S = T_1 \cup T_2$, such that $q(x) = 1$ for all $x \in T_1$, and $q(x) = -1$ for all $x \in T_2$. Then if we define $R \subseteq S$ by

$$R = \begin{cases} T_1 & \text{if } |T_1| \text{ is odd,} \\ T_2 & \text{if } |T_1| \text{ is even,} \end{cases}$$

we have that $F_v(T, \cdot)(R, \cdot) = q$, and then (7) implies that $q = F_v(U, \cdot)$, where $U = (T \cup R) \setminus (T \cap R)$. Uniqueness of $U$ follows because there are exactly $2^m$ subsets of $S$, and $2^m$ distinct maps $r : S \to \{1, -1\}$.

We now assume that $m$ is odd, and prove the two subcases. Suppose $q : S \to \{1, -1\}$ is a map such that $f(q) \equiv f(v) \mod 2$, as stated in the lemma. If we define the sets

$$T = \{ x \in S : v(x) = 1 \}, \quad R = \{ x \in S : q(x) = 1 \}, \quad \text{and } \mathcal{V} = (T \cup R) \setminus (T \cap R),$$

then it follows that $q = F_v(t, \cdot)(R, \cdot) = F_v(T, \cdot)$. It is also easily checked that because $m$ is odd, we have $F_v(V, \cdot) = F_v(V, \cdot)$. The fact that $W \subseteq S, W \notin \{V, S \setminus V\}$ implies $q \not\equiv F_v(W, \cdot)$, follows because there are exactly $2^{m-1}$ distinct maps $r : S \to \{1, -1\}$ with $f(r) \equiv f(v) \mod 2$. Since this exhausts all possible subsets of $S$, it also means that there does not exist any subset $W \subseteq S$ with $r = F_v(W, \cdot)$, for every map $r : S \to \{1, -1\}$ such that $f(r) \not\equiv f(v) \mod 2$. This finishes the proof.
Given an anticommuting minimal generating set \( \mathcal{G} \), we can now prove the following theorem that completely characterizes the commutativity maps on the cosets of \( \langle \mathcal{G} \rangle \).

**Theorem 4.10.** Let \( \mathcal{G} \) be an anticommuting minimal generating set with \( |\mathcal{G}| = m \). If \( \mathcal{G} = \{I\} \), all elements of \( \mathcal{P}_n/K \) commute with \( I \). Otherwise the commutativity maps with respect to \( \mathcal{G} \) of the elements in the cosets of \( \langle \mathcal{G} \rangle \), have the following structure:

(a) If \( m \) is even, then in every coset of \( \langle \mathcal{G} \rangle \), for every commutativity map \( q : \mathcal{G} \to \{1, -1\} \) there exists exactly one element \( P \), such that \( \Omega_{P, \mathcal{G}} = q \).

(b) If \( m \) is odd and \( T \) is a coset of \( \langle \mathcal{G} \rangle \), then for all \( Q_1, Q_2 \in T \), \( f(\Omega_{Q_1, \mathcal{G}}) \equiv f(\Omega_{Q_2, \mathcal{G}}) \mod 2 \), using the notation in (4). Moreover if \( P \in T \), then for every commutativity map \( q : \mathcal{S} \to \{1, -1\} \) such that \( f(q) \equiv f(\Omega_{P, \mathcal{G}}) \mod 2 \), there exist exactly two elements \( Q_1, Q_2 \in T \) with \( Q_2 = Q_2(\langle \mathcal{G} \rangle) \), such that \( \Omega_{Q_1, \mathcal{G}} = \Omega_{Q_2, \mathcal{G}} = q \); while for every commutativity map \( q : \mathcal{G} \to \{1, -1\} \) such that \( f(q) \neq f(\Omega_{P, \mathcal{G}}) \mod 2 \), \( \Omega_{Q, \mathcal{G}} \neq q \) for all \( Q \in T \).

(c) If \( m \) is odd, the cosets of \( \langle \mathcal{G} \rangle \) can be grouped into two disjoint sets \( \mathcal{F}_0 \) and \( \mathcal{F}_1 \), with \( |\mathcal{F}_0| = |\mathcal{F}_1| = 2^{n-m-1} \), such that for all \( T_0 \in \mathcal{F}_0 \) and all \( P_0 \in T_0 \) it holds that \( f(\Omega_{P_0, \mathcal{G}}) \equiv 0 \mod 2 \), while for all \( T_1 \in \mathcal{F}_1 \) and all \( P_1 \in T_1 \) it holds that \( f(\Omega_{P_1, \mathcal{G}}) \equiv 1 \mod 2 \).

**Proof.** The case \( \mathcal{G} = \{I\} \) is obvious.

(a), (b) If \( T \) is a coset of \( \langle \mathcal{G} \rangle \), then choosing any element \( P \in T \), we have \( T = P \ast \langle \mathcal{G} \rangle \). Because \( \mathcal{G} \) is a minimal generating set, this induces a bijection \( h : 2^\mathcal{G} \to T \), defined by \( h(U) = P \cup U \). Given any element \( Q \in T \), we have \( Q = P \cup U \) for some \( U \subseteq \mathcal{G} \). Moreover, the commutativity map \( \Omega_{Q, \mathcal{G}} \), can be expressed in terms of the commutativity map \( \Omega_{P, \mathcal{G}} \) as

\[
\Omega_{Q, \mathcal{G}}(x) = \begin{cases} 
\Omega_{P, \mathcal{G}}(x)(-1)^{|U|-1} & \text{if } x \in U, \\
\Omega_{P, \mathcal{G}}(x)(-1)^{|U|} & \text{if } x \notin U,
\end{cases}
\]

for all \( x \in \mathcal{G} \). The results then follow by applying Lemma 4.9 with \( v(x) = \Omega_{P, \mathcal{G}}(x) \). For all commutativity maps \( q \) that satisfy \( f(q) \equiv f(\Omega_{P, \mathcal{G}}) \mod 2 \), we can find the corresponding sets using the constructions in Lemma 4.9, and additionally for the odd case, by noting that for any \( R \subseteq \mathcal{G} \), \( P(\bigcup R)(\bigcup \mathcal{G}) = P(\bigcup (\mathcal{G} \setminus R)) \).

(c) Lemma 2.2 guarantees that \( \mathcal{P}_n/K = \mathcal{E} \sqcup \mathcal{O} \), with \( |\mathcal{E}| = |\mathcal{O}| = 4^n/2 \), where

\[
\mathcal{E} = \{ y \in \mathcal{P}_n/K : f(\Omega_{y, \mathcal{G}}) \equiv 0 \mod 2 \}, \quad \text{and} \quad \mathcal{O} = \{ y \in \mathcal{P}_n/K : f(\Omega_{y, \mathcal{G}}) \equiv 1 \mod 2 \}.
\]

As the cardinality of each coset is \( 2^m \), we get that \( |\mathcal{F}_0| = |\mathcal{F}_1| = (4^n/2)/2^m = 2^{2n-m-1} \). The desired result then follows by using (b).

\[\square\]

We now have all the necessary ingredients for an efficient randomized algorithm to create a minimal generating set \( \mathcal{G} \) that is anticommuting and has maximum cardinality \( 2n \). The algorithm is summarized in Algorithms 1 and 2 and works as follows. We initialize the set \( T \) with a given initial anticommuting minimal generating set \( \mathcal{G} \). As long as the size of \( T \) is less than \( 2n \) we add feasible elements until the size is \( 2n \). This is done by first drawing an element from \( \mathcal{P}_n/K \) uniformly at random, and then using this element, along with the results from Theorem 4.10 to construct a feasible element. This is always possible when the size of the current set \( T \) is even, but fails if the size is odd and the randomly sampled element commutes with less than half of the elements in \( T \). If we succeed in finding a new element we add it to \( T \), otherwise we simply repeat the outer loop without adding a new element. The complexity to determine set \( \mathcal{C} \) in Algorithms 1 is \( \mathcal{O}(n|T|) \), and matches the worst-case complexity to evaluate the subsequent products \( \bigcup \mathcal{C} \) and \( \bigcup (T \setminus \mathcal{C}) \). The computational complexity of Algorithm 1 is therefore \( \mathcal{O}(n|T|) \). Randomly sampling an element from \( \mathcal{P}_n/K \) takes \( \mathcal{O}(n) \) time, and addition succeeds with probability at least \( 1/2 \). If \( 2n - |\mathcal{G}| \) is \( \mathcal{O}(n) \), then the expected runtime of Algorithms 1 is \( \mathcal{O}(n^3) \).

## 5 Number of unique sets

In this section we consider the number of unique sets that are maximally commuting or anticommuting, for which we derive explicit expressions.
Algorithm 1 Extend anticommuting minimal generating set to cardinality 2n

1: procedure EXTEND_GENERATING_SET($G$) \> $G$ is an anticommuting minimal generating set
2: \> Set $T \leftarrow G$, $P \leftarrow \prod G$, and $k \leftarrow \mid G\mid$
3: \> while $k < 2n$ do
4: \> \> $U \leftarrow$ Sample uniformly from $P_n/K$
5: \> \> $V \leftarrow$ ANTICOMMUTING_ELEMENT_COSET($T$, $U$) \> \> Find anticommuting element in coset
6: \> \> if ($k$ even and $V \neq P$) or ($k$ odd and $V \neq 0$) then \> \> \> Acceptance criteria
7: \> \> \> $T \leftarrow T \cup \{V\}$, $P \leftarrow PV$
8: \> \> $k \leftarrow k + 1$
9: \> return $T$

Algorithm 2 Find anticommuting Pauli in coset

1: procedure ANTICOMMUTING_ELEMENT_COSET($T$, $P$) \> $G$ is an anticommuting minimal generating set
2: \> Set $C \leftarrow \{x \in T : \Omega_{P,T}(x) = 1\}$ \> \> Find elements in $T$ that commute with $P$
3: \> if $\mid T \mid$ odd and $\mid C \mid$ odd then \> \> Anticommuting element does not exist in coset
4: \> \> $U \leftarrow 0$
5: \> else if $\mid T \mid$ even and $\mid C \mid$ even or $\mid C \mid \leq \frac{\mid T \mid}{2}$ then
6: \> \> $U \leftarrow P(\prod C)$
7: \> else
8: \> \> $U \leftarrow P(\prod (T \setminus C))$
9: \> return $U$

5.1 Commuting sets

The first lemma gives the number of ways a commuting minimal generating set can be extended to a larger commuting minimal generating set.

**Lemma 5.1.** Let $G \subseteq P_n/K$ be a commuting minimal generating set, possibly empty, and $\mid G\mid = m$. If $G = \{I\}$, then it cannot be extended to a larger commuting minimal generating set. When $m' = 1$ and $m = 0$, there are $4^n$ distinct ways to perform the extension. Otherwise there are $(\prod_{k=m}^{m'-1}(4^n/2^k - 2^k)) / (m' - m)!$ distinct ways to extend $G$ to a larger commuting minimal generating set $G' \subseteq P_n/K$, such that $G \subseteq G'$, $\mid G' \mid = m' > 1$, with $m < m' \leq n$.

**Proof.** If $G = \{I\}$, then it cannot be extended to a minimal generating set because of Lemma 2.4(b). For the case $m' = 1$, $m = 0$, every singleton set is a commuting minimal generating set, and so there are $4^n$ ways to extend $G$.

For the rest of the proof we assume that $m' > 1$, $G \neq \{I\}$, and fix any arbitrary ordering of the elements in $G$. By Lemma 2.1(b), we then also have that $I \notin G$. First consider the case $m' = k + 1$, and $m = k$. Lemma 2.4(b) implies that the cardinality of the set $H = \{P \in P_n/K : \text{comm}(P, Q) = 1, \forall Q \in G\}$ is $4^n/2^k$, and clearly $\{G\} \subseteq H$ with $\mid \{G\} \mid = 2^k$. Thus the number of distinct ways to extend $G$ to $G'$ is $4^n/2^k - 2^k$, because we can choose any element of $H \setminus \{G\}$.

Returning now to the case of a general $m'$, we can first order the elements in $G'$ such that the first $m$ elements are always those of $G$ in the fixed order. If we count all the possible orderings of the remaining elements in $G'$, it follows from the previous paragraph and by noting that if $G = \emptyset$, then there are $4^n - 1$ ways to extend $G$ by one element without including $I$, that the number of ways to extend $G$ to $G'$ is given by $\prod_{k=m}^{m'-1}(4^n/2^k - 2^k)$. Since there are exactly $(m' - m)!$ permutations of the newly added elements, the number of distinct extensions of $G$ to $G'$ is given by $(\prod_{k=m}^{m'-1}(4^n/2^k - 2^k)) / (m' - m)!$.

The next lemma counts the number of commuting minimal generating sets that generate the same commuting subgroup.

**Lemma 5.2.** Let $S \subseteq P_n/K$, be a subgroup such that all elements commute. By Lemma 2.4(b) and Theorem 2.8, $\mid S \mid = 2^n$, for $0 \leq n \leq n$. Then the number $N_m$ of distinct commuting minimal generating sets $G$ such that $\{G\} = S$ is given by

$$N_m = \frac{1}{m!} \prod_{k=0}^{m-1} (2^n - 2^k).$$  \hspace{1cm} (14)
Proof. The case $S = \{I\}$ is obvious, so assume that $|S| \geq 2$. By Lemma 2.4(b), if $G$ is a minimal generating set of $S$, then $I \notin G$, and so the first element of $G$ can be chosen in $(2^n - 1)$ ways. Now suppose the first $k < m$ elements of $G$ have already been chosen. These $k$ elements form a minimal generating set that generates a subgroup of $S$ of order $2^k$. Thus the $(k+1)$st element can be chosen in $(2^n - 2^k)$ ways. Iterating over $0 \leq k \leq m - 1$, the number of ways to form the minimal generating set $G$ using this process is $\prod_{k=0}^{m-1} (2^n - 2^k)$. Since we do not want to count the permutations of the elements in $G$, the number of distinct commuting minimal generating sets $G$ is $\left(\prod_{k=0}^{m-1} (2^n - 2^k)\right)/m!$.

We can now easily count the number of commuting subgroups of a fixed order.

**Lemma 5.3.** The number $N_m$ of distinct commuting subgroups of $\mathcal{P}_n/K$ of order $2^m$, for $0 \leq m \leq n$, is

$$N_m = \prod_{k=0}^{m-1} \frac{(4^n/2^k - 2^k)}{(2^m - 2^k)}.$$

**Proof.** If $m = 0$, $S = \{I\}$ is the only commuting subgroup of order 1, and so the statement is true. Now assume that $m > 0$, and so by Lemma 2.4(b), if $G$ is a minimal generating set of a commuting subgroup $S$ of order $2^m$, then $I \notin G$. By Lemma 5.2, the number of distinct ways to form a commuting minimal generating set of cardinality $m$ is $\left(\prod_{k=0}^{m-1} (4^n/2^k - 2^k)\right)/m!$, where we note that the formula is correct even when $m = 1$. These generate all possible commuting subgroups of $\mathcal{P}_n/K$ of order $2^m$, but as each such subgroup is generated exactly by $\left(\prod_{k=0}^{m-1} (2^n - 2^k)\right)/m!$ distinct commuting minimal generating sets by Lemma 5.2, we have that

$$N_m = \frac{\left(\prod_{k=0}^{m-1} (4^n/2^k - 2^k)\right)/m!}{\left(\prod_{k=0}^{m-1} (2^n - 2^k)\right)/m!} = \prod_{k=0}^{m-1} \frac{(4^n/2^k - 2^k)}{(2^n - 2^k)}.$$

Corollary 5.4. The number of distinct maximally commuting subgroups of $\mathcal{P}_n/K$ is $\prod_{k=0}^{n-1} (1 + 2^{n-k})$.

**Proof.** The proof follows from Lemma 5.3 by setting $m = n$ in (15).

## 5.2 Anticommuting sets

We now return to the question of how many ways it is possible to extend a minimal generating set of anticommuting abelian Paulis, which was originally raised in Section 4.4. The following theorem specifies in how many ways this can be achieved so that the larger set is still a minimal generating set.

**Theorem 5.5.** Let $G \subseteq \mathcal{P}_n/K$ be an anticommuting minimal generating set, possibly empty, and $|G| = m$. If $G = \{I\}$, then it cannot be extended. When $m' = 1$ and $m = 0$, there are $4^n$ distinct ways to perform the extension. Otherwise there are $\left(\prod_{k=m}^{m'-1} s(k)\right)/(m' - m)!$ distinct ways to extend $G$ to a larger anticommuting minimal generating set $G' \subseteq \mathcal{P}_n/K$, such that $G \subseteq G'$, $|G'| = m' > 1$, and $m < m' \leq 2n$, where

$$s(k) = \begin{cases} 4^n/2^k & \text{if } k \text{ is odd}, \\ 4^n/2^k - 1 & \text{if } k \text{ is even}. \end{cases}$$

**Proof.** If $G = \{I\}$, then it is maximally anticommuting and cannot be extended. For the case $m' = 1$, $m = 0$, every singleton set is an anticommuting minimal generating set, and so there are $4^n$ ways to extend $G$.

For the rest of the proof we assume $m' > 1$, and $G \neq \{I\}$. Fix any arbitrary ordering of the elements in $G$. We first consider the case when $m' = k + 1$ and $m = k$. There are exactly $4^n/2^k$ cosets of $\langle S \rangle$. When $k$ is odd, half of the cosets contain exactly 2 elements that anticommute with all the elements in $G$, and the other half contain none, by Theorem 4.10(b) and (c). Moreover none of these elements are in $\langle G \rangle$: it follows from equation 6 that for any element $P \in G$ we have $f(Z_P) \equiv 1 \mod 2$, and so Theorem 4.10(b) applies. This gives exactly $4^n/2^k$ distinct ways to extend $G$. If $k$ is even, then by Theorem 4.10(a) each coset contains exactly one element that anticommutes with all the elements in $G$, and so there are exactly $4^n/2^k - 1$ distinct ways to extend $G$ (counting every element in each coset, except $\prod G$), because if we include $\prod G', G', \{\prod G\}$ is not a minimal generating set.

We now return to the case of a general $m'$. If $G = \emptyset$, then there are $4^n - 1$ ways to initialize $G'$, since we have to exclude $I$. It follows from the previous paragraph that adding the $(k + 1)$-th element for $k > 0$, can be done in $s(k)$ distinct ways, with $s(k)$ defined as in (17). Since there are exactly
commuting sets, and \( \Theta(n) \) shows that for \( \mathbb{F}_3 \) question of how large such sets can be is studied in \([5, 6]\). The \( y \) show that the asymptotic size is \( \Theta(2^{k}) \) therefore require for all \( \ell \) \( G \) any anticommuting set \( n \) it is easy to show that this is not the case for \( n \) the maximum size of 2 \( \kappa \) restricted anticommuting sets with \( \sigma \) the maximum possible size of commuting sets; at the very least, the \( \limits \prod_{m}^{m} s(k) \) permutations of the new elements, the number of distinct extensions of \( G \) to \( G' \) is given by \( \left( \prod_{k=m+1}^{m-1} s(k) \right) / (m' - m)! \).

As a result of the previous theorem, we can now immediately count the number of maximally anticommuting sets. This is carried out in the next corollary.

**Corollary 5.6.** If \( N_m \) is the number of maximally anticommuting subsets of \( \mathcal{P}_n / \mathcal{K} \) of cardinality \( m \), then using \( s(k) \) as defined in \( [17] \)

\[
N_m = \begin{cases} \\
\frac{1}{m!} \prod_{k=0}^{m-2} s(k) & \text{if } m \text{ odd, and } m \leq 2n + 1, \\
0 & \text{otherwise.}
\end{cases}
\]  

(18)

**Proof.** By Theorem [4.11] and Lemma [4.5] the assertion is clearly true when \( m \) is even, or when \( m > 2n + 1 \). The statement is also true for \( m = 1 \), as \( \{I\} \) is the only such set. Now let \( \mathcal{G} \subseteq \mathcal{P}_n / \mathcal{K} \) be a maximally anticommuting set with \( |\mathcal{G}| = m \), \( m \) odd, and \( 3 \leq m \leq 2n + 1 \). Then there are \( m \) distinct ways to remove an element from \( \mathcal{G} \) to obtain a minimal generating set. Noting that \( I \notin \mathcal{G} \) when \( m \geq 3 \), the statement then follows as there are \( \left( \prod_{k=0}^{m-2} s(k) \right) / (m - 1)! \) distinct anticommuting minimal generating sets of cardinality \( m - 1 \), by Theorem [5.5] \( \square \)

### 6 Discussion

An interesting class of commuting and anticommuting Paulis is one in which all Paulis are formed exclusively by Kronecker products of the three Pauli matrices \( \sigma_x, \sigma_y, \) and \( \sigma_z \). Obviously, this restriction limits the maximum possible size of commuting sets; at the very least, the \( I \) element is no longer present. The size of anticommuting sets is also affected, and whereas the maximum size of \( 2n + 1 \) can be attained for \( n \)-Paulis for \( n = 1 \) and \( n = 4 \):

\[
\mathcal{M}_1 = \begin{bmatrix} x & y & z \end{bmatrix}, \quad \mathcal{M}_4 = \begin{bmatrix} x & x & x & y & y & y & z & z & z & z \\
x & y & z & x & x & y & z & y & z & z \\
x & y & z & y & x & x & z & x & y & z \\
x & y & z & y & y & x & x & y & y & x \\
x & y & z & y & y & y & x & x & y & z \\
x & y & z & y & y & y & y & x & x & z \\
x & y & z & y & y & y & y & y & x & x \\
x & y & z & y & y & y & y & y & y & x \end{bmatrix}
\]

it is easy to show that this is not the case for \( n = 2 \) and \( n = 3 \). Indeed, it follows from Theorem [4.14] that any anticommuting set \( \mathcal{G} \) of maximum size consisting of only \( \sigma_x, \sigma_y, \) and \( \sigma_z \) terms, must satisfy \( |\mathcal{C}_\ell| \geq 3 \) for all \( \ell \in \{x, y, z\} \), since otherwise these sets could not multiply to \( I \). For the set to be maximal, we therefore require \( k \geq 9 \), but this exceeds the maximum possible size of \( 2n + 1 \) for these values of \( n \).

An alternative formulation of commutativity and anticommutativity is to ask for sets of vectors in \( \mathbb{GF}(3)^n \) such that the Hamming distance between every pair of vectors is even or odd, respectively. The question of how large such sets can be is studied in \([3, 6]\). They show that the asymptotic size is \( \Theta(2^n) \) for commuting sets, and \( \Theta(n) \) for anticommuting sets, but also provide more specific bounds. For instance, \([5, \text{Corollary 2.10}] \) shows that for \( n \geq 1 \), any commuting subset \( \mathcal{G}_{xyz} \subset \mathcal{P}_n / \mathcal{K} \) satisfies

\[
|\mathcal{G}_{xyz}| \leq \frac{2^n}{1 - \left( \frac{2}{3} \right)^n + \left( \frac{2}{3} \right)^n}.
\]

Numerical values for the maximum possible sizes of restricted anticommuting sets with \( n \in [8] \) are given in \([7]\). For \( n = 8 \) this shows that it is again possible to attain the maximum size of \( 2n + 1 \), and indeed we have

\[
\mathcal{M}_8 = \begin{bmatrix} \\
 x & x & x & x & x & x & x & y & y & y \\
x & x & x & x & x & y & y & y & z & z \\
x & x & x & x & y & y & z & y & z & z \\
x & x & x & x & y & z & z & z & z & z \\
x & x & x & y & y & x & x & y & y & z \\
x & x & x & y & x & y & y & z & z & z \\
x & x & x & y & x & x & y & y & z & z \\
x & x & x & y & y & y & y & y & y & z \\
x & y & y & y & y & y & y & y & z & z \\
x & y & y & y & y & y & y & y & y & z \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \\
x & y & y & y & y & y & y & y & y & y \end{bmatrix}
\]

The values of \( n \) for which these restricted anticommuting sets can attain the maximum size remains an open question.
