(Dated: August 11, 2020)

We consider the possibility that a quantum particle, at the fundamental level, travels through a series of Planckian wormholes where the distance between the mouths of the wormholes is fundamentally invariant. Similar to topometry, the space in the presence of a quantum particle can be described by an array of possible points corresponding to the mouths of the wormholes where the quantum particle will emerge. This “topometric” description of quantum spacetime will be derived from a new conformal gravity theory that is postulated to apply at Planck scale. It will also be used as the basis of a new geometric formulation and interpretation of Quantum Mechanics. The new quantum interpretation will be used to derive a possible proof of Susskind-Maldacena’s ‘ER=EPR” conjecture and a new explanation of the interference pattern in the double-slit experiment.

I. INTRODUCTION

Conformal Gravity is a term given for any alternative gravity theory that is invariant under a conformal transformation known as the Weyl transformation. Such alternative gravity theories are also called as “Weyl-squared” theories as its Lagrangian involves square of the Weyl curvature tensor. The first conformal gravity theory was proposed by Weyl in 1920s in his attempt to unify General Relativity to Maxwell’s electromagnetic field theory. Weyl believed that the scale parameter \( \omega \) in a conformal transformation might be related to gauge transformation property of electromagnetism involving the change of 4-vector potential, \( A^\mu \rightarrow A^\mu + \partial_\mu \omega \). Weyl’s theory failed, but it spurred a considerable amount of research in gravitational theories based on conformal invariance. In late 1920s, Weyl, London and others successfully resurrected Weyl’s idea when they applied it to Quantum Mechanics although the gauge transformation is no longer with the metric tensor but with the wave function. A comprehensive history and review of the use of Weyl Geometry on various topics such as Quantum Gravity and Foundations of Quantum Mechanics can be found in the work of Scholz[1], Mannheim[2] and in related paper on Conformal Field Theory[3]. Also of great interest are the works of J.T. Wheeler[4], Wood and Papini[5], Castro[6], Shojaei et.al.[7], and Faria[8]. All are very much rooted to the work initiated by Weyl in 1918.

In standard Weyl transformation, the conformal factor is usually in the form of a real exponential function, i.e.,

\[
g_{\mu\nu} \rightarrow e^{2\omega} g_{\mu\nu}
\]

where \( \omega \) is a scalar function. When Weyl applied it on Reimannian Geometry, the affine connection need to be modified to be invariant by including a pseudo-vector \( \phi \) that must undergo a gauge transformation \( \phi \rightarrow \phi + d \log \omega \). The introduction of the pseudo-vector would then satisfy the non-metricity condition where the covariant derivative of metric tensor is non-vanishing. The corresponding Weyl curvature tensor (in 4 dimensions),

\[
W^\lambda_{\nu\alpha\beta} = R^\lambda_{\nu\alpha\beta} + \frac{1}{2}(\delta^\lambda_\alpha R_{\nu\alpha\beta} - \delta^\lambda_\beta R_{\nu\alpha\beta} + g_{\nu\alpha} R^\lambda_{\beta})
\]

is also invariant under Weyl transformation and known to be important in describing compression and tidal deformation. From this tensor, a unique Langrangian can be derived which is now called as the Weyl Langrangian

\[
L_\omega = \sqrt{-g} W_{\mu\nu\alpha\beta} W^{\mu\nu\alpha\beta}
\]

\[
= \sqrt{-g}(R_{\mu\nu\alpha\beta} R^{\mu\nu\alpha\beta} - 2R_{\mu\nu} R^{\mu\nu} + \frac{1}{3} R^2)
\]

which is also invariant under the conformal transformation written in Eq. (3). It is useful, nowadays, in formulating an alternative gravity theory at macroscopic scale.

Despite of all the successes of Weyl’s original theory, the idea that it can be used in unifying gravity with Quantum Mechanics still remains unproven. In this paper, we wanted to show that conformal invariance can still be used to unify gravity and Quantum Mechanics but at Planck scale and not at macroscopic scale. To do this, we suggest here that Weyl transformation must be modified first and one must have a new description of gravity at Planck scale that go beyond Differential Geometry as the mathematical tool to describe gravity. Here, we suggest the use of a well-known mathematical tool in Differential Topology called Ricci Flow to describe gravity...
at Planck scale. Then we apply a modified Weyl transformation which involves a complex exponential function as the conformal factor. These modifications to General Relativity and Weyl transformation are the basis of the postulates of the new theory of gravity that we proposed here. These postulates are stated as follows:

1. **Weyl Transformation**, \( g_{\mu\nu} \rightarrow \Omega^2 g_{\mu\nu} \), is a fundamental symmetry in nature, where the conformal term \( \Omega^2 \) is not necessarily a positive real function.

2. **Ricci Flow** is a statistical system that can be used to describe the spacetime fluctuation at Planck Scale.

In Postulate 1, the demand for Weyl transformation to be a fundamental symmetry in nature, means that it should also be applicable at quantum and Planck scale and not just at macroscopic scale. At macroscopic scale, the particular type of conformal transformation used by Weyl was successful in adding additional degree of freedom in General Relativity and explains compression and tidal forces. It failed in electromagnetism because Weyl was working on a classical and incomplete theory of electromagnetism. However, applying it to Quantum Mechanics also becomes difficult and problematic as there is still no accepted geometric theory of Quantum Mechanics. Furthermore, the metric tensor \( g_{\mu\nu} \) does not have a fundamental role in the mathematical formalism of Quantum Mechanics. Another reason being offered here why Weyl transformation failed in Quantum Mechanics is perhaps a different form of Weyl transformation is needed for Quantum Mechanics. Historically, modifying Weyl transformation is not something new. When London and Weyl apply his conformal transformation in Quantum Mechanics they modified it to become a local phase transformation of the wave function, i.e., they change the conformal factor from real function into a complex function and change the metric tensor into the wave function \( \psi \),

\[
\psi \rightarrow \psi' = e^{i\alpha} \psi
\]

for some scalar function \( \alpha \). In our case, we retain the metric tensor and we also change the conformal factor into a complex function, i.e.,

\[
g_{\mu\nu} \rightarrow \tilde{g}_{\mu\nu} = \varphi^2 g_{\mu\nu}
\]

for some complex function \( \varphi = e^{2\pi i \chi} \) in terms of scalar function \( \chi \). For the case of applying Weyl transformation at Planck scale, it is important first to have the necessary Physics to describe what is going on in such region. Particularly, we wanted to know the Physics of spacetime at Planck scale. Hitherto, many are working on finding a quantum theory of gravity at Planck scale. Others wanted to find a gravity theory of Quantum Mechanics at Planck scale. Here, a combination of both approaches will be considered. The proposed gravity theory at Plack Scale will be shown to be more fundamental than Quantum Mechanics (QM) which serves only as a low energy approximation of the theory. The goal of the theory is to show that the “Physics at the Planck scale” would explain all the observed properties in Quantum Mechanics such as entanglement, quantized values of physical quantities, indeterminacy and probabilistic nature of a quantum system among others. Particularly, the wormhole solution of the new gravity theory and the invariant minimum length and energy scale requirement as well as the variation of fundamental constants at Planck scale will be used to explain all quantum-mechanical properties.

In Postulate 2, the significant role of the Ricci Flow would be in the formulation of a new mathematical formalism of Quantum Mechanics. Our approach is basically to use a modified form of Weyl transformation and a normalized second- order Ricci Flow as a modified Einstein Field Equation to the mathematical formalism of Quantum Mechanics. By postulating a modified form of Weyl transformation as a fundamental symmetry in nature, it introduces the use of conformal function \( \varphi \) to modify the metric tensor \( g_{\mu\nu} \). In contrast, the conventional quantum formalism (CQF) postulates the use of a wave function or a probability amplitude \( \psi \) as a fundamental function, but no where it uses the metric tensor in a fundamental way. The main reason why the metric tensor is usually excluded in CQF, is because the role of gravity was always considered negligible at the microscopic world. Here, we suggest that the metric tensor must also have a fundamental role for a complete description of a quantum system as it will always have an inherent energy fluctuations that will lead for spacetime to fluctuate or to have a foam-like structure. Also, CQF postulates an evolution equation for \( \psi \) in the form of Schrödinger Equation or Dirac Equation. Here, we also postulates an evolution equation, but it is an evolution equation of the metric tensor that represents the spacetime fluctuation not only at Planck scale but also at quantum scale. The paper is organized as follows: In Section II a link between the quantum probability amplitude and the conformal function will be established where a modified Quantum Mechanics at Planck scale will be put forward. In Section III the Ricci Flow approach to quantum formalism will be elaborated where a generalized form of Dirac Equation and Einstein Field Equation will be derived and unified. In Section IV, a new quantum interpretation and proof of “ER=EPR” conjecture will be presented. The section also presents a new explanation for the origin of interference pattern in the double slit experiment, uncertainty in physical quantities and the probabilistic nature of Quantum Mechanics.

**II. MODIFIED QUANTUM PHYSICS**

In this section, we wanted to evaluate the conformal function \( \varphi \) and show how it can be linked to Quantum Mechanics. To do this, it is first necessary to establish the connection of Quantum Mechanics with what we called as the “Physics at the Planck Scale”. By this we mean, we
will be using some of the well-known assumptions about the Planck Scale that are currently being considered by so many authors [3, 27] such as: the existence of minimum energy and length scale, variation of fundamental constants, spacetime fluctuation and modification of Relativity and Quantum Mechanics.

Applying the modified Weyl transformation given by Eq. (11) on energy dispersion relation, it gives us

$$g_{\mu \nu} p^\mu p^\nu \rightarrow \varphi^2 g_{\mu \nu} p^\mu p^\nu = g_0 \tilde{E}^2 - g_{ij} \tilde{p}^i \tilde{p}^j$$

(6)

where \( \tilde{E} = \varphi E, \tilde{p} = \varphi \tilde{p} \), \( \varphi \) and \( \tilde{p} \) are complex energy and momenta. Evaluating the complex energy and momentum, we use \( i2\pi \varphi = \frac{\partial \varphi}{\partial \chi}, E = - \frac{\partial S}{\partial t}, \tilde{p}^i = \frac{\partial S}{\partial x^i} = p_x \) and inserting the imaginary number \( i = \sqrt{-1} \), we have

$$\varphi E = -\frac{i}{2\pi} (i2\pi \varphi) E = -\frac{i}{2\pi} \left( \frac{\partial \varphi}{\partial \chi} \right) \left( - \frac{\partial S}{\partial t} \right) = \frac{i}{2\pi} \left( \frac{\partial \varphi}{\partial \chi} \right) \left( \frac{1}{f} \frac{\partial S}{\partial t} \right)$$

(7)

$$\varphi p_x = -\frac{i}{2\pi} (i2\pi \varphi) p_x = -\frac{i}{2\pi} \left( \frac{\partial \varphi}{\partial \chi} \right) \left( \frac{\partial S}{\partial x} \right) = -\frac{i}{2\pi} \left( \frac{\partial \varphi}{\partial \chi} \right) \left( \lambda \frac{\partial S}{\partial x} \right)$$

(8)

where \( S \) is the classical action and the following variables were defined:

$$\frac{1}{f} = \frac{\partial t}{\partial \chi} \quad \text{and} \quad \lambda = \frac{\partial x}{\partial \chi}$$

(9)

Simplifying further, we define the variable,

$$\tilde{h} = \frac{1}{f} \frac{\partial S}{\partial t} = \lambda \frac{\partial S}{\partial x} = \frac{\partial S}{\partial \chi}$$

(10)

such that from (7) and (8), we yield the following equations;

$$\varphi E = i\tilde{h} \partial t \varphi \quad \varphi p_x = -i\tilde{h} \partial x \varphi$$

(11)

where \( \partial x \) and \( \partial t \) are partial derivatives in space and time, respectively, and \( \tilde{h} = \frac{2\pi}{2\pi} \). Since \( \varphi \) commutes with \( E \) and \( p_x \), we have the following eigenvalue equations,

$$E \varphi = \tilde{E} \varphi \quad p_x \varphi = \tilde{p} \varphi$$

(12)

which gives us an operator correspondence,

$$E \equiv i\tilde{h} \partial t = \tilde{E} \quad p_x \equiv -i\tilde{h} \partial x = \tilde{p}$$

(13)

similar to Quantum Mechanics. Lastly, we use Eq. (10) and set \( S = S(\chi) \). Then integrating and setting the variable \( \tilde{h} \) equal to a constant \( \tilde{h}_c \), it will yield us

$$\chi = S/\tilde{h}_c + k$$

(14)

for some integration constant \( k \). This will transform \( \varphi \) as follows:

$$\varphi \rightarrow \varphi_c = A e^{iS/\tilde{h}}$$

(15)

which is similar to quantum probability amplitude where \( \tilde{h} = \tilde{h}_c/2\pi \) and \( A \) is a constant. All of these results are equivalent to Quantum Mechanics if and only if the energy-dependent variable \( \tilde{h} \) becomes constant and equal to the Planck constant. Note that the idea of a varying Planck’s “constant” is not something new. A varying and energy-dependent Planck “constant” was also derived by Smolin and Maguiko [28] in their work on Deformed Special Relativity at Planck Scale. Others [29] consider it to be a time-dependent variable at Planck scale. If it is true that the Planck constant is varying at Planck Scale, it would therefore modify all known quantum-mechanical laws. Such modification may also allow for Relativity to be applicable at Planck Scale at a certain extent although it must be different compare with the usual Relativity at macroscopic scale. It is suggested here that the simple modification of quantum-mechanical equations above applies at Planck scale. Consequently, the variables \( f \) and \( \lambda \) will be interpreted here as quantities that describe the fundamental fluctuation of space and time at Planck scale in terms of variable \( \chi \). We may also call it as the “frequency” and “wavelength” of a wave that describes the spacetime fluctuation at Planck Scale. On the other hand, the variable \( \tilde{h} \), represents the fundamental energy fluctuation at Planck scale in terms of \( \chi \). We can relate it to \( f \) and \( \lambda \) by using Eq. (10) to derive a modified de Broglie-Planck equations which can be expressed as follows:

$$E = \tilde{h} f \quad p = \frac{\tilde{h}}{\lambda}$$

(16)

Take note that the energy \( E \) is the total energy of the system. What we wanted to define also is the minimum energy scale at Planck scale. For a constant total energy, Eq. (14) becomes,

$$\chi = S/\tilde{h}_c + k = \frac{E t}{\tilde{h}_c} = \frac{E}{E_p}$$

(17)

where we set the integration constants to cancel each other, \( E_p = \tilde{h}_c f_m \) and \( f_m = 1/t \). If we define \( E_p \) as the minimum energy, we can now define the total energy \( E \) in terms of \( E_p \).

$$E = \chi E_p$$

(18)

Now if at Planck scale, the distance travelled by a quantum particle is in \( N \) units of minimum length, \( L_p \), i.e.,

$$x = NL_p$$

(19)

then by Eq. (10), we have,

$$\lambda = \frac{\partial N}{\partial \chi} L_p + N \frac{\partial L_p}{\partial \chi} \quad \frac{1}{f} = \frac{\partial N}{\partial \chi} v + \frac{\partial L_p}{\partial \chi} v$$

(20)

where \( v = \frac{\partial \chi}{\partial \chi} \) is the constant velocity. If \( L_p \) is fundamentally invariant and \( N \) is changing, we have,

$$\lambda = \frac{\partial N}{\partial \chi} L_p \quad \frac{1}{f} = \frac{\partial N}{\partial \chi} v$$

(21)
The partial derivative is related to the energy density \( \rho \),
\[
\rho = \frac{\chi E_p}{NL_p} = \frac{\chi}{N}\rho_p
\]  
(22)
where \( \rho_p = E_p/L_p \) is the minimum energy density. Thus,
\[
\begin{align*}
\lambda &= \left[ N \frac{\partial}{\partial N} \left( \frac{\rho}{\rho_p} \right) + \frac{\rho}{\rho_p} \right] L_p \\
f &= \left[ N \frac{\partial}{\partial N} \left( \frac{\rho}{\rho_p} \right) + \frac{\rho}{\rho_p} \right]^{-1} \frac{v}{L_p}
\end{align*}
\]  
(23)
(24)
If, on the average, the energy density ratio is constant, we have,
\[
\lambda = \frac{\rho}{\rho_p} L_p \quad f = \frac{\rho_p}{\rho} L_p
\]  
(25)
We note that the value of the energy density ratio is inherently dependent on the measurement process as any measurement process will unavoidably add an energy to the system. If the energy density ratio is in the \( 10^{20} \) order and \( L_p \) is in the order of Planck length \( (10^{-33} \text{ cm}) \), then \( \lambda \) would be in the order of Compton Scale \( (10^{-12} \text{ cm}) \) which is historically called as the de Broglie wavelength. At present, the way by which we do our measurement process is only at low energy resolution such that anything at Planck scale can only be observed in the order of Compton scale. If we have enough energy to increase the resolution of our measurement, such that we can send a single fundamental unit of energy to observe a single unit of fundamental length \( L_p \), then \( N = \chi = 1 \) and \( \rho = \rho_p \). This will yield us,
\[
\lambda = L_p \quad f = \frac{v}{L_p}
\]  
(26)
Combining these results with equation Eq.(16), we have,
\[
E = \frac{\hbar}{L_p} \quad p = \frac{\hbar}{L_p}
\]  
(27)
as the Planck scale equivalent of de Broglie-Planck equations which consider an invariant minimum length and a varying energy-dependent Planck “constant”. All of these results will be used and explained later in the formulation of a new quantum interpretation.

To end this section, we note the advantage of modifying the Weyl transformation by changing the conformal term to become a complex function instead of just the usual real function. It allows the possibility of linking the conformal transformation to Quantum Mechanics by showing that the complex conformal term can be written as the quantum probability amplitude. More importantly, the results give us one of the ways by which to describe the Planck scale, i.e., via a modified form of Quantum Mechanics. Another way is to describe the spacetime at Planck scale by formulating a new gravity theory to describe the spacetime fluctuation happening at Planck scale. This will be the topic of the next section where a piece-wise definition of a more general conformal transformation is needed, i.e.,
\[
g_{\mu\nu} \rightarrow \Omega^2 g_{\mu\nu} = \begin{cases} 
\varphi^2 g_{\mu\nu} & \text{(Planck/Quantum Scale)} \\
Y^2 g_{\mu\nu} & \text{(Classical/Macroscopic Scale)}
\end{cases}
\]
where \( \varphi = \varphi(\chi) = e^{i2\pi\chi} \) is a complex function in terms of the variable \( \chi \) while \( Y = Y(\omega) = e^\omega \) is a real function in terms of scalar function \( \omega \). The conformal metric tensor
\[
\tilde{g}_{\mu\nu} = \psi^2 g_{\mu\nu}
\]  
(28)
is suggested here as a low-energy approximation of the metric tensor at Planck scale where its conformal function \( \tilde{\varphi} \) becomes the quantum probability amplitude \( \psi \). It defines not only the so-called “Quantum Spacetime” but also the state of a quantum system. This is in line with the work of Dzhunushaliev\[30\] where he suggested that the metric tensor can be considered as a microscopical state in a statistical system and by Isidro et.al.\[31\] that the State Vector or the wave function is related to the conformal term of the metric tensor.

### III. RICCI FLOW FORMALISM

In the first two decades of the 21st century, tools in Differential Topology like the Ricci Flow had been widely used in theories that attempt to describe the spacetime at Planck Scale\[32–37\]. One of such theories is the work of Dzhunushaliev\[30\] where he suggested that the Ricci Flow is a statistical system that can be used to describe the topology change at Planck Scale. In fact, Isidro et.al.\[31, 58\] showed that Schrödinger Equation can be derived from a conformally flat metric under Ricci Flow. A similar approach will be used here but a generalized form of Dirac Equation will be derived upon consideration of the invariance of the Ricci Flow under Weyl transformation. Also, instead of the usual Ricci Flow, a second-order version of the Ricci Flow will be postulated to describe the topology change at quantum scale. This is to account for the wave nature of a quantum particle and relating it to the wave nature of spacetime curvatures.

#### A. Normalized Ricci Flow

Ricci Flow (R.F.) is a first order partial differential equation formulated by Hamilton\[39\] in 1982 to be used as an analytical tool to solve topological problems. In 2003, it was used by Perelman\[40, 41\] to prove Poincare’s conjencture and Thurston’s Geometrization conjencture\[42\]. It is usually expressed as follows,
\[
\frac{\partial g_{ij}}{\partial t} = -2R_{ij}
\]  
(29)
It is a mean to stretching the metric tensor $g_{ij}$ from negative curvature to positive curvature or to smooth out an arbitrary Reimannian manifold to make it look more symmetric. This is from the point of view of mathematicians. For it to have a physical meaning, we relate it here to General Relativity which is possible since Einstein Field Equation in vacuum case is derivable from a normalized Ricci Flow. For our purpose, the partial derivative in Eq. (29) is considered here to be in terms of the real physical time $t$ and $R_{ij}$ is the Ricci Tensor which has a physical significance in General Relativity as it measures the spacetime curvature.

Consider the following evolution equations for the Ricci tensor($R_{ij}$) and Weyl tensor($W_{ijkl}$) under R.F. [43, 44],

$$\frac{\partial R_{ij}}{\partial t} = \nabla^2 R_{ij} + 2g^{pr}g^{qs}R_{pjql}R_{rs} - 2g^{pr}R_{pi}R_{qj}$$

$$\frac{\partial W_{ijkl}}{\partial t} = \nabla^2 W_{ijkl} + 2(D_{ijkl} - D_{ijlk} + D_{ikjl} - D_{dklj}) - g^{pr}(R_{ip}W_{qjkl} + R_{jp}W_{iqkl} + R_{kp}W_{ijql} + R_{lp}W_{ijqk})$$

$$+ \frac{1}{2}g^{pr}(R_{ip}R_{qk}g_{jl} - R_{ip}R_{qg}g_{jl} + R_{jp}R_{qk}g_{il} - R_{jp}R_{qg}g_{il}) - \frac{R}{2}(R_{ik}g_{jl} - R_{il}g_{jk} + R_{lj}g_{ik} - R_{lj}g_{ik})$$

$$+ R_{ik}R_{jl} - R_{lk}R_{il} + \frac{R^2}{2}(g_{ij}g_{kl} - g_{ik}g_{jl})$$

where $D_{ijkl} = g^{pr}g^{qs}W_{pijr}W_{stkl}$ and

$$\nabla^2 = g^{ij}\nabla_i \nabla_j = g^{ij}\left(\frac{\partial^2}{\partial x^i \partial x^j} - \Gamma^k_{ij} \frac{\partial}{\partial x^k}\right)$$

is the Laplacian with respect to the evolving metric with the ordinary affine connection $\Gamma$ in Reimannian geometry. These equations describe the evolution of the curvatures. However, what is also important for our purpose is the preservation of the volume structure and not just the evolution of spacetime curvatures. The evolution of the volume element $dv = \sqrt{(det g_{ij})}dx$ of the spacetime $M$ is given by [39],

$$\frac{\partial}{\partial t} \log \sqrt{(det g_{ij})}dx = \frac{1}{2}g^{ij} \frac{\partial}{\partial t} g_{ij} = r - R$$

where $r = \frac{\int_{M} R dv}{\int_{M} dv}$ is the average scalar curvature and serves to normalize the R.F., so that the volume is constant. If the volume is not constant and fluctuating in time, to prevent the solution of Eq. (33) from shrinking to a point or expanding to $\infty$, we must consider the Normalized Ricci Flow (NRF) [39],

$$\frac{\partial g_{ij}}{\partial t} = \frac{2}{n}g_{ij} - 2R_{ij}$$

such that,

$$\frac{\partial}{\partial t} \log \sqrt{(det g_{ij})} = 0$$

where $n$ is the number of dimension. However, a general case would be to consider the non-linear NRF by getting the second derivative of Eq. (34) and using Eq. (30),

$$\frac{\partial^2 g_{ij}}{\partial t^2} - \frac{2}{n} \frac{\partial g_{ij}}{\partial t} + 2\nabla^2 R_{ij} + 4g^{pr}g^{qs}R_{pjql}R_{rs} - 4g^{pr}R_{pi}R_{qj} = 0$$

for constant $r$. If we consider the manifold to be an Einstein manifold where $R_{ij} = -\frac{1}{2}kg_{ij}$ for some constant $k$, we have the following wave equation,

$$\frac{\partial^2 g_{ij}}{\partial t^2} - k\nabla^2 g_{ij} + F = 0$$

where $F = F\left(\frac{\partial g_{ij}}{\partial t}, g_{ij}\right)$ is a damping term which is a function of $g_{ij}$ and its first order derivative. However, a more natural starting point would be to consider a nonlinear form of Ricci Flow expressed by a wave equation of the metric tensor,

$$\frac{\partial^2 g_{ij}}{\partial t^2} = -2R_{ij}$$

known as the Hyperbolic Geometric Flow (HGF). It is an equation first introduced by De-Xing Kong and Kefeng Lui in 2006. We postulate that it is an equation that describes the inherent fundamental spacetime fluctuation at the Planck Scale. If we confine such spacetime fluctuation within an invariant volume of space, then HGF must be normalized. Kong and Lui [45] derived a normalized form of HGF,

$$a_{ij}\partial^2_t g_{ij} + b_{ij}\partial_t g_{ij} + c_{ij}g_{ij} = -2R_{ij}$$

where $\partial_t$ is the partial derative in time, while $a_{ij}, b_{ij}$ and $c_{ij}$ are certain smooth functions in $M$. Similar to Eq. (36), the normalized HGF can also be written into a wave equation with a damping term. To show this explicitly, an approximation for the Ricci Tensor $R_{ij}$ in terms of the metric tensor can also be used, i.e.,

$$R_{ij} \approx -\frac{1}{2}\nabla^2 g_{ij}$$

which will then transform the normalized Hyperbolic Geometric Flow (nHGF) as follows:

$$\Box g_{\mu\nu} = 0$$
where \( \Box = a_{\mu\nu} \partial^2 - \nabla^2 + b_{\mu\nu} \partial_\mu + c_{\mu\nu} \) is a modified d’Alembert operator and all Latin indices were replaced to Greek indices for 4-dimensional consideration.

**B. Modified General Relativity**

The connection of nHGF to General Relativity is the case when \( a_{\mu\nu} = b_{\mu\nu} = 0 \) and \( c_{\mu\nu} = c \), where \( c \) is constant which gives us the vacuum case for EFE

\[
R_{\mu\nu} = \frac{1}{2} c g_{\mu\nu}
\]

(41)

For such case, nHGF can be considered as a modified Einstein Field Equation (EFE) for vacuum case. We can add in nHGF an external energy source given by an energy tensor \( T_{\mu\nu} \) to have a modified EFE,

\[
G_{\mu\nu} = k T_{\mu\nu} + W
\]

(42)

where \( G_{\mu\nu} \) is the Einstein Tensor and

\[
W = -(a_{\mu\nu} \partial^2 g_{\mu\nu} + b_{\mu\nu} \partial_\mu g_{\nu\mu})
\]

(43)

is an extra term that modify EFE. This result will be used in the formulation of a new quantum interpretation in Section IV.

**C. Generalized Dirac Equation**

To describe the spacetime fluctuation in Quantum Mechanics, we apply now the modified Weyl transformation on nHGF, it transforms nHGF as follows,

\[
\Box g_{\mu\nu} \rightarrow \Box g_{\mu\nu} = 2 g_{\mu\nu} \Box \psi + \psi^2 \Box g_{\mu\nu}
\]

(44)

where we consider the quantum case of the modified Weyl transformation given by Eq. (28). In order for nHGF to be invariant under Weyl transformation, the first term in Eq. (44) must vanish which gives us the following equation,

\[
\Box \psi = a_{\mu\nu} \partial^2 \psi - \nabla^2 \psi + b_{\mu\nu} \partial_\mu \psi - c_{\mu\nu} \psi = 0
\]

(45)

Notice that by setting the values of \( a_{\mu\nu}, b_{\mu\nu} \) and \( c_{\mu\nu} \) as follows:

\[
a_{\mu\nu} = 1, \quad b_{\mu\nu} = 2 \left( \frac{i m_0 c^2 \beta}{\hbar} \right), \quad c_{\mu\nu} = \left( \frac{i m_0 c^2 \alpha}{\hbar} \right)^2
\]

where \( 1 \) is the identity matrix, \( \alpha = \begin{pmatrix} 0 & \sigma \\ \sigma & 0 \end{pmatrix} \) is written in terms of Pauli matrices \( \sigma \) and \( \beta = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \), Eq. (45) will yield us the following equation:

\[
1 \partial^2 \psi - \nabla^2 \psi + 2 \left( \frac{i m_0 c^2 \beta}{\hbar} \right) \partial_\mu \psi - \left( \frac{i m_0 c^2 \alpha}{\hbar} \right)^2 \psi = 0
\]

(46)

which was derived by Arbab et. al. [47,48] using a quaternion formalism of Quantum Mechanics. He called Eq. (45) as the “Unified Quantum Wave Equation” (UQWE) as he was able to show that Dirac Equation, Klein-Gordon Equation, Schrödinger Equation and Quantum Heat Transport Equation can all be derived from such single equation [49]. In fact, it is just a second order version of Dirac equation. From Eq. (46), it yields us a second-order operator

\[
(\alpha \cdot \nabla)^2 = 1 \partial^2_t + 2 \left( \frac{i m_0 c^2 \beta}{\hbar} \right) \partial_\mu - \left( \frac{m_0 c^2}{\hbar} \right)^2
\]

(47)

where \( \alpha^2 = \beta^2 = 1^2 = 1 \). Factoring and getting the square root will give us the following linear operator:

\[
\alpha \cdot \nabla = 1 \partial_t + \frac{i m_0 c^2 \beta}{\hbar}
\]

(48)

Arranging and putting back the function \( \psi \), it will give us

\[
1 \partial_t \psi - \alpha \cdot \nabla \psi + \frac{i m_0 c^2 \beta}{\hbar} \psi = 0
\]

(49)

which is the Dirac Equation [50]. Though this is definitely not an exact derivation of Dirac Equation as values of \( a_{\mu\nu}, b_{\mu\nu} \) and \( c_{\mu\nu} \) were arbitrarily given, the derivation of a generalized UQWE and Dirac Equation in geometric terms is enough for our goal in this paper. More importantly, a unifying link between UQWE (a generalized and modified Dirac Equation) and nHGF (a generalized and modified Einstein Field Equation) was established as expressed by Eq. (41). This connection will be used later for a fundamental description of a quantum particle at Planck scale.

**D. Other Quantum Equations**

Consider now a charge in a quantum system which modifies the space in the vicinity as it gives additional energy into the system. In the presence of an electric charge \( q \), it yields us a phase transformation in \( \psi \) since the action \( S \) will transform as follows:

\[
S = \int \{ T - q A^\mu \} dt
\]

(50)

where \( T \) is the kinetic energy, \( A^\mu = (A, \phi) \) is the electromagnetic 4-potential and we use the convention \( \hbar = c = 1 \). Using Eq. (44), we yield another wave equation,

\[
\Box A^\mu = 0
\]

(51)

since \( \Box \psi = i(\Box S) \psi = i \{ \int (\Box T - q \Box A^\mu) dt \} \psi = 0 \). Expanding the equation, we have

\[
\Box A^\mu = \Box A^\mu + b_{\mu\nu} \partial_\nu A^\mu + m_0^2 A^\mu = 0
\]

(52)
where we can set \( b_{\mu\nu} = 2i\alpha \beta \neq 0 \) and
\[
b_{\mu\nu} \partial_0 A^\nu = \partial^\mu (\partial_\nu A^\nu) \tag{53}
\]
such that \( \partial_\nu A^\nu \neq 0 \) and we get
\[
\Box A^\mu + \partial^\mu (\partial_\nu A^\nu) + m_0^2 A^\mu = 0 \tag{54}
\]
which is the Proca equation \[51\]. Similar to Eq.\[42\] where an energy stress tensor \( T_{\mu\nu} \) was added, we can add an external source-charge by adding the 4-current density \( J^\mu = (J, \rho) \). The equation becomes;
\[
\Box A^\mu + \partial^\mu (\partial_\nu A^\nu) + m_0^2 A^\mu = J^\mu \tag{55}
\]
which is the inhomogenous Maxwell equation if \( m_0 = 0 \) and Lorenz gauge is preserved. We take note of the fact that the generalization of the Lorenz gauge as expressed in Eq.\[53\] is naturally integrated in the theory in order to derive Proca Equation. On the other hand, if we consider the Kinetic Energy \( T \) as the average kinetic energy of the quantum system, then it is related to the temperature \( T_H \) of the system via the equation: \( T = \frac{1}{2} k_b T_H \), which gives us the following equation
\[
\Box T_H = a_{\mu\nu} \partial_\mu^2 T_H - \nabla^2 T_H + b_{\mu\nu} \partial_\mu T_H + c_{\mu\nu} T_H = 0 \tag{56}
\]
The equation above is known as the Quantum Hyperbolic Heat Transport equation \[52\] but in its most generalized form. This implies that a quantum particle serves as a carrier of heat and by itself can be considered as a thermodynamic system.

IV. BLACK HOLE INTERPRETATION

In this section, a new quantum interpretation will be put forward by analyzing the metric solution of the nHGF. However, it is not intended here to come up with a fully developed quantum interpretation. The section is meant to be a starting point to a more comprehensive presentation of a new quantum interpretation. Survey of other quantum interpretations will not be done except for a very short review of Copenhagen Interpretation for comparison. Topics such as entanglement, measurement problem and double slit experiment among others will be discussed and explained within the context of the new quantum interpretation which we formally called here as Black Hole Interpretation (BHI). The focus would be on the fundamental nature of a quantum particle and the proof of Susskind and Maldacena’s “ER=EPR” conjecture.

In retrospect, the root cause of all the confusion surrounding the interpretational problem of Quantum Mechanics is due to the fact that no one really knows what is the true nature of the so-called “quantum wave”. It all started with the double-slit experiment which seems to suggest that a quantum particle is behaving like a wave, but no one is really sure if the electron is the wave itself or the electron is just riding or moving along with a “guiding wave”. Feynman called the problem of explaining the double-slit experiment as “the central mystery” \[53\]. Without the full grasp of the physical nature of the wave that is associated with a quantum particle, Bohr and others resort to suggest that there is really no physical wave that exists or propagated. The so-called wave properties of a quantum system are said to be just an illusion brought about either by a classical way of thinking of the observer or the classical nature of the instrument being used by the observer at the macroscopic level. This pragmatic approach of Copenhagen Interpretation (CI) became the favored interpretation among physicists nowadays. For CI, the wave function \( \psi \) and its corresponding wave equation, should not be postulated to describe a “quantum wave” that physically exists as what de Broglie and Bohm suggested \[54, 55\]. The Wave Function for CI is just a mathematical tool to describe a quantum state or to predict the possible outcome of an experiment. Here, a new interpretation as an alternative to CI will be put forward based on the new quantum formalism presented in the previous section.

A. The Quantum Wave

The so-called quantum field is suggested here to be an ensemble of waves or fluctuations that physically exist in a quantum system. As discussed in the previous section, for an electrically charged particle, there are three types of wave which are described by the following wave equations:
\[
\Box \psi = 0, \quad \Box A^\mu = 0, \quad \Box g_{\mu\nu} = 0 \tag{57}
\]
that can be unified under a single equation
\[
\left[ \int \left( \Box T - q \Box A^\mu \right) dt + g^{\mu\nu} \Box g_{\mu\nu} \right] \psi^2 = 0 \tag{58}
\]
using Eq.\[14\] and Eq.\[51\]. The first type of wave is an “energy wave” and described by the wave equation,
\[
\Box T = a_{\mu\nu} \partial_\mu^2 T - \nabla^2 T + b_{\mu\nu} \partial_\mu T + c_{\mu\nu} T = 0 \tag{59}
\]
It is a wave equation that describe the energy fluctuation of a quantum system. If the kinetic energy \( T \) is under the equipartition rule \( T = k_b T_H \) where the quantum system is composed of \( \chi \) number of fundamental units of energy, then the equation becomes the Quantum Hyperbolic Heat Transport Equation
\[
\Box T_H = a_{\mu\nu} \partial_\mu^2 T_H - \nabla^2 T_H + b_{\mu\nu} \partial_\mu T_H + c_{\mu\nu} T_H = 0 \tag{60}
\]
in its most generalized form which implies the thermodynamical nature of a quantum system as carrier of heat. For the second type of wave, it involves the fluctuation of electromagnetic vector and scalar potential. It is a
fluctuation is described by the equation below

\[ \Box A^\mu = a_{\mu\nu} \partial_\mu A_\nu - \nabla^2 A^\mu + b_{\mu\nu} \partial_\mu A_\nu + c_{\mu\nu} A^\nu = 0 \]  

which is a general case of Proca Equation in the vacuum case. This wave must have a physical significance since the Aharonov-Bohm Experiment (ABE) is known to establish the physical effect in the presence of electromagnetic potential \( A^\mu \). However, ABE does not give us details on the physical nature of the associated wave for \( A^\mu \). What is definitely clear is that the presence of a charge (not necessarily an electric charge) gives additional energy into the system. Hence, the presence of any charge adds to the energy fluctuations that is associated with a quantum field. The consequence of such energy fluctuations is for the spacetime to fluctuate. The spacetime fluctuation that is associated with a quantum field. A further proof of this will be elaborated in the succeeding section by analyzing the behavior of a quantum field.

The damping term account to the localization of the spacetime fluctuation in a given volume of space. In a quantum system, this could account for the particle-like behavior of a quantum field. A further proof of this will be elaborated in the succeeding section by analyzing the metric solution of nHGF.

B. Black Hole Nature

In their paper on nHGF, Shu and Shen were able to show that nHGF satisfies Birkhoff’s Theorem and were able to solve an exact metric solution of it which turns out to be a black hole solution [56]. The metric was shown to be,

\[ ds^2 = u(r) \left( 1 - \frac{2m}{r} - \frac{\Lambda}{3} r^2 \right) c^2 dt^2 - \left( 1 - \frac{2m}{r} - \frac{\Lambda}{3} r^2 \right) dr^2 + r^2 d\Omega^2 \]  

where \( u(r) = (r - r_a)^{\sigma_a} (r - r_b)^{\sigma_b} (r - r_c)^{\sigma_c}, \sigma_i = \frac{\Lambda}{\kappa_i}, \kappa_i \) corresponds to the surface gravity of the black hole, while \( r_a, r_b, r_c \) are three roots of \[ 1 - \frac{2m}{r} - \frac{\Lambda}{3} r^2 = 0 \]

which depends on the value of decoupled constant \( \Lambda \). For \( \Lambda = 0 \), the solution gives a Schwarzschild metric which is well-known to have a wormhole solution. The solution was first derived by Einstein and Rosen in their 1935 paper [57], i.e.,

\[ ds^2 = \frac{c^2}{\epsilon^2 + 2m} dt^2 - 4(\epsilon^2 + 2m)du^2 - (\epsilon^2 + 2m)^2 d\Omega^2 \]

by setting \( \epsilon^2 = r - 2m \) such that the metric describes two regions of space (or sheets) for \( \epsilon < 0 \) and \( \epsilon > 0 \) that is joined at the hyperplane \( r = 2m \). For \( \Lambda \neq 0 \), Shu and Shen derived a black hole solution that comes in two types. The first type is the case for \( \frac{1}{\kappa} \geq \frac{4}{9} r_c^2 \), where \( r_g = 2m \) is the Schwarzschild radius. This type has two horizons with radii \( r_a, r_c \) since \( r_a < 0 \) and \( r_c > r_b > 0 \). It was assumed that between the two horizons, with radii \( r_c \) and \( r_b \), the true event horizon is the outermost horizon with radius \( r_c \). The second type is for the case \( \frac{1}{\kappa} < \frac{4}{9} r_c^2 \). For this case, Shu and Shen considered only one event horizon as the solution involves three radii in which two of them are complex \( (r_b = r^* \) while the other one is real \( (r_a) \).

Note however that if we set \( \Lambda = \frac{1}{2} q^2 \), for an electric charge \( q \), we get the following Schwarzschild static and spherically symmetric solution for the combined field, gravity and electricity, that Einstein and Rosen also derived in their 1935 paper

\[ ds^2 = u(r) \left( 1 - \frac{2m}{r} - \frac{q^2}{2r^2} \right) c^2 dt^2 - \left( 1 - \frac{2m}{r} - \frac{q^2}{2r^2} \right) dr^2 + r^2 d\Omega^2 \]

which by setting \( \epsilon = r^2 - \frac{q^2}{2r} \) to eliminate singularities and \( m = 0 \), the metric becomes

\[ ds^2 = \left( \frac{2c^2}{2\epsilon^2 + \frac{q^2}{2}} \right) dt^2 - du^2 - \left( \epsilon^2 + \frac{q^2}{2} \right) d\Omega^2 \]

Again, the metric exhibit a wormhole solution. However, in 1962, John Archibald Wheeler and Robert W. Fuller published a paper [58] showing that the type of wormhole that was derived by Einstein and Rosen, is unstable. If it connects two parts of the same universe, it will pinch off too quickly for light (or any particle moving slower than light) that falls in from one exterior region to make it to the other exterior region. May that be the case, what is clear at this point is that the theory presented here suggests that there must be an associated sub-microscopic black hole in every quantum field.

The idea that quantum fields/particles are associated with black holes at the fundamental level is not something new as it was already explored by others [59, 60] since the pioneering work of Carter [61]. Carter considered quantum particles as black holes with naked singularity. Here, a quantum field is considered to be an energy fluctuation within a sub-microscopic black hole as mathematically described by Eq. [44]. The confined
energy fluctuation is described by $\Box \psi = 0$ while the sub-microscopic black hole is described by $\Box g_{\mu\nu} = 0$. This black hole configuration of a quantum field is inferred here to act like a kind of mechanism which gives the quantum field the appearance of a point-like particle at low-energy approximation.

C. Traversable Wormholes

In order for the sub-microscopic black hole that is associated with a quantum field to be a traversable wormhole, an external energy must be added. Instead of using the metric solution of Shu and Shen, we can use the black hole solution of the modified EFE that we derived in Section III B

$$ G_{\mu\nu} = kT_{\mu\nu} + W $$ (67)

where $W = -(a_{\mu\nu}\partial_{\mu}g_{\nu\alpha} + b_{\mu\nu}\partial_{\nu}g_{\mu\alpha})$, is considered here to be associated with the inherent (negative) energy of empty space due to quantum fluctuations. A similar modification of EFE was also done by Novikov [68] which also involves additional terms that contain second and first order derivative of the metric tensor $g_{\mu\nu}$ with particular values for $a_{\mu\nu}$ and $b_{\mu\nu}$. He called it as “Quantum Modification of General Relativity” as the extra terms added in EFE represent the quantum effects of the production of matter/energy by the vacuum or empty space. Another approach is to include an exotic matter content in the energy tensor $T_{\mu\nu}$ which can be expressed as an anisotropic fluid,

$$ T_{\mu\nu} = (\rho + p_t)u_{\mu}u_{\nu} - p_t g_{\mu\nu} + (p_r - p_t)x_{\mu}x_{\nu} $$ (68)

where $\rho$ is the energy density, $p_r$ and $p_t$ are the radial and tangential pressure, respectively, while $u_{\mu}$ and $x_{\mu}$ are the 4-vector velocities along the traverse and tangential directions which satisfy the relations $u_{\mu}u^{\mu} = -1$ and $x_{\mu}x^{\mu} = 1$. These types of wormhole is what we called here as “Planckian wormholes” where quantum consideration will allow enough time for it to be traversable upon interaction with the negative energy generated by the surrounding empty space.

In the past, different models of traversable wormhole had been put forward that consider the role of quantum fluctuations. Most prominent of these models can be found in the work of Morris and Thorne [63] where they proposed traversable wormholes as solutions of Einstein’s Field Equation that contain exotic matter with negative energy density. The stability of the wormhole depends on the exotic matter content. Classically, it is not possible to have enough negative energy sources as it violates the Average Null Energy Condition (ANEC). There are many attempts to have a model of traversable wormhole which not necessarily needed an exotic matter or negative energy sources like some of the wormhole models of Visser [70]. All of this however is at the macroscopic level. At Planck scale, one must also consider quantum effect. The only known pure quantum effect to produce negative energy as source of exotic matter is the Casimir effect.

Casimir effect is a phenomenon predicted in 1948 and later observed in which it involves the existence of an attractive force $F_c$ between pair of neutral and parallel conducting plates [71],

$$ F_c = -\frac{\pi^2}{240 d^4} A_c $$ (69)

where $d$ is the distance of separation between the plates and $A_c$ is the surface area of the plates. This force exists because of the negative energy density between the plates [72],

$$ \rho_c = -\frac{\pi^2}{720} \frac{1}{d^4} $$ (70)

which is associated with the zero point energy of quantum electrodynamics vacuum. The pressure can be derived by renormalizing the negative energy,

$$ p_c = \frac{F_c}{A_c} = -\frac{\pi^2}{240} \frac{1}{d^4} $$ (71)

On the other hand, if fundamentally, a quantum particle is an energy fluctuation within a sub-microscopic black hole, then we can use some of the well-known theorems in Black Hole Physics. One of which is the idea that all black holes are thermodynamic systems that obeys the 1st Law of Thermodynamics,

$$ F dx = T_H dS_E $$ (72)

from which we can define an entropic force by using the Bekenstein Formula [62],

$$ dS_E = k_b \frac{mc}{h} dA $$ (73)

where $S_E$ is the entropy, $k_b$ is the Boltzmann’s constant, $m$ is the mass of a test particle and $dx$ is its distance from the associated black hole of the quantum system with a horizon area $A$. The entropic force is given by,

$$ F = \frac{dS_E}{dx} T_H = k_b \frac{mc}{h} T_H \frac{dA}{dx} $$ (74)

Now, the heat generated is brought about by the motion of the quantum particle. As the quantum particle moves in empty space, it interacts with virtual particles and accelerates as it moves randomly in any direction similar to a Brownian motion. The interaction and acceleration will cause for the system to generate heat, a phenomenon known as the Unruh effect where the corresponding temperature can be expressed in terms of the particle’s acceleration [63],

$$ T_H = \frac{h}{2\pi c k_b a} $$ (75)
where $\hbar$ is the reduced Planck constant, $a$ is the acceleration, and $c$ is the speed of light. The particle will then acquire additional energy and increases its horizon area. However, as soon as the corresponding black hole releases an excess heat by emission of the so-called Hawking-Unruh radiation, the horizon area decreases ($\frac{dA}{dt} < 0$) and the black hole returns to its initial horizon area $A_b$ with initial radius $x_0$. If we set $\frac{dA}{dx}|_{x_0} = -\hbar k_0 A_b$, i.e., the change in $A$ is proportional to the initial horizon area for some constant of proportionality $k_0$, we yield an entropic force given by

$$F = -k_0 m \frac{c}{\hbar} T_H A_b = -k_0 \frac{ma}{2\pi} A_b \quad (76)$$

by substituting Eq.(75). The corresponding pressure is given by,

$$p = \frac{F}{A_b} = -k_0 \frac{ma}{2\pi} \quad (77)$$

We note the striking similarity in nature of the derived entropic force and the so-called Casimir force. We inferred here that the entropic force is similar in nature to the Casimir force and therefore a possible source of negative energy. With this result, we ought to suggest that the type of traversable wormhole that can be associated to a quantum field, would be those considered as a Casimir type of wormhole similar to the one described by Garattini [72]. This is due to the unique interaction of a sub-microscopic black hole to its surrounding empty space. We picture the surface of the sub-microscopic black hole that is associated with a quantum field, to be a place where there is always a build up of negative energy. Such build up of negative energy triggers the opening of a wormhole and stabilizing it to be traversable. In addition, the corresponding field of entropic force reminds us of Bohm’s idea of “quantum potential” [54] or de Broglie’s concept of “pilot wave” [53] as the quantum particle can interact with its own entropic field. It is suggested here to be the root cause of the probabilistic nature of quantum particle’s motion. The motion is suggested here to be similar with Brownian motion but under the influence of field of entropic force that act like a kind of a “sub-quantum medium” as inferred by others [65, 66]. However, as we have shown here, the probabilistic nature of Quantum Mechanics is not just thermodynamic in nature but also “geometric-dynamic” as suggested by John Wheeler [67]. His concept of “quantum foam” on the nature of spacetime at Planck scale was considered here which he pictured as a region where there is a continuous generation of sub-microscopic wormholes. Once the black hole associated with the quantum field consistently turns into a traversable wormhole, it will allow for the quantum field to travel from one point in space to another by passing through a series of sub-microscopic wormhole for a given period of time. Such period of time must be within the limit set by Heisenberg Uncertainty Principle. However, at Planck scale, one must consider the inclusion of a minimum length and energy scale that will generalized the Heisenberg Uncertainty Principle. In fact, this is currently being explored by people who are working on traversable wormhole. One example of it is the very recent work of Jusufi et.al. [74] by which they construct a traversable Casimir wormhole that uses a generalized uncertainty principle that is modified by the inclusion of a minimum length scale in the order of Planck length. However, we will not go into details on the suitable wormhole solution for our theory as it will discreet too much on the current topic of this paper. At this point, it is enough to say that a traversable Casimir wormhole that obeys a modified Heisenberg Uncertainty Principle is what we suggest to be the type of wormhole that can be associated with a quantum field. The modification of the Heisenberg Uncertainty Principle by inclusion of a minimum length and energy scale will be the topic of the next subsection.

### D. Modified Uncertainty Principle

At present, almost all quantum interpretations have always considered Heisenberg Uncertainty Principle to be a fundamental principle. In the original formulation of Heisenberg, the line of thought would be that the nature of the measuring process to observe a quantum particle is fundamentally limited. Hence, the origin of the uncertainties in Quantum Mechanics is not Nature itself but primarily by the limitation of the observer and the measurement process that the observer uses. Here we suggest that the origin of the uncertainties is also brought about by the fundamental nature of spacetime at Planck scale that is different from the classical macroscopic world where spacetime is always considered smooth and continuous. Here we suggest that at Planck scale, spacetime is not smooth and continuous but has “holes”. These holes are like a tiny rip in a smooth fabric of spacetime which are actually the mouths of a sub-microscopic wormholes. The generation of these wormholes is brought about by the presence of a quantum field.

As pointed out in the previous subsection, the black hole associated with the quantum field can become a wormhole as it interacts with its surrounding empty space. Since the quantum field is continuously in contact with the negative Casimir energy in empty space, it is therefore possible that it travels through a series of wormholes. Since the throats of the wormholes are theoretically unobservable, a quantum field will simply appear to emerge from one point in space to another as it travels from one wormhole to another. It is as if the quantum particle is in a state of continuous quantum tunneling in space without any barrier. Thus, the distance $L_p$ travelled by a quantum field from one mouth of the wormhole to another can never be known with certainty. As it enters from one mouth of the wormhole to another, the total distance travelled $x$ from one wormhole to another is given by Eq.(19) and has a corresponding...
uncertainty, 
\[
\delta x = N \delta L_p \tag{78}
\]
where \( \delta L_p \) is the uncertainty in measuring \( L_p \). Substituting this to Eq.(27), it yield us
\[
\delta E = \hbar \frac{v}{\delta L_p} = \hbar \frac{N v}{\delta x}, \quad p = \frac{\hbar}{\delta L_p} = \frac{N \hbar}{\delta x} \tag{79}
\]
Thus we have, (for \( N > 0 \))
\[
\delta E \delta t > \hbar \quad \delta p \delta x > \hbar \tag{80}
\]
where \( \delta x \) and \( \delta t = \delta x/v \) are the uncertainties in position and time, respectively, while \( \delta E \) and \( \delta p \) are the uncertainties in energy and momentum, respectively. Note that unlike with other quantum gravity theories, the length \( L_p \) is not only interpreted here as a fundamental unit of a quantized spacetime but it is also the distance between two mouths of a Planckian wormhole. Furthermore, while other quantum gravity theories such as Loop Quantum Gravity considers the notion of loops\[62\], spins\[60\] and causal sets\[77, 78\] as the fundamental building blocks of a quantized spacetime, here we have “holes” and “handles” which correspond to the “mouths” and “throats” of the Planckian wormholes. Thus, the main advantage of our theory is that, in principle, one can formally describe the whole theory using Differential Topology.

**E. Born’s Conjecture**

Born’s conjecture, which is sometimes called as Born Postulate or Born rule, is the foundation upon which the probabilistic formalism of Quantum Mechanics rested upon. In its basic form, it states that the square of the absolute value of probability amplitude \( \psi \) is equal to the probability \( P \) of finding the quantum particle at a given point in space. Consequently, the value of \( |\psi|^2 \) must be normalized to have a value between zero and one, i.e.,
\[
0 \leq |\psi|^2 \leq 1 \tag{81}
\]
Born Principle is closely connected with the Measurement Problem since the act of measurement causes the collapse of \( |\psi|^2 \) to unity. To prove Born’s conjecture within the context of BHI, we consider the fact that in any measurement process there are particles that interact, i.e., the particle being observed and the particle within a measuring device that is used in the measurement process. In Standard Model, interaction between two particles is via exchange of mediating particles. In BHI, the interaction between two sub-microscopic black holes is via an energy transfer of one black hole to another. If the interaction is attractive, the black holes tends to merge into a single black hole. What keeps two black holes from merging are other properties of the black holes such as its charges and spins. The energy transfer will lead to an increase in the entropy and volume of the black holes. As the observed black hole emit a Hawking radiation, it will compress or “collapse” itself into a smaller volume \( V_f \) from its initial volume \( V_i \). The probability \( P \) of finding \( \chi \) number of fundamental unit of energy in a smaller volume is given by,
\[
P = \left( \frac{V_f}{V_i} \right)^\chi \tag{82}
\]
while \( 1 - P \) is the probability of finding the particles outside \( V_f \). Rearranging will give us,
\[
\chi = \ln^{-1} \left( \frac{V_f}{V_i} \right) \ln P \tag{83}
\]
Now, if there is no energy transfer, the energy remains constant. We can use an energy-dependent conformal function \( \psi = e^{i 2 \pi E t / \hbar} \) to represent the observed particle with constant energy \( E \). Its natural logarithm is given by,
\[
-\frac{i}{2 \pi} \ln \psi = \frac{Et}{\hbar} = \frac{E}{h f} = \frac{E}{E_q} = \chi \tag{84}
\]
where \( f = 1/t \) and \( E_q = h f \) is the minimum energy in the order of Compton scale which is the energy scale of our current measurement processes at the quantum scale. Combining the conjugate \( \chi = \frac{i}{2 \pi} \ln \psi^* \) with Eq.(83), we have,
\[
\chi = \frac{i}{4 \pi} \ln \left[ \frac{|\psi|^2}{\psi^2} \right] \tag{85}
\]
Comparing this with Eq.(83), we have \( \ln^{-1} (V_f/V_i) = i/4\pi \), which implies \( V_f = V_i \) or the volume remains constant, and
\[
P = \frac{|\psi|^2}{\psi^2} \tag{86}
\]
Since \( 0 \leq P \leq 1 \), then \( 0 \leq P|\psi|^2 \leq \psi^2 \) and
\[
0 \leq |\psi|^2 \leq \psi^2 \tag{87}
\]
Since \( |\psi|^2 \) is always real, then the value for \( \psi^2 \) should always be real. The only way for it to be real is for \( \chi \) to have integral values in order to eliminate the imaginary part of \( \psi \). This will make \( \psi^2 = 1 \) and gives us the normalization condition,
\[
0 \leq |\psi|^2 \leq 1 \tag{88}
\]
and the expression
\[
P = |\psi|^2 \tag{89}
\]
which is Born’s conjecture. In retrospect, Born simply hypothesized that the quantity \( |\psi|^2 \) is equal to the probability of observing a particle at a given point in space and therefore need to be normalized. Here, we suggest
that Born’s conjecture is not a fundamental principle. It can be derived from the consideration that quantum particles are black holes which have entropy that changes as they interact with one another. It is a principle that was amazingly hypothesized by Born, not of course by sheer luck but by impressive physical intuition on how the mathematics can be related to the interaction that is happening between a physical system and a measurement process.

In comparison with String Theory, the interaction we just discussed in a measurement process is similar to the interaction between two closed strings, but instead of 1-dimensional strings, a 3-dimensional sub-microscopic black holes are involve. In contrast, our theory does not need an extra dimensions as required in String Theory. In fact, the description of a black hole can be thought of as encoded on a lower-dimensional boundary of the black hole’s region if one is to uphold the Holographic Principle in Black Hole Physics.

F. The “ER=EPR” Conjecture

Historically, quantum entanglement was realized as a fundamental quantum property upon resolution of the Einstein-Podolsky-Rosen (EPR) paradox by series of experimental confirmation in the 1980s of the violation of Bell’s Inequality. One of the recently proposed ideas to explain quantum entanglement is the so-called “ER=EPR” conjecture of Susskind and Maldacena. The conjecture posit the idea that quantum particles are entangled because it is physically connected via an Einstein-Rosen (ER) bridges or wormholes. To prove it here in the context of BHI, we use Hawking’s Area Theorem which states that the horizon area of a black hole never decreases between two not intersecting hypersurfaces under certain conditions. It implies an inequality between the initial and final horizon area of the black hole, say for two merging black holes with Horizon Area $A_1$ and $A_2$, we have

$$A_1 + A_2 < A_{tot}$$  \hspace{1cm} (90)

where $A_{tot}$ is the resulting horizon area. If the Holographic Principle holds, then the number of bits (units of information) on the horizon area is given by

$$\chi = \frac{c^3}{G\hbar} A$$ \hspace{1cm} (91)

where each bit corresponds to a unit of energy such that by equipartition rule the total energy $E$ is given by

$$E = \frac{1}{2} k_b \chi T_H$$ \hspace{1cm} (92)

Thus, for two black holes merging,

$$E_1 + E_2 < E_{tot}$$ \hspace{1cm} (93)

where $E_1$ and $E_2$ is the corresponding initial energy of the two black holes and $E_{tot}$ is the final energy. Since the conformal function $\psi = \psi(E)$ is a function of energy, there must be an inequality also between the initial and final conformal functions, i.e., $\psi_1 + \psi_2 < \psi_{tot}$ which also implies that

$$\psi_1^2 + \psi_2^2 < \psi_{tot}^2$$ \hspace{1cm} (94)

The inequality requires an additional term $m(A_1, A_2) \geq 0$ such that

$$\psi_{tot}^2 = \psi_1^2 + \psi_2^2 + m(A_1, A_2)$$ \hspace{1cm} (95)

Now, using Eq. (94), we therefore have,

$$|\psi_{tot}|^2 = |\psi_1|^2 + |\psi_2|^2 + m(A_1, A_2)$$ \hspace{1cm} (96)

If we let $P_{tot} = P_1 = P_2 = 1$, we can write Eq. (96) in a more compact form,

$$|\psi_{tot}|^2 = |\psi_1|^2 + |\psi_2|^2 + m(A_1, A_2) = |\psi_1 + \psi_2|^2$$ \hspace{1cm} (97)

which is the familiar equation for quantum superposition by setting $m(A_1, A_2)$ as the quantum interference term. This implies that the two conformal functions can be represented by a single conformal function, i.e.,

$$\psi_{tot} = \psi_1 + \psi_2$$ \hspace{1cm} (98)

By multiplying Eq. (95) with $g_{\mu\nu}$, a conformal metric tensor can be defined as a linear combination of three conformal metric tensors,

$$\bar{g}^{(tot)}_{\mu\nu} = \bar{g}^{(1)}_{\mu\nu} + \bar{g}^{(2)}_{\mu\nu} + \bar{g}^{m}_{\mu\nu}$$ \hspace{1cm} (99)

where $\bar{g}^{m}_{\mu\nu} = m(A_1, A_2) g_{\mu\nu}$. This gives us a metric tensor fluctuation,

$$\square \bar{g}^{(tot)}_{\mu\nu} = \square \bar{g}^{(1)}_{\mu\nu} + \square \bar{g}^{(2)}_{\mu\nu} + \square \bar{g}^{m}_{\mu\nu} = 0$$ \hspace{1cm} (100)

which can be interpreted as two quantum particles, represented by $\square \bar{g}^{(1)}_{\mu\nu} = 0$, and $\square \bar{g}^{(2)}_{\mu\nu} = 0$, connected by a wormhole given by $\square \bar{g}^{m}_{\mu\nu} = 0$. Another interpretation would be that the two particles are not connected by a single wormhole but by a series of interconnected wormholes since the entanglement term can be written as

$$m(A_1, A_2) = m_1 + m_2 + m_3 + \ldots$$ \hspace{1cm} (101)

such that we have a superposition of conformal metric tensors

$$\bar{g}^{m}_{\mu\nu} = \bar{g}^{m_1}_{\mu\nu} + \bar{g}^{m_2}_{\mu\nu} + \bar{g}^{m_3}_{\mu\nu} + \ldots$$ \hspace{1cm} (102)

which gives us,

$$\square \bar{g}^{m}_{\mu\nu} = \square \bar{g}^{m_1}_{\mu\nu} + \square \bar{g}^{m_2}_{\mu\nu} + \square \bar{g}^{m_3}_{\mu\nu} + \ldots = 0$$ \hspace{1cm} (103)

where each term is equal to zero and represents a wormhole. Thus, even if two particles are separated by a very large distance they can still be connected by a wormhole.
G. The Interference Pattern

As mentioned in the previous subsections, a quantum particle in motion will appear to emerge from one point in space to another corresponding to every mouth of the wormhole it enters. This would easily explain the so-called “quantum tunneling” where particle seems to emerge beyond a barrier. Similarly, the famous double slit experiment can also be explained where a single particle seems to pass thru both the slits, when in fact, it is possible that it does not at all pass thru any of the slits. Simply, the two regions or points in space, before and beyond the slits, are connected by a wormhole. The number of points in space or mouths of the wormholes, where the quantum field enters and emerges is given by $2^N$ where $N$ is the number of minimum length $L_p$ or the number of wormholes it enters. In Eq. (22), the variable $N$ is proportional to $\chi$, i.e.,

$$N = \left( \frac{\rho_p}{\rho} \right) \chi$$  \hspace{1cm} (104)

where, on the average, the energy density ratio is constant. For the case of particle in motion, the variable $N$ changes in time. The distance travelled by the particle is in $N$ units of $L_p$ while the velocity $v$ is proportional to the rate of change of $N$ in time,

$$v = \frac{dx}{dt} = L_p \frac{dN}{dt}$$  \hspace{1cm} (105)

The time derivative of $N$ can be expressed as follows

$$\frac{dN}{dt} = \left( \frac{\rho_p}{\rho} \right) \frac{d\chi}{dt} = \left( \frac{T_H \rho_p}{Q} \right) \frac{dS_E}{dt}$$  \hspace{1cm} (106)

since the entropy $S_E$ can be expressed in terms of $\chi$,

$$S_E = \frac{E_H}{T_H} = \frac{Q}{T_H} \chi$$  \hspace{1cm} (107)

where $E_H$ is the total heat of the system which is equal to $\chi$ units of heat $Q$ that is generated by each unit of fundamental energy. Since by Second Law of Thermodynamics, $\frac{dS}{dt} > 0$, then,

$$\frac{dN}{dt} > 0$$  \hspace{1cm} (108)

This implies that, as $N$ increases in time, it limits the possible points in space where the particle will emerge. This limitation dictates the path of the particle and could form a pattern. In a set up like in a double slit experiment, the pattern that emerge is very much similar with the interference pattern that we see in the phenomenon of wave interference (See Figure 1.).

V. SUMMARY AND RECOMMENDATION

A new quantum formalism and interpretation were presented based on the idea that at the Planck Scale, the spacetime is inherently quantized and fluctuating where the Laws of Quantum Mechanics and Relativity are modified. The quantized nature of the spacetime is described via an inclusion of a minimum length and energy scale. On the other hand, the inherent spacetime fluctuation at Planck scale was suggested to be described by a second-order version of the Ricci Flow and the transformation of the metric tensor via a modified Weyl transformation. Out of theory describing the dynamics of such spacetime, Quantum Mechanics was shown to be a low-energy approximation of such theory. The theory, in essence, is a conformal gravity theory of Quantum Me-
mechanics at Planck scale. We formally called the theory as “Topometrodynamics” since it involves a topological, topometric and geometrodynamical description of spacetime at Planck scale. One of the advantages of the theory, is it offers a new approach for the resolution of the foundational problems of Quantum Mechanics such that a new quantum formalism and interpretation were formulated. The new quantum formalism suggests that, everything that can possibly known in a quantum system are encapsulated not just in the wave function \( \psi \) alone but in a conformal metric tensor \( g_{\mu\nu} = \psi^2 g_{\mu\nu} \) as the formalism considers also the spacetime fluctuation at the quantum scale. On the other hand, the new quantum interpretation suggests that a quantum field can be considered as an energy fluctuation at Planck Scale that is confined within a sub-microscopic black hole that can turn into a wormhole. The probabilistic nature and “non-classical” properties of Quantum Mechanics were shown to be associated with the role of an entropic force, as it allows for the passage of the quantum particle through a series of Planckian wormholes. Also, “ER=EPR” conjecture and Born’s conjecture were both proven using some of the theorems in Black Hole Physics, while Einstein-Planck equations and Heisenberg Uncertainty Principle were generalized by inclusion of a minimum energy/length scale and a varying Planck “constant”.

It is recommended that a full-blown quantum interpretation and formalism should be developed out of the theory with perhaps a more rigorous formalism using Differential Topology. Also, a possible link and implication of the theory to Standard Model, Loop Quantum Gravity and String Theory can be considered. Lastly, possible application of the theory to the origin of inertia, proton radius puzzle and cosmological problems can also be explored.

Acknowledgments

I am very much grateful to the NEU Board of Trustees and Administration, Office of the Vice President for Research and the University Research Center. Also to my loving wife who supported me in this time of pandemic.
