THE SUSPENSION OF A 4-MANIFOLD AND ITS APPLICATIONS

TSELEUNG SO AND STEPHEN THERIAULT

Abstract. Let $M$ be a smooth, orientable, closed, connected 4-manifold and suppose that $H_1(M;\mathbb{Z})$ is finitely generated and has no 2-torsion. We give a homotopy decomposition of the suspension of $M$ in terms of spheres, Moore spaces and $\Sigma\mathbb{C}P^2$. This is used to calculate the $K$-theory of $M$ as a group and to determine the homotopy types of certain current groups and gauge groups.

1. Introduction

Let $M$ be a smooth, orientable, closed, connected 4-manifold. This implies by Morse theory that $M$ has a $CW$-structure with one 4-cell. Suppose that $H_1(M;\mathbb{Z})$ is finitely generated and has no 2-torsion. Specifically, assume that:

- $H_1(M;\mathbb{Z}) \cong \mathbb{Z}^m \oplus \bigoplus_{j=1}^n \mathbb{Z}/b_j\mathbb{Z}$;

- each $b_j$ is a prime power, where the prime is odd.

From (1), by Poincaré Duality, the integral homology of $M$ is:

<table>
<thead>
<tr>
<th>$i$</th>
<th>$H_i(M;\mathbb{Z})$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$\mathbb{Z}$</td>
</tr>
<tr>

</table>

where $d \geq 0$ can be any integer. Our main theorem identifies the homotopy type of $\Sigma M$.

Theorem 1.1. Let $M$ be a smooth, orientable, closed, connected 4-manifold and suppose that $H_1(M;\mathbb{Z})$ is finitely generated and has no 2-torsion. If $M$ is Spin then there is a homotopy equivalence

$$\Sigma M \simeq \left( \bigvee_{i=1}^m (S^2 \vee S^4) \right) \vee \left( \bigvee_{j=1}^n (P^3(b_j) \vee P^4(b_j)) \right) \vee \left( \bigvee_{k=1}^d S^3 \right) \vee S^5.$$ 

If $M$ is non-Spin then there is a homotopy equivalence

$$\Sigma M \simeq \left( \bigvee_{i=1}^m (S^2 \vee S^4) \right) \vee \left( \bigvee_{j=1}^n (P^3(b_j) \vee P^4(b_j)) \right) \vee \left( \bigvee_{k=1}^{d-1} S^3 \right) \vee \Sigma\mathbb{C}P^2.$$
Notice that Theorem 1.1 implies that the homotopy type of $\Sigma M$ is completely determined by only two properties: (i) whether $M$ is Spin or not and (ii) $H_\ast(M; \mathbb{Z})$ (or equivalently, $H^\ast(M; \mathbb{Z})$).

Interestingly, while suspending a manifold loses all the geometry, it does give access to many other properties. Theorem 1.1 is applied in three different contexts: to determine the real, complex and quaternionic $K$-theory of $M$, to determine the homotopy type of certain current groups associated to $M$, and to determine the homotopy type of certain gauge groups associated to $M$. These applications are discussed in detail in Section 6.

To prove Theorem 1.1 new methods are developed that use homology and cohomology to detect whether certain maps are null homotopic. This generalizes Neisendorfer’s work in defining and determining the mod-$p^r$ Hopf invariant [17].

2. Preliminary information on Moore spaces

This section records some information on the homotopy groups of Moore spaces which will be needed later. For $m \geq 2$ and $k \geq 2$, the mod-$k$ Moore space $P^m(k)$ of dimension $m$ is the homotopy cofibre of the degree $k$ map on $S^{m-1}$. Notice that $\Sigma P^m(k) \simeq P^{m+1}(k)$.

**Lemma 2.1.** If $p$ is an odd prime and $r \geq 1$ then $\pi_3(P^3(p^r)) \cong \mathbb{Z}/p^r\mathbb{Z}$.

**Proof.** Consider the homotopy fibration $F^3(p^r) \longrightarrow P^3(p^r) \longrightarrow S^3$ where $q$ is the pinch map to the top cell. This induces an exact sequence

$$[S^3, \Omega S^2] \longrightarrow [S^3, F^3(p^r)] \longrightarrow [S^3, P^3(p^r)] \xrightarrow{q_*} [S^3, S^3].$$

At odd primes, $\pi_3(\Omega S^3) \cong 0$. Since $P^3(p^r)$ is rationally trivial, any map $f : S^3 \longrightarrow P^3(p^r)$ lifts to a map $f' : S^3 \longrightarrow F^3(p^r)$. Hence $q_* = 0$. Thus, by exactness, $\pi_3(F^3(p^r)) \cong \pi_3(P^3(p^r))$.

To complete the proof it is now equivalent to show that $\pi_2(\Omega F^3(p^r)) \cong \mathbb{Z}/p^r\mathbb{Z}$. For $m \geq 1$, let $S^{2m+1}\{p^r\}$ be the homotopy fibre of the degree $p^r$ map on $S^{2m+1}$. In particular, $S^{2m+1}\{p^r\}$ is $(2m-1)$-connected. By [16, Proposition 14.2] there is a homotopy equivalence

$$\Omega F^3(p^r) \simeq S^1 \times \left( \prod_{j=1}^{\infty} S^{2p^j-1}\{p^{j+1}\} \right) \times \Omega R^3(p^r)$$

where $R^3(p^r)$ is a wedge of mod-$p^r$ Moore spaces consisting of a single copy of $P^4(p^r)$ and all other wedge summands being at least 3-connected. In particular, for $R^3(p^r)$, by the Hilton-Milnor Theorem there is an isomorphism $\pi_3(R^3(p^r)) \cong \pi_3(P^4(p^r))$. Further, the Hurewicz homomorphism implies that $\pi_3(P^4(p^r)) \cong H_3(P^4(p^r)) \cong \mathbb{Z}/p^r\mathbb{Z}$. Returning to the decomposition of $\Omega F^3(p^r)$, since each space $S^{2p^j-1}\{p^{j+1}\}$ is at least 3-connected, we obtain $\pi_2(\Omega F^3(p^r)) \cong \pi_2(\Omega R^3(p^r))$ and we have just seen that $\pi_2(\Omega R^3(p^r)) \cong \mathbb{Z}/p^r\mathbb{Z}$.

**Lemma 2.2.** [19, Lemma 3.3] If $p$ is an odd prime and $r \geq 1$ then $\pi_4(P^3(p^r)) \cong 0$ and $\pi_4(P^4(p^r)) \cong 0$.

**Lemma 2.3.** [16, Corollary 6.6] Let $p$ be an odd prime, $s, t \geq 1$ and $m, n \geq 2$. Then there is a homotopy equivalence

$$P^m(p^s) \land P^n(p^t) \simeq P^{m+n-1}(p^{\min(s,t)}) \lor P^{m+n}(p^{\min(s,t)}).$$

**Lemma 2.4.** Let $p$ be an odd prime and $s, t \geq 1$. Then $\pi_3(\Sigma P^2(p^s) \land P^2(p^t)) \cong \mathbb{Z}/p^{\min(s,t)}\mathbb{Z}$. 
Proposition 3.2. Let $P$ be an odd prime and let $s$ and $t$ be integers such that $s, t \geq 1$. Then there is an isomorphism

$$H^4(P^2(p^s) \times P^2(p^t); \mathbb{Z}/p^{\min(s,t)}\mathbb{Z}) \cong \mathbb{Z}/p^{\min(s,t)}\mathbb{Z}$$

and $u_s \cup u_t$ is a generator.

Proof. One case of the Künneth Theorem (see, for example, [7, Theorem 3.15]) is as follows. If $X$ and $Y$ are CW-complexes, $R$ is a ring, and $H^k(Y; R)$ is a finitely generated $R$-module for all $k$ then the cross product $H^*(X; R) \otimes_R H^*(Y; R) \rightarrow H^*(X \times Y; R)$ is a ring isomorphism. In our case, if $r = \min(s, t)$ then both $H^*(P^2(p^s); \mathbb{Z}/p^r\mathbb{Z})$ and $H^*(P^2(p^t); \mathbb{Z}/p^r\mathbb{Z})$ are finitely generated free $\mathbb{Z}/p^r\mathbb{Z}$-modules. Therefore, by the Künneth Theorem, there are isomorphisms

$$H^4(P^2(p^s) \times P^2(p^t); \mathbb{Z}/p^r\mathbb{Z}) \cong H^2(P^2(p^s); \mathbb{Z}/p^r\mathbb{Z}) \otimes H^2(P^2(p^t); \mathbb{Z}/p^r\mathbb{Z})$$

$$\cong \mathbb{Z}/p^r\mathbb{Z} \otimes \mathbb{Z}/p^r\mathbb{Z} \cong \mathbb{Z}/p^r\mathbb{Z}$$

and $u_s \cup u_t$ is a generator.

Propositions 3.2 and 3.3 give useful tests for when a certain map is null homotopic.

Proposition 3.3. Let $p$ be an odd prime and $s, t \geq 1$. Let $f : S^3 \rightarrow \Sigma P^2(p^s) \wedge P^2(p^t)$ be a map and let $C$ be the homotopy cofiber of the composite

$$S^3 \xrightarrow{f} \Sigma P^2(p^s) \wedge P^2(p^t) \xrightarrow{[1,z]} P^3(p^s) \vee P^3(p^t).$$

The following are equivalent:

(a) the map $f$ is null homotopic;

(b) $H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^{\min(s,t)}\mathbb{Z}) \xrightarrow{f^*} H^3(S^3; \mathbb{Z}/p^{\min(s,t)}\mathbb{Z})$ is the zero map;
(c) all cup products in $H^*(C; \mathbb{Z}/p^{\min(s,t)}\mathbb{Z})$ are trivial.

Proof. (a) $\Leftrightarrow$ (b). Let $u = \min(s, t)$ and consider the following string of isomorphisms:

$$\pi_3(\Sigma P^2(p^s) \wedge P^2(p^t)) \cong H_3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z})$$

$$\cong H_3(P^4(p^s) \wedge P^5(p^u); \mathbb{Z})$$

$$\cong H_3(P^4(p^s) \wedge P^5(p^u); \mathbb{Z}/p^u\mathbb{Z})$$

$$\cong H^3(P^4(p^u); \mathbb{Z}/p^u\mathbb{Z})$$

$$\cong H^3(\Sigma P^2(p^s) \wedge P^4(p^t); \mathbb{Z}/p^u\mathbb{Z})$$

The first isomorphism is due to the Hurewicz Theorem because $\Sigma P^2(p^s) \wedge P^2(p^t)$ is 2-connected. The second isomorphism holds by Lemma 2.3. The third isomorphism holds since $H_3(P^4(p^s) \wedge P^5(p^u); \mathbb{Z}) \cong H_3(P^4(p^u); \mathbb{Z}) \cong \mathbb{Z}/p^u\mathbb{Z}$ and changing homology coefficients from $\mathbb{Z}$ to $\mathbb{Z}/p^u\mathbb{Z}$ induces an isomorphism here. The fourth isomorphism holds by the Universal Coefficient Theorem. The fifth isomorphism holds by Lemma 2.3. Observe that under these isomorphisms the map $S^3 \xrightarrow{f} \Sigma P^2(p^s) \wedge P^2(p^t)$ is sent to $H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^u\mathbb{Z}) \xrightarrow{f^*} H^3(S^3; \mathbb{Z}/p^u\mathbb{Z})$. Thus $f$ is null homotopic if and only if $f^* = 0$ in degree $3 \mod p^u$ cohomology.

(a) $\Rightarrow$ (c). If $f$ is null homotopic then $C \cong P^3(p^s) \vee P^3(p^t) \vee S^4$ is a suspension, so all cup products in $H^*(C; \mathbb{Z}/p^u\mathbb{Z})$ are trivial.

(c) $\Rightarrow$ (b). Consider the diagram of homotopy cofibrations

\[
\begin{array}{ccc}
S^3 \xrightarrow{f} \Sigma P^2(p^s) \wedge P^2(p^t) & \xrightarrow{C_f} \\
\downarrow^*[1,1,2] & \downarrow^d \\
P^3(p^s) \vee P^3(p^t) & \xrightarrow{\mathbf{C}} \\
\end{array}
\]

that defines the space $C_f$ and the map $d$. As $C_f$ is 2-connected, there is an isomorphism $d^* : H^2(P^3(p^s) \times P^3(p^t); \mathbb{Z}/p^u\mathbb{Z}) \to H^2(C; \mathbb{Z}/p^u\mathbb{Z})$. Therefore $H^2(C; \mathbb{Z}/p^u\mathbb{Z})$ is generated by $d^*(u_s \otimes 1)$ and $d^*(1 \otimes u_t)$.

The right column of (2) induces the exact sequence

\[
H^3(C; \mathbb{Z}/p^u\mathbb{Z}) \to H^3(C_f; \mathbb{Z}/p^u\mathbb{Z}) \xrightarrow{b} H^4(P^3(p^s) \times P^3(p^t); \mathbb{Z}/p^u\mathbb{Z}) \xrightarrow{d^*} H^4(C; \mathbb{Z}/p^u\mathbb{Z}).
\]

By Lemma 3.1, $H^4(P^3(p^s) \times P^3(p^t); \mathbb{Z}/p^u\mathbb{Z}) \cong \mathbb{Z}/p^u\mathbb{Z}$ is generated by the cup product $u_s \cup u_t$. The naturality of the cup product implies that $d^*(u_s \cup u_t) = d^*(u_s) \cup d^*(u_t)$. But by assumption, cup products in $H^*(C; \mathbb{Z}/p^u\mathbb{Z})$ are zero. Therefore $d^* = 0$ in (3), implying that $b$ is onto. Hence the order of $H^3(C_f; \mathbb{Z}/p^u\mathbb{Z})$ is at least $p^u$.

On the other hand, the top row of (2) induces the exact sequence

\[
H^2(S^3; \mathbb{Z}/p^u\mathbb{Z}) \to H^2(C_f; \mathbb{Z}/p^u\mathbb{Z}) \xrightarrow{a} H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^u\mathbb{Z}) \xrightarrow{f^*} H^3(S^3; \mathbb{Z}/p^u\mathbb{Z}).
\]

Since $H^2(S^3; \mathbb{Z}/p^u\mathbb{Z}) = 0$, the map $a$ is an injection, and by Lemma 2.3,

$$H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^u\mathbb{Z}) \cong \mathbb{Z}/p^u\mathbb{Z}.$$
Hence the order of $H^3(C_f; \mathbb{Z}/p^n\mathbb{Z})$ is at most $p^u$.

Thus $H^3(C_f; \mathbb{Z}/p^n\mathbb{Z})$ has order $p^u$. But this implies that $a$ is a monomorphism between finite groups of the same order and so must be an isomorphism. Therefore $f^*$ in (4) is the zero map. □

A similar argument to Proposition 3.2, but with variations, gives the following.

**Proposition 3.3.** Let $p$ be an odd prime and $r, s, t \geq 1$. Let $f : P^3(p^r) \to \Sigma P^2(p^s) \wedge P^2(p^t)$ be a map and let $C$ be the homotopy cofiber of the composite

$$P^3(p^r) \to [1_{1,2}] P^3(p^r) \vee P^3(p^t).$$

Let $v = \min(r, s, t)$. Then the following are equivalent:

(a) the map $f$ is null homotopic;
(b) $H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^n\mathbb{Z}) \xrightarrow{f^*} H^3(P^3(p^r); \mathbb{Z}/p^n\mathbb{Z})$ is the zero map;
(c) all cup products in $H^*(C; \mathbb{Z}/p^n\mathbb{Z})$ are trivial.

**Proof.** (a) $\iff$ (b): Let $u = \min(s, t)$ and consider the following string of isomorphisms

$$[P^3(p^r), \Sigma P^2(p^s) \wedge P^2(p^t)] \cong H_3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^n\mathbb{Z})
\cong H^3(\Sigma P^2(p^s) \wedge P^2(p^t); \mathbb{Z}/p^n\mathbb{Z})
\cong H^3(P^4(p^u) \vee P^5(p^u); \mathbb{Z}/p^n\mathbb{Z})
\cong \begin{cases} 
\mathbb{Z}/p^n\mathbb{Z} & \text{if } r < u \\
\mathbb{Z}/p^n\mathbb{Z} & \text{if } r \geq u
\end{cases}
\cong \mathbb{Z}/p^n\mathbb{Z}
\cong H^3(P^4(p^u) \vee P^5(p^u); \mathbb{Z}/p^n\mathbb{Z})
\cong H^3(\Sigma P^2(p^r) \wedge P^2(p^t); \mathbb{Z}/p^n\mathbb{Z})$$

The first isomorphism is due to the mod-$p^n$ Hurewicz isomorphism since $\Sigma P^2(p^s) \wedge P^2(p^t)$ is 2-connected. The second isomorphism holds by the Universal Coefficient Theorem and the third holds by Lemma 2.3. The fourth isomorphism is the calculation of degree 3 cohomology, the fifth holds since $v = \min(r, s, t) = \min(r, u)$, the sixth is calculation again, and the seventh holds by Lemma 2.3. The transition from the second to the seventh is induced by the map of coefficient rings induced by the epimorphism $\mathbb{Z}/p^n\mathbb{Z} \to \mathbb{Z}/p^u\mathbb{Z}$. Thus, under these isomorphisms, a map $f : P^3(p^r) \to \Sigma P^2(p^s) \wedge P^2(p^t)$ is sent to the map it induces in mod-$p^n$ cohomology. Thus $f$ is null homotopic if and only if $f^* = 0$ in mod-$p^n$ cohomology.

(b) $\iff$ (c): Consider the diagram of homotopy cofibrations

$$
\begin{array}{ccc}
P^3(p^r) & \xrightarrow{f} & \Sigma P^2(p^s) \wedge P^2(p^t) \\
\downarrow & & \downarrow [1_{1,2}] \\
P^3(p^r) & \xrightarrow{\Sigma [1_{1,2}] \circ f} & P^3(p^r) \vee P^3(p^t) \\
\downarrow & & \downarrow d \\
* & \xrightarrow{=} & P^3(p^r) \times P^3(p^t) \xrightarrow{=} P^3(p^r) \times P^3(p^t)
\end{array}
$$
that defines the space $C_f$ and the map $d$. As $C_f$ is 2-connected, $d^*: H^2(\Sigma^2 P^g \times P^g; \mathbb{Z}/p^v \mathbb{Z}) \to H^2(\Sigma^2 P^g \times P^g; \mathbb{Z}/p^v \mathbb{Z})$ is an isomorphism. Therefore $H^2(C; \mathbb{Z}/p^v \mathbb{Z})$ is generated by $d^*(u_s \otimes 1)$ and $d^*(1 \otimes u_t)$. The diagram also induces a diagram of exact sequences:

\[
\begin{array}{cccc}
H^3(C_f; \mathbb{Z}/p^v \mathbb{Z}) & \overset{a}{\longrightarrow} & H^3(\Sigma P^2(p^r) \wedge P^2(p^r); \mathbb{Z}/p^v \mathbb{Z}) & \overset{f^*}{\longrightarrow} & H^3(\Sigma P^2(p^r); \mathbb{Z}/p^v \mathbb{Z}) \\
\downarrow{b} & & \downarrow{c} & & \downarrow{d^*} \\
H^4(P^3(p^r) \times P^3(p^r); \mathbb{Z}/p^v \mathbb{Z}) & \overset{}{\longrightarrow} & H^4(\Sigma P^2(p^r) \wedge P^2(p^r); \mathbb{Z}/p^v \mathbb{Z}) & \overset{}{\longrightarrow} & H^4(P^3(p^r); \mathbb{Z}/p^v \mathbb{Z}) \\
\downarrow{d^*} & & & & \downarrow{d^*} \\
H^4(C; \mathbb{Z}/p^v \mathbb{Z}) & \overset{}{\longrightarrow} & H^4(\Sigma P^2(p^r) \wedge P^2(p^r); \mathbb{Z}/p^v \mathbb{Z}) & \overset{}{\longrightarrow} & H^4(P^3(p^r); \mathbb{Z}/p^v \mathbb{Z}) = 0
\end{array}
\]

where $a$, $b$ and $c$ are names for the maps induced in cohomology. Observe that, in the middle column, $s, t \geq v$ so $H^3(\Sigma P^2(p^r) \wedge P^2(p^r); \mathbb{Z}/p^v \mathbb{Z}) \cong H^4(P^3(p^r) \times P^3(p^r); \mathbb{Z}/p^v \mathbb{Z}) \cong \mathbb{Z}/p^v \mathbb{Z}$, implying that $c$ is an isomorphism. Therefore, the commutativity of the top square implies that $a$ is surjective if and only if $b$ is. On the other hand, the top row implies that $a$ is surjective if and only if $f^*$ is the zero map, while the left column implies that $b$ is surjective if and only if $d^*$ is the zero map. Thus $f^* = 0$ if and only in $d^* = 0$. Since $H^4(P^3(p^r) \times P^3(p^r); \mathbb{Z}/p^v \mathbb{Z})$ is generated by $u_s \cup u_t$, $d^* = 0$ if and only if $H^4(C; \mathbb{Z}/p^v \mathbb{Z})$ has no cup products. Hence $f^* = 0$ if and only if $H^4(C; \mathbb{Z}/p^v \mathbb{Z})$ has no cup products. \(\Box\)

4. A homological test for a null homotopy II

In this section we aim towards Proposition 4.4, which gives homological and cohomological criteria for when certain maps are null homotopic, and which is applicable much more widely than Propositions 3.2 and 3.3. It also generalizes a result of Neisendorfer [17, Corollary 11.12] on the mod-$p^r$ Hopf invariant. We rephrase that result in weaker form for a better comparison to Proposition 4.4.

**Lemma 4.1.** Let $p$ be an odd prime and $r, s \geq 1$. Let $f: P^3(p^r) \to P^3(p^s)$ be a map and let $C_f$ be its cofibre. If

- $f_*: \tilde{H}_*(P^3(p^r); \mathbb{Z}) \to \tilde{H}_*(P^3(p^s); \mathbb{Z})$ is the zero map, and
- $H^*(C_f; \mathbb{Z}/p^{\min(r,s)} \mathbb{Z})$ has trivial cup products

then $f$ is null homotopic. \(\Box\)

Lemma 4.1 will be generalized to maps $f: X \to \bigvee_{i=1}^m P^3(p^{r_i})$ for $X = S^3$ or $X = P^3(p^r)$. This requires some initial work, the first aspect of which is a general lemma concerning trivial cup products related to maps of wedges.

**Lemma 4.2.** Let $f: \bigvee_{i=1}^m A_i \to \bigvee_{j=1}^n B_j$ be a map with homotopy cofibre $C_f$ and suppose that $f^* = 0$ for cohomology with coefficient group $G$ and all cup products in $H^*(C_f; G)$ are zero. For $1 \leq i \leq m$ and $1 \leq j \leq n$, let $f_{i,j}$ be the composite

$$f_{i,j}: A_i \looparrowright \bigvee_{i=1}^m A_i \xrightarrow{f} \bigvee_{j=1}^n B_j \to B_j$$

where the left map is the inclusion of the $i^{th}$ wedge summand and the right map is the pinch onto the $j^{th}$ wedge summand. If $C_{f_{i,j}}$ is the homotopy cofibre of $f_{i,j}$ then all cup products in $H^*(C_{f_{i,j}}; G)$ are zero.
Proof. We use an intermediate map. Let $f_j$ be the composite

$$f_j: \bigvee_{i=1}^m A_i \xrightarrow{f} \bigvee_{j=1}^n B_j \to B_j$$

and let $C_{f_j}$ be the homotopy cofibre of $f_j$. Consider the homotopy cofibration diagram

$$\begin{array}{c}
\bigvee_{i=1}^m A_i \xrightarrow{f} \bigvee_{j=1}^n B_j \to C_{f_j} \\
\bigvee_{i=1}^m A_i \xrightarrow{f_j} B_j \to C_{f_j}
\end{array}$$

d where $d$ is the induced map of cofibres. Take cohomology with coefficient group $G$. The homotopy cofibration diagram induces a map between long exact sequences in cohomology.

By hypothesis, $f^* = 0$ so the definition of $f_j$ implies that $f_j^* = 0$ as well. Therefore, for every $k \geq 1$, there is a commutative diagram of exact sequences

$$\begin{array}{c}
0 \to H^k(\bigvee_{i=1}^m \Sigma A; G) \to H^k(C_{f_j}; G) \to H^k(B_j; G) \to 0 \\
0 \to H^k(\bigvee_{i=1}^m \Sigma A; G) \to H^k(C_{f_j}; G) \to H^k(\bigvee_{i=1}^n B_i; G) \to 0.
\end{array}$$

A diagram chase shows that $d^*$ is injective, and this is true for all $k \geq 1$. Thus, by the naturality of the cup product, the vanishing of cup products in $H^*(C_{f_j}; G)$ implies their vanishing in $H^*(C_{f_j}; G)$.

Next, let $g_j$ be the composite

$$g_j: \bigvee_{i=1}^m A_i \xleftarrow{\bigvee_{i=1}^m A_i} f_j \bigvee_{i=1}^n B_j \to C_{f_{i,j}}.$$ 

Consider the homotopy cofibration diagram

$$\begin{array}{c}
A_i \xrightarrow{f_{i,j}} B_j \to C_{f_{i,j}} \\
A_i \xrightarrow{g_j} B_j \to C_{f_{i,j}}
\end{array}$$

which defines the map $d'$. Since $f_{j}^* = 0$, the definition of $g_j$ implies that $g_{j}^* = 0$ as well. Therefore, from the right vertical cofibration in the preceding diagram we obtain a surjection

$$H^*(C_{f_{j}}; G) \xrightarrow{(d')^*} H^*(C_{f_{i,j}}; G).$$

Therefore, as cup products in $H^*(C_{f_{j}}; G)$ are zero and $(d')^*$ is a surjection, cup products in $H^*(C_{f_{i,j}}; G)$ are also zero. \qed
Next, we make a transition from a hypothesis that a map is zero in cohomology as in Lemma 4.2 to a map being zero in homology. In general, if the coefficient group $G$ in Lemma 4.2 is a field then the Universal Coefficient Theorem immediately implies that if $f_* = 0$ then $f^* = 0$. The coefficient ring we care about is $\mathbb{Z}/p^t\mathbb{Z}$, so we need to be more cautious. Perhaps overdoing it, we focus on the 3-dimensional Moore space case again.

**Lemma 4.3.** Let $p$ be an odd prime and let $r \geq 1$. Let $X = P^3(p^r)$ or $S^3$ and let $f : X \to \bigvee_{i=1}^m P^3(p^r)$ be a map. If $f_* : \tilde{H}_*(X; \mathbb{Z}) \to \tilde{H}_*(\bigvee_{i=1}^m P^3(p^r); \mathbb{Z})$ is trivial then for any abelian group $G$ the map $f^* : H^*(\bigvee_{i=1}^m P^3(p^r); G) \to H^*(X; G)$ is trivial.

**Proof.** It suffices to prove the lemma in the $m = 1$ case. For $X = P^3(p^r)$ it is obvious that $f^* : H^2(\tilde{P}^3(p^r); G) \to H^2(\tilde{P}^3(p^r); G)$ is trivial except possibly for $j \in \{2, 3\}$. By the Universal Coefficient Theorem, there are natural isomorphisms

$$H^2(\tilde{P}^3(p^r); G) \cong \text{Hom}(H_2(\tilde{P}^3(p^r); \mathbb{Z}), G)$$

and

$$H^3(\tilde{P}^3(p^r); G) \cong \text{Ext}(H_2(\tilde{P}^3(p^r); \mathbb{Z}), G).$$

By hypothesis, $f_* : H_2(\tilde{P}^3(p^r); \mathbb{Z}) \to H_2(\tilde{P}^3(p^r); \mathbb{Z})$ is the zero map, so the naturality of the Universal Coefficient Theorem implies that $f^* : H^3(\tilde{P}^3(p^r); G) \to H^3(\tilde{P}^3(p^r); G)$ is the zero map for $j \in \{2, 3\}$.

For $X = S^3$, it suffices to show that $f^* : H^3(\tilde{P}^3(p^r); G) \to H^3(S^3; G)$ is trivial. Let $\rho : P^3(p^r) \to S^3$ be the pinch map to the top cell and consider the composite

$$H^3(S^3; G) \xrightarrow{\rho^*} H^3(\tilde{P}^3(p^r); G) \xrightarrow{f^*} H^3(S^3; G).$$

Observe that the long exact sequence in cohomology determined by the homotopy cofibration $S^2 \to P^3(p^r) \xrightarrow{\rho} S^3$ implies that $\rho^*$ in (5) is an epimorphism. Therefore, in (5), $f^* = 0$ if and only if $f^* \circ \rho^* = 0$. But $\rho \circ f$ is a self-map of $S^3$ which factors through a rationally contractible space, implying that it is null homotopic. Hence $f^* \circ \rho^* = 0$, and so $f^* = 0$. \qed

In general, the Hilton-Milnor Theorem states that there is a homotopy equivalence

$$(6) \quad \Omega\left(\bigvee_{i=1}^m \Sigma Y_i\right) \simeq \prod_{\alpha \in \mathcal{I}} \Omega \Sigma(Y_1^{\wedge \alpha_1} \wedge \cdots \wedge Y_m^{\wedge \alpha_m})$$

where $\mathcal{I}$ runs over a module basis for the free Lie algebra $L\langle v_1, \ldots, v_m \rangle$, and if $\alpha \in L\langle v_1, \ldots, v_m \rangle$ is a module basis element then for $1 \leq i \leq m$ the integer $\alpha_i$ records the number of instances of $v_i$ in $\alpha$. Here, if $\alpha_i = 0$ for some $i$ then the smash product $Y_1^{\wedge \alpha_1} \wedge \cdots \wedge Y_m^{\wedge \alpha_m}$ is regarded as omitting $Y_i$ rather than being a point; for example, $Y_1^{\wedge 2} \wedge Y_2^{\wedge 0} \wedge Y_3^{\wedge 3}$ is regarded as $Y_1^{\wedge 2} \wedge Y_3^{\wedge 3}$. Moreover, for $1 \leq k \leq m$ let

$$t_k : \Sigma Y_k \longrightarrow \bigvee_{i=1}^m \Sigma Y_i$$

be the inclusion of the $k^{th}$ wedge summand. For $\alpha \in \mathcal{I}$, let

$$w_\alpha : \Sigma(Y_1^{\wedge \alpha_1} \wedge \cdots \wedge Y_m^{\wedge \alpha_m}) \longrightarrow \bigvee_{i=1}^m \Sigma Y_i$$

be the iterated Whitehead product formed from the maps $t_k$ where each instance of $v_k$ in $\alpha$ is represented by the map $t_k$. Then the homotopy equivalence (6) is realized by taking the product of all the maps $\Omega w_\alpha$. 

In our case, we have
\[ \Omega(\bigvee_{i=1}^{m} P^3(p^r_i)) \simeq \prod_{\alpha \in I} \Omega \Sigma P^2(p^{r_1}_1)^{\wedge \alpha_1} \wedge \ldots \wedge P^2(p^{r_m}_m)^{\wedge \alpha_m}. \]

Observe that \( P^2(p^{r_1}_1)^{\wedge \alpha_1} \wedge \ldots \wedge P^2(p^{r_m}_m)^{\wedge \alpha_m} \) is \((\alpha_1 + \cdots + \alpha_m) - 1\)-connected. Suppose that \( X' \) is 2-dimensional. Then \([X', \Omega \Sigma P^2(p^{r_1}_1)^{\wedge \alpha_1} \wedge \ldots \wedge P^2(p^{r_m}_m)^{\wedge \alpha_m}] \simeq 0\) if \((\alpha_1 + \cdots + \alpha_m) \geq 3\).

Observe also that there are \( m \) cases for which \((\alpha_1 + \cdots + \alpha_m) = 1\) and \( \binom{m}{2} \) cases for which \((\alpha_1 + \cdots + \alpha_m) = 2\). So if \( X = \Sigma X' \) then
\[
[X, \bigvee_{i=1}^{m} P^3(p^r_i)] \simeq [X', \Omega(\bigvee_{i=1}^{m} P^3(p^r_i))] \simeq [X', \prod_{j=1}^{m} \Omega P^3(p^r_j) \times \prod_{k \neq l} \Omega \Sigma P^2(p^r_k) \wedge P^2(p^r_l)] \simeq \prod_{j=1}^{m} [X, P^3(p^r_j)] \times \prod_{k \neq l} [X, \Sigma P^2(p^r_k) \wedge P^2(p^r_l)].
\]

Further, the \( j \)th factor \([X, P^3(p^r_j)]\) is mapped to \([X, \bigvee_{i=1}^{m} P^3(p^r_i)]\) by the inclusion \( t_j \) and the \( \binom{m}{2} \) factors \([X, \Sigma P^2(p^r_k) \wedge P^2(p^r_l)]\) may be arranged so that they map to \([X, \bigvee_{i=1}^{m} P^3(p^r_i)]\) by the Whitehead products
\[
\Sigma P^2(p^r_k) \wedge P^2(p^r_l) \xrightarrow{[t_j, t_l]} P^3(p^r_j) \vee P^3(p^r_l) \hookrightarrow \bigvee_{i=1}^{m} P^3(p^r_i)
\]
where \( 1 \leq k < l \leq m \). Hence if \( f : X \to \bigvee_{i=1}^{m} P^3(p^r_i) \) then we may write
\[
f \simeq \sum_{j=1}^{m} t_j \circ g_j + \sum_{1 \leq k < l \leq m} [t_k, t_l] \circ h_{k,l}
\]
for maps \( X \xrightarrow{g_j} P^3(p^r_j) \) and \( X \xrightarrow{h_{k,l}} \Sigma P^2(p^r_k) \wedge P^2(p^r_l) \).

**Proposition 4.4.** Let \( X = P^3(p^r) \) where \( p \) is an odd prime and \( r \geq 1 \) or let \( X = S^3 \) and set \( r = \infty \). Let \( f : X \to \bigvee_{i=1}^{m} P^3(p^r_i) \) be a map and let \( C_f \) be its cofiber. If
\begin{itemize}
  \item \( f_* : \tilde{H}_*(X; \mathbb{Z}) \to \tilde{H}_*(\bigvee_{i=1}^{m} P^3(p^r_i); \mathbb{Z}) \) is the zero map and
  \item \( H^*(C_f; \mathbb{Z}/p^{\min\{r_i,r\}}\mathbb{Z}) \) has trivial cup products for all \( 1 \leq i \leq m \),
\end{itemize}
then \( f \) is null homotopic.

**Proof.** Since \( X \) is \( S^3 \) or \( P^3(p^r) \) we have \( X \simeq \Sigma X' \) where \( X' \) is 2-dimensional. Therefore, by \((7)\), we have \( f \simeq \sum_{j=1}^{m} t_j \circ g_j + \sum_{1 \leq k < l \leq m} [t_k, t_l] \circ h_{k,l} \) for maps \( X \xrightarrow{g_j} P^3(p^r_j) \) and \( X \xrightarrow{h_{k,l}} \Sigma P^2(p^r_k) \wedge P^2(p^r_l) \). To show that \( f \) is null homotopic it suffices to show that each \( g_j \) and \( h_{k,l} \) is null homotopic.

First consider the map \( g_j \) when \( X = P^3(p^r) \). Notice that \( g_j \) is the composite
\[ g_j : P^3(p^r) \xrightarrow{f} \bigvee_{i=1}^{m} P^3(p^r_i) \xrightarrow{q} P^3(p^r_j) \]
where \( q \) is the pinch map onto the \( j \)th wedge summand. Since \( f \) induces the zero map in integral homology, so does \( g_j \). The spaces involved let us apply Lemma 4.3, showing that
$g_j$ induces the zero map in mod-$p_{\min(r, r_j)}$ cohomology. By hypothesis, all cup products in $H^*(C_f; \mathbb{Z}/p_{\min(r, r_j)}\mathbb{Z})$ are zero, so by Lemma 4.2, all cup products in $H^*(C_{g_j}; \mathbb{Z}/p_{\min(r, r_j)}\mathbb{Z})$ are also zero. Thus, by Lemma 4.1, $g_j$ is null homotopic.

Next, consider the map $g_j$ when $X = S^3$. Now $g_j$ is the composite $S^3 \xrightarrow{f} \bigvee_{i=1}^{m} P^3(p^{r_i}) \xrightarrow{q} P^3(p^{r_j})$. Consider the composite

$$g_j : P^3(p^{r_j}) \xrightarrow{\pi} S^3 \xrightarrow{g_j} P^3(p^{r_j})$$

where $\pi$ is the pinch map to the top cell. The argument in the previous paragraph implies that $g_j$ is null homotopic. Therefore $g_k$ extends across the cofibre of $\pi$, implying that $g_k$ factors as a composite $S^3 \xrightarrow{p^{r_j}} S^3 \xrightarrow{\gamma_j} P^3(p^{r_j})$ for some map $\gamma_j$. By Lemma 2.1, $\pi_3(P^3(p^{r_j})) \cong \mathbb{Z}/p^{r_j}\mathbb{Z}$, so $g_j \simeq p^{r_j} \cdot \gamma_j$ is null homotopic.

At this point, we have shown that for either $X = S^3$ or $P^3(p^r)$ we have $g_j$ null homotopic for $1 \leq j \leq m$. Thus (7) implies that $f \simeq \sum_{1 \leq k < l \leq m} [t_k, t_l] \circ h_{k,l}$. Let

$$q_{k,l} : \bigvee_{i=1}^{m} P^3(p^{r_i}) \longrightarrow P^3(p^{r_k}) \vee P^3(p^{r_l})$$

be the pinch map onto the $k^{th}$ and $l^{th}$ wedge summands. Observe that every Whitehead product $[t_s, t_t]$ for $1 \leq s < t \leq m$ composes trivially with $q_{k,l}$ except $[t_k, t_l]$. Therefore $q_{k,l} \circ f \simeq q_{k,l} \circ (\sum_{1 \leq s < t \leq m} [t_s, t_t] \circ h_{s,t}) \simeq [t_k, t_l] \circ h_{k,l}$. That is, $q_{k,l} \circ f$ is homotopic to the composite

$$h_{k,l} : X \xrightarrow{h_{k,l}} \Sigma P^2(p^{r_k}) \vee P^2(p^{r_l}) \xrightarrow{[t_k, t_l]} P^3(p^{r_k}) \vee P^3(p^{r_l}).$$

Since $f$ induces the zero map in integral homology, so does $h_{k,l}$. Let $C_{h_{k,l}}$ be the homotopy cofibre of $h_{k,l}$. By hypothesis, cup products in $H^*(C_f; \mathbb{Z}/p_{\min(r, r_k)}\mathbb{Z})$ are zero for $1 \leq i \leq m$ so cup products in $H^*(C_{f}; \mathbb{Z}/p_{\min(r, r_k)}\mathbb{Z})$ are zero. By Lemma 4.2 (with $B_j = P^3(p^{r_k}) \vee P^3(p^{r_l})$), cup products in $H^*(C_{h_{k,l}}; \mathbb{Z}/p_{\min(r, r_k)}\mathbb{Z})$ are also zero. Therefore, by Proposition 3.2 in the case $X = S^3$ and Proposition 3.3 in the case $X = P^3(p^r)$, the map $h_{k,l}$ is null homotopic. As this is true for all $1 \leq k < l \leq m$ we obtain $f \simeq *$. \hfill $\square$

5. The homotopy type of $\Sigma M$

Recall from the Introduction that $M$ is a smooth, orientable, closed, connected 4-manifold, implying that it has a $CW$-structure with one 4-cell. Assume that $H_1(M; \mathbb{Z})$ is finitely generated and has no 2-torsion, that is

- $H_1(M; \mathbb{Z}) \cong \mathbb{Z}^m \oplus \bigoplus_{j=1}^{n} \mathbb{Z}/b_j\mathbb{Z}$;

- each $b_j$ is a prime power, where the prime is odd.
By Poincare Duality, the homology of $M$ is as follows:

$$
\begin{array}{c|c}
  i & H_i(M; \mathbb{Z}) \\
  \hline \\
  0 & \mathbb{Z} \\
  1 & \mathbb{Z}^m \oplus \bigoplus_{j=1}^n \mathbb{Z}/b_j\mathbb{Z} \\
  2 & \mathbb{Z}^d \oplus \bigoplus_{j=1}^n \mathbb{Z}/b_j\mathbb{Z} \\
  3 & \mathbb{Z}^m \\
  4 & \mathbb{Z} \\
  \geq 5 & 0 \\
\end{array}
$$

(8)

First consider the integer summands of $H_1(M; \mathbb{Z})$. Since the Hurewicz homomorphism $\pi_1(M) \to H_1(M; \mathbb{Z})$ is an epimorphism, each direct summand $\mathbb{Z}$ of $H_1(M; \mathbb{Z})$ is generated by the Hurewicz image of some map $\alpha_i: S^1 \to M$. Let

$$a: \bigvee_{i=1}^m S^1 \to M$$

be the wedge sum of the maps $\alpha_i$ and let $W$ be the homotopy cofibre of $a$.

**Lemma 5.1.** The map $\Sigma a$ has a left homotopy inverse and there is a homotopy equivalence

$$\Sigma M \simeq \left( \bigvee_{i=1}^m S^2 \right) \vee \Sigma W.$$

**Proof.** The Hurewicz Theorem implies that the image of $a_*$ is $H_1(M; \mathbb{Z})_{\text{free}} \cong \mathbb{Z}^m$. The Universal Coefficient Theorem implies that $H^1(M; \mathbb{Z})_{\text{free}} \cong H_1(M; \mathbb{Z})_{\text{free}}$. Let $a_i \in H_1(M; \mathbb{Z})$ be the image of $(\alpha_i)_*$ and $\tilde{a}_i \in H^1(M; \mathbb{Z})$ be the dual of $a_i$. Then $\tilde{a}_i$ is represented by a map $\epsilon_i: M \to K(\mathbb{Z}, 1) \simeq S^1$ and the composite $S^1 \xrightarrow{\alpha_i} M \xrightarrow{\epsilon_i} S^1$ is the identity map. After suspending the maps $\epsilon_i$ may be added to give a map $\epsilon: \Sigma M \to \bigvee_{i=1}^m S^2$ which is a left homotopy inverse for $\Sigma a$. Therefore, with respect to the homotopy cofibration, $\bigvee_{i=1}^m S^2 \xrightarrow{\Sigma a} \Sigma M \xrightarrow{\Sigma w} \Sigma W$ where $w: M \to W$ is the quotient map, if $\sigma$ is the cocomplication on $\Sigma M$, the composite

$$e: \Sigma M \xrightarrow{\sigma} \Sigma M \vee \Sigma M \xrightarrow{\epsilon \vee \Sigma w} \left( \bigvee_{i=1}^m S^2 \right) \vee \Sigma W$$

induces an isomorphism in homology. As the domain and range of $e$ are simply-connected, Whitehead’s Theorem implies that $e$ is a homotopy equivalence. \qed

The description of $H_*(M; \mathbb{Z})$ in (8) implies that the homology of $W$ is as follows:

$$
\begin{array}{c|c}
  i & H_i(W; \mathbb{Z}) \\
  \hline \\
  0 & \mathbb{Z} \\
  1 & \bigoplus_{j=1}^n \mathbb{Z}/b_j\mathbb{Z} \\
  2 & \mathbb{Z}^d \oplus \bigoplus_{j=1}^n \mathbb{Z}/b_j\mathbb{Z} \\
  3 & \mathbb{Z}^m \\
  4 & \mathbb{Z} \\
  \geq 5 & 0 \\
\end{array}
$$
We wish to give a homotopy decomposition of $\Sigma W$ as a wedge of spheres and Moore spaces. To do so we analyze the homology decomposition of $\Sigma W$.

Define $M(\mathbb{Z}/k\mathbb{Z}, n) = P^{n+1}(k)$ and $M(\mathbb{Z}, n) = S^n$, and for any finitely generated abelian groups $A$ and $B$ define $M(A \oplus B, n) = M(A, n) \vee M(B, n)$. Then $\tilde{H}_i(M(A, n); \mathbb{Z})$ is $A$ for $i = n$ and zero otherwise. The following lemma describes the homology decomposition of a simply-connected CW-complex.

**Lemma 5.2** (Theorem 4H.3, [7]). Let $X$ be an $n$-dimensional simply-connected CW-complex and let $H_i = H_i(X; \mathbb{Z})$. Then there is a sequence of subcomplexes $\{X_i\}_{i=1}^n$ such that

1. $H_i(X_m; \mathbb{Z}) \cong H_i(X; \mathbb{Z})$ for $i \leq m$ and $H_i(X_m; \mathbb{Z}) = 0$ for $i > m$;
2. $X_2 = M(H_2, 2)$ and $X \simeq X_n$;
3. $X_{m+1}$ is the mapping cone of a map $f_m: M(H_{m+1}, m) \to X_m$ that induces a trivial homomorphism $(f_m)_*: H_m(M(H_{m+1}, m); \mathbb{Z}) \to H_m(X_m; \mathbb{Z})$.

In our case, to describe the homology decomposition of $\Sigma W$ we need some notation. Let

$$P = \bigvee_{j=1}^n P^3(b_j) \quad \text{and} \quad S = \bigvee_{k=1}^d S^2.$$  

Starting with $W_2 = P$, Lemma 5.2 implies that there are homotopy cofibrations

$$S \vee P \xrightarrow{f_2} W_2 \longrightarrow W_3$$

$$\bigvee_{i=1}^m S^3 \xrightarrow{f_3} W_3 \longrightarrow W_4$$

(9)    $$S^4 \xrightarrow{f_4} W_4 \longrightarrow \Sigma W$$

where $f_2$, $f_3$ and $f_4$ induce the zero map in integral homology. In Lemmas 5.5 and 5.7 we will show that the maps $f_2$ and $f_3$ are null homotopic, and in Lemma 5.8 we will show that the map $f_4$ is either null homotopic or factors is an entirely controllable way. As this will involve analyzing maps between Moore spaces of different torsion orders, a preliminary lemma is required.

**Lemma 5.3.** If $p$ and $q$ are distinct primes and $m, n \geq 3$, then $[P^n(p^r), P^n(q^t)]$ is trivial.

**Proof.** The homotopy cofibration $S^{m-1} \xrightarrow{p^r} S^{m-1} \longrightarrow P^n(p^r)$ induces an exact sequence

$$\pi_m(P^n(q^t)) \xrightarrow{p^r} \pi_m(P^n(q^t)) \longrightarrow [P^n(p^r), P^n(q^t)] \longrightarrow \pi_{m-1}(P^n(q^t)) \xrightarrow{p^r} \pi_{m-1}(P^n(q^t)).$$

By Serre’s Theorem, the groups $\pi_i(P^n(q^t))$ are finite abelian and consist only of $q$-torsion. Thus multiplying $\pi_i(P^n(q))$ by $p^r$ is an isomorphism. Hence $[P^n(p^r), P^n(q^t)] \cong 0$. \hfill \Box

We also need a lemma concerning cup products in $W_3$.

**Lemma 5.4.** Cup products vanish in $H^*(W_3; \mathbb{Z}/p^r\mathbb{Z})$.

**Proof.** In general, suppose that $\{X_i\}_{i=1}^n$ is the homology decomposition of an $n$-dimensional simply-connected CW-complex. Let $Y_i$ be the $i$-skeleton of $X$. Then, by cellular approximation and the definition of $X_i$, the inclusion $Y_i \longrightarrow X$ factors as a composite $Y_i \longrightarrow X_i \longrightarrow X$ for some map $g_i$. In our case, $X = \Sigma W$ and each $Y_i$ is the suspension of the $(i - 1)$-skeleton of $W$. Note, though, that $X_i$ need not be a suspension.
Suppose that there are elements \( x, y \in H^*(W_3; \mathbb{Z}/p^r \mathbb{Z}) \) such that \( x \cup y \neq 0 \). Since \( W_3 \) is simply-connected and of dimension 4, it must be the case that \( |x| = |y| = 2 \). Consider the map \( Y_3 \xrightarrow{g_3} W_3 \). For dimensional reasons, \( x = g_3^*(\bar{x}) \) and \( y = g_3^*(\bar{y}) \) for elements \( \bar{x}, \bar{y} \in H^2(Y_3; \mathbb{Z}/p^r \mathbb{Z}) \). Since \( Y_3 \) is a suspension, all cup products in \( H^*(Y_3; \mathbb{Z}/p^r \mathbb{Z}) \) are zero. In particular, \( \bar{x} \cup \bar{y} = 0 \). The naturality of the cup product therefore implies that \( x \cup y = g_3^*(\bar{x} \cup \bar{y}) = g_3^*(\bar{x} \cup \bar{y}) = 0 \), a contradiction. Hence it must be the case that all cup products in \( H^*(W_3; \mathbb{Z}/p^r \mathbb{Z}) \) are zero. \( \square \)

**Lemma 5.5.** There is a homotopy equivalence \( W_3 \simeq P \vee \Sigma S \vee \Sigma P \).

**Proof.** We will show that the map \( S \vee P \xrightarrow{f_2} W_2 \) in (9) is null homotopic, implying the statement of the lemma. It will be helpful to partition the Moore spaces in \( P \) by primes. Recall that \( P = \bigvee_{j=1}^n P^3(b_j) \) where each \( b_j \) is an odd prime power. List the primes appearing as \( \{p_1, \ldots, p_t\} \). Write

\[
P = \bigvee_{s=1}^t P_s \quad \text{where} \quad P_s = \bigvee_{\ell=1}^{n_s} P^3(p_s^{r_s,\ell}).
\]

Note that \( n = n_1 + \cdots + n_t \). Isolating \( P_1 \), let

\[
Q = \bigvee_{s=2}^t P_s.
\]

For convenience, write \( p_1 \) as \( p \) and \( r_{1,\ell} \) as \( r_\ell \) for \( 1 \leq \ell \leq n_1 \) so that \( P_1 = \bigvee_{\ell=1}^{n_1} p^{r_\ell} \). The homotopy cofibration \( S \vee P \xrightarrow{f_2} W_2 = P \rightarrow W_3 \) may then be rewritten as

\[
S \vee P_1 \vee Q \xrightarrow{f_2} P_1 \vee Q \rightarrow W_3.
\]

To show that \( f_2 \) is null homotopic it is equivalent to show that each of the composites

\[
f_S : S \hookrightarrow S \vee P_1 \vee Q \xrightarrow{f_2} P_1 \vee Q
\]

\[
f_P : P_1 \hookrightarrow S \vee P_1 \vee Q \xrightarrow{f_2} P_1 \vee Q
\]

\[
f_Q : Q \hookrightarrow S \vee P_1 \vee Q \xrightarrow{f_2} P_1 \vee Q
\]

is null homotopic. Since \( f_2 \) induces the trivial map in integral homology, so do each of \( f_P \), \( f_Q \) and \( f_S \).

First, consider \( f_S \). Since \( S \) is 2-dimensional, \( P_1 \vee Q \) is 1-connected, and \( f_S \) induces the trivial map in degree two integral homology, the Hurewicz homomorphism implies that \( f_S \) is null homotopic.

Next, consider \( f_P \). Since \( P_1 = \bigvee_{\ell=1}^{n_1} P^3(p_{s,\ell}) \), to show that \( f_P \) is null homotopic it suffices to show that the restriction

\[
f_P^\ell : P^3(p_{s,\ell}) \rightarrow P_1 \xrightarrow{f_P} P_1 \vee Q
\]

of \( f_P \) to the \( \ell \)-th wedge summand is null homotopic. Since \( Q \) consists of mod-\( p_{s,\ell}^* \) Moore spaces for primes \( p_s \neq p \), Lemma 5.3 implies that \( f_P^\ell \) factors as a composite

\[
P^3(p_{s,\ell}) \xrightarrow{g_{p_s}^{r_\ell}} P_1 \hookrightarrow P_1 \vee Q
\]
for some map $g^f_P$. We will show that $g^f_P$ is null homotopic, thereby implying that $f^f_P$ is null homotopic.

Observe that as $f_P$ induces the zero map in homology, so does $f^f_P$ and therefore so does $g^f_P$. Let $C g^f_P$ be the homotopy cofibre of $g^f_P$. If cup products vanish in $H^*(C g^f_P; \mathbb{Z}/p_{\min(r, r_1)}\mathbb{Z})$ for $1 \leq i \leq n_1$ then Proposition 4.4 implies that $g^f_P$ is null homotopic.

It remains to show that cup products vanish in $H^*(C g^f_P; \mathbb{Z}/p_{\min(r, r_1)}\mathbb{Z})$. First, as $g^f_P$ induces the zero map in integral homology, by Lemma 4.3 it also induces the zero map in mod-$p_{\min(r, r_1)}$ cohomology. Second, notice that $g^f_P$ is homotopic to the composite $P^3(p^r) \xrightarrow{f^f_P} P_1 \vee Q \xrightarrow{\text{pinch}} P_1$. The definitions of $f^f_P$ and $f_P$ then imply that $g^f_P$ is homotopic to the composite $P^3(p^r) \longrightarrow P_1 \longrightarrow S \vee P \vee Q \xrightarrow{f} P_1 \vee Q \xrightarrow{\text{pinch}} P_1$. As $W_3$ is the homotopy cofibre of $f_2$ and cup products vanish in $H^*(W_3; \mathbb{Z}/p_{\min(r, r_1)}\mathbb{Z})$ by Lemma 5.4, the factorization of $g^f_P$ through $f_2$ and Lemma 4.2 imply that cup products vanish in $H^*(C g^f_P; \mathbb{Z}/p_{\min(r, r_1)}\mathbb{Z})$.

Finally, consider $f_Q$. Separating out the mod-$p^r_k$ Moore spaces in $Q$ one prime at a time as was done for $p_1$ and $P_1$, the same argument as for $f_P$ can be used iteratively. Thus $f_Q$ is null homotopic and the proof is complete.

Observe that the space $W_4$ in (9) is the same as the suspension of the 3-skeleton of $W$. That is, $W_4 \simeq \Sigma Y$ for $Y$ the 3-skeleton of $W$. Our approach to dealing with the maps $f_3$ and $f_4$ in (9) will be to use the fact that both $W_4$ and $\Sigma W$ are suspensions. This requires a general lemma.

**Lemma 5.6.** Let $A_i$ be simply connected for $1 \leq i \leq m$. Suppose that there is a map $g: \bigsqcup_{i=1}^m A_i \longrightarrow \Sigma X$ and a sequence $\{i_1, \ldots, i_k\}$ with $1 \leq i_1 < \cdots < i_k \leq m$ such that, for $1 \leq j \leq k$, the pinch map $q_j: \bigsqcup_{i=1}^m A_i \longrightarrow A_{i_j}$ extends across $g$ to a map $r_j: \Sigma X \longrightarrow A_{i_j}$. Then the composite $b: \bigsqcup_{j=1}^k A_{i_j} \xrightarrow{g} \bigsqcup_{i=1}^m A_i \xrightarrow{q} \Sigma X$ has a left homotopy inverse.

**Proof.** Let $r$ be the composite

$$r: \Sigma X \xrightarrow{\sigma} \bigsqcup_{j=1}^k \Sigma X \xrightarrow{\bigsqcup_{j=1}^k r_j} \bigvee_{j=1}^k A_{i_j}$$

where $\sigma$ is defined using the comultiplication on $\Sigma X$. We claim that $r \circ b$ is homotopic to a homotopy equivalence. Observe that for $1 \leq j \leq k$ we have $\tilde{q}_j \circ r \simeq r_j$ where $\tilde{q}_j: \bigsqcup_{i=1}^m A_{i_j} \xrightarrow{g} A_{i_j}$ is the pinch map. By hypothesis, $r_j \circ q_j \simeq q_{i_j}$, so by definition of $b$ we also have $r_j \circ b \simeq \tilde{q}_j$. Therefore $\tilde{q}_j \circ r \circ b \simeq r_j \circ b \simeq \tilde{q}_j$. In homology, the direct sum of finitely many $\mathbb{Z}$-modules is the same as the direct product, so the map

$$\tilde{H}_*(\bigvee_{j=1}^k A_{i_j}; \mathbb{Z}) \xrightarrow{r \circ b_*} \tilde{H}_*(\bigvee_{i=1}^m A_i; \mathbb{Z}) \cong \bigoplus_{j=1}^k \tilde{H}_*(A_{i_j}; \mathbb{Z})$$

is determined by the projection to each $\tilde{H}_*(A_{i_j}; \mathbb{Z})$. This projection is given by $(\tilde{q}_j)_*$. Thus the fact that $(\tilde{q}_j)_* = (\tilde{q}_j)_* \circ r_* \circ b_*$ implies that $r_* \circ b_*$ is the identity map. Hence, by Whitehead’s Theorem, $r \circ b$ is a homotopy equivalence.

**Lemma 5.7.** There is a homotopy equivalence $W_4 \simeq P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^m S^4$. 

Proof. By (9) and Lemma 5.5 there is a homotopy cofibration

\[
\bigvee_{i=1}^{m} S^3 \xrightarrow{f_3} P \vee \Sigma S \vee \Sigma P \to W_4
\]

where \( f_3 \) induces the trivial map in integral homology. We will show that \( f_3 \) is null homotopic and then the statement of the lemma follows.

Consider the composites

\[
S^3 \leftarrow \bigvee_{i=1}^{m} S^3 \xrightarrow{f_3} P \vee \Sigma S \vee \Sigma P \to P \to P^3(b_j)
\]

(10)

\[
S^3 \leftarrow \bigvee_{i=1}^{m} S^3 \xrightarrow{f_3} P \vee \Sigma S \vee \Sigma P \to \Sigma S \to S^3
\]

\[
S^3 \leftarrow \bigvee_{i=1}^{m} S^3 \xrightarrow{f_3} P \vee \Sigma S \vee \Sigma P \to \Sigma P \to P^4(b_j)
\]

where the three right-hand maps pinch onto a single wedge summand. Let \( g \) be the first composite in (10) and let \( C_g \) be its cofiber. Since the cofiber of \( f_3 \) is \( W_4 \) which is the suspension of the 3-skeleton of \( W \), all cup products in \( H^*(W_4; \mathbb{Z}/p_j^r \mathbb{Z}) \) are zero. Therefore, by Lemma 4.2, all cup products in \( H^*(C_g; \mathbb{Z}/p_j^r \mathbb{Z}) \) are zero. Hence, by Proposition 4.4, \( g \) is null homotopic.

Since \( f_3 \) induces the zero map in integral homology, the second and third composites in (10) are null homotopic by the Hurewicz Theorem. These null homotopies hold for the inclusion of each \( S^3 \) into \( \bigvee_{i=1}^{m} S^3 \), so \( f_3 \) composes trivially with each of the pinch maps \( P \vee \Sigma S \vee \Sigma P \to X \) for \( X = P^3(b_j) \), \( S^3 \) or \( P^4(b_j) \). Thus each of these pinch maps extends to a map \( W_4 \to X \). Since \( W_4 \) is a suspension, Lemma 5.6 implies that the map \( P \vee \Sigma S \vee \Sigma P \to W_4 \) has a left homotopy inverse. Hence \( f_3 \) is null homotopic.

Lemma 5.8. Suppose that \( H^*(W; \mathbb{Z}) \) has no 2-torsion. If the Steenrod operation \( Sq^2 \) acts trivially on \( H^*(W; \mathbb{Z}/2 \mathbb{Z}) \) then there is a homotopy equivalence

\[
\Sigma W \simeq P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \vee S^5.
\]

If \( Sq^2 \) acts nontrivially on \( H^*(W; \mathbb{Z}/2 \mathbb{Z}) \) then there is a homotopy equivalence

\[
\Sigma W \simeq P \vee \bigvee_{k=2}^{d} S^3 \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \vee \Sigma \mathbb{C}P^2.
\]

Proof. By (9) and Lemma 5.7 there is a homotopy cofibration

\[
S^4 \xrightarrow{f_4} P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \to \Sigma W
\]

where \( f_4 \) induces the trivial map in integral homology. Consider the composites

\[
S^4 \xrightarrow{f_4} P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \to P \to P^3(b_j)
\]

(11)

\[
S^4 \xrightarrow{f_4} P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \to \Sigma S \to S^3
\]

\[
S^4 \xrightarrow{f_4} P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \to \Sigma P \to P^4(b_j)
\]

\[
S^4 \xrightarrow{f_4} P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^{m} S^4 \to \bigvee_{i=1}^{m} S^4 \to S^4
\]
where the middle and right maps pinch onto a single wedge summand.

Suppose that $Sq^2$ acts trivially on $H^*(W; \mathbb{Z}/2\mathbb{Z})$. Since each $b_j$ is a power of an odd prime, by Lemma 2.2, $\pi_4(P^3(b_j)) \cong 0$ and $\pi_4(P^4(b_j)) \cong 0$, implying the first and third composites in (11) are null homotopic. Since $\pi_4(S^3) \cong \mathbb{Z}/2\mathbb{Z}$ is generated by a map $\eta$ which is detected by $Sq^2$, the assumption that $Sq^2$ acts trivially on $H^*(W; \mathbb{Z}/2\mathbb{Z})$ implies that the second composite in (11) is null homotopic. Since $f_4$ induces the zero map in homology, the Hurewicz homomorphism implies that the fourth composite in (11) is null homotopic. Thus each of the pinch maps $P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^m S^4 \longrightarrow X$ for $X = P^3(b_j)$, $S^3$, $P^4(b_j)$ or $S^4$ extends to a map $\Sigma W \longrightarrow X$. Therefore, by Lemma 5.6, the map $P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^m S^4 \rightarrow \Sigma W$ has a left homotopy inverse. Hence $f_4$ is null homotopic, implying that

$$\Sigma W \cong P \vee \Sigma S \vee \Sigma P \vee \left( \bigvee_{i=1}^m S^4 \right) \vee S^5.$$  

Next, suppose that $Sq^2$ acts nontrivially on $H^*(W; \mathbb{Z}/2\mathbb{Z})$. Arguing as before, the first, third and fourth composites in (11) are null homotopic. As $Sq^2$ detects the generator $\eta$ of $\pi_4(S^3) \cong \mathbb{Z}/2\mathbb{Z}$, the nontrivial action of $Sq^2$ on $H^*(W; \mathbb{Z}/2\mathbb{Z})$ implies that the second composite in (11) is nontrivial for at least one of the pinch maps $\Sigma S = \bigvee_{k=1}^d S^3 \longrightarrow S^3$. Possibly the second composite in (11) could be nontrivial for several such pinch maps. However, by [19], any map $h: S^4 \overset{\bigvee_{k=1}^d \epsilon_k \eta}{\longrightarrow} \bigvee_{k=1}^d S^3$ with $\epsilon_k \in \{0, 1\}$ for all $1 \leq k \leq d$, and having at least one $\epsilon_k = 1$, can be composed with a self-equivalence $e$ of $\bigvee_{k=1}^d S^3$ so that $e \circ h$ is homotopic to the composite $S^4 \overset{\eta}{\longrightarrow} S^3 \hookrightarrow \bigvee_{k=1}^d S^3$ where the inclusion can be assumed to be the first wedge summand. Altering the copy of $\Sigma S$ in $P \vee \Sigma S \vee \Sigma P \vee \bigvee_{i=1}^m S^4$ by the same self-equivalence $e$, we obtain that each of the pinch maps $P \vee \bigvee_{k=2}^d S^3 \vee \Sigma P \vee \bigvee_{i=1}^m S^4 \longrightarrow X$ for $X = P^3(b_j)$, $S^3$ for $2 \leq k \leq d$, $P^4(b_j)$ or $S^4$ extends to a map $\Sigma W \longrightarrow X$. Therefore, by Lemma 5.6, the map $P \vee \bigvee_{k=2}^d S^3 \vee \Sigma P \vee \bigvee_{i=1}^m S^4 \longrightarrow \Sigma W$ has a left homotopy inverse. Therefore $f_4$ factors as the composite

$$S^4 \overset{\eta}{\longrightarrow} S^3 \hookrightarrow P \vee \bigvee_{k=1}^d S^3 \vee \Sigma P \vee \bigvee_{i=1}^m S^4$$

implying that $\Sigma W \cong P \vee \bigvee_{k=2}^d S^3 \vee \Sigma P \vee \left( \bigvee_{i=1}^m S^4 \right) \vee \Sigma \mathbb{C}P^2$ since $\Sigma \mathbb{C}P^2$ is the homotopy cofibre of $\eta$.

If the orientable, closed, compact 4-manifold $M$ is Spin then the Steenrod operation $Sq^2$ acts trivially on $H^*(M; \mathbb{Z}/2\mathbb{Z})$ and if it is non-Spin then $Sq^2$ acts nontrivially. Finally, we can determine the homotopy type of $\Sigma M$ and prove Theorem 1.1.

**Proof of Theorem 1.1.** Combine the homotopy decomposition $\Sigma M \simeq \left( \bigvee_{i=1}^m S^2 \right) \vee \Sigma W$ in Lemma 5.1 with that of $\Sigma W$ in Lemma 5.8. \qed

### 6. Applications

Suppose that $M$ satisfies the hypotheses of Theorem 1.1. In this section we give three applications of the homotopy decomposition of $\Sigma M$.

The first application is to calculate the reduced complex $K$-theory of $M$, as a group.
Proposition 6.1. Let $M$ be a smooth, orientable, closed, connected 4-manifold satisfying the hypotheses of Theorem 1.1. If $M$ is Spin there is a group isomorphism
\[ \tilde{K}(M) \cong \bigoplus_{i=1}^{m} (\tilde{K}(S^1) \oplus \tilde{K}(S^3)) \oplus \bigoplus_{j=1}^{n} (\tilde{K}(P^2(b_j)) \oplus \tilde{K}(P^3(b_j))) \oplus \bigoplus_{k=1}^{d} \tilde{K}(S^2) \oplus \tilde{K}(S^4). \]
If $M$ is non-Spin there is a group isomorphism
\[ \tilde{K}(M) \cong \bigoplus_{i=1}^{m} (\tilde{K}(S^1) \oplus \tilde{K}(S^3)) \oplus \bigoplus_{j=1}^{n} (\tilde{K}(P^2(b_j)) \oplus \tilde{K}(P^3(b_j))) \oplus \bigoplus_{k=2}^{d} \tilde{K}(S^2) \oplus \tilde{K}(\mathbb{C}P^2). \]

Proof. In general, $\tilde{K}(X) \cong [X, BU]$ where $BU$ is the classifying space of the infinite unitary group and $[X, BU]$ is the set of pointed homotopy classes of maps. Let $BU\langle 2 \rangle$ be the 2-connected cover of $BU$ (this happens to be $BSU$, but in the interest of Remark 6.2 we’ll continue to use $BU\langle 2 \rangle$). By Bott periodicity, there is a homotopy equivalence $BU \cong \Omega^2 BU\langle 2 \rangle$. Suppose that $\Sigma^2 X \cong \Sigma^2 A \vee \Sigma^2 B$. Then there is a sequence of isomorphisms
\[ \tilde{K}(X) = [X, BU] \cong [X, \Omega^2 BU\langle 2 \rangle] \cong [\Sigma^2 X, BU\langle 2 \rangle] \cong [\Sigma^2 A, BU\langle 2 \rangle] \oplus [\Sigma^2 B, BU\langle 2 \rangle] \cong [A, \Omega^2 BU\langle 2 \rangle] \oplus [B, \Omega^2, BU\langle 2 \rangle] \cong [A, BU] \oplus [B, BU] = \tilde{K}(A) \oplus \tilde{K}(B). \]

Notice that all isomorphisms are as groups except possibly the one induced by the decomposition $\Sigma^2 X \cong \Sigma^2 A \vee \Sigma^2 B$, which may only be a homotopy equivalence of spaces. If this were a homotopy equivalence of co-$H$-spaces then we obtain a group isomorphism $\tilde{K}(X) \cong \tilde{K}(A) \oplus \tilde{K}(B)$.

In our case, the homotopy decomposition for $\Sigma M$ in Theorem 1.1 implies a homotopy decomposition for $\Sigma^2 M$ as co-$H$-spaces, so the asserted group isomorphisms for $\tilde{K}(M)$ follow immediately from the homotopy decomposition of $\Sigma M$. \qed

Remark 6.2. The same argument works for real $K$-theory $\tilde{KO}(M)$ using the Bott periodicity isomorphism $BO \cong \Omega^4 BSp(4)$, and quaternionic $K$-theory $\tilde{K}Sp(M)$ using the Bott periodicity isomorphism $BSp \cong \Omega^4 BO\langle 4 \rangle$.

The second application is to current groups. Let $X$ be a smooth manifold and let $G$ be a connected Lie group. The current group associated to $X$ and $G$ is the space of smooth maps from $X$ to $G$, which is homotopy equivalent to $\text{Map}(X, G)$. The most famous example is the loop group $\text{Map}(S^1, G)$. Current groups have received considerable attention, notably in [2, 14, 18].

In our case, consider $\text{Map}(M, G)$. There is a fibration $\text{Map}^*(M, G) \longrightarrow \text{Map}(M, G) \xrightarrow{ev} G$ where $ev$ evaluates a map at the basepoint of $M$. The multiplication on $G$ induces one on $\text{Map}(M, G)$ so the right inverse of $ev$ induced by projecting $M$ to the constant map implies that there is a homotopy equivalence
\[ \text{(12)} \quad \text{Map}(M, G) \cong G \times \text{Map}^*(M, G). \]
Note that $\text{Map}^*(S^n, G) = \Omega^n G$. For $k \in \mathbb{Z}$, let $G \xrightarrow{k} G$ be the $k^{th}$-power map and let $G\{k\}$ be its homotopy fibre. Applying $\text{Map}^*(\cdot, G)$ to the homotopy cofibration $S^n \xrightarrow{k} S^n \rightarrow P^{n+1}(k)$ gives a homotopy fibration $\text{Map}^*(P^{n+1}(k), G) \rightarrow \Omega^n G \xrightarrow{k} \Omega^n G$, implying that $\text{Map}^*(P^{n+1}(k), G) \simeq \Omega^n G\{k\}$.

**Proposition 6.3.** Let $M$ be a smooth, orientable, closed, connected 4-manifold satisfying the hypotheses of Theorem 1.1 and let $G$ be a connected topological group. If $M$ is Spin there is a homotopy equivalence

$$
\text{Map}(M, G) \simeq G \times \prod_{i=1}^{m} (\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n} (\Omega G\{b_j\} \times \Omega^2 G\{b_j\}) \times (\prod_{k=1}^{d} \Omega^2 G) \times \Omega^4 G.
$$

If $M$ is non-Spin there is a homotopy equivalence

$$
\text{Map}(M, G) \simeq G \times \prod_{i=1}^{m} (\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n} (\Omega G\{b_j\} \times \Omega^2 G\{b_j\}) \times (\prod_{k=2}^{d} \Omega^2 G) \times \text{Map}^*(\mathbb{C}P^2, G).
$$

**Proof.** In general, if $\Sigma X \simeq \Sigma A \vee \Sigma B$ then

$$
\text{Map}^*(X, G) \simeq \text{Map}^*(\Sigma X, BG)
\simeq \text{Map}^*(\Sigma A, BG) \times \text{Map}^*(\Sigma B, BG)
\simeq \text{Map}^*(A, G) \times \text{Map}^*(B, BG).
$$

In our case, the homotopy decomposition of $\Sigma M$ in Lemma 1.1 implies that if $M$ is Spin there is a homotopy equivalence

$$
\text{Map}^*(M, G) \simeq \prod_{i=1}^{m} (\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n} (\Omega G\{b_j\} \times \Omega^2 G\{b_j\}) \times (\prod_{k=1}^{d} \Omega^2 G) \times \Omega^4 G
$$

and if $M$ is non-Spin there is a homotopy equivalence

$$
\text{Map}^*(M, G) \simeq \prod_{i=1}^{m} (\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n} (\Omega G\{b_j\} \times \Omega^2 G\{b_j\}) \times (\prod_{k=2}^{d} \Omega^2 G) \times \text{Map}^*(\mathbb{C}P^2, G).
$$

The asserted homotopy decompositions for $\text{Map}(M, G)$ now follow from (12).
In Propositions 6.4 and 6.5 the Spin and non-Spin cases of smooth, orientable, closed, connected 4-manifolds are considered separately due to some additional delicacy in the non-Spin case.

**Proposition 6.4.** Let $M$ be a smooth, orientable, closed, connected 4-manifold and let $G$ be a simply-connected, compact, simple Lie group. If $M$ is Spin and satisfies the hypotheses of Theorem 1.1 then there is a homotopy equivalence

$$
\mathcal{G}_k(M) \simeq \mathcal{G}_k(S^4) \times \prod_{i=1}^{m} (\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n} (\Omega G \{b_j\} \times \Omega^2 G \{b_j\}) \times \prod_{i=1}^{d} \Omega^2 G.
$$

**Proof.** The pinch map $q: M \to S^4$ to the top cell induces an isomorphism $[S^4, BG] \to [M, BG]$, so by the naturality of the evaluation fibration there is a homotopy fibration diagram

$$
\begin{array}{ccc}
G & \longrightarrow & \text{Map}_k^*(S^4, BG) \\
\downarrow & & \downarrow \\
G & \longrightarrow & \text{Map}_k^*(M, BG)
\end{array}
\quad
\begin{array}{ccc}
\text{Map}_k^*(S^4, BG) & \longrightarrow & \text{Map}_k^*(S^4, BG) \\
\downarrow & & \downarrow \\
\text{Map}_k^*(M, BG) & \longrightarrow & \text{Map}_k^*(M, BG)
\end{array}
\quad
\begin{array}{ccc}
& \longrightarrow & \longrightarrow \\
& \text{ev} & \text{ev} \\
BG & \longrightarrow & BG
\end{array}
$$

Consider the homotopy cofibration sequence $S^3 \xrightarrow{f} M_3 \longrightarrow M \xrightarrow{q} S^4$ where $M_3$ is the 3-skeleton of $M$ and $f$ is the attaching map for the top cell. This induces a homotopy fibration $\text{Map}^*(S^4, BG) \longrightarrow \text{Map}^*(M, BG) \longrightarrow \text{Map}^*(M_3, BG)$. Since $\text{Map}^*(M_3, BG)$ has one component, restricting to the $k^{th}$ component of $\text{Map}^*(M, BG)$ we obtain a homotopy fibration $\text{Map}_k^*(S^4, BG) \longrightarrow \text{Map}_k^*(M, BG) \longrightarrow \text{Map}^*(M_3, BG)$. Notice that the connecting map for this homotopy cofibration is $\Sigma f$, which is null homotopic by Theorem 1.1 since it is assumed that $M$ is Spin.

From the left square in (13) we therefore obtain a homotopy fibration diagram

$$
\begin{array}{ccc}
& \longrightarrow & \longrightarrow \\
& \Omega \text{Map}_k^*(M, BG) & \Omega \text{Map}_k^*(M, BG) \\
\Omega \mathcal{G}_k(S^4) & \longrightarrow & \Omega \mathcal{G}_k(M) \\
\downarrow & & \downarrow \\
\mathcal{G}_k(S^4) & \longrightarrow & \mathcal{G}_k(M)
\end{array}
\quad
\begin{array}{ccc}
& \longrightarrow & \longrightarrow \\
& \text{Map}_k^*(S^4, BG) & \text{Map}_k^*(S^4, BG) \\
\downarrow & & \downarrow \\
\text{Map}_k^*(M, BG) & \longrightarrow & \text{Map}_k^*(M, BG)
\end{array}
\quad
\begin{array}{ccc}
& \longrightarrow & \longrightarrow \\
& \text{(\Sigma f)}^* & \\
\text{Map}_k^*(M_3, BG) & \longrightarrow & \text{Map}_k^*(M_3, BG)
\end{array}
$$

that defines the maps $a$ and $b$. Since $(\Sigma f)^*$ is null homotopic, $b$ has a right homotopy inverse. The homotopy commutativity of the top right square then implies that $a$ has a right homotopy inverse. Therefore, using the multiplication on $\mathcal{G}_k(M)$ we obtain a homotopy equivalence

$$
\mathcal{G}_k(M) \simeq \mathcal{G}_k(S^4) \times \text{Map}^*(\Sigma M_3, BG).
$$
As $M$ is Spin, the homotopy decomposition of $\Sigma M$ in Theorem 1.1 implies that

$$\Sigma M_3 \simeq \bigvee_{i=1}^{m} (S^2 \vee S^4) \vee \bigvee_{j=1}^{n} (P^3(b_j) \vee P^4(b_j)) \vee \bigvee_{l=1}^{d} S^3.$$  

Substituting this into $\text{Map}^*(\Sigma M_3, BG)$ then gives the homotopy equivalence asserted in the statement of the Proposition.

Next, consider the non-Spin case. We aim for an argument mirroring the Spin case, but using a map $M \to \mathbb{CP}^2$ instead of the pinch map $M \to S^4$. However, the existence of such a map is not obvious. We produce a near substitute using the approach in [19]. To do so an extra hypothesis is introduced on $\pi_1(M)$ involving the graph product of groups.

Let $\Gamma = (V,E)$ be a finite undirected graph with vertex set $V$ and edge set $E$, and let $\hat{G} = \{G_v \mid v \in V\}$ be a collection of groups associated to the vertices of $\Gamma$. The graph product $\Gamma \hat{G}$ of $\hat{G}$ over $\Gamma$ is the quotient group $F/R$, where $F = \ast_{v \in V} G_v$ is the free product of $G_v$’s and $R$ is the normal subgroup generated by commutator groups $[G_u, G_v]$ wherever $(u,v)$ is in $E$. For example, if $\Gamma$ is a complete graph then $\Gamma \hat{G} = \bigoplus_{v \in V} G_v$ or if $\Gamma$ is a graph of discrete points then $\Gamma \hat{G} = \ast_{v \in V} G_v$.

If each $G_v$ is cyclic then the abelianization of $\Gamma \hat{G}$ is $\bigoplus_{v \in V} G_v$. It is known that if a group $H$ is finitely presented then there is a smooth, orientable, closed, connected 4-manifold whose fundamental group is $H$ (see, for example, [3, Theorem 1.2]). For example, if $\Gamma \hat{G}$ is a graph product of cyclic groups $\{G_{v} \mid v \in V\}$ then there is a smooth, orientable, closed, connected 4-manifold with $\pi_1(M) \cong \Gamma \hat{G}$ and $H_1(M; \mathbb{Z}) \cong \bigoplus_{v \in V} G_v$. A specific interesting case is when $M = M' \times S^1$ where $M'$ is a smooth, orientable, closed, connected 3-manifold with $\pi_1(M')$ the graph product of copies of $\mathbb{Z}$ (a right-angled Artin group) or copies of $\mathbb{Z}/2\mathbb{Z}$ (a right-angled Coxeter group).

**Proposition 6.5.** Let $M$ be a smooth, orientable, closed, connected 4-manifold and let $G$ be a simply-connected, compact, simple Lie group. Let $\Gamma \hat{G}$ be a graph product of $\{G_{v} \mid v \in V\}$ where $G_v = \mathbb{Z}$ for $1 \leq i \leq m$, $G_{j+m} = \mathbb{Z}/b_j\mathbb{Z}$ for $1 \leq j \leq n$, and each $b_j$ is odd. If $M$ is non-Spin and $\pi_1(M) \cong \Gamma \hat{G}$ then there is a homotopy equivalence

$$G_k(M) \simeq G_k(\mathbb{CP}^2) \times \prod_{i=1}^{m} (\Omega G \times \Omega^2 G) \times \prod_{j=1}^{n} (\Omega G \{b_j\} \times \Omega^2 G \{b_j\}) \times \bigoplus_{l=2}^{d} \Omega^2 G.$$  

**Proof.** For $1 \leq i \leq m$, denote the generator of $G_i = \mathbb{Z}$ by $\alpha_i$. For $1 \leq j \leq n$, denote the generator of $G_{j+m} = \mathbb{Z}/b_j\mathbb{Z}$ by $\beta_j$. Then each $\alpha_i$ has infinite order and each $\beta_j$ has finite order $b_j$. Since the Hurewicz homomorphism $h : \pi_1(M) \to H_1(M; \mathbb{Z})$ is the abelianization, $h(\alpha_i)$ has infinite order and $h(\beta_j)$ has order $b_j$. They generate the direct summands of

$$H_1(M) \cong \bigoplus_{i=1}^{m} \mathbb{Z} \oplus \bigoplus_{j=1}^{n} \mathbb{Z}/b_j\mathbb{Z}.  
$$

In particular, $M$ satisfies the hypotheses of Theorem 1.1.

For $1 \leq i \leq m$, each $\alpha_i$ is represented by a map $x_i : S_1 \to M$ of infinite order and for $1 \leq j \leq n$, each $\beta_j$ is represented by a map $y_j : S^1 \to M$ of order $b_j$. Since $\beta_j$ has order $b_j$,
it extends to a map $\tilde{\beta}_j : P^2(b_j) \to M$. Let

$$\xi : \bigvee_{i=1}^m S^1 \vee \left( \bigvee_{j=1}^n P^2(b_j) \right) \longrightarrow M$$

be the wedge sum of the maps $\alpha_i$ and $\tilde{\beta}_j$. The graph product hypothesis on $\pi_1(M)$ implies that $\xi$ induces an epimorphism on $\pi_1$. By (1), $\xi_*$ is an isomorphism in degree 1 integral homology, and the description of $H_*(M; \mathbb{Z})$ in (8) together with the homotopy decomposition of $\Sigma M$ in Theorem 1.1 implies that $\Sigma \xi$ has a left homotopy inverse. Define the space $C$ and the map $g$ by the homotopy cofibration

$$\left( \bigvee_{i=1}^m S^1 \right) \vee \left( \bigvee_{j=1}^n P^2(b_j) \right) \xrightarrow{\xi} M \xrightarrow{g} C.$$ 

Since $\xi$ induces an epimorphism on $\pi_1$, $C$ is simply-connected, and since $\Sigma \xi$ has a left homotopy inverse, $\Sigma g$ has a right homotopy inverse. Explicitly, the homotopy equivalence for $\Sigma M$ in Theorem 1.1 implies that $\Sigma C \simeq \left( \bigvee_{i=1}^m S^4 \right) \vee \left( \bigvee_{j=1}^n P^4(b_j) \right) \vee \left( \bigvee_{l=1}^{d-1} S^3 \right) \vee \Sigma \mathbb{C}P^2$.

This homotopy equivalence may not desuspend but observe that if $C_3$ is the 3-skeleton of $C$ then

$$\Sigma C_3 \simeq \left( \bigvee_{i=1}^m S^4 \right) \vee \left( \bigvee_{j=1}^n P^4(b_j) \right) \vee \left( \bigvee_{l=1}^{d-1} S^3 \right) \vee S^3$$

and this homotopy equivalence does desuspend because $C_3$ has cells only in dimensions 2 and 3. Let $D$ be the subwedge of $C_3$ given by

$$D = \left( \bigvee_{i=1}^m S^3 \right) \vee \left( \bigvee_{j=1}^n P^3(b_j) \right) \vee \left( \bigvee_{l=1}^{d-1} S^2 \right).$$

Then the composite of inclusions $D \longrightarrow C_3 \longrightarrow C$ has homotopy cofibre $X$, where $\Sigma X \simeq \Sigma \mathbb{C}P^2$.

Define the map $q'$ by the composite $q' : M \xrightarrow{g} C \longrightarrow X$ and define the space $Y$ and the map $f'$ by the homotopy cofibration

$$M \xrightarrow{q'} X \xrightarrow{f'} Y.$$ 

As $\Sigma q'$ has a left homotopy inverse, $f'$ is null homotopic and the homotopy equivalence for $\Sigma M$ in Theorem 1.1 implies that

$$Y \simeq \left( \bigvee_{i=1}^m (S^2 \vee S^4) \right) \vee \left( \bigvee_{j=1}^n (P^3(b_j) \vee P^4(b_j)) \right) \vee \left( \bigvee_{l=1}^{d-1} S^3 \right).$$

Now replace the homotopy cofibration $M \xrightarrow{q} S^4 \xrightarrow{\Sigma f} \Sigma M_3$ and the null homotopy for $\Sigma f$ in the argument for the Spin case with the homotopy cofibration $M \longrightarrow X \xrightarrow{f'} Y$ and the null homotopy for $f'$ to obtain a homotopy equivalence

$$\mathcal{G}_k(M) \simeq \mathcal{G}_k(X) \times \text{Map}^*(Y, BG).$$
Substituting the homotopy equivalence for \( Y \) in (14) into \( \text{Map}^*(Y, BG) \) then gives a homotopy equivalence

\[
G_k(M) \simeq G_k(X) \times \prod_{i=1}^{m}(\Omega G \times \Omega^3 G) \times \prod_{j=1}^{n}(\Omega G\{b_j\} \times \Omega^2 G\{b_j\}) \times \prod_{l=2}^{d}\Omega^2 G.
\]

Notice that \( X \) only contains one 2-cell and one 4-cell, so it is the cofiber of \( a\eta \) for some odd number \( a \). While \( X \) may not be homotopy equivalent to \( \mathbb{CP}^2 \), and while \( G_k(X) \) may not be homotopy equivalent to \( G_k(\mathbb{CP}^2) \), by [19, Lemma 2.12] there is a homotopy equivalence \( G_k(X) \times \Omega^2 G \simeq G_k(\mathbb{CP}^2) \times \Omega^2 G \) for \( d \geq 2 \). If \( d = 1 \), by the construction of \( X \), the map \( M \to X \) induces isomorphisms \( H^2_{\text{free}}(M; \mathbb{Z}) \cong H^2_{\text{free}}(X; \mathbb{Z}) \) and \( H^4(M; \mathbb{Z}) \cong H^4(X; \mathbb{Z}) \). Furthermore, the cup products of degree 2 free elements are preserved under these identifications. So \( X \) is a Poincaré complex and must be \( \mathbb{CP}^2 \). Consequently, \( G_k(X) \simeq G_k(\mathbb{CP}^2) \). Thus, in all cases, from (15) we obtain the asserted homotopy decomposition of \( G_k(M) \).

Propositions 6.4 and 6.5 greatly generalize the results in [19], which considered the special cases when \( \pi_1(M) \) is: (i) free, (ii) isomorphic to \( \mathbb{Z}/p^r\mathbb{Z} \), or (iii) a free product of groups in (i) and (ii). It is worth emphasizing that the decomposition of \( G_k(M) \) can be simply read off from \( H_*(M; \mathbb{Z}) \).

Further, Huang and Wu [8] proved a cancellation result in \( p \)-local homotopy theory. From this we obtain the following.

**Corollary 6.6.** Let \( M \) be a manifold as in Propositions 6.4 or 6.5 and let \( p \) be a prime. If \( M \) is Spin there is a \( p \)-local homotopy equivalence \( G_k(M) \simeq G_l(M) \) if and only if there is a \( p \)-local homotopy equivalence \( G_k(S^4) \simeq G_l(S^4) \). If \( M \) is non-Spin there is a \( p \)-local homotopy equivalence \( G_k(\mathbb{CP}^2) \simeq G_l(\mathbb{CP}^2) \).

A classification of when there is a \( p \)-local homotopy equivalence \( G_k(S^4) \simeq G_l(S^4) \) for any prime \( p \) has been determined for \( G = SU(2) \) [12], \( G = SU(3) \) [5], \( G = SU(5) \) [25], and \( G = Sp(2) \) [23]. For example, when \( G = SU(3) \) there is a \( p \)-local homotopy equivalence \( G_k(S^4) \simeq G_l(S^4) \) if and only if \((k, 12) = (l, 12)\), where \((a, b)\) is the greatest common denominator of integers \( a \) and \( b \). Partial classifications have been determined in many other cases [6, 10, 11, 13, 20, 24, 26].
