PETERZIL-STEINHORN SUBGROUPS AND $\mu$-STABILIZERS IN ACF

MOSHE KAMENSKY, SERGEI STARCHENKO, AND JINHE YE

Abstract. We consider $G$, a linear algebraic group defined over $k$, an algebraically closed field. By considering $k$ as an embedded residue field of an algebraically closed valued field $K$, we can associate to it a compact $G$-space $S^\mu_G(k)$, consisting of $\mu$-types on $G$. We showed that for each $p_\mu \in S^\mu_G(k)$, $\text{Stab}^\mu(p) = \text{Stab}(p_\mu)$ is a solvable infinite algebraic group when $p_\mu$ is centered at infinity and residually algebraic. Moreover we give a description of the dimension $\text{Stab}(p_\mu)$ in terms of dimension of $p$.

1. Introduction

Let $G$ be a group definable in an o-minimal theory, and let $\gamma : (a, b) \to G$ be a definable curve which is unbounded, in the sense that the limit at $b$ does not exist. In [7], it was shown that one can associate to this datum a definable one-dimensional torsion-free group $H_\gamma \subseteq G$, that can be viewed as the “stabilizer of $\gamma$ at $\infty$”. The group $H_\gamma$ is called the Peterzil–Steinhorn subgroup associated to $\gamma$. For example, when $G$ is a Cartesian power of the additive group, $H_\gamma$ is the linear subspace whose translate is the asymptote of $\gamma$ at $\infty$.

Assume now that $G$ is an affine algebraic group over the complex numbers, and $X$ is an algebraic curve embedded in $G$. If we view $\mathbb{C}$ as the algebraic closure of a real closed field $\mathbb{K}$, the set of complex points of $X$ can be viewed as the set of $\mathbb{K}$-points of an $\mathbb{K}$-definable set $X^{an}$ in the o-minimal structure $\mathbb{K}$. This set is unbounded, and we may therefore choose an unbounded curve $\gamma$ inside $X^{an}$, and consider the corresponding PS-group $H_\gamma$. Taking its Zariski closure, we obtain an algebraic subgroup $G_\gamma$ of $G$, of (algebraic) dimension 1.

It is natural to ask, to which extent does the subgroup $G_\gamma$ depend on the non-algebraic data involved, namely, the dependence on the real closed field $\mathbb{K}$ of choice and the curve $\gamma$? And if it does not depend on the above, can the construction be described in a purely algebraic manner? We first note that a choice of $\gamma : (a, b) \to X^{an}$ determines an additional algebraic datum: the curve $X$ (which we may assume to be smooth) has a canonical compactification $\bar{X}$, its projective model, which is obtained from $X$ by adding finitely many points. Viewing $\gamma$ as taking values in $\bar{X}^{an}$ rather than $X^{an}$, the limit of $\gamma$ at $b$ will be precisely one of these points, and curves $\gamma$ corresponding to different such points definitely might give rise to different subgroups $G_\gamma$. Hence, any hope of providing an algebraic construction of $G_\gamma$ should take into account the choice of such a point at infinity.

Main results. The main result of this paper (stated below) provides an algebraic construction as expected above, once the additional datum of a limit point is chosen:
**Theorem 1.1.** Let $k$ be an algebraically closed field and $G$ be a linear algebraic group over $k$, and let $X \subseteq G$ be an irreducible curve over $k$. Then there are finitely many 1-dimensional linear subgroups of $G$, naturally associated to points at infinity of a smooth projective model of the curve $X$. In fact, they are the $\mu$-stabilizers of those points at infinity, as explained later.

A more precise version is given in Theorem 3.12 and the notion of the $\mu$-stabilizers will be introduced later. The main result of the paper, Theorem 1.2, includes a generalization of the above to higher dimensions, and some analysis of the structure of the resulting group. These results are obtained by viewing $G$ as a definable group in ACVF, the theory of algebraically closed valued fields, and applying some results from [4]. The relation of the $\mu$-stabilizers to the original construction of Peterzil–Steinhorn is explained in Remark 3.13.

To state the main result, we need to introduce some additional terminology. The subgroups we are interested in were introduced in an abstract setup in [7]. There, one considers (suitably defined) definable topological groups. To such a group $G$, one associates an “infinitesimal subgroup” $\mu$, the intersection of all definable neighbourhoods of the identity. If $P$ is a (partial) type on $G$, the set $\mu \cdot P$ can be viewed geometrically as a tube around $P$, and the $\mu$-stabilizer $\text{Stab}^\mu(P)$ of $P$ is defined to be the stabilizer of this set.

In the o-minimal context, the datum of a curve $\gamma$ as above determines a “type at infinity” $p_\gamma$, and it is easy to see that the PS-group $H_\gamma$ depends only on this type. It is shown in [7] that $H_\gamma$ is precisely the $\mu$-stabilizer of $p_\gamma$. Similarly, every closed point of the projective model of a smooth curve $X$ determines an ACVF type on $X$, and the associated group is defined as the $\mu$-stabilizer of this type. To see that the definition is reasonable, it is shown that the resulting group is 1-dimensional. Furthermore, it is contained in the (algebraic) stabilizer of the corresponding point in every equivariant compactification of $G$ (Remark 3.4).

The definition of $\mu$-stabilizer makes sense for types of higher Zariski dimensions as well. However, two types of different Zariski dimension might have the same tube (Example 2.17), so the dimension comparison is not straightforward. We say that a type is $\mu$-reduced if it is of minimal dimension among all types with a given tube. With this terminology, we have the following generalization of Theorem 1.1:

**Theorem 1.2 (Main theorem).** Let $G$ be a linear algebraic group defined over $k$ and $p$ be a residually algebraic type. If $p$ is centered at infinity, then $\text{Stab}^\mu(p)$ is infinite. Furthermore, if $p$ is $\mu$-reduced, then $\dim(\text{Stab}^\mu(p)) = \dim p$. And for each type $p$, $\text{Stab}^\mu(p)$ is a solvable linear algebraic group.

Here the term “centered at infinity” should be understood as “unbounded” in the o-minimal counterpart. Do note that one cannot hope for the group to be torsion-free, as in the result on PS-groups, since the underlying field may have positive characteristic. The three parts of the theorem are proved as Cor 4.13 in §4.3 and as Theorem 4.20 respectively.

**Structure of the paper.** The structure of the paper is as follows: In §2 we review some definitions and results related to group actions, and provide an alternative
approach to $\mu$-stabilizers. In §3 we consider the one-dimensional case of Theorem 1.1. Though formally included in the general case, the situation is considerably simpler in this case, and sheds light on the more complicated general case. Then in §4 we deal with the general case.

2. $\mu$-stabilizers over ACF

Let $k$ be an arbitrary algebraically closed field, and a linear algebraic group $G$ defined over $k$. In this section, we develop the theory of $\mu$-types and their stabilizers in this context following [7]. Before going into $\mu$-types, let’s begin with some generality on definable group actions.

2.1. Definable group actions. Let us start by recalling some general facts about stabilizers of definable types in an arbitrary complete theory $T$, following [7, Section 2]. We fix a monster model $U$ of $T$ and all the models of $T$ we consider will be elementary submodels of $U$.

Let $X$ be a definable set (over 0), and let $A$ be a small set of parameters. We use $\mathcal{L}_X(A)$ to denote the set of formulas $\psi$ over $A$ such that $\psi(x) \Rightarrow x \in X$. Such formulas will occasionally be called $X$-formulas. And by a (partial) $X$-type over $A$, we mean a consistent collection of formulas in $\mathcal{L}_X(A)$.

We fix $H$ to be a definable group with a definable action on $X$. For an $H$-formula $\phi(x)$ and $X$-formula $\psi(y)$, let $(\phi \cdot \psi)(z)$ be

$$\exists x \exists y \phi(x) \land \psi(y) \land z = x \cdot y.$$ 

And for a partial $X$-type $p$, $\phi \cdot p = \{\phi \cdot \psi : \psi \in p\}$.

By a definable $X$-type over $A$, we mean a $X$-type over $A$ such that for any formula $\phi(x, y)$, $\{a \in A : \phi(x, a) \in p\} = \{a \in A : d_p \phi(a)\}$ for some formula $d_p \phi$ over $A$. Note in the above definition, $a$ can be tuples in $A$.

Let $M$ a model of $T$ such that $A = Y(M)$ for some $M$-definable set $Y$. Then any two such definitions $d_p \phi$ will be equivalent. Moreover, $p$ can be extended to a unique type $p|L$ over $Y(L)$ determined by $\{\phi(x, c) : c \in d_p \phi(Y(L))\}$, for any $L$ such that $M \preceq L$.

Convention 2.1. For the remainder of the paper, we will assume that we are working over a set of parameters $A$ such that $A = Y(M)$ for some model $M$, and we assume further that $H$ and its action on $X$ is defined over $A$. We assume further that $H \subseteq Y^n$ for some Cartesian product of $Y$.

Definition 2.2. Let $p$ be a definable partial $X$-type over $A$ as in Convention 2.1. We define

$$\text{Stab}(p)(M) = \{h \in H(M) : \text{For any } \phi \in \mathcal{L}_X(A) \text{ } p \models h \cdot \phi \Leftrightarrow p \models \phi\}$$
where $h \cdot \phi$ stands for $(x = h) \cdot \phi$. We will occasionally denote $\text{Stab}(p)(M)$ by $\text{Stab}(p)(A)$.

The following is [7, Proposition 2.13].

**Fact 2.3.** Let $H$ be a definable group with a definable action on $X$ and assume we are in the setting of Convention 2.1. Let $p$ be a partial definable $X$-type over $A$. Then $\text{Stab}(p)$ is an $A$-type-definable subgroup of $H$ in the following sense: there is a small system $H_\alpha$ of $A$-definable subgroups of $H$ such that for every elementary extension $M \preceq L$, for $a \in H(L)$, we have that $a \in \text{Stab}(p|L)(L)$ if and only if $a \in H_\alpha(L)$ for all $\alpha$.

With the language set up, we will now look at the setting to talk about $\mu$-types as in [7] over algebraically closed fields.

### 2.2. $\mu$-stabilizers over ACF

Let $k$ be an algebraically closed field. The theory of algebraically closed fields is not rich enough to have a good notion of infinitesimal subgroups as in [7]. Hence, it is natural to work with the theory $T_{\text{loc}}$ as introduced in [3, Section 6]. The language for $T_{\text{loc}}$ has two sorts, a sort $\text{VF}$ for the valued field, and a sort $\Gamma$ for the value group. The sort $\text{VF}$ is has a unary predicate $\text{RES}$ for an embedded copy of the residue field, which can be viewed as an additional sort. Thus we have function symbols $\text{res} : \text{VF}^2 \to \text{RES}$ and $\text{val} : \text{VF} \to \Gamma$. The theory $T_{\text{loc}}$ asserts that the $\text{VF}$ sort is an algebraically closed valued field, $\text{RES}$ is a subfield, $\text{val}$ is a valuation map, $\text{res}(x, y) = \text{res}(x/y)$, the residue of $x/y$ if $\text{val}(x) \geq \text{val}(y)$ and 0 otherwise, with $\text{res}(c, 1) = c$ for $c \in \text{RES}$. For notational simplicity, we will use $\text{res}(x)$ to denote $\text{res}(x, 1)$ for $x \in \mathcal{O}$, the valuation ring.

We further assume that we have constants for the elements of the field $k$ in $\text{RES}$. Thus, models of $T_{\text{loc}}$ are algebraically closed valued fields with embedded residue field extending $k$.

**Fact 2.4 ([3, Lemma 6.3]).** $T_{\text{loc}}$ admits quantifier elimination in this language. The sorts $\Gamma$ and $\text{RES}$ are stably embedded and orthogonal to each other. The induced structures on $\Gamma$ and $\text{RES}$ are of divisible ordered abelian groups algebraically closed fields, respectively.

**Remark 2.5.** In the paper [3], a constant symbol 1 in the $\Gamma$-sort for some positive element was included. But the proof of quantifier elimination does not rely on the constant.

In some cases, we will work in the reduct of $T_{\text{loc}}$ in the 3-sorted language $\mathcal{L}_{\text{val}}$. $\mathcal{L}_{\text{val}}$ consists of the valued field sort $\text{VF}$, the value group sort $\Gamma$ and the residue field sort $\text{RES}$ and maps $\text{val} : \text{VF} \to \Gamma$, $\text{res} : \text{VF} \to \text{RES}$. In this language, we have constants for $k$ in both $\text{VF}$-sort and $\text{RES}$-sort. The induced theory on the reduct is $\text{ACVF}_k$, the theory of algebraically closed valued fields with constants for $k$, which admits quantifier elimination in $\mathcal{L}_{\text{val}}$. Since this is a reduct, we will freely view formulas in $\mathcal{L}_{\text{val}}$ as definable sets in $T_{\text{loc}}$. The main point of working with this reduct is the application of topological results from [4] available for this restricted class of definable sets.
Recall that we are given a linear algebraic group $G$ defined over $k$. In our context, this group determines a number of distinct definable groups: The definable group $G$ of $VF$-points of $G$, and the definable subgroups $G(O)$ and $G$ of $O$- and $RES$-points, respectively. The (pointwise) residue map res : $G(O) \to \overline{G}$ is a definable group theoretic retraction (since $G$ is over $k$), whose kernel we denote by $\mu$. Note $\mu$ is definable over $k$ as well. Geometrically, $\mu$ can be viewed as an (infinitesimal) neighbourhood of the identity in $G$.

Let $P$ be an algebraic variety over $k$ on which $G$ acts (Our main example will be $P = G$, with $G$ acting on itself by left multiplication, but occasionally we will need the more general setup.) Then $P$ determines a definable set $\mathcal{P}$ in $VF$, and a definable action of $G$ on $\mathcal{P}$, which restricts to an action of $\overline{G} \leq G$. We are therefore in the setting of Convention 2.1, where we set $T = T_{loc}$, $X = P$, $Y = RES$ and $H = \overline{G}$. In fact, one can take $k = RES(M)$, where $M$ is a field of Hahn series with coefficients in $k$.

**Definition 2.6.** Let $P$ and $G$, and the associated terminology be as above. We denote by $S_P(k)$ the space of complete $L_{val}$-$P$-types over $k$. For $p \in S_P(k)$, the $\mu$-stabilizer $Stab^\mu(p)$ of $p$ is $Stab_{\overline{G}}(\mu \cdot p)$.

Note that a complete $L_{val}$-$P$-type might be a partial type in $T_{loc}$. By quantifier elimination, such types correspond to pairs of the form $(Z, v)$, where $Z$ is an irreducible closed subvariety of $P$ and $v$ is a valuation on the function field of $Z$ which is trivial on $k$. By Fact 2.4, the $RES$-sort is stably embedded as an algebraically closed field. In particular, each $p \in S_P(k)$ is definable over $k$ in $L_{val}$.

**Proposition 2.7.** Let $p \in S_P(k)$. Then $\mu \cdot p$ is a definable partial type over $k$.

**Proof.** Let $Z$ be a $L_{val}$-definable set over $k$. Then $\mu \cdot p \models Z$ if and only if

$$p(x) \models \forall \epsilon \in \mu(\epsilon \cdot x \in Z)$$

The latter condition is $L_{val}$-definable over $k$, hence the result follows from the definability of $p$. \hfill $\square$

By Fact 2.3 and the above discussion, $Stab^\mu(p)$ is given by an intersection of $L_{val}$-definable subgroups of $\overline{G}$. However, $\overline{G}$ has the descending chain condition on subgroups. Hence by Fact 2.4 we have:

**Corollary 2.8.** Let $p$ be an $L_{val}$-complete $G$-type over $k$. Then the $\mu$-stabilizer $Stab^\mu(p)$ of $p$ is a $k$-definable subgroup of $\overline{G}$, in the sense that there is a $k$-definable subgroup $H$ of $\overline{G}$, such that $Stab^\mu(p|L)(L) = H(L)$ for any model $L \geq M$.

For $p$ and $q \in S_P(k)$, define $p \sim q$ if $\mu \cdot p = \mu \cdot q$. It is easy to check that $\mu \cdot p = \mu \cdot q$ iff in a monster model $\mathbb{U}$, there are $a \models p$, $b \models q$ and $\epsilon \in \mu$ such that $\epsilon \cdot a = b$.

We denote by $S_P^\mu(k)$ the quotient by this equivalence relation and for each $p \in S_P(k)$, we denote by $p_\mu$ its equivalence class. Since $\mu$ is normal in $G(O)$, the $\overline{G}(k)$ action on $S_P(k)$ given in Subsection 2.1 respects the equivalence relation. Hence $\overline{G}(k)$ acts on $S_P^\mu(k)$, and $Stab^\mu(p) = Stab(p_\mu)$, where the right hand side is by considering $\overline{G}(k)$ acting on $S_P^\mu(k)$.

Lastly, we note that stabilizers for types in the same orbit are conjugate:
Lemma 2.9. Let $g \in \overline{G}(k)$ be such that $g \cdot p_\mu = q_\mu$. Then $\text{Stab}^\mu(q) = g \text{Stab}^\mu(p)g^{-1}$.

We finish this subsection with two basic examples. These can be compared to the computations in the o-minimal setting.

Example 2.10. Let $G = \text{SL}_2(k)$. Let

$$X_1 = \{ \begin{pmatrix} x & 1 \\ 0 & x^{-1} \end{pmatrix} : x \in G_m \},$$

a closed subvariety of $G$. Since this subvariety is isomorphic (as an algebraic variety) to $G_m$, the definable subset given by $\text{val}(x) < 0$ isolates a complete type $p$ on $G$ (in the language $\mathcal{L}_{\text{val}}$ over $k$).

We claim that the left $\mu$-stabilizer $H$ of $p$ is the subgroup

$$G_1 = \left\{ \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} : a \right\}.$$ 

Indeed, let $g \in \text{RES}$ and choose $\alpha \in \text{VF}$ with $\text{val}(\alpha) < 0$. Then

$$\begin{pmatrix} 1 & g \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \alpha & 1 \\ 0 & \alpha^{-1} \end{pmatrix}^{-1} = \begin{pmatrix} \alpha & 1 + g\alpha^{-1} \\ 0 & \alpha^{-1} \end{pmatrix} = \begin{pmatrix} 1 + \varepsilon & 0 \\ 0 & (1 + \varepsilon)^{-1} \end{pmatrix} \begin{pmatrix} \beta & 1 \\ 0 & \beta^{-1} \end{pmatrix},$$

where $\varepsilon = g\alpha^{-1}$ and $\beta = (1 + \varepsilon)^{-1}\alpha$. Since $\text{val}(\varepsilon) > 0$, we have $(1 + \varepsilon, 0, (1 + \varepsilon)^{-1}) \in \mu$ and $(\beta, 1, \beta^{-1}) \models p$.

Thus $G_1 \subseteq H$. By (the easy part of) Theorem 3.12, $H$ is 1-dimensional, so $G_1$ is the connected component of $H$, and $H$ has the form

$$H = \left\{ \begin{pmatrix} \xi & a \\ 0 & \xi^{-1} \end{pmatrix} : \xi^n = 1 \right\}.$$ 

for some $n$. By a similar computation, such an element will take $\mu \cdot p$ to $\mu \cdot p_\xi$ where $p_\xi$ is the type of elements $(x \xi_0)$ with $\text{val}(x) < 0$, so we must have $\xi = 1$ and $G_1 = H$.

This example will be considered again in 3.5.

Example 2.11. Similarly to Example 2.10, we now consider the closed subvariety

$$X_2 = \{ \begin{pmatrix} x & 0 \\ 1 & x^{-1} \end{pmatrix} : x \in G_m \} \subseteq G = \text{SL}_2,$$

and let $q$ the type on $G$ determined inside it by the condition $\text{val}(x) < 0$.

We claim that the left $\mu$-stabilizer $H$ of $q$ is now the subgroup $G_2 = \{ \begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix} : a \in G_m \}$. The computation is similar: For $g \in G_m(\text{RES})$ and $\alpha \in \text{VF}$ with $\text{val}(\alpha) < 0$ we have

$$\begin{pmatrix} g & 0 \\ 0 & g^{-1} \end{pmatrix} \begin{pmatrix} \alpha & 0 \\ 1 & \alpha^{-1} \end{pmatrix} = \begin{pmatrix} g\alpha & 0 \\ g^{-1}(g\alpha)^{-1} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \varepsilon & 1 \end{pmatrix} \begin{pmatrix} \beta & 0 \\ 1 & \beta^{-1} \end{pmatrix},$$

where $\beta = g\alpha$ and $\varepsilon = a^{-1-1}$.

Since $\text{val}(\varepsilon) > 0$ and $\text{val}(\beta) < 0$, we obtain $G_2 \subseteq H$. The only one-dimensional algebraic subgroup of $G$ that properly contains $G_2$ is its normalizer, which contains the element $w = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. This elements sends $q$ to the type of elements $(\frac{x}{1} \frac{x^{-1}}{0})$ with $\text{val}(x) < 0$, so cannot be in $H$. Hence the $\mu$-stabilizer is $G_2$ in this case.
2.3. A different view on $\mu$-stabilizers. Instead of viewing the $\mu$-stabilizers syntactically as in the previous section, we have some concrete constructions to realize them in the monster model as well. In this section, we describe the construction, following the same idea of [11, §2.4]. We work in a fixed monster model of $T_{\text{loc}, \mathbb{U}}$, and identify definable sets and (partial) types with their realisations in $\mathbb{U}$. From now on, we restrict our attention to the case $\mathcal{P} = G$, unless mentioned otherwise.

**Definition 2.12.** For $p \in S_G(\mathbb{k})$ we use $\overline{G}_p$ to denote the following set $((\mu \cdot p) \cdot (\mu \cdot p)^{-1}) \cap G$.

**Proposition 2.13.** Let $a \in \mu \cdot p$. The following are equivalent for an element $b \in G(\mathbb{k})$:

1. $b \in \mu \cdot p \cdot a^{-1} \cap G$
2. $b = \text{res}(a_1 a^{-1})$ for some $a_1 \models p$ for which $a_1 a^{-1} \in G(\mathcal{O})$
3. $b \in \overline{G}_p$
4. $b = \text{res}(a_1 a_2^{-1})$ for some $a_1, a_2 \models p$ for which $a_1 a_2^{-1} \in G(\mathcal{O})$

Hence, $\overline{G}_p(\mathbb{k}) = \mu \cdot p \cdot a^{-1} \cap G(\mathbb{k})$

**Proof.** The equivalence of (1) and (2) follows directly from the definitions, and likewise for (3) and (1). Hence we need to show (1) implies (2). Assume $b = \text{res}(a_1 a_2^{-1})$. Since $a$ and $a_2$ satisfy the same type over $\mathbb{k}$, and $\text{RES}$ is stably embedded and stable, there is an automorphism $\tau$ over $\mathbb{k}$ such that $\tau(a_2) = a$. Then $b = \tau(b) = \text{res}(\tau(a_1)a_1^{-1})$, with $\tau(a_1)$ also satisfying $p$, showing (2) for $b$. $\square$

We now have the following description of $\overline{G}_p$.

**Corollary 2.14.** $\overline{G}_p(\mathbb{k}) = \text{Stab}^\mu(p)(\mathbb{k})$

**Proof.** Assume $g \in G$ stabilizes $\mu \cdot p$. Then for any $a \in \mu \cdot p$, $g \cdot a = \mu \cdot p$, hence $g \in \mu \cdot p \cdot a^{-1}$, so is in $\overline{G}_p$. Conversely, if $g \in \overline{G}_p$ and $a \in \mu \cdot p$, writing $g = a_1 a^{-1}$ as above we obtain $g \cdot a \in \mu \cdot p$. $\square$

**Remark 2.15.** We would like to have Cor. 2.14 to hold for $\text{RES}$-points, instead of just $\mathbb{k}$-points. This is not automatic, since $\overline{G}_p$ is not, a-priori, a definable set. However, in the special case as in Theorem 1.1 it is indeed the case.

2.4. $\mu$-reduced types. For $p \in S_G(\mathbb{k})$ we denote by $\dim(p)$ the dimension of its Zariski closure in $G$ over $\mathbb{k}$. Most of the rest of this paper is devoted to comparing this dimension to the dimension of $\text{Stab}^\mu(p)$. We first note that if $X$ is a variety over a valued field $L$ whose valuation ring is $\mathcal{O}$, then the Zariski dimension of $\text{res}(X) \cap \mathcal{O}$ is at most the dimension of $X$ (this follows for example from [11, Lemma 00QK], by choosing a model of $X$ over $\mathcal{O}$). Applying this observation to $X = Ya^{-1}$, where $Y$ is a variety containing $p$, we obtain:

**Proposition 2.16.** For any $p \in S_G(\mathbb{k})$, $\dim(\text{Stab}^\mu(p)) = \dim \overline{G}_p(\mathbb{k}) \leq \dim(p)$, where $\dim$ means the Krull dimension in $\text{Stab}^\mu(p)$ and $\overline{G}_p(\mathbb{k})$ respectively. $\dim(p)$ is the minimal $\text{VF}$-dimension of the formulas $\varphi \in p$.

In general, the above bound will not be sharp, since types of different dimensions may have the same $\mu$-type:
Example 2.17. Let $G = \mathbb{A}^2$ as an additive group. Let $K$ be a large enough Hahn series in variable $t$ over $k$. Let $p = tp((t^{-1}, t^{-1} + t^r)/k)$ where $r > 0, r \notin \mathbb{Q}$, and $tp$ denotes the $L_{\text{val}}$-type. Then $\dim(p) = 2$, since $t^{-1} + t^r$ is transcendental over $t^{-1}$. But $\mu \cdot p = \mu \cdot q$, where $q = tp((t^{-1}, t^{-1})/k)$, since $(t^{-1}, t^{-1} + t^r)$ and $(t^{-1}, t^{-1})$ differ by $(0, -t^r) \in \mu$, so $\dim(\mathcal{G}_p) \leq 1$ (as we will later see, they are in fact equal). Furthermore, when $\text{Char}(k) = p > 0$, we see that $\text{Stab}^\mu(p)$ is not torsion-free.

This observation motivates the following definition.

Definition 2.18. For $p \in \mathit{SC}(k)$, we say that $p$ is $\mu$-reduced if $p$ is a type of minimal dimension in $p_{\mu}$. An element $a \in G$ is $\mu$-reduced over $k$ if $a \models p$ for some $\mu$-reduced $p$.

2.5. Bounded types. In this sub-section, we revert to working with a general $G$-variety $P$. We recall the following definition (e.g., from [4, §4.2]):

Definition 2.19. Let $V$ be an affine variety, viewed as a definable set in ACVF, and let $X \subseteq V$ be a $L_{\text{val}}$-definable subset. We say that $X$ is bounded if for every regular function $f$ on $V$ there is $\gamma \in \Gamma$ such that $\text{val}(f(X)) \geq \gamma$.

For a general variety $V$, a subset $X \subseteq V$ is bounded if it is covered by bounded subsets of an affine cover.

A partial type $p$ in $V$ is bounded if $p \models X$ for some bounded $X \subseteq V$. A type in $V$ is said to be centered at infinity if it is not bounded.

Note that the property of a definable set to be bounded depends on the ambient variety (for example, $\mathbb{A}^1$ is bounded as a subset of $\mathbb{P}^1$, but not as a subset of $\mathbb{A}^1$). However, if $V$ is a closed subvariety of $W$, then $X \subseteq V$ is bounded in $V$ if and only if it is bounded in $W$. Also, it suffices to check the conditions for generators of the regular functions. In particular, a subset $X$ of a closed subvariety of $\mathbb{A}^n$ is bounded if and only if $\text{val}(X) \geq \gamma$ for some $\gamma$.

Over $k$, we have in our situation the following:

Proposition 2.20. A $k$-definable set $X \subseteq V$ is bounded if and only if it is contained in $V(\mathcal{O})$

Proof. By definition, it suffices to prove the statement for $V$ affine, and by the remarks above, for $V = \mathbb{A}^n$.

If $X \subseteq \mathcal{O}^n$ we may take $\gamma = 0$ in the definition. Conversely. We may assume $n = 1$ by projecting. If $a \in X \setminus \mathcal{O}$ then $\gamma = \text{val}(a) < 0$ has the same type as any other negative value $\gamma'$, so there is an automorphism of $\Gamma$ taking $\gamma$ to $\gamma'$, and since $\Gamma$ is stably embedded and $\Gamma$ and $\text{RES}$ are orthogonal, it extends to an automorphism over $k$ that takes $a$ to $a' \in X$, with $\text{val}(a') = \gamma'$. Thus, $X$ is unbounded.

Let $p$ be a bounded type on $P$, a variety endowed with an action of $G$. A realization $a$ of $p$ is then an $\mathcal{O}$-point of $P$, and so determines a point $\pi$ of $P$ in the residue field. The type of $\pi$ depends only on $p$ (since it is encoded there), and we denote it by $\overline{\pi}$. The group $\mathcal{G}$ acts on the set of all types in $P$, the variety $P$ viewed as a definable set in $\text{RES}$. In particular, we may consider the stabilizer of $\overline{\pi}$.

Proposition 2.21. For any bounded type $p$ on $P$ we have $\text{Stab}^\mu(p) \leq \text{Stab}(\overline{p})$. 

Proof. Let $\overline{a}$ be a realization of $\overline{p}$, and let $a$ be a realization of $p$ whose residue is $\overline{a}$. Assume that for some $g \in G$ we have $g \cdot a = \epsilon \cdot b$ for some $\epsilon \in \mu$ and $b$ realizing $p$ (so that $g \in \text{Stab}^\mu(p)$). Since all elements involved are in $O$, we may apply the residue map, and obtain $g \cdot \overline{a} = \overline{b}$. Since $b$ realizes $p$, $\overline{b}$ realizes $\overline{p}$. Thus $g \cdot \overline{p} = \overline{p}$, i.e., $g \in \text{Stab}(\overline{p})$. □

Returning to the case $P = G$, we obtain:

**Corollary 2.22.** If $p$ is a bounded type on $G$ such that $\overline{p}$ is realized in $k$ then its $\mu$-stabilizer is trivial.

**Proof.** In this case $\overline{p}$ corresponds to a (closed) point of $G$, hence the stabilizer is trivial. □

Because of the last corollary, we shall concentrate on types centered at infinity.

### 3. Analyzing the one-dimensional case

In this section, we prove the main theorem in dimension 1 (Theorem 1.1). We think this section worth including even though it follows from the general case, since it is relatively simple, and it sheds light on the important idea in proving the general case. The result in this section is first proved by Moshe Kamensky and Sergei Starchenko in their unpublished notes via the language of places.

#### 3.1. Points on curves.

Each smooth curve $X$ over $k$ embeds in a unique smooth projective one over $k$, its projective model $\tilde{X}$. Every closed point $c$ on $\tilde{X}$ corresponds to a valuation $\text{val}_c$ on the function field $k(X)$, given by the order of vanishing at $c$. In particular, $\text{val}_c$ is trivial on $k$. The projective model contains a finite number of closed points outside of $X$, which we call the points at infinity.

In our case, $X$ is an affine curve, embedded as a closed subvariety in a fixed affine space $A^n$. To any point $c \in \tilde{X}$ we associate the complete type on $X$ determined by

$$p_c(a) = \{\text{val}(f(a)) > 0 : \text{val}_c(f) > 0\}$$

where $f$ runs over all elements of the local ring corresponding to $X$, and $\overline{f}$ is the corresponding element in $k(X)$.

We would like to describe the types that occur in this way intrinsically, in a way that will be helpful later. The condition that $c$ is a closed point corresponds to the following.

**Definition 3.1.** An extension of (possibly trivially) valued fields is *residually algebraic* if the corresponding residue field extension is algebraic. For $L$ a (possibly trivially) valued field, an $L_{\text{val}}$-type $p$ over $L$ is *residually algebraic* if for a/every realization $a$ of $p$, $L(a)$ is residually algebraic over $L$.

**Proposition 3.2.** Let $X$ be a smooth curve embedded in $\mathbb{A}^n$ (viewed as a definable set in $\text{VF}^n$). A $L_{\text{val}}$-type $p$ over $k$ on $X$ is residually algebraic if and only if it is of the form $p_c$ for a closed point $c$ of $\tilde{X}$, the smooth projective model of $X$. Furthermore, $c \in \tilde{X} \setminus X$ if and only if $p_c$ is unbounded.
There is then a curve \( X \), the \( \mu \)-stabilizer. Example 2.10 provides an instance of the situation here, with \( X \) and Remark 2.15 that Stab \( \mu \) \( X \) additional points, 0 and \( \infty \) type with the roles of \( x \) stabilizer). The space \( \text{PSL}_2 \) \( \mu \)-subgroup of upper triangular matrices, so properly contains our \( p \)-stabilizer. Otherwise, \( k \)-point \( c \) of \( X \) by the discussion earlier in this subsection, and it is clear that the two procedures are inverse to each other. The last statement also follows from the above.

We have been working with smooth curves, but since we are interested in points at infinity, hence the assumption is immaterial, since the singularity of varieties are at least codimension 1, hence varieties are smooth at generic points.

**Corollary 3.3.** For \( X \) a curve, there are finitely many residually algebraic types centered at infinity. Moreover, they are isolated by \( L_{\text{val}} \)-formulas over \( k \).

**Proof.** It remains to prove the moreover part of the statement. Since we know that there are only finitely many types on \( X \) centered at infinity, call them \( p_1, \ldots, p_m \).

Without loss of generality, for each \( i, j \), there will be regular functions \( f_{ij}, g_{ij} \) such that \( p_i \models \text{val}(f_{ij}) < \text{val}(g_{ij}) \) but \( p_j \models \text{val}(f_{ij}) \geq \text{val}(g_{ij}) \). Hence some Boolean combinations of the formulas above together with the formula \( x \notin X(O) \) will isolate the above types.

**Remark 3.4.** Let \( X \) be an affine curve embedded in \( G \), and assume that we are given a \( G \)-equivariant embedding of \( G \) in a \( G \)-variety \( P \). Assume that the closure \( X' \) of \( X \) in \( P \) includes the point \( c \in X \). The type \( p_c \) is then bounded in \( P \), and by Prop. 2.21 the \( \mu \)-stabilizer of \( p_c \) is contained in the stabilizer of the residue type of \( p_c \), which is simply \( c \). Hence, the \( \mu \)-stabilizer of \( c \) is contained in the stabilizer of this point in every equivariant “compactification” where the point is realized.

This fact, along with the dimension equalities for the \( \mu \)-stabilizers justifies viewing the \( \mu \)-stabilizer as a “canonical stabilizer” for the corresponding point.

**Example 3.5.** Example 2.10 provides an instance of the situation here, with \( X = X_1 \). Since \( X_1 = G_m \) as an abstract variety, its projective model \( \tilde{X}_1 \) is \( \mathbb{P}^1 \), so has two additional points, 0 and \( \infty \) (with 0 the one included in the chart where \( x \) is defined).

Hence, the type \( p \) considered there is \( p_\infty \) in our notation, and \( p_0 \) corresponds to the type with the roles of \( x \) and \( x^{-1} \) reversed.

We may alter it a bit by considering the image of \( X_1 \) in \( \text{PSL}_2 \) (the computation remains essentially the same, but we now also have the elements \( \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \) in the stabilizer).

The space \( \text{PSL}_2 \) can be compactified equivariantly by mapping it into \( \mathbb{P}^3 \), viewed as the projective space associated to the space of all linear endomorphisms of \( \mathbb{A}^2 \). It is easy to compute that under this embedding, the point \( \infty \) maps to the element \( c = \left[ \begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix} \right] \) of \( \mathbb{P}^3 \). The stabilizer of this point under the action of \( \text{SL}_2 \) is the subgroup of upper triangular matrices, so properly contains our \( \mu \)-stabilizer.

Let \( p \in S_G(k) \) be a residually algebraic type of Zariski dimension 1 inside \( G \). There is then a curve \( X \) in \( G \) containing \( p \). We had explained in Proposition 2.13 and Remark 2.15 that Stab\( \mu \)(\( p \)) = \( \mu \cdot p \cdot a^{-1} \cap \overline{G}(k) \) for any realization \( a \) of \( p \) (this will be shown again for residually algebraic types in Cor. 3.8). However, since \( p \) is isolated by Corollary 3.3 we see that Stab\( \mu \)(\( p | L \))(\( L \)) = \( \mu \cdot p \cdot a^{-1}(L) \cap \overline{G}(L) \) for
any \( L \) extending \( M \) and \( a \). In particular, one can work with a model \( L \) of \( T_{\text{loc}} \) with \( \text{RES}(L) = k \). Working in this model, let \( p_i, p_j \) be two types as above. If \( g \in G(k) \) satisfies \( g \cdot p_i \in p_j \mu \) (i.e., if \( \mu \cdot g \cdot p_i = \mu \cdot p_j \)), then \( \mu \cdot p_j \cdot a^{-1} = g \cdot \text{Stab}^u(p_i) \), for any \( a \models p_i \).

To complete the proof, we would like to show that this set is infinite for some realization \( a \) of \( p \). This amounts to showing that \( \mu \cdot p \cdot a^{-1} \) cannot be covered by a finite number of open balls. To do that, we will use topological methods from [4], which we review below.

### 3.2. Tame topology on definable sets

We make a slight digression into the tame topology of definable sets in ACVF, as developed in [4]. This is an important ingredient in the proof of the main result.

The results in this section can be found in [4]. In this section, the underlying theory is ACVF, and the main motivation is to study the topological structure of \( L_{\text{val}} \)-definable sets in the \( \text{VF} \)-sort.

**Definition 3.6.** Let \( V \) be an algebraic variety over a valued field \( F \), a subset \( X \subseteq V \) is \( v \)-open if it is open for the valuative topology.

A subset \( X \subseteq V \) is \( g \)-open if it is a positive Boolean combination of Zariski open, closed sets and sets of the form \( \{ x : v \circ f(x) > v \circ g(x) \} \) where \( f \) and \( g \) are regular functions defined on \( U \), a Zariski open subset of \( V \).

If \( Z \subseteq V \) is a definable subset of \( V \), a subset \( W \) of \( Z \) is said to be \( v \)(respectively \( g \))-open if \( W \) is of the form \( Z \cap Y \), where \( Y \) is \( v \) (respectively \( g \))-open in \( V \).

The complement of a \( v \)(respectively \( g \))-open is called \( v \)(respectively \( g \))-closed.

We say \( X \) is \( v+g \)-open (respectively \( v+g \)-closed) if it is both \( v \)-open and \( g \)-open (respectively both \( v \)-closed and \( g \)-closed).

Note that the \( v+g \)-opens does not form a topology, as it is not even closed under arbitrary union. However, it is still makes sense to talk about connectedness in this setting:

**Definition 3.7.** Let \( X \) be a definable subset of \( V \), an algebraic variety. We say that \( X \) is **definably connected** if \( X \) cannot be written as a disjoint union of two non-empty \( v+g \)-open subsets of \( X \).

We say that \( X \) has **finitely many definably connected components** if \( X \) can be written as a finite disjoint union of \( v+g \)-clopen definably connected subsets.

**Definition 3.8.** Let \( f : V \to W \) be a definable function from \( V \) to \( W \), we say \( f \) is \( v \)-continuous if \( f^{-1}(X) \) is \( v \)-open for \( X \) a \( v \)-open subset of \( W \), and we define \( g \)-continuous functions similarly. We say \( f \) is \( v+g \)-continuous if \( f \) is both \( v \)-continuous and \( g \)-continuous.

**Proposition 3.9** (Hrushovski, Loeser). If \( f \) is \( v+g \)-continuous and \( X \) is a definably connected and \( f \) is defined on \( X \), then \( f(X) \) is definably connected.

If \( V \) is an geometrically/absolutely irreducible variety, then \( V \) is definably connected.
The following is an easy corollary of [1, Theorem 11.1.1].

**Theorem 3.10** (Hrushovski, Loeser). Given a definable subset \( X \subseteq V \), where \( V \) is some quasi-projective variety, \( X \) has finitely many definably connected components.

We also have the following.

**Theorem 3.11.** Let \( V \subseteq A^n \) be a closed subvariety. \( V \) is bounded iff \( V \) is zero dimensional.

**Proof.** If \( V \) is bounded, then \( V \) will be definably compact as in Section 4 of [1]. This implies \( V \) is proper by [1, Proposition 4.2.30], hence \( V \) is zero dimensional. The converse is clear. \( \square \)

We may now prove the following more precise version of Theorem 1.1 (the case of curves).

**Theorem 3.12.** Let \( p \in S_G(k) \) be a residually algebraic type, centered at infinity with \( \dim(p) = 1 \). Then \( \dim(\text{Stab}^\mu(p)) = 1 \).

**Proof.** By Prop. 3.16 and the discussion preceding Section 3.2, it suffices to show that the \( \mu \)-stabilizer is infinite. Let \( X \) be the Zariski closure of \( p \) in \( G \) and let \( a \) be a point realizing \( p \). Assume to the contrary, that \( \text{Stab}^\mu(p) \) is finite. Then \( \text{res}(\mu \cdot p \cdot a^{-1} \cap G(O)) \) is finite by Prop. 3.13 Note that \( \mu \cdot X \cdot a^{-1} \cap G(O) = \bigcup q (\mu \cdot q \cdot a^{-1} \cap G(O)) \), where \( q \) ranges over types centered at infinity on \( X \). By Cor. 3.3, there are only finitely many types centered at infinity on \( X \), so the set \( X \cdot a^{-1} \cap G(O) \) is the intersection of \( X \cdot a^{-1} \) with a (disjoint) union of finitely many balls \( \mu \cdot g \), for \( g \in \overline{G}(k) \).

Therefore, \( X \cdot a^{-1} \cap G(O) \) is a non-empty \( v+g \)-open subset of \( X \cdot a^{-1} \). However, it is also a \( v+g \)-closed subset of \( X \cdot a^{-1} \) since \( G(O) \) is \( v+g \)-closed. By Prop. 3.9, \( X \cdot a^{-1} \) is definably connected, so \( X \cdot a^{-1} \subseteq G(O) \subseteq A^n \). However, this is impossible since this implies that \( X \cdot a^{-1} \) as an affine curve is bounded in \( A^n \), contradicting Theorem 3.11. \( \square \)

**Remark 3.13** (Relation to o-minimal PS-subgroups). Recall that in the o-minimal context, for each definable group \( G \) and an unbounded semi-algebraic curve \( \gamma : (a,b) \to G \), we use \( H_\gamma \) to denote the PS-subgroup of \( \gamma \) (or in other words, the o-minimal \( \mu \)-stabilizer of the type of \( \gamma \) at \( b \)).

In the case when \( k = \mathbb{C} \), the \( \mu \)-stabilizers of a point at infinity in Theorem 3.12 is closely related to the group \( G_\gamma \), the Zariski-closure of \( H_\gamma \), as described in the construction in the beginning of the introduction. (both viewed as definable in \( R \))

Namely, assume we are given a complex curve \( X \) embedded in the complex affine algebraic group \( G \), and a point \( \alpha \in \overline{X} \setminus X \). Let \( \gamma : (a,b) \to X \) be a semi-algebraic curve over \( \mathbb{R} \) whose limit at \( b \) is \( \alpha \) (in the sense discussed in the introduction).

Let \( R \) be a sufficiently saturated real closed field extending \( \mathbb{R} \), and let \( C \) be \( R^2 \), viewed as an algebraic closure of \( R \). We may view \( X, G \) and \( \gamma \) as definable in \( R \).

By [7], one can compute the PS-subgroup \( H_\gamma \) associated to \( \gamma \) as the \( \mu \)-stabilizer of \( t_{p_{sa}}(\alpha/\mathbb{R}) \), the type of \( \alpha \) in the theory of real closed fields.

Let \( O_R \) be the convex hull of \( \mathbb{R} \) in \( R \), and let \( O = O_R^2 \), viewed as a subring of \( C \). Then \( C \) equipped with \( O \) as a valuation ring is a model of \( T_{loc} \), and the type
\( q = \text{tp}_{\text{ACVF}}(\alpha/{\Bbb C}) \text{ is contained in } p = \text{tp}_{\text{sa}}(\alpha/{\Bbb R}) \text{ because the maximal ideal can be viewed as a partial type. Hence } H_\gamma \subseteq \text{Stab}^\mu(q). \text{ However, Stab}^\mu(q) \text{ is 1-dimensional and } H_\gamma \text{ is infinite, so } G_\gamma \subseteq \text{Stab}^\mu(q) \text{ and the index is finite.} \)

4. Proof of the main theorem

4.1. Residually algebraic saturation. We would like to work with saturation in a residually algebraic context, i.e., without extending the residue field. Thus we make the following definition.

**Definition 4.1.** A model \( K \) of \( T_{\text{loc}} \) is (sufficiently) \( \Gamma \)-saturated if every \( \mathcal{L}_{\text{val}} \)-residually algebraic type over a (sufficiently) small subset of \( K \) is realised in \( K \).

**Theorem 4.2.** Let \( L \) be a (possibly trivially) valued field, then there is a \( \Gamma \)-saturated extension of \( L \).

**Proof.** Let \( \Gamma \) be a sufficiently saturated ordered abelian group and \( k \) the algebraically closed closure of \( \text{RES}(L) \). Consider the Hahn series field

\[
k((t^\Gamma)) = \left\{ \sum_{\gamma} c_{\gamma} t^\gamma : c_{\gamma} \in k, \{\gamma : c_{\gamma} \neq 0\} \text{ is well ordered} \right\}
\]

Clearly \( L \) embeds into \( K \) (see [4] for example). Then, by a result of Poonen ([10, Theorem 2]), is a \( \Gamma \)-saturated model (with residue field \( k \)). \( \square \)

From now on, \( K \) will be a fixed sufficiently \( \Gamma \)-saturated model \( K \) with residue field \( k \) and we will identify definable sets and \( p \in S_G(k) \) with their realizations in \( K \). In particular, we will only consider residually algebraic types unless otherwise stated.

As a first application, we note:

**Lemma 4.3.** Let \( p \in S_G(k) \) be residually algebraic. Then there is \( q \in p_\mu \) which is \( \mu \)-reduced and residually algebraic.

**Proof.** Let \( a \) be a realization of \( p \) in \( K \). There is a variety \( V \) over \( k \) of minimal dimension that intersects \( \mu \cdot a \). The above can be expressed as \( \mathcal{L}_{\text{val}} \)-formula, so it is witnessed by some element of \( K \). Take \( q \) to be the \( \mathcal{L}_{\text{val}} \)-type of this element over \( k \).

We would like to give a syntactic (or geometric) description of types realised in \( K \). To this end, we use another result from [4], which requires the following definition.

**Lemma 4.4.** (Hrushovski, Loeser) Let \( F \) be a valued field, \( V \) be an \( F \)-variety, and \( X \subseteq V \) be a \( F \)-definable \( g \)-open set, then \( X(M_2) \subseteq X(M_1) \) whenever \( M_1 \) and \( M_2 \) are algebraically closed valued field extensions of \( F \) with the same underlying field, and \( \mathcal{O}_{M_1} \subseteq \mathcal{O}_{M_2} \).

We now have the following description:

**Proposition 4.5.** Let \( \Phi(x) \) be a small finitely consistent collection of \( g \)-open sets, with parameters in \( L \subseteq K \). Then \( \Phi \) is realised in \( K \). In addition, if \( p \) is a \( \mathcal{L}_{\text{val}} \)-residually algebraic type, then it is the intersection of the \( g \)-open formulas that it implies.
In other words, every partial type $\Sigma$ of $g$-open sets admits an extension to a $\mathcal{L}_{\text{val}}$-residually algebraic complete type $p$ over the same set of parameters.

**Remark 4.6.** It is worth pointing out that Proposition 4.5 has an easy proof in the case when $L = k = \mathbb{C}$. See [8, Section 3.1].

**Proof.** Let $b$ be any realisation of $\Phi$ in $U$, and let $k$ be the residue field of $L(b)$. Then $k$ is the function field of some variety $X$ over $k$, fix a valuation $\text{val}'$ of $k$ over $k$, with residue field $k$.

Let $M_2$ be the algebraic closure of $L(b)$ with the induced valuation from $U$. Consider a valuation of $\text{RES}(M_2)$ extending $\text{val}'$. Abusing notation, we call the valuation $\text{val}'$ as well. Let $\mathcal{O}$ be the valuation ring of $\text{RES}(M_2)$. Consider $\text{res}^{-1}(\mathcal{O}) \subseteq M_2$, this is again a valuation ring of the underlying field of $M_2$ over $k$. We use $M_1$ to denote the same field as $M_2$ with the valuation determined by $\text{res}^{-1}(\mathcal{O})$. Note that $M_1$ has residue field $k$.

Then by Lemma 4.4 $\phi(M_2) \subseteq \phi(M_1)$ for each $\phi \in \Phi$. In particular, $b$ is a realisation of $\Phi$ in $M_1$. But the residue field of $M_1$ is $k$, so $tp_M_1(b/L)$ is residually algebraic and hence realizable in $K$.

For the converse, let $p$ be a complete $\mathcal{L}_{\text{val}}$-residually algebraic type. By quantifier elimination in $\text{ACVF}$, it is given within its Zariski closure by formulas of the form $f(x) \neq 0$, $\text{val}(f(x)) > \text{val}(g(x))$ and $\text{val}(f(x)) = \text{val}(g(x)) \neq \infty$. Each formula of the last form is equivalent to $\text{val}(f(x)/g(x)) = 0$, so that $f(x)/g(x)$ has non-zero residue. Since $p$ is residually algebraic, the residue is actually a well determined element $b$ of $k$, so the original formula is implied by $\text{val}(f(x) - bg(x)) > \text{val}(bg(x))$, which is also in $p$. \hfill $\square$

We now apply this result in our context:

**Corollary 4.7.** Let $p \in S_G(k)$ and residually algebraic. Then $\mu(K) \cdot p(K) = (\mu \cdot p)(K)$.

**Proof.** Since $K$ is contained in the monster model, $\mu(K) \cdot p(K) \subseteq (\mu \cdot p)(K)$. For the reverse containment, for $p$ residually algebraic, fix $a \in (\mu \cdot p)(K)$. Recall that it means that for any $\phi \in p$, there is $\varepsilon_\phi \in \mu$ such that $\models \phi(\varepsilon_\phi \cdot a)$. Since $p$ is residually algebraic, we may, by Prop. 4.5 assume that each such $\phi$ is $g$-open.

Consider the following partial type: $\Sigma(y) = \{ \phi(y \cdot a) : \phi \in p \text{ g-open} \}$. Each $\phi$ there is $g$-open, hence also $\phi(y \cdot a)$ (since the group is algebraic) and $\mu$ is given by strict inequalities, so this is a small collection of $g$-open sets, consistent by assumption. By the other direction of Prop. 4.5, we can find $\varepsilon \in \mu(K)$ such that $\varepsilon \cdot a$ satisfies $p$. \hfill $\square$

**Corollary 4.8.** Let $p$ be a residually algebraic $G$-type over $k$, and let $a$ be a realization in $K$. Then $\text{Stab}^p(p)(k) = \text{res}(\mu(K) \cdot p(K) \cdot a^{-1} \cap G(\mathcal{O}))$.

**Proof.** Since $\text{res}(\mu(K) \cdot p(K) \cdot a^{-1} \cap G(\mathcal{O})) \subseteq \text{res}(\mu(\mathcal{U}) \cdot p(\mathcal{U}) \cdot a^{-1} \cap G(\mathcal{O}))$, we have that $\text{Stab}^p(p)(k) \supseteq \mu(K) \cdot p(K) \cdot a^{-1} \cap G(\mathcal{O})$ by Cor. 2.1. The reverse containment follows from Cor. 4.7. \hfill $\square$
4.2. \( \mu \)-reduced types and their stabilizers. In this section we prove Cor. 4.11, an analogue of Corollary 3.3 for types of higher dimension.

Recall that we are working within \( K \), a \( \Gamma \)-saturated model, and all the elements in the statement are from \( K \) and definable sets are identified with their realization in \( K \).

In particular, we have the following.

**Lemma 4.9.** If \( a \) is \( \mu \)-reduced and \( g \in G(\mathcal{O}) \), then \( g \cdot a \) is also \( \mu \)-reduced, of the same dimension.

**Proof.** Assume \( \varepsilon \cdot g \cdot a \in W \) with \( \varepsilon \in \mu \) and \( W \) a variety over \( k \). Since \( \varepsilon \cdot g \cdot a = \bar{g} \cdot \varepsilon' \cdot a \) for some \( \bar{g} \in G(k) \) and \( \varepsilon' \in \mu \), we have \( \varepsilon' \cdot a \in \bar{g}^{-1} \cdot W \), a variety over \( k \) of the same dimension as \( W \). \( \square \)

The following is an important observation about \( \mu \)-reduced types.

**Proposition 4.10.** Let \( p \in S_G(k) \) be a \( \mu \)-reduced residually algebraic type centered at infinity, and let \( a \models p \). Let \( V \) be the unique irreducible \( k \)-variety such that \( a \in V \) and \( \dim(V) = \dim(p) \). For any definable set \( X \), assume that \( X \subseteq G(\mathcal{O}) \cdot a \cap V \) be definably connected and \( a \in X \). Then for every \( b \in X \) we have \( tp(a/k) = tp(b/k) \), where \( tp(\cdot/k) \) denotes the \( L_{val} \)-type over \( k \).

**Proof of 4.10.** By Lemma 4.9, \( b \) is not contained in any proper subvariety of \( V \), so is nonzero when evaluated by any regular function on \( V \). Hence, every element of the function field \( k(V) \) is well defined as a \( k \)-definable function on \( X \).

Assume that the types of \( a \) and \( b \) are different. By quantifier elimination in ACVF, without loss of generality, there is \( f \in k(V) \) such that \( \text{val}(f(a)) < 0 \leq \text{val}(f(b)) \).

We may further assume that the last inequality is strict, by subtracting the residue.

By [4], it can be easily checked that rational functions are \( v+g \)-continuous on their domain, so the image \( f(X) \) is again definably connected. As a definable subset of \( K \), it is a union of “Swiss cheeses”, and by definable connectedness, the Swiss cheese decomposition of the image will be of the form \( B \cup \bigcup_{i \leq m} C_i \), where \( B \) is a ball and \( C_i \)'s are disjoint sub-balls of \( B \).

**Claim.** \( f(X) \) contains a \( k \)-point.

**Proof of claim.** Since \( B \) contains both a point with positive valuation and point with valuation \( \leq 0 \), then it must contain \( O \). If \( f(X) \) contains no \( k \)-point, \( k \) must be covered by \( \bigcup_{i \leq m} C_i \). This implies one of the \( C_i \) contains at least two points in \( k \) and hence contains \( O \). But this is a contradiction since that means that there is no point in \( f(X) \) with positive valuation.

Hence, we know that there must be some \( c \in k \) such that \( c \in f(X) \). Note however that each element in \( X \) is a generic point of \( V \) by Lemma 4.9 and we know that this would imply that the rational function \( f \) is constant, a contradiction to the assumption. Hence we know that \( tp(a/k) = tp(b/k) \).

Using a similar argument, we have the following, which is the key fact that will replace Cor. 3.3 for our proof of the main theorem.
Corollary 4.11. Let \( a \in V(K) \) be \( \mu \)-reduced, with \( V \) the Zariski closure of \( a \) over \( k \). Then there are finitely many types \( p_1, ..., p_m \in S_G(k) \) for some \( m \) such that if \( g \in G(O) \) and \( g \cdot a \in V \), then \( tp(g \cdot a/k) = p_i \) for some \( i \).

Proof. From Theorem 3.10 we know that there are only finitely definably connected components of the set \( G(O) \cdot a \cap V \), call them \( X_i \) for \( i = 1, ..., n \) for some \( n \). By Proposition 4.10 we have that for each \( b, b' \in X_i \), we have that \( tp(b/k) = tp(b'/k) \). Hence there are only finitely many types \( p_i \)'s with the property stated in the statement of the corollary.

Here, we stated a variant that is similar to the \([7]\)'s Claim 3.13.

Corollary 4.12. In the same setting as above, there is a \( L_{val} \)-definable set \( X \) over \( k \) containing \( a \), such that for each \( b \in G(O) \cdot a \cap X \), \( tp(b/k) = tp(a/k) \). Furthermore, \( X \) is \( v+g \)-open and \( X \cdot a^{-1} \) is \( v+g \)-clopen in \( G(O) \).

Proof. By the above corollary, we see that there are finitely many regular functions \( f_{ij}, g_{ij} \) such that for the formula \( val(f_{ij}) < val(g_{ij}) \) \( p_i \) and \( p_j \) disagrees. The set defined by some boolean combinations of the above formulas containing \( tp(a/k) \) will define the set \( X \).

In particular, we have the following.

Corollary 4.13. \( Stab^\mu(p)(k) \) is infinite for each \( p \) residually algebraic and centered at infinity.

Proof. Without loss of generality, we can assume that \( p \) is \( \mu \)-reduced and let \( a \models p \) be any realization and \( V \) denote its Zariski closure. We have \( \dim V > 0 \) since \( p \) is centered at infinity. Also, \( V \) is an irreducible \( k \)-variety hence \( v+g \)-connected and so is \( V \cdot a^{-1} \). By Proposition 2.13, if \( Stab^\mu(p)(k) = \overline{G_p}(k) \) is finite, \( V \cdot a^{-1} \cap G(O) \) can be covered by finitely many \( v+g \)-open sets and hence is \( v+g \)-open. But \( V \cdot a^{-1} \setminus G(O) \) is also \( v+g \)-open by definition, a contradiction to the fact that non-zero dimensional affine varieties are not bounded in the affine space.

It is worth noting that the above proof uses the same idea in the 1-dimensional case where the key ingredient is the connectedness of irreducible varieties.

4.3. Dimension of the \( \mu \)-stabilizers. Corollary 4.13 forms the first part of the main theorem. Before proving the other part, we need some machinery about varieties over \( O \). The main facts can be found in [5] and [2].

Definition 4.14. Let \( O \) be a valuation ring, let \( L = \text{Frac}(O) \) and \( k = \text{res}(O) \). By a variety over \( O \), we mean a flat reduced scheme \( V \) of finite type over \( O \). In particular, it has a generic fiber \( V_L \), which is a variety over \( L \), obtained by base change with respect to the morphism \( O \to L \), and a special fiber \( V_k \), which is a variety over \( k \), obtained by base change with respect to \( O \to k \).

Remark 4.15. It is worth noting that since \( O \) is a valuation ring, \( A = O[x_1, ..., x_n]/I \) is flat over \( O \) iff no nonzero element in \( O \) is a zero divisor in \( A \).

In particular, if \( S \) is any subset of \( O^n \), then
\[
I = \{ f \in O[x_1, ..., x_n] : f(s) = 0 \forall s \in S \} \subseteq O[\overline{x}]
\]
is an ideal and \( A = \mathcal{O}[x_1, \ldots, x_n]/I \) is flat over \( \mathcal{O} \).

We use \( I_L \) and \( I_k \) to denote the ideal generated by \( I \) in \( A \otimes L \) and \( A \otimes k \) respectively. Then the generic (respectively special) fiber of \( \text{Spec}(A) \) is \( \text{Spec}(A \otimes L/I_L) \) (respectively \( \text{Spec}(A \otimes k/I_k) \)). Given an affine variety \( \mathcal{V} \) over \( L \), we may always choose a variety \( \mathcal{V} \) affine over \( \mathcal{O} \) whose generic fibre is \( \mathcal{V} \).

The following is \cite[Theorem 3.2.4]{2}.

**Theorem 4.16** (Halevi). Let \( K \) be a model of ACVF and \( \mathcal{V} \) be an irreducible variety over \( \mathcal{O}_K \). If \( \mathcal{V}_K \) has an \( \mathcal{O}_K \)-point then the \( \mathcal{O}_K \)-points are Zariski dense, and the canonical map \( \text{res} : \mathcal{V}_K(\mathcal{O}_K) \to \mathcal{V}_k(k) \) is surjective, where \( \text{res} \) is given by taking residue pointwise.

Now let us get back to the proof of the main theorem, we will prove the part concerning the dimension now.

**Proof of Theorem 1.2**. The first part of the theorem is the statement of Corollary \cite{1.13} so it remains to show the equality of dimensions, in the case the type \( p \) is \( \mu \)-reduced. Under this assumption, let \( a \) realize \( p \), and let \( \mathcal{V} \) be its Zariski closure. In particular, \( \mathcal{V} \) is irreducible.

We first note that if \( g \in G(\mathcal{O}) \) and \( g \cdot a \in \mathcal{V} \), then \( tp(g \cdot a/\mathfrak{k}) \) will be one of the finitely many types \( p_i \) provided by Corollary \cite{1.14}. Hence \( \mu \cdot \mathcal{V} \cdot a^{-1} \cap G(\mathcal{O}) \) will be a finite union of cosets of \( \mu \cdot G_p \). Thus it suffices to show that \( \text{res}(\mathcal{V} \cdot a^{-1} \cap G(\mathcal{O})) \) and \( \mathcal{V} \) have the same dimension.

As above, the affine \( K \)-variety \( \mathcal{V} \cdot a^{-1} \) can be viewed as the generic fibre of a variety \( \mathcal{V} \) over \( \mathcal{O}_K \). Furthermore, \( \mathcal{V} \) has an \( \mathcal{O}_K \)-point, namely \( e \), the identity of the group \( G \). It follows from Theorem \cite{1.16} that the map \( \text{res} : \mathcal{V} \cdot a^{-1} \cap G(\mathcal{O}) \to \overline{G} \) is onto the special fiber of \( \mathcal{V} \cdot a^{-1} \). Also, by flatness, the special fiber has the same dimension as the generic fiber, which is the dimension of \( p \).

This completes the proof of the dimension part in the main result. The solvability of the group is proved separately, as Theorem \cite{1.20}. \( \square \)

The proof also shows that the special fiber, being the image of \( \mathcal{V} \cdot a^{-1} \cap G(\mathcal{O}) \), is a finite union of cosets of \( \text{Stab}^\mu(p) \). Therefore, we have established the following.

**Corollary 4.17**. Let \( \mathcal{V} \subseteq G \) be a variety over \( \mathfrak{k} \), let \( a \models p \), where \( p \in S_G(\mathfrak{k}) \) is a \( \mu \)-reduced residually algebraic type centered at infinity. Assume further that the Zariski closure of \( p \) over \( \mathfrak{k} \) is \( \mathcal{V} \).

Then the special fiber of \( \mathcal{V} \cdot a^{-1} \) is equi-dimensional i.e. each irreducible component of it has the same dimension. Moreover, each irreducible component of the special fiber of \( \mathcal{V} \cdot a^{-1} \) is a coset of an algebraic subgroup of \( \overline{G} \).

4.4 **Structure of \( \text{Stab}^\mu(p) \).** In this section, we analyze the structure of \( \text{Stab}^\mu(p) \). Note that due to trivial constraints on characteristic, it is not possible to show in general such a group is torsion-free. However, in characteristic 0, we can indeed show it is torsion free.

**Lemma 4.18**. Let \( p \in S_G(\mathfrak{k}) \) be residually algebraic and let \( H \) be a \( \mathfrak{k} \)-definable linear subgroup of \( G \) with \( p \in H \). Then \( \text{Stab}^\mu(p) \) computed in \( G \) and in \( H \) coincide, where \( H \) denotes the group \( H \) viewed as a subset in \( \text{VF} \).
Proof. Since the Zariski closure $V$ of $p$ is contained in $H$ in this case since $H$ is a Zariski-closed subgroup and $\mu_G \cap H = \mu_H$. Hence, the arguments of computing the $\mu$-stabilizers of $p$ can be carried out in both $H$ and $G$ and the results will be the same. □

The following is the Iwasawa Decomposition over non-archimedean fields, it can be found in [1, Proposition 4.5.2].

**Theorem 4.19.** Let $G$ be a reductive linear algebraic group over $k$, there is a solvable subgroup $H$ over $k$ such that $G(K) = G(\mathcal{O}) \cdot H(K)$.

For $GL_n$ we may take $H$ to be the standard Borel subgroup (upper triangular matrices).

**Theorem 4.20.** Let $p \in S_G(k)$ be centered at infinity and residually algebraic. Then $\text{Stab}^\mu(p)$ is solvable. 

Proof. We can embed $G \subseteq GL_n$ over $k$ for some $n$, and use the Lemma 4.18 to reduce to the case $G = GL_n$. Let $H$ be the Borel. By the Iwasawa decomposition, we have some $g \in G(\mathcal{O})$ such that $g^{-1} \cdot a = \beta \in H(K)$. Let $g_1 \in \overline{G}(k)$ be such that $g_1 \cdot g^{-1} \in \mu$. Hence $g_1^{-1} \cdot a \in \mu(K) \cdot \beta$, so $\text{Stab}^\mu(g_1^{-1} \cdot p) = \text{Stab}^\mu(q) \subseteq H$. By Lemma 2.29 this group is conjugate to $\text{Stab}^\mu(p)$, hence $\text{Stab}^\mu(p)$ is solvable. □

**Corollary 4.21.** If $G$ is not solvable and $G$ is irreducible, then there is no $\mu$-reduced residually algebraic $G$-type of full dimension.

**Remark.** We briefly introduce the Zariski-Riemann space of a variety over $k$, and explain its connection with our setting.

**Definition.** Let $V$ be an variety over $k$, the Zariski-Riemann space of $V$ over $k$, is the set of valuation rings of $k(V)$ over $k$, denoted by $RZ_k(V)$.

Note that by quantifier elimination in ACVF, for a linear algebraic group $G$ over $k$, it is not hard to see that the above set $RZ_k(G)$ is in canonically embeddable into the set $S_G(k)$. Hence we can identify $RZ_k(G)$ with its image in $S_G(k)$. Note further, since $\mu$ is Zariski dense in $G$, we see that for each $p \in S_G(k)$, there is some $q \in RZ_k(G)$ such that $p \sim_\mu q$.

The above argument implies that we can consider the quotient of $RZ_k(G)$ under $\mu$, which exactly the space $S_G^\mu(k)$. Note further that the equivalence relation induced by $\mu$ on $RZ_k(G)$ is independent of the $k$-closed-immersion of $G$ into $k^n$, since every embedding over $k$ will respect $\mu$. We will explore more on the relation induced by $\mu$ on $RZ_k(G)$ in a subsequent paper.
