Mass splitting in the Thomas-Fermi-Dirac-von Weizsäcker model
with background potential

Abstract

We consider minimization problems of the Thomas-Fermi-Dirac-von Weizsäcker (TFDW) type, in which the Newtonian potential is perturbed by a background potential satisfying mild conditions and which ensures the existence of minimizers. We describe the structure of minimizing sequences for those variants, and obtain a more precise characterization of patterns in minimizing sequences for the TFDW functionals regularized by long-range perturbations.

I. Introduction

In this paper we are concerned with energy functionals which include the Thomas-Fermi-Dirac-von Weizsäcker (TFDW) model, a physical model describing ground state electron configurations of many-body systems. More precisely, we consider the following variational problem

\[ I_V(M) := \inf \{ \mathcal{E}_V(u) : u \in H^1(\mathbb{R}^3), ||u||^2_2 = M \}, \] (1.1)

where the energy \( \mathcal{E}_V \) is defined as

\[
\mathcal{E}_V(u) := \int_{\mathbb{R}^3} \left( |\nabla u(x)|^2 + c_1 |u(x)|^4 - c_2 |u(x)|^8 - V(x)u^2(x) \right) dx \\
+ \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dxdy,
\]

with \( c_1, c_2 > 0 \),

\( V \geq 0, \quad V \in L^\frac{4}{3}(\mathbb{R}^3) + L^\infty(\mathbb{R}^3), \quad \text{and} \quad \lim_{|x| \to \infty} V(x) = 0. \) (1.2)

Conditions above ensure \( I_V \) is finite, \( \mathcal{E}_V \) is coercive on the constraint set, and

\[ u \in H^1(\mathbb{R}^3) \mapsto \int_{\mathbb{R}^3} V(x)u^2(x) dx \]

is weakly continuous.
The TFDW model corresponds to the choice

\[ V_{TF}(x) = \sum_{k=1}^{K} \frac{\alpha_k}{|x - r_k|}, \quad (1.3) \]

with \( K \in \mathbb{N}, \{\alpha_k\}_{k=1}^{K} \subset \mathbb{R}^+ \) and \( \{r_k\}_{k=1}^{K} \subset \mathbb{R}^3 \) all fixed. In this case, \( \delta_V(M) \) is to be thought of as the energy of a system of \( M \) electrons interacting with \( K \) nuclei. Each nucleus has charge \( \alpha_k > 0 \) and it is fixed at a position \( r_k \). The total nuclear charge is denoted

\[ Z = \sum_{k=1}^{K} \alpha_k > 0, \]

and plays a key role in existence results (see the works of Frank, Nam, and Van Den Bosch \[6\], and Lieb \[9\] for a survey).

In this paper we explore the structure of minimizing sequences for \( I_V \), with \( V \) chosen to be a perturbation of the molecular potential \( V_{TF} \). Despite the coercivity of the problem, existence of a minimizer for \( I_V \) is a highly nontrivial problem, due to a lack of compactness at infinity. For the unperturbed TFDW problem, \( V = V_{TF} \), Lions \[11\] proved that there exists a minimizer if \( M \leq Z \), and Le Bris \[8\] extended this result to \( M \leq Z + \epsilon \) for some \( \epsilon = \epsilon(Z) > 0 \). In regard to non-existence, Nam and Van Den Bosch proved there are no minimizers if both \( M \) is sufficiently large and \( Z \) is sufficiently small, and Frank, Nam, and Van Den Bosch \[13\] proved nonexistence of a minimizer for \( M > Z + C \), for some universal \( C > 0 \), in the case there is only one nucleus (ie, \( K = 1 \) in (1.3).)

There is a special class of potentials \( V \) for which the existence problem for \( I_V \) is completely understood. We say \( V \) is a long-range potential if it satisfies (1.2) and

\[ \liminf_{t \to \infty} t \left( \inf_{|x|=t} V(x) \right) = \infty. \quad (1.4) \]

For example, the homogeneous potentials \( V^\nu(x) = |x|^{-\nu} \) are of long-range for \( 0 < \nu < 1 \). For long-range potentials \[13\], Alama, Bronsard, Choksi, and Topaloglu \[12\] showed that \( I_V(M) \) is attained for every \( M > 0 \). Thus, we may perturb the TFDW potential via a long-range potential of the form \( V^\nu \), and think of this as a “regularized” version of TFDW. We thus define a family of long-range potentials,

\[ V_Z(x) = V_{TF}(x) + \frac{Z}{|x|^\nu}, \quad 0 < \nu < 1, \quad (1.5) \]

with parameter \( Z > 0 \). By taking a sequence \( Z_n \to 0 \) we recover the TFDW model, but via a special minimizing sequence \( u_n \) composed of minimizers of the long-range problem, \( \delta_{V_n}(u_n) = I_{V_n} \). A special role is played by the minimization problem \( I_0 \), that is with potential \( V \equiv 0 \), which is the “energy at infinity” obtained by translating \( u(\cdot + x_n) \) with \( |x_n| \to \infty \). The existence properties for \( I_0(M) \) are analogous to those of \( I_{V_{TF}} \): the minimizer exists for sufficiently small \( M > 0 \) (see \[13\], Lemma 9 (iii)), and there is no minimizer for all large \( M \) (see \[12\].)
It will be convenient to introduce the following sets of values of the constrained mass \( M \) in \( I_V(M) \):

\[
\mathcal{M}_V := \left\{ M > 0 \mid \mathcal{E}_V \text{ attains a minimizer } u \in H^1(\mathbb{R}^3), \int_{\mathbb{R}^3} u^2 = M \right\}.
\]

It is an open question to determine whether \( \mathcal{M}_V \) is an interval, for any choice of potential \( V \).

In case \( u \in H^1(\mathbb{R}^3) \) attains the minimum in \( I_V \) (respectively, \( u_0 \in H^1(\mathbb{R}^3) \) attains the minimum in \( I_0 \)), the minimizers will satisfy the PDEs,

\[
-\Delta u + \frac{5}{3} c_1 u |u|^{\frac{4}{3}} - \frac{4}{3} c_2 u |u|^{\frac{2}{3}} - Vu + \left( |u|^2 \star | \cdot |^{-1} \right) u = \mu u, \quad (1.6)
\]

\[
-\Delta u_0 + \frac{5}{3} c_1 u_0 |u_0|^{\frac{4}{3}} - \frac{4}{3} c_2 u_0 |u_0|^{\frac{2}{3}} + \left( |u_0|^2 \star | \cdot |^{-1} \right) u_0 = \mu u_0, \quad (1.7)
\]

with Lagrange multiplier \( \mu \) induced by the mass constraint.

As mentioned above, the existence question is complicated by noncompactness due to translations of mass to infinity. However, minimizing sequences may be characterized using a general Concentration-Compactness structure (see [10], [11]).

**Concentration Theorem I.1.** Let \( \{u_n\}_{n \in \mathbb{N}} \) be a minimizing sequence for \( I_V(M) \) where \( V \) satisfies (1.2). Then, there exist a number \( N \in \mathbb{N} \cup \{0\} \), masses \( \{m_i\}_{i=0}^N \subset \mathbb{R}^+ \), translations \( \{x_{in}\}_{n \in \mathbb{N}}, \ldots, \{x_{in}^N\}_{n \in \mathbb{N}} \subset \mathbb{R}^3 \), and functions \( \{u^i\}_{i=0}^N \subset H^1(\mathbb{R}^3) \) such that, up to a subsequence,

\[
u_n(\cdot) - \sum_{i=0}^N u^i(\cdot - x_{in}^i) \rightarrow 0 \text{ in } H^1(\mathbb{R}^3),
\]

\[
I_V(m^0) = \mathcal{E}_V(u^0), \quad I_0(m^i) = \mathcal{E}_0(u^i), \quad i > 0,
\]

where \( ||u^i||_2^2 = m^i \);

\[
\sum_{i=0}^N m^i = M, \quad I_V(m^0) + \sum_{i=0}^N I_0(m^i) = I_V(M), \quad (1.10)
\]

\[
|x_{in}^i - x_{jn}^j| \rightarrow \infty, \quad i \neq j.
\]

*The functions \( u^i \) satisfy (1.6) for \( i = 1, \ldots, N \), and \( u^0 \) satisfies (1.7), each with the same Lagrange multiplier \( \mu \leq 0 \).*

Moreover, if \( V \neq 0 \), then we can take \( x_{n}^0 = 0 \).

If a minimizer exists then no splitting is necessary, and there exist minimizing sequences with \( N = 0 \). This occurs for \( V_{TF} \) when the mass is not much larger than the total charge, \( M \leq \mathcal{Z} + \epsilon \) (by [8]), for instance, or for any \( M > 0 \) in the class of long-range potentials.
However, for TFDW with large mass $M$ we expect splitting, but the pieces resulting from noncompactness must each minimize $I_V$ or $I_0$ for its given mass, that is,

$$m^0 \in \mathcal{M}_V, \quad m^i \in \mathcal{M}_0, i > 0.$$ 

The basic idea behind the result is very elegant and intuitive. Minimizing sequences $u_n$ for $I_V(M)$ may lose compactness due to splitting into widely spaced components, each of which tends to a minimizer of $I_V$ or (for those components which translate off to infinity) $I_0$. Asymptotically, all of the mass $M$ is accounted for by this splitting. Although the pieces eventually move infinitely far away, they retain some information of the original minimization problem in that they share the same Lagrange multiplier.

Concentration results of this type have appeared in many papers. For TFDW, a very similar result is outlined (although with possibly infinitely many components $u^i$) in [11] and a proof of the exact decomposition of energy (1.10) for the case $V \equiv 0$ is given in [13, Lemma 9]. Since this Concentration Theorem is central to the statements and proof of our results we provide a proof in Appendix A. The finiteness of the components is a result of the concavity of the energy $E_V$ for small masses, which we prove in Appendix B.

For perturbations of TFDW we obtain more precise information on the splitting structure. In particular, when mass splits off to infinity, the piece which remains localized must have mass $m^0 \geq \mathcal{Z}$, the total nuclear charge.

**Theorem I.2.** Assume $V$ satisfies (1.2) and

$$V(x) \geq V_{TF}(x) = \sum_{k=1}^{K} \frac{\alpha_k}{|x - r_k|}, \quad a.e. \ in \ \mathbb{R}^3,$$

for some $K \in \mathbb{N}$, $\{\alpha_k\}_{k=1}^{K} \subset \mathbb{R}^{+}$ and $\{r_k\}_{k=1}^{K} \subset \mathbb{R}^{3}$.

Then, with the notation of Theorem I.1, for any minimizing sequence $\{u_n\}_{n \in \mathbb{N}}$ of $I_V(M)$, either $M \in \mathcal{M}_V$ or splitting occurs with $m^0 \geq \mathcal{Z} = \sum_{k=1}^{K} \alpha_k$.

Heuristically, this is a satisfying result: after splitting, the nuclei should still capture as many electrons as the total nuclear charge $\mathcal{Z}$. One might expect that it should be able to retain strictly more, to form a negatively charged ion, and we can prove this for perturbations of the form (1.5):

**Theorem I.3.** Let $Z_n \to 0$ and

$$V_n(x) = V_{TF}(x) + \frac{Z_n}{|x|^\nu}, \quad (1.12)$$

with $0 < \nu < 1$, and $\mathcal{Z} = \sum_{k=0}^{K} \alpha_k$. Let $u_n$ minimize $I_{V_n}(M)$, $n \in \mathbb{N}$. Then,

(i) $\{u_n\}_{n \in \mathbb{N}}$ is a minimizing sequence for $I_{V_{TF}}$.

(ii) Either $M \in \mathcal{M}_{V_{TF}}$ or splitting occurs with $m^0 > \mathcal{Z}$. 

Finally, we consider in greater detail the loss of compactness which occurs for the long-range regularized families $V_n$ satisfying (1.12) with $0 < \nu < 1$. When $M$ is large compared to $2^\nu$, compactness is lost and mass splits off to infinity as described in Theorem 1.1. The nonlocal term in $E_{V_n}$ exerts a repulsive effect on the components $u^i$, while the vanishing long-range potential provides some degree of containment. The combination of attractive and repulsive terms generally leads to pattern formation, at a scale determined by the relative strengths of the competitors. This phenomenon has been identified in nonlocal isoperimetric problems (such as the Gamow liquid drop model; see [1, 4].)

However, for potentials $V_n$ of the form (1.12), the interactions between the fleeing components $u^i$ appear in the energy at order $Z_n^{-\nu}$. Thus, we require some information about the spatial decay of the minimizers of $E_{V_n}$ away from the centers of the support in order to control the errors in an expansion of the energy in terms of $Z_n \to 0$. In the liquid drop problems, the splitting is in compactly supported domains, and this issue does not arise. In order to calculate interactions we require exponential decay of the solutions, which is connected to the delicate question of the Lagrange multiplier $\mu$. In particular, we obtain exponential decay when $\mu < 0$, $|u(x)| \leq Ce^{-\lambda|x|}$, for any $0 < \lambda < \sqrt{-\mu}$. As the energy value $I_{V}(M)$ is strictly decreasing in $M$, we have $\mu \leq 0$ and in fact we would expect that $\mu < 0$ should hold, if not always, at least for all but a residual set of $M$. It is an open question whether $\mu < 0$ holds whenever $M \in \mathcal{M}$. The strict negativity is known for the cases $V \equiv 0$ with sufficiently small mass, or with $V = V_{TF}$ with $M < 2^\nu + \kappa$ with $\kappa = \kappa(V_{TF}) > 0$; see Proposition II.2.

We may now state our result on the distribution of masses in the case of splitting. Define $\mathcal{M}_V^*$ to consist of all $M \in \mathcal{M}_V$ for which every minimizer $u$ satisfies (1.6) with $\mu < 0$.

**Theorem I.4.** Let $u_n$ be minimizers of $I_{V_n}(M)$ with $V_n$ satisfying (1.12) with $0 < \nu < 1$ and $Z_n \to 0$. With the notation of Theorem I.1, assume $N \geq 1$ and $m^0 \in \mathcal{M}_V^*$. Let $\{m^i\}_{i=0,\ldots,N}$ and $\{x^i_n\}_{i=1,\ldots,N}$ be as in Theorem I.1. Then, up to a subsequence,

$$Z_n^{1-\nu} x^i_n \to y^i,$$

where $(0, y^1, \ldots, y^N)$ minimizes the interaction energy

$$F_{N, (m^0, m^1, \ldots, m^N)}(w^0, w^1, \ldots, w^N) := \sum_{0 < i < j} \frac{m^i m^j}{|w^i - w^j|} + (m^0 - 2^\nu) \sum_{i=1}^{N} \frac{m^i}{|w^i|} - \sum_{i=1}^{N} \frac{m^i}{|w^i|^{\nu}}$$

over the set

$$\Sigma_N := \{(w^0, w^1, \ldots, w^N) \in \mathbb{R}^{3(N+1)} : w^0 = 0\}.$$

**Remark I.5.** 1. The proof of the fact that $\inf F$ is attained for all choices of $N$ and $(m^0, \ldots, m^N)$ with $m^0 > 2^\nu$ is essentially the same as the one of Proposition 8 of Alama, Bronsard, Choksi, and Topaloglu [1]. Note that $m^0 > 2^\nu$ follows from Theorem I.3.
2. By Theorem [1.1], each of the components $u^i$ shares the same Lagrange multiplier $\mu$, and hence it suffices that any one of the components satisfy (1.6) with $\mu < 0$.

3. We do not know whether the condition $\mu < 0$ could be improved. We use $\mu < 0$ for uniform exponential decay of the functions $u_n$ away from $x_n^i$, but some weaker uniform decay away from the mass centers may be sufficient. However, it is unclear how rapidly minimizers of (1.1) decay when $\mu = 0$.

Finally, we note that the specific choice of powers $p = \frac{10}{3}$ and $q = \frac{8}{3}$ in the nonlinear potential well $W(u) = c_1|u|^p - c_2|u|^q$ are physically appropriate for the TFDW model, but from the point of view of analysis other choices are possible. Indeed, most of the results of this paper may be extended to the case $2 < q < 3$ and $q < p < 6$. However, for $q > 3$ the behavior of minimizers may be substantially different: in such case $I_V(M) = I_{p,q}^V(M)$ may vanish identically, and minimizers may never exist for any $M > 0$. (See Lions [11] for various examples.) Thus, it is not sufficient to have potentials $W$ with a “double well” structure to observe the properties of TFDW minimizers; the relationship between the powers appearing in the functional is also of importance.

II. Boundedness and decay of minimizers

In this section we prove various basic properties of $I_V(M)$ and its minimizers, and we discuss the role of the Lagrange multiplier in the decay of solutions.

The following properties are well-known for variational problems of the form (1.1):

Proposition II.1. Let $V$ satisfy (1.2).

(i) For any $M > 0$, $I_V(M) < 0$, and strictly decreasing in $M$.

(ii) The following “binding inequality” holds for any $0 < m < M$:

$$I_V(M) \leq I_V(m) + I_0(M - m). \quad (2.1)$$

(iii) If $I_V(M)$ is attained at $u \in H^1(\mathbb{R}^3)$, then $u$ solves (1.6) with Lagrange multiplier $\mu \leq 0$ and we may take $u \geq 0$ in $\mathbb{R}^3$. It is possible to choose $u > 0$ if $V = V_{TF}$ or $V = V_Z$ as defined in (1.5).

Proof. Statements (i) and (ii) can be proven as Lemma 5 was in Nam and Van Den Bosch [13]. In regard to (iii), (1.6) corresponds to the Euler-Lagrange equation associated with $I_V(M)$, while $\mu \leq 0$ due to $I_V(M)$ being decreasing in $M$. We may take $u \geq 0$ in $\mathbb{R}^3$ as $I_V(M) = \mathcal{E}_V(u) = \mathcal{E}(|u|)$. Finally, for potentials of the form $V_{TF}$ or as perturbed in (1.5) the positivity of minimizers follows from the Harnack inequality.

When the Lagrange multiplier $\mu < 0$ we obtain exponential decay (see (66) in Lions [11]): for all $0 < \lambda < \sqrt{-\mu}$, there exists a constant $C$ with

$$|u(x)| + |\nabla u(x)| \leq Ce^{-\lambda x}, \quad a.e. \text{ in } \mathbb{R}^3 \quad (2.2)$$
A categorization of the potentials $V$ and masses $M$ for which $\mu < 0$ remains an important open question. The following proposition gives various criteria under which the Lagrange multiplier $\mu < 0$.

**Proposition II.2.**  
(i) For $V \equiv 0$, $\exists M_0 > 0$ so that if $M < M_0$ then $M \in \mathcal{M}_V^*$;  
(ii) For $V \geq V_{TF}$ satisfying (1.2), $\exists \kappa = \kappa(\mathcal{Z}) > 0$ so that if $M < \mathcal{Z} + \kappa$ then $M \in \mathcal{M}_{V_{TF}}^*$;  
(iii) For $V$ with long-range decay (1.4), every $M \in \mathcal{M}_V^*$.

(iv) For $V$ satisfying (1.2) such that  
\[
E := \inf \left\{ \int_{\mathbb{R}^3} (|\nabla u|^2 - Vu^2) \, dx : u \in H^1(\mathbb{R}^3), ||u||_2 = 1 \right\} < 0, \quad (2.3)
\]
there exists $M_V > 0$ so that if $M < M_V$ then $M \in \mathcal{M}_V^*$;  
(v) For  
\[
V(x) = \sum_{k=1}^{K} \frac{\alpha_k}{|x - r_k|^\tau}, \text{ a.e. in } \mathbb{R}^3,
\]
with $\{\alpha_k\}_{k=1}^{K} \subset \mathbb{R}^+$, $\{r_k\}_{k=1}^{K} \subset \mathbb{R}^3$, and $0 < \tau < 2$, there exists $M_V > 0$ so that if $M < M_V$ then $M \in \mathcal{M}_V^*$.

**Proof.** To verify (i), suppose that $u$ is a minimizer. Equation (1.7) corresponds to the Euler-Lagrange equation associated with $I_0(M)$. Regarding the strict negativity of $\mu$, note that from (1.7),  
\[
\mu M = \int_{\mathbb{R}^3} |\nabla u(x)|^2 \, dx + \frac{5}{3} \int_{\mathbb{R}^3} |u(x)|^{\frac{10}{3}} \, dx - \frac{4}{3} c_1 \int_{\mathbb{R}^3} |u(x)|^{\frac{8}{3}} \, dx
\]
\[
+ \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} u^2(x)u^2(y) \frac{|x - y|}{|x - y|^\tau} \, dx \, dy. \quad (2.4)
\]
Moreover, since $I_0(M) = \varepsilon_0(u)$ and $||\sigma^2 u(\sigma) ||_2^2 = M$ for all $\sigma > 0$,  
\[
0 = \left. \frac{d}{d\sigma} [\varepsilon_0(\sigma^2 u(\sigma))] \right|_{\sigma=1}
\]
\[
= 2 \int_{\mathbb{R}^3} |\nabla u(x)|^2 \, dx + 2c_1 \int_{\mathbb{R}^3} |u(x)|^{\frac{10}{3}} \, dx - c_2 \int_{\mathbb{R}^3} |u(x)|^{\frac{8}{3}} \, dx
\]
\[
+ \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} u^2(x)u^2(y) \frac{|x - y|}{|x - y|^\tau} \, dx \, dy,
\]
or, equivalently,  
\[
\frac{5}{3} c_1 \int_{\mathbb{R}^3} |u(x)|^{\frac{10}{3}} \, dx = \frac{5}{3} \int_{\mathbb{R}^3} |\nabla u(x)|^2 \, dx + \frac{5}{6} c_2 \int_{\mathbb{R}^3} |u(x)|^{\frac{8}{3}} \, dx
\]
\[
- \frac{5}{12} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} u^2(x)u^2(y) \frac{|x - y|}{|x - y|^\tau} \, dx \, dy. \quad (2.5)
\]
Then, inserting (2.5) into (2.4) gives

\[
\mu M = -\frac{2}{3} \int_{\mathbb{R}^3} |\nabla u(x)|^2 dx - \frac{1}{2} c_2 \int_{\mathbb{R}^3} |u(x)|^2 dx + \frac{7}{12} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dxdy.
\]

We conclude by noting that, by Hardy-Littlewood’s inequality and the interpolation inequality in Lebesgue spaces,

\[
\int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dxdy \leq CM^\frac{2}{3} \int_{\mathbb{R}^3} |u(x)|^2 dx.
\]

It is worth to mention that the Pohozaev identity associated with (1.7) does not bring new information about \(\mu\).

Statement (ii) is Theorem 1 by Le Bris [8], and (iii) is Theorem 2 in Alama-Bronsard-Choksi-Topaloglu [2].

Statement (iv) follows by the same reasoning as in the proof of Lions [11, Corollary II.2]. Finally, (v) is a consequence of part (iv). Indeed, note that the \(L^2\)-norm in \(\mathbb{R}^3\) is invariant under the transformation \(u \mapsto u_\sigma := \sigma^2 u(\sigma \cdot)\). Therefore, we can prove equation (2.3) holds by first fixing any \(u \in H^1(\mathbb{R}^3)\) with \(\|u\|_2 = 1\), and then taking \(\sigma\) sufficiently small so that

\[
\int_{\mathbb{R}^3} (|\nabla u_\sigma|^2 - V u_\sigma^2) dx = \int_{\mathbb{R}^3} \left[ \sigma^2 |\nabla u(x)|^2 - \sigma^\tau \sum_{k=1}^K \frac{\alpha_k}{|x-\sigma r_k|^\tau} u^2(x) \right] dx < 0.
\]

\(\square\)

We will require the following basic energy bound in many of our proofs. This result is proven in Lemma 6 of Alama-Bronsard-Choksi-Topaloglu [2]; although there it is stated for minimizing sequences, it is clear from the proof that in fact it applies to any sequence with negative energy:

**Lemma II.3.** Assume \(V\) satisfies (1.2), and \(\{u_n\}_{n \in \mathbb{N}}\) be a sequence with \(\|u_n\|_2^2 = M\) and \(E_V(u_n) < 0\), \(\forall n \in \mathbb{N}\).

Then, there exists a constant \(C_0 = C_0(V) > 0\) such that

\[
\|u_n\|_{H^1(\mathbb{R}^3)}^2 + \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dxdy + \int_{\mathbb{R}^3} V u_n^2 dx \leq C_0 M. \tag{2.6}
\]

**Remark II.4.** Note that boundedness of \(\{u_n\}_{n \in \mathbb{N}}\) in \(H^1(\mathbb{R})\) implies boundedness of the same sequence in \(L^r(\mathbb{R}^3)\), for \(2 \leq r \leq 6\).

The following is stated as part of Theorem I.3 but its proof only depends on the bounds stated in Lemma II.3 and the result will be needed below.

**Proposition II.5.** Let \(u_n\) minimize \(I_{V_n}(M)\), where \(V_n\) is as in (1.12). Then \((u_n)_{n \in \mathbb{N}}\) is a minimizing sequence for \(I_{V_{TF}}(M)\).
Proof. Let \{u_n\} be minimizers for \(I_{V_n}, \ n \in \mathbb{N}\). First, note that \(V_1 \geq V_n(x) \geq V_{TF}(x)\) for all \(x\), and hence
\[
\mathcal{E}_{V_1}(u_n) \leq \mathcal{E}_{V_n}(u_n) = I_{V_n} \leq I_{TF} < 0
\]
for all \(n\). Applying Lemma 11.3 with \(V = V_1\), the sequence \((u_n)_{n \in \mathbb{N}}\) satisfies the bounds (2.6) uniformly in \(n \in \mathbb{N}\). Next, we observe that \(|x|^{-\nu} \in L^3_{loc}\) for \(0 < \nu < 1\), and thus
\[
Z_n \int_{\mathbb{R}^3} \frac{u_n^2}{|x|^{\nu}} \, dx \leq Z_n \int_{B(0)} \frac{u_n^2}{|x|^{\nu}} \, dx + Z_n \int_{\mathbb{R}^3 \setminus B(0)} u_n^2 \, dx
\]
\[
\leq Z_n \|u_n\|^2_{L^3(\mathbb{R}^3)} \left\| \left| |x|^{-\nu} \right| \right\|_{L^3(B(0))} + Z_n M
\]
\[
\leq c Z_n \|\nabla u_n\|^2_{2/3} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x) u^2(y)}{|x-y|} \, dx \, dy + Z_n M
\]
\[
\to 0.
\]
In particular, \(\mathcal{E}_{V_n}(u_n) = \mathcal{E}_{V_{TF}}(u_n) + o(1)\), and therefore we may conclude,
\[
I_{V_{TF}} \leq \liminf_{n \to \infty} \mathcal{E}_{V_{TF}}(u_n) = \liminf_{n \to \infty} \mathcal{E}_{V_n}(u_n) = \liminf_{n \to \infty} I_{V_n} \leq \limsup_{n \to \infty} I_{V_n} \leq I_{V_{TF}}.
\]

Lemma II.6. Under all hypotheses of Theorem I.4, we have that, up to a subsequence, for all \(0 < t < \sqrt{-\mu}\), there exists a constant \(C\) independent of \(n\) with
\[
0 < |u_n(x)| + |\nabla u_n(x)| \leq Ce^{-t \sigma_n(x)}, \ a.e. \ in \ \mathbb{R}^3,
\]
where
\[
\sigma_n(x) := \min_{0 \leq i \leq N} |x - x_n^i|
\]
and \(x_n^i\) are as in the Concentration Theorem I.1.

Proof. By Proposition I.1 (iii), we may take \(u_n(x) > 0\) in \(\mathbb{R}^3\). Alama, Bronsard, Choksi, and Topaloglu [2] proved that
\[
-\Delta u_n = \left( \mu_n - \frac{5}{3} c_1 u_n^4 + \frac{4}{3} c_2 u_n^2 + V_n - u_n^2 \ast | \cdot |^{-1} \right) u_n,
\]
for some \(\mu_n < 0\). In addition to this, by the final step in the proof of the Concentration Theorem I.1, the Lagrange multipliers \(\mu_n \to \mu\) converge. Fix \(t \in (0, \sqrt{-\mu})\); then, for all \(n\) sufficiently large,
\[
-\Delta u_n + t^2 u_n < \left[ \frac{1}{2} (t^2 + \mu) + \frac{4}{3} c_2 u_n^2 \right] u_n.
\]
Moreover, by Lemma 11.3 and equation (2.8) we have that \(\{u_n\}_{n \in \mathbb{N}}\) is bounded in \(H^2(\mathbb{R}^3)\), and hence in \(L^{\infty}(\mathbb{R}^3)\). Therefore, we can make use of Theorem 8.17 by Gilbarg and Trudinger [7] to obtain
\[
\|u_n\|_{L^\infty(B_1(y))} \leq C \|u_n\|_{L^2(B_2(y))} \leq C \|u_n\|_{L^2(\mathbb{R}^3 \setminus B_{R/2}(x_n))}, \ y \in \mathbb{R}^3 \setminus B_R(x_n^i), \ R \gg 1,
\]
where $C$ is a constant independent of $n, R$ and $y$. By covering $\mathbb{R}^3 \setminus \cup B_R(x_i^n)$ with balls of radius one centered at points in the same set we obtain

$$||u_n||_{L^\infty(\mathbb{R}^3 \setminus \cup B_R(x_i^n))} \leq C||u_n||_{L^2(\mathbb{R}^3 \setminus \cup B_{R/2}(x_i^n))}.$$  

On the other hand, by Proposition \[1.5\] $\{u_n\}_{n \in \mathbb{N}}$ is a minimizing sequence for $I_V T F (M)$, and hence the conclusions of Concentration Theorem \[I.1\] hold. In particular, this implies that given $\epsilon > 0$, there exists $R_0 = R_0(\epsilon) \geq 1$ such that

$$||u_i||_{L^2(B_R/2(0))} < \epsilon, \quad i = 0, \ldots, N, \quad R \geq R_0,$$

and \[I.8\], \[I.11\], Rellich-Kondrakov Theorem, and the decay of all $u^i$ \[2.2\] ensure that, up to a subsequence,

$$u_n(\cdot + x_i^n) \to u^i \text{ in } L^2(B_{R/2}(0)), \quad i = 0, \ldots, N, \quad R \geq R_0.$$

As a result,

$$\lim_{n \to \infty} ||u_n||_{L^2(\mathbb{R}^3 \setminus \cup B_{R/2}(x_i^n))}^2 = M - \lim_{n \to \infty} ||u_n||_{L^2(\cup B_{R/2}(x_i^n))}^2 \leq M - \sum_{i=0}^N ||u_i||_{L^2(B_R/2(0))}^2 < \epsilon.$$

Then, given any $\epsilon > 0$, by choosing $R_0 = R_0(\epsilon)$ larger if necessary, we have

$$\limsup_{n \to \infty} ||u_n||_{L^\infty(\mathbb{R}^3 \setminus \cup B_R(x_i^n))} \leq \epsilon, \quad R \geq R_0,$$

and hence for large enough $n$ and $R$,

$$-\Delta u_n + t^2 u_n < 0, \quad \text{a.e. in } \mathbb{R}^3 \setminus \cup B_R(x_i^n).$$

Next, it is not hard to check that

$$-\Delta e^{-t\sigma_n} + t^2 e^{-t\sigma_n} > 0, \quad \text{a.e. in } \mathbb{R}^3 \setminus \cup B_R(x_i^n),$$

and that there exists $C > 0$ so that

$$u_n|_{\partial \cup B_R(x_i^n)} \leq C e^{-tR} = C e^{-t\sigma_n(x)}|_{\partial \cup B_R(x_i^n)}.$$

Thus,

$$-\Delta [u_n(x) - C e^{-t\sigma_n(x)}] + t^2 [u_n(x) - C e^{-t\sigma_n(x)}] < 0, \quad \text{a.e. in } \mathbb{R}^3 \setminus \cup B_R(x_i^n).$$
At this point, we would like to invoke the maximum principle to assert that $u_n(x)$ is dominated by the supersolution $v(x) = Ce^{-t\alpha_n}$ in the domain $\Omega_n := \mathbb{R}^3 \setminus \bigcup B_R(x_i^n)$. As the domain is unbounded, this requires some care, but applying Stampacchia’s method as in Benguria, Brezis and Lieb [3, Lemma 8] we obtain the desired bound,

$$0 < u_n(x) \leq v(x) = Ce^{-t\alpha_n(x)}, \quad \forall x \in \Omega_n.$$

The estimate on $|\nabla u_n|$ then follows from standard elliptic estimates; see for instance Theorems 8.22 and 8.32 of [7].

At this point we would like to note that the functions $u^i$ decay to zero at infinity, even if $m^0 \notin \mathcal{M}_{{\mathcal{V}_T F}}$. This follows from Proposition III.1(iii) and Theorem 8.17 uniformly by Gilbarg and Trudinger [7], again.

III. Proof of Theorems I.2 and I.3

The proofs of Theorems I.2 and I.3 both rely on the splitting structure given in the Concentration Theorem I.1, and on the idea that, when calculating the interaction energy between very widely separated components $u^i(x + x_i^n)$, only the mass $m^i$ and centers $x_i^n$ enter into the computation at first order. The following simple lemma makes this precise, at least for compactly supported components:

**Lemma III.1.** (a) Let $v^1, v^2 \in \mathcal{H}^1(\mathbb{R}^3)$ with compact support, $\text{supp } v^i \subset B_\rho(\zeta^i)$, $i = 1, 2$, with $1 < \rho < \frac{1}{4} R$, $R = |\zeta^1 - \zeta^2| > 0$. Then,

$$\left| \int_{B_\rho(\zeta^1)} \int_{B_\rho(\zeta^2)} \frac{|v^1(x)|^2|v^2(y)|^2}{|x - y|} dx \, dy - \frac{\|v^1\|_2^2\|v^2\|_2^2}{|\zeta^1 - \zeta^2|} \right| \leq \frac{4\rho}{R^2}\|v^1\|_2^2\|v^2\|_2^2.$$

(b) Let $v \in \mathcal{H}^1(\mathbb{R}^3)$ with compact support, $\text{supp } v \subset B_\rho(\zeta)$, with $1 < \rho < \frac{1}{4} R = |\zeta|$. For any $\nu > 0$ and fixed vector $r \in \mathbb{R}^3$ with $0 < |r| < \frac{1}{4} R$,

$$\int_{B_\rho(\zeta)} \frac{|v(x)|^2}{|x - r|^\nu} dx - \frac{\|v\|_2^2}{|\zeta|^\nu} \leq C_\nu \frac{\rho}{R^{\nu+1}}\|v\|_2^2.$$

**Proof.** These follow from the pointwise estimates,

$$\left| \frac{1}{|\zeta^1 - \zeta^2|} - \frac{1}{|x - y|} \right| \leq \frac{2\rho}{(R - \rho)^2} \leq \frac{4\rho}{R^2},$$

$$\left| \frac{1}{|\zeta|^\theta} - \frac{1}{|x - r|^\theta} \right| \leq \frac{\theta\rho}{(|\zeta| - \rho - |r|)^{\theta+1}} \leq C_\theta \frac{\rho}{R^{1+\theta}},$$

for all $x \in B_\rho(\zeta^1), y \in B_\rho(\zeta^2), \text{ and } 1 < \rho < \frac{1}{4} R$. 

Unlike the case of the Gamow liquid drop problem, our components $u^i$ are not of compact support, so we need to resort to truncation. This will prove effective provided we are in a
situation where the minimizers \( u^i \) have exponential decay. To generate localization functions, fix any smooth \( \phi : \mathbb{R} \to [0, 1] \) for which

\[
\phi 1_{(-\infty, 0]} \equiv 1, \quad \phi 1_{[1, \infty)} \equiv 0, \quad ||\phi'||_{L^\infty(\mathbb{R})} \leq 2.
\]

We are now ready to prove Theorems 1.2 and 1.3 on the size of the compact part of minimizing sequences. The argument for the first theorem is similar to that of Lions’ [11] proof of existence of minimizes for TDFW with \( M \leq \mathcal{F} \).

**Proof of Theorem 1.2.** We write the potential \( V = V_{TF} + W \), where \( W(x) \geq 0 \) and \( W \) satisfies (1.2). To obtain a contradiction, assume \( \{u_n\} \) is a minimizing sequence for \( I_V(M) \) for which there is splitting (i.e., \( N \geq 1 \) in Theorem 1.1) but \( 0 < m^0 < \mathcal{F} \). We let \( u^i \), \( m^i = ||u^i||^2_2 \), \( i = 0, \ldots, N \) be as given by Theorem 1.1. Fix \( N \) unit vectors \( e^i \in \mathbb{R}^3 \), and for \( \rho > 1 \) define \( q^i \) by

\[
q^0 = 0, \quad q^1 = \rho^2 e^1, \quad q^i = \rho^3 e^i, \quad i = 2, \ldots, N.
\]

Then we define the truncated components,

\[
U^i_\rho(x) := \phi(|x - q^i| - \rho + 1) u^i(x - q^i), \quad i = 0, \ldots, N.
\]

That is, each \( U^i_\rho \) has been truncated to have support in the ball \( B_\rho(q^i) \).

As \( m^0 < \mathcal{F} \), by Proposition 1.2 (ii), \( \mu < 0 \) for all Lagrange multipliers corresponding to \( u^i \), \( i = 0, \ldots, N \), and hence the exponential decay estimate (2.2) holds for each. Let \( \lambda = \frac{1}{2} \sqrt{-\mu} \) for simplicity. Then,

\[
m^i_\rho := ||U^i_\rho||^2_2 \leq \int_{B_\rho(q^i)} |u^i(x)|^2 dx = m^i - O(e^{-\lambda \rho}),
\]

and

\[
\mathcal{E}_V(U^0_\rho) = \mathcal{E}_V(u^0) + O(e^{-\lambda \rho}), \quad \mathcal{E}_0(U^i_\rho) = \mathcal{E}_0(u^i) + O(e^{-\lambda \rho}), \quad i = 1, \ldots, N.
\]

Let \( w_\rho := U^0_\rho + \sum_{i=1}^N U^i_\rho \). As \( ||w_\rho||^2_2 < M \), by monotonicity of \( I_V(M) \) we have

\[
I_V(M) < I_V(||w_\rho||^2_2) \leq \mathcal{E}_V(w_\rho)
\]

\[
\leq \mathcal{E}_V(U^0_\rho) + \sum_{i=1}^N |\mathcal{E}_0(U^i_\rho)| + \sum_{i,j=0, i \neq j} \int_{B_\rho(q^i)} \int_{B_\rho(q^j)} \frac{|U^i_\rho(x)|^2 |U^j_\rho(y)|^2}{|x - y|} dx dy
\]

\[
- \sum_{i=1}^N \int_{B_\rho(q^i)} [V_{TF}(x) + W(x)] |U^i_\rho(x)|^2 dx + O(e^{-\lambda \rho})
\]

\[
\leq I_V(m^0) + \sum_{i=1}^N I_0(m^i) + \sum_{i,j=0, i \neq j} \int_{B_\rho(q^i)} \int_{B_\rho(q^j)} \frac{|U^i_\rho(x)|^2 |U^j_\rho(y)|^2}{|x - y|} dx dy
\]

\[
- \sum_{i=1}^N \int_{B_\rho(q^i)} [V_{TF}(x) + W(x)] |U^i_\rho(x)|^2 dx + O(e^{-\lambda \rho}).
\]

(3.2)
Next, we use Lemma [III.1] to evaluate the interaction terms. Note that \( R^{i,j} = |q^i - q^j| \) is of order \( \rho^2 \) when \( i = 0, j = 1 \), and of order \( \rho^3 \) otherwise, and \( 0 < m^i - m^i_\rho < O(e^{-\lambda\rho}) \). Thus, we have:

\[
\int_{B_\rho(q^i)} \int_{B_\rho(q^j)} \frac{|U^i_\rho(x)|^2 |U^j_\rho(y)|^2}{|x - y|} \, dx \, dy = \begin{cases} 
\frac{m^0 m^1}{\rho^2} + O(\rho^{-3}), & \text{if } i + j = 1, \\
O(\rho^{-3}), & \text{otherwise},
\end{cases}
\]

and for \( i = 1, \ldots, N, k = 1, \ldots, K \), we evaluate the interaction with \( V_{TF} \) by:

\[
\int_{B_\rho(q^i)} \frac{|U^i_\rho(x)|^2}{|x - r^k|} \, dx = \begin{cases} 
\frac{m^1}{\rho^2} + O(\rho^{-3}), & \text{if } i = 1, \\
O(\rho^{-3}), & \text{if } i \geq 2.
\end{cases}
\]

Substituting into (3.2), and using \( W \geq 0 \), we obtain the strict subadditivity of \( I_V(M) \),

\[
I_V(M) - \left[ I_V(m^0) + \sum_{i=1}^{N} I_0(m^i) \right] \leq \frac{m^0 m^1 - 2^{e+1}}{\rho^2} + O(\rho^{-3}) < 0, \tag{3.3}
\]

for all \( \rho \) sufficiently large, since we are assuming \( m^0 < 2^e \). However, this contradicts (1.10) in the Concentration Theorem, and thus \( m^0 \geq 2^e \), and the theorem is proven.

Proof of Theorem [I.3] The proof of Theorem [I.3] uses a very similar construction, with the same notation as above. Assume that \( u_n \) minimizes \( I_{V_n} \) for each \( n \). Then, we already showed in Proposition [II.5] that \( (u_n)_{n \in \mathbb{N}} \) is a minimizing sequence for \( I_{V_{TF}} \) (which is statement (i) in the theorem.)

We prove (ii) via a contradiction argument: assume there is splitting with \( N \geq 1 \), but \( m^0 \leq 2^e \). By Theorem [I.2] the only possibility is \( m^0 = 2^e \). With the same notation as in the proof of that theorem, we obtain the expansion (3.2), with \( W(x) = Z_n/|x|^\nu \). With \( m^0 = 2^e \) the leading order term in (3.3) vanishes, and so we need to use the long-range part to conclude the argument. We apply Lemma [III.1] once more, to evaluate the perturbation term,

\[
\int_{B_\rho(q^i)} \frac{|U^i_\rho(x)|^2}{|x|^\nu} \, dx = \begin{cases} 
\frac{m^1}{\rho^{2\nu}} + O(\rho^{-2(1+\nu)}), & \text{if } i = 1, \\
O(\rho^{-3\nu}), & \text{otherwise}.
\end{cases}
\]

Substituting into (3.2) we now obtain,

\[
I_V(M) - \left[ I_V(m^0) + \sum_{i=1}^{N} I_0(m^i) \right] \leq -\frac{Z_n}{\rho^{2\nu}} m^1 + O(\rho^{-3}) + O(Z_n \rho^{-3\nu}) < 0,
\]

provided we choose \( \rho = \rho_n \gg Z_n^{-\frac{1}{2\nu}} \). (For example, \( \rho_n = Z_n^{-\frac{1}{2\nu}} \) is an appropriate choice.) As in part (a), strict subadditivity contradicts (1.10) in the Concentration Theorem.
IV. Proof of Theorem I.4

The proof of Theorem I.4 is more intricate than that of Theorem I.2, as it requires us to make a finer estimate of the smaller order terms in the expansion of the energy.

By (i) of Theorem I.3, \( \{u_n\}_{n \in \mathbb{N}} \) is a minimizing sequence for \( I_{Vr}(M) \), and hence the conclusions of Concentration Theorem I.1 hold. We assume there is splitting, that is \( N \geq 1 \), and let \( u^i, m^i = \|u^i\|^2_2 \), and \( x^i_n \) (with \( x^0_n = 0 \)) be as in the Concentration Theorem. By hypothesis, the common value of the Lagrange multipliers of the limit components \( u^i \) is negative, \( \mu < 0 \).

As in the proof of Theorem I.2 we construct comparison functions by localization to balls with centers \( q^i \) spreading to infinity. However, we have little control on the errors introduced by the passage of \( u_n(\cdot - x^i_n) \rightharpoonup u^i \), and thus we use truncations of the minimizers \( u_n \) themselves to make these constructions.

Denote by
\[
R_n := \min_{0 \leq i < j} |x^i_n - x^j_n|.
\]
Consider also a sequence \( \rho_n \to \infty \) and translations \( \{q^0_n = 0\}_{n \in \mathbb{N}}, \ldots, \{q^N_n\}_{n \in \mathbb{N}} \subset \mathbb{R}^3 \) (all to be chosen later,) with
\[
1 \leq \rho_n \leq \frac{1}{4} \min\{R_n, Q_n\} \quad \text{where} \quad Q_n := \min_{i < j} |q^i_n - q^j_n|.
\]

Using the same cutoff functions \( \phi \) defined in (3.1), we then set
\[
\chi_{\rho_n}(\cdot) := \phi(|\cdot| - \rho_n + 1), \quad G^i_n(\cdot) := \chi_{\rho_n}(\cdot - x^i_n)u_n(\cdot), \quad \text{and} \quad H^i_n(\cdot) := G^i_n(\cdot + x^i_n - q^i_n).
\]
Thus, \( G^i_n \) are compactly supported in balls \( B_{\rho_n}(x^i_n) \) centered at the \( x^i_n \), chosen by the Concentration Theorem, while \( H^i_n \) are the same functions but translated to have centers at \( q^i_n \), which we will choose to create appropriate comparison functions.

We first confirm that these truncations provide a good approximation to the limit profiles \( u^i \), in the \( L^2 \) sense.

Lemma IV.1. For any \( \rho_n \) satisfying (4.1),
\[
m^i = \|u^i\|^2_2 = \lim_{n \to \infty} \|G^i_n\|^2_2.
\]

Since they only differ by translation, Lemma IV.1 applies to \( H^i_n \) as well.

Proof. First, it is easy to show that \( G^i_n(\cdot + x^i_n) \rightharpoonup u^i, i = 0, \ldots, N \) weakly in \( \mathcal{H}^1(\mathbb{R}^3) \), and in the norm on \( L^2_{\text{loc}}(\mathbb{R}^3) \). As a consequence,
\[
m^i = \|u^i\|^2_2 \leq \liminf_{n \to \infty} \|G^i_n\|^2_2.
\]

To obtain the complementary bound, we note that \( \sum_{i=0}^N G^i_n(x) \leq u_n(x) \) pointwise on \( \mathbb{R}^3 \), and since the supports of the \( G^i_n \) are disjoint we have
\[
\limsup_{n \to \infty} \sum_{i=0}^N \|G^i_n\|^2_2 \leq \|u_n\|^2_2 = M = \sum_{i=0}^N m^i.
\]
\[
\leq \sum_{i=0}^{N} \lim_{n \to \infty} \|G_{n}^{i}\|_{2}^{2} \leq \lim_{n \to \infty} \left( \sum_{i=0}^{N} \|G_{n}^{i}\|_{2}^{2} \right).
\]

In particular, the limit \( M = \lim_{n \to \infty} \sum_{i=0}^{N} \|G_{n}^{i}\|_{2}^{2} \) exists. Since individually the terms are bounded below via (4.2), we claim that each of the terms \( A_{n}^{i} := \|G_{n}^{i}\|_{2}^{2} \to m^{i} \), \( i = 0, \ldots, N \).

Indeed, for any \( \epsilon > 0 \) there exists \( K > 0 \) for which \( \sum_{i=0}^{N} A_{n}^{i} < M + \epsilon \) and for any \( i \), \( A_{n}^{i} \geq m^{i} - \epsilon/N \), whenever \( n \geq K \). Thus, for each \( j \) we have

\[
A_{n}^{j} + \sum_{i \neq j} m^{i} - \epsilon \leq \sum_{i=0}^{N} A_{n}^{i} < \sum_{i=0}^{N} m^{i} + \epsilon,
\]

and so \( A_{n}^{j} < m^{j} + 2\epsilon \), for all \( n \geq K \), that is, \( \limsup_{n \to \infty} \|G_{n}^{i}\|_{2}^{2} \leq m^{i} \), for each \( i \), and the claim is proven. \( \square \)

Since we are assuming \( \mu < 0 \), the exponential decay of \( u_{n} \) away from balls \( B_{\rho_{n}}(x_{n}^{i}) \) allows us to localize the energy \( \mathcal{E}_{V_{n}}(u_{n}) \) with an exponentially small error:

**Lemma IV.2.** Let \( \rho_{n} \to \infty \) with \( \rho_{n} \leq \frac{1}{4} R_{n} \). Then,

\[
\mathcal{E}_{V_{n}}(u_{n}) \geq \mathcal{E}_{V_{n}}(G_{n}^{0}) + \sum_{i=1}^{N} \mathcal{E}_{0}(G_{n}^{i}) - Z_{n} \int_{\mathbb{R}^{3}} \frac{|G_{0}^{i}(x)|^{2}}{|x|^{\nu}} \, dx
\]

\[
+ \sum_{0<i<j} m_{n}^{i} m_{n}^{j} \frac{1}{|x_{n}^{i} - x_{n}^{j}|} + \left( m_{n}^{0} - \mathcal{E}\right) \sum_{i=1}^{N} m_{n}^{i} \frac{1}{|x_{n}^{i}|} - Z_{n} \sum_{i=1}^{N} \frac{m_{n}^{i}}{|x_{n}^{i}|} \nu - \epsilon_{n},
\]

where

\[
|\epsilon_{n}| \leq C \left( \frac{\rho_{n}}{R_{n}^{2}} + \frac{Z_{n}\rho_{n}}{R_{n}^{1+\nu}} + e^{-\sqrt{\frac{\rho_{n}}{R_{n}}}} \right), \tag{4.3}
\]

as \( n \to \infty \), with \( C \) depending on \( \{m^{i}\} \) and \( \mathcal{E} \) but independent of \( \{x_{n}^{i}\} \).

**Proof.** By Lemma [11.6] for sufficiently large \( n \),

\[
|u_{n}(x) - \sum_{i=0}^{N} G_{n}^{i}(x)| \leq C e^{-\sqrt{\frac{\rho_{n}}{R_{n}}}} \sigma_{n}(x), \quad \forall x \in \Omega_{n} := \mathbb{R}^{3} \setminus \bigcup_{i=0}^{N} B_{\rho_{n}}(x_{n}^{i}),
\]

where \( \sigma_{n}(x) \) is as in Lemma [11.6]. This together with (2.7), (2.8), \( \mu_{n} \to \mu \), Lemma [11.3] \( \|\nabla \chi_{n,\rho_{n}}\|_{L^{\infty}(\mathbb{R}^{3})} \leq 2 \), and Hölder estimates for first derivatives imply

\[
|\nabla \left( u_{n}(x) - \sum_{i=0}^{N} G_{n}^{i}(x) \right)| \leq C e^{-\sqrt{\frac{\rho_{n}}{R_{n}}}} \sigma_{n}(x).
\]

As \( G_{n}^{i}(x) = u_{n}(x) \) in \( B_{\rho_{n}}(x_{n}^{i}) \), and has support in \( B_{\rho_{n}+1}(x_{n}^{i}) \), the contribution to the energy is unchanged in \( \bigcup_{i} B_{\rho_{n}}(x_{n}^{i}) \), and is exponentially small in the complementary region, \( \Omega_{n} \).
Moreover, the energy density is integrable over $\Omega_n$, and of order $\epsilon_n = O(e^{-\sqrt{\epsilon_n} \rho_n})$. Hence, we calculate:

$$
\mathcal{E}_{V_n}(u_n) = \sum_{i=0}^{N} \mathcal{E}_{V_n}(G_n^i) + \sum_{i<j} \int_{B_{\rho_n}(x_n^i)} \int_{B_{\rho_n}(x_n^j)} \frac{|G_n^i(x)|^2 |G_n^j(y)|^2}{|x-y|} \, dx \, dy + \epsilon_n
$$

$$
= \mathcal{E}_{V_{TF}}(G_n^0) - Z_n \int_{B_{\rho_n}(0)} \frac{|G_n^0(x)|^2}{|x|^\nu} \, dx
$$

$$
+ \sum_{i=1}^{N} \left[ \mathcal{E}_0(G_n^i) - \int \nabla(x)|G_n(x)|^2 \, dx - Z_n \int_{B_{\rho_n}(x_n^i)} \frac{|G_n^i(x)|^2}{|x|^\nu} \, dx \right]
$$

$$
+ \sum_{i<j} \int_{B_{\rho_n}(x_n^i)} \int_{B_{\rho_n}(x_n^j)} \frac{|G_n^i(x)|^2 |G_n^j(y)|^2}{|x-y|} \, dx \, dy + \epsilon_n
$$

$$
= \mathcal{E}_{V_{TF}}(G_n^0) + \sum_{i=1}^{N} \mathcal{E}_0(G_n^i) - Z_n \int_{B_{\rho_n}(0)} \frac{|G_n^0(x)|^2}{|x|^\nu} \, dx
$$

$$
+ \sum_{i<j} \int_{B_{\rho_n}(x_n^i)} \int_{B_{\rho_n}(x_n^j)} \frac{|G_n^i(x)|^2 |G_n^j(y)|^2}{|x-y|} \, dx \, dy
$$

$$
- N \sum_{i=1}^{N} \int_{R^3} |G_n^i(x)|^2 \, dx - Z_n \sum_{i=1}^{N} \int_{B_{\rho_n}(x_n^i)} \frac{|G_n^i(x)|^2}{|x|^\nu} \, dx + \epsilon_n. \tag{4.4}
$$

Now, we apply Lemma [III.1] to evaluate the interaction terms. In this way we have:

$$
\int_{B_{\rho_n}(x_n^i)} \int_{B_{\rho_n}(x_n^j)} \frac{|G_n^i(x)|^2 |G_n^j(y)|^2}{|x-y|} \, dx \, dy \geq \frac{m_i \cdot m_j}{|x^i_n - x^j_n|} - 4m_i \cdot m_j \frac{\rho_n}{R_n^2},
$$

$$
\int_{R^3} \frac{|G_n^i(x)|^2}{|x-r_k|} \, dx \leq \frac{m_i}{|x^i_n|} + C_1 m_i \frac{\rho_n}{R_n^2},
$$

$$
\int_{B_{\rho_n}(x_n^i)} \frac{|G_n^i(x)|^2}{|x|^\nu} \, dx \leq \frac{m_i}{|x^i_n|^{\nu}} + C_\nu m_i \frac{\rho_n}{R_n^{\nu+1}}.
$$

By substituting these estimates into (4.4) we arrive at the desired lower bound. \square

Next we create an upper bound estimate on the minimum energy by moving the localized components $H_n^i$ (which are simply translates of $G_n^i$) to study the role of the $x_n^i$. That is, we consider a trial function $w_n = \sum_{i=0}^{N} H_n^i$, which has the same localized components as $u_n$ but with centers $q_n^i$. The advantage of this over the upper bound constructed for the proof of Theorem [II.2] is that the terms of order $O(1)$ will exactly match those in the lower bound given by Lemma [IV.2].

**Lemma IV.3.** Let $\{\rho_n\}_{n \in \mathbb{N}} \subset (1, \infty)$ and $\{q_n^0\}_{n \in \mathbb{N}}, \ldots, \{q_n^N\}_{n \in \mathbb{N}} \subset \mathbb{R}^3$ satisfy (4.1). Then,

$$
\mathcal{E}_{V_n}(u_n) < \mathcal{E}_{V_{TF}}(G_n^0) + \sum_{i=1}^{N} \mathcal{E}_0(G_n^i) - Z_n \int_{R^3} \frac{|G_n^0(x)|^2}{|x|^\nu} \, dx
$$

$$
+ \sum_{0<i<j} \frac{m_i \cdot m_j}{|q_n^i - q_n^j|} + (m_n - 2C) \sum_{i=1}^{N} \frac{m_i}{|q_n^i|} - Z_n \sum_{i=1}^{N} \frac{m_i}{|q_n^i|^\nu} + \hat{\epsilon}_n,
$$
where

$$|\hat{\epsilon}_n| \leq C \left( \frac{\rho_n}{Q_n^2} + \frac{Z_n \rho_n}{Q_n^{1+\nu}} + e^{-\frac{\sqrt{n}}{\rho_n}} \right),$$  \hspace{1cm} (4.5)$$

as $n \to \infty$, with $C$ depending on $\{m^i\}$ and $\mathcal{F}$ but independent of $\{q_n^i\}$.

Proof. Set

$$w_n := \sum_{i=0}^{N} H_n^i.$$

As $0 \leq w_n(x) \leq u_n(x)$ for all $x \in \mathbb{R}^3$, $\|w_n\|_2^2 \leq \|u_n\|_2^2$. By the monotonicity of $I_{V_n}(M)$ (Proposition II.1 (i)),

$$\mathcal{E}_{V_n}(u_n) = I_{V_n}(M) < I_{V_n} \left( \|w_n\|_2^2 \right) \leq \mathcal{E}_{V_n}(w_n).$$

Using the support properties of $H_n^i$ and recognizing $\mathcal{E}_{\mathcal{V}_F}(H_n^i) = \mathcal{E}_{\mathcal{V}_F}(G_n^i)$, $\mathcal{E}_0(H_n^i) = \mathcal{E}_0(G_n^i)$, we expand as in the proof of Lemma IV.2 to obtain the desired upper bound.

By matching the lower bound from Lemma IV.2 with the upper bound from Lemma IV.3, we conclude for any choice of $\rho_n$, $\{q_n^i\}$ satisfying (4.1), we have the following bound satisfied by the translations $\{x_n^i\}$:

$$\sum_{0<i<j} m_n^i m_n^j \frac{|x_n^i - x_n^j|}{|x_n^i| - |x_n^j|} + (m_n^0 - \mathcal{F}) \sum_{i=1}^{N} m_n^i \frac{|x_n^i|}{|x_n^i|^\nu} - Z_n \sum_{i=1}^{N} m_n^i \frac{|x_n^i|^\nu}{|x_n^i|} \leq \sum_{0<i<j} m_n^i m_n^j \frac{|q_n^i - q_n^j|}{|q_n^i| - |q_n^j|} + (m_n^0 - \mathcal{F}) \sum_{i=1}^{N} m_n^i \frac{|q_n^i|}{|q_n^i|^\nu} - Z_n \sum_{i=1}^{N} m_n^i \frac{|q_n^i|^\nu}{|q_n^i|} + \epsilon_n + \hat{\epsilon}_n,$$

where $\epsilon_n, \hat{\epsilon}_n$ are defined in the statements of the Lemmas IV.2 and IV.3.

In what follows we exploit the freedom we have of choosing vectors $q_n^i$ and radii $\rho_n$ to prove Theorem I.4. Let us start by showing that the distance among vectors $x_n^i$ is of order at least $Z_{n}^{-\frac{1}{1+\nu}}$.

Lemma IV.4. $\liminf_{n \to \infty} R_n Z_{n}^{-\frac{1}{1+\nu}} > 0$. 

Proof. To derive a contradiction, assume that (along some subsequence) $R_n Z_{n}^{-\frac{1}{1+\nu}} \to 0$. Choose $q_n^i = R_n p^i$, for distinct fixed vectors $p^i$, $i = 1, \ldots, N$, and $p^0 = 0$. We also denote by $y_n^i = R_n^{-1} x_n^i$, and note that by the definition of $R_n$, we have $|y_n^i - y_n^j| \geq 1$ for all $i \neq j$, and in fact by choosing a further subsequence we may assume $|y_n^0 - y_n^i| = 1$ for all $n \in \mathbb{N}$. Set $\rho_n = \sqrt{R_n}$, and so (4.1) is satisfied for these choices.

We multiply (4.6) by $R_n$ to obtain:
\[
\sum_{0<i<j} \frac{m_n^i m_n^j}{|y_n^i - y_n^j|} + (m_n^0 - \mathcal{E}) \sum_{i=1}^N \frac{m_n^i}{|y_n^i|} < \sum_{0<i<j} \frac{m_n^i m_n^j}{|p^i - p^j|} + (m_n^0 - \mathcal{E}) \sum_{i=1}^N \frac{m_n^i}{|p^i|}

- Z_n R_n^{1-\nu} \sum_{i=1}^N \frac{m_n^i}{|p^i|^\nu} + Z_n R_n^{1-\nu} \sum_{i=1}^N m_n^i |y_n^i|^\nu + R_n \epsilon_n + R_n \hat{\epsilon}_n

< \sum_{0<i<j} \frac{m_n^i m_n^j}{|p^i - p^j|} + (m_n^0 - \mathcal{E}) \sum_{i=1}^N \frac{m_n^i}{|p^i|} + o(1),
\]

as \(Z_n R_n^{1-\nu} \to 0\) by the contradiction hypothesis, and hence \(R_n Z_n^{\rho_n / R_n^{\nu + \nu}} = Z_n R_n^{1-\nu} \rho_n / R_n \to 0\), which also assures \(R_n \epsilon_n, R_n \hat{\epsilon}_n \to 0\). Recalling that \(m_n^0 = \lim_{n \to 0} m_n^0 > \mathcal{E}\) and \(|y_n^0 - y_n^0| = 1\) for all \(n\), we then obtain

\[
m_n^{i0} m_n^{j0} \leq \sum_{0<i<j} \frac{m_n^i m_n^j}{|p^i - p^j|} + (m_n^0 - \mathcal{E}) \sum_{i=1}^N \frac{m_n^i}{|p^i|} + o(1),
\]

which holds for all \(n\) and any choice of vectors \(p^i\). Since \(m_n^i \to m^i > 0\), we obtain a contradiction by choosing \(|p^i|\) sufficiently large. \(\square\)

We now prove the main theorem on the convergence of concentration points at the scale \(R_n = O(Z_n^{-\frac{1}{1-\nu}}}).

**Proof of Theorem 1.4.** Let \(u_n\) attain the minimum in \(I_{V_n}\) for each \(n \to \infty\). Applying the Concentration Theorem 1.1 we obtain values of \(N\), masses \(m_n^0, \ldots, m_n^N\), and translations \(\{x_n^i\}\). By Theorem 1.2 we have \(m_n^0 > \mathcal{E}\).

For any choice of \(N\) and masses \(m_n^0, \ldots, m_n^N\) with \(m_n^0 > \mathcal{E}\), all minimizing sequences for \(F_{N,(m_n^0,\ldots,m_n^N)}(w^0, \ldots, w^N)\) on \(\Sigma_N\) are convergent. This follows by exactly the same argument as in the proof of Proposition 8 of Alama, Bronsard, Choksi, and Topaloglu 1. Let \((a^0, \ldots, a^N) \in \Sigma_N\) be such a minimizer,

\[
F_{N,(m^0,\ldots,m^N)}(a^0, \ldots, a^N) = \min_{(w^0, \ldots, w^N) \in \Sigma_N} F_{N,(m^0,\ldots,m^N)}(w^0, \ldots, w^N) < 0.
\]

Define \(\xi_n^i := Z_n^{\frac{1}{1-\nu}} x_n^i\).

Set

\[
\rho_n := Z_n^{-\frac{1}{2(1-\nu)}} \text{ and } q_n^i := Z_n^{-\frac{1}{2}} a^i.
\]

Then, by the previous Lemma, up to a subsequence,

\[
1 \leq \rho_n \leq \frac{1}{4} \min_{i<j} \{ |q_n^i - q_n^j|, R_n \},
\]

so that, equation 4.16 holds. Equivalently, we have that
Proof of Theorem I.1. We first present the proof with a more complete proof here (with specific references to steps appearing in other articles.)

Since we make heavy use of the decomposition into minimizers in the main results of the paper, we provide although not as a single theorem and with many details left to the reader. The result of the Concentration Theorem I.1 is essentially contained in Lions [11], for whom these problems were an important motivation for the development of the general Compactness techniques in Thomas-Fermi-type problems goes back at least to Lions [11], In addition to this, by Lemma IV.4.

\[
\lim_{n \to \infty} |\xi_i^n - \xi_j^n| \geq \liminf_{n \to \infty} Z_n^{\frac{1}{1-\nu}} R_n > 0.
\] (4.8)

By Lemma IV.4, \( \lim_{n \to \infty} m_i^n = m_n \), and hence applying (4.7) and (4.8) we obtain

\[
\limsup_{n \to \infty} F_{N,(m^0,\ldots,m^N)}(0,\xi_1^n,\ldots,\xi_N^n)
\]

\[
= \limsup_{n \to \infty} \left[ \sum_{0<i<j} m_i^n m_j^n \left| \xi_i^n - \xi_j^n \right| + (m^0_n - 2\nu) \sum_{i=1}^N m_i^n \frac{1}{|\xi_i^n|} \right]
\]

\[
\leq \limsup_{n \to \infty} \left[ \sum_{0<i<j} m_i^n m_j^n \frac{1}{|a_i - a_j|} + (m^0_n - 2\nu) \sum_{i=1}^N m_i^n \frac{1}{|a_i|} \right]
\]

\[
= F_{N,(m^0,\ldots,m^N)}(0f,a^1,\ldots,a^N)
\]

\[
= \min_{(w^0,\ldots,w^N) \in \Sigma_N} F_{N,(m^0,\ldots,m^N)}(w^0,\ldots,w^N).
\]

Therefore, \( (\xi_i^n)_{n=0,\ldots,N} \) form a minimizing sequence for \( F_{N,(m^0,\ldots,m^N)} \) in \( \Sigma_N \), and by Proposition 8 of [1], \( \xi_i^n = x_i^n Z_n^{\frac{1}{1-\nu}} \to y_i \), \( n = 0,\ldots,N \), with \( (y_i)_{n=0,\ldots,N} \) a minimizing configuration for \( F_{N,(m^0,\ldots,m^N)} \). The completes the proof of Theorem I.4.

A. Appendix: Proof of the Concentration Theorem

In this section we prove the Concentration Theorem I.1. The use of Concentration-Compactness techniques in Thomas-Fermi-type problems goes back at least to Lions [11], for whom these problems were an important motivation for the development of the general theory. The result of the Concentration Theorem I.1 is essentially contained in Lions [11], although not as a single theorem and with many details left to the reader. Since we make heavy use of the decomposition into minimizers in the main results of the paper, we provide a more complete proof here (with specific references to steps appearing in other articles.)

Proof of Theorem I.1. We first present the proof with \( V \not\equiv 0 \); the case \( V \equiv 0 \) requires only a simple modification. Let \( \{u_n\}_{n \in \mathbb{N}} \) be a minimizing sequence for \( \mathcal{E}_V \) with \( \|u_n\|_2 = M \). Since \( \mathcal{E}_V \) is coercive, \( \{u_n\}_{n \in \mathbb{N}} \) is bounded in \( \mathcal{H}^1(\mathbb{R}^3) \). Hence, there exists \( u^0 \in \mathcal{H}^1(\mathbb{R}^3) \) and a subsequence for which \( u_n \rightharpoonup u^0 \) weakly in \( \mathcal{H}^1(\mathbb{R}^3) \). At this point it is not clear if \( u^0 \) is
By the same argument as in (A1), this implies that 
\[ E_I \]
for 
\[ u \]
By definition, 
\[ L_m \]
nontrivial; this will be shown later. Let 
\[ \text{the energy decouples in the limit (see [9, 13]),} \]
weak convergence, 
\[ \|u_n^0\|_2 \rightarrow M - m^0, \]
and by weak convergence and the Brezis-Lieb Lemma, the energy decouples in the limit (see [9, 13]),
\[ \lim_{n \to \infty} [\mathcal{E}_V(u_n) - \mathcal{E}_V(u^0) - \mathcal{E}_0(u_n^0)] = 0, \]
and thus
\[ I_V(M) = \lim_{n \to \infty} \mathcal{E}_V(u_n) = \mathcal{E}_V(u^0) + \lim_{n \to \infty} \mathcal{E}_0(u_n^0) \geq I_V(m^0) + I_0(M - m^0). \]
By the binding inequality (2.1), we have
\[ I_V(m^0) + I_0(M - m^0) \geq I_V(M) \geq \mathcal{E}_V(u^0) + \lim_{n \to \infty} \mathcal{E}_0(u_n^0) \geq I_V(m^0) + I_0(M - m^0), \quad (A1) \]
and hence we obtain equality of each expression,
\[ \mathcal{E}_V(u^0) = I_V(m^0) \quad \text{and} \quad \lim_{n \to \infty} \mathcal{E}_0(u_n^0) = I_0(M - m^0), \]
that is, the remainder sequence \( \{u_n^0\} \) is a minimizing sequence for \( I_0(M - m^0) \).

We next consider the residual sequence \( \{u_n^0\} \) and show it concentrates after translation. First, we must eliminate the possibility of “vanishing” in the Concentration Compactness framework [10]. To this end, for any bounded sequence we define (as in Nam-van den Bosch [13]),
\[ \omega(\{v_n\}) := \sup \{ \|v\|^2 \mid \exists y_n \in \mathbb{R}^3 \text{ and a subsequence such that } v_n(\cdot - y_n) \rightharpoonup v \text{ in } \mathcal{H}^1(\mathbb{R}^3) \}. \]
We claim that \( \omega(\{u_n^0\}) > 0 \). Indeed, applying [10, Lemma I.1], if \( \omega(\{u_n^0\}) = 0 \), then \( u_n^0 \to 0 \) in \( L^q(\mathbb{R}^3) \) norm, \( \forall 2 < q < 6 \), so in particular \( \int_{\mathbb{R}^3} |u_n^0|^{8/3} \to 0 \). In addition, by (1.2) we have \( \int_{\mathbb{R}^3} V |u_n^0|^2 \to 0 \), and hence \( I_V(M) = \lim_{n \to \infty} \mathcal{E}_V(u_n^0) \geq 0 \), which contradicts Proposition I.1. Hence “vanishing” cannot occur.

We can therefore choose a sequence \( x_n^1 \in \mathbb{R}^3 \) for which \( u_n^0(\cdot - x_n^1) \rightharpoonup u^1, \) for some \( u^1 \in \mathcal{H}^1(\mathbb{R}^3) \), with mass \( m^1 := \|u^1\|_2^2 \geq \frac{3}{2} \omega(\{u_n^0\}) > 0 \). As \( u_n^0 \rightharpoonup 0 \), we must have \( |x_n^1| \to \infty \). In case \( m^0 = M - m^1 \), the sequence converges strongly in \( \mathcal{L}^2 \), and \( u^1 \) minimizes \( I_V(M - m^1) \), and we obtain (1.8), (1.9), (1.10), and (1.11), with \( N = 1 \).

If \( m^1 < M - m^0 \), we again define the remainder sequence, \( u_n^1(x) := u_n^0(x) - u^1(x + x_n^1) \).
By definition, \( u_n^1 \rightharpoonup 0, u^1(\cdot - x_n^1) \rightharpoonup 0, \) and \( \|u_n^1\|_2 \to M - m^0 - m^1, \) and the energy splits,
\[ \mathcal{E}_0(u_n^0) = \mathcal{E}_0(u^1) + \mathcal{E}_0(u_n^1) + o(1) \]
By the same argument as in (A1), this implies that \( \mathcal{E}_0(u^1) = I_0(m^1), I_0(M - m^0) = I_0(m^1), \) and \( \{u_n^1\} \) is a minimizing sequence for \( I_0(M - m^0 - m^1) \).
Substituting for \( I_0(M - m^0) \) in (A1) we conclude:
\[ I_V(M) = I_V(m^0) + I_0(m^1) + I_0(M - m^0 - m^1). \]
We iterate the above process: for each $k = 2, 3, \ldots$ we obtain translations $\{x_n^k\}$ in $\mathbb{R}^3$, $|x_n^k| \to \infty$, functions $u^k \in \mathcal{H}^1(\mathbb{R}^3)$ with
\[ \|u^k\|^2_2 := m^k \geq \frac{1}{2} \omega(\{u_{n}^{k-1}\}), \tag{A2} \]
and remainder sequences
\[ u_n^k(x) := u_n^{k-1}(x) - u^k(x + x_n^k) = u_n(x) - u^0(x) - \sum_{i=1}^{k} u^i(x + x_n^i), \]
satisfying:
\[ \|u_n^k\|^2_2 = M - \left( m^0 + \sum_{i=1}^{k} m^i \right) + o(1), \]
\[ u_n^k(\cdot - x_n^k) \to 0, \text{ weakly in } \mathcal{H}^1(\mathbb{R}^3), \]
\[ I_V(M) = I_V(m^0) + \sum_{i=1}^{k} I_0(m^i), \text{ and hence } \]
\[ \mathcal{E}_0(u^k) = I_V(m^k). \]

Next we show that $|x_n^k - x_n^i| \to \infty$ for all $i \neq k$. Suppose not, and take the smallest $k > i$ for which $|x^k - x^i|$ remains bounded along some subsequence. (And so $|x_n^i - x_n^j| \to \infty$ for all $i < j < k$.) Taking a further subsequence, $(x^k - x^i) \to \xi$ for some $\xi \in \mathbb{R}^3$. Now note that
\[ u_n^i(x) = u_n^k(x) + \sum_{j=i+1}^{k} u^j(x + x_n^j), \text{ and hence } \]
\[ u_n^i(x - x_n^i) = u_n^k(x - x_n^i) + u^k(x - x_n^i + x_n^i) + \sum_{j=i+1}^{k} u^j(x - x_n^i + x_n^i). \tag{A3} \]

Since $|x_n^j - x_n^i| \to \infty$ for $i < j < k$, $u^i(\cdot - x_n^i + x_n^j) \to 0$, while $u^k(\cdot - x_n^i + x_n^j) \to u^k(\cdot + \xi)$. And $u_n^k(\cdot - x_n^i) \to 0$, and hence we pass to the limit in (A3) to obtain $u_n^i(\cdot - x_n^i) \to u^k(\cdot + \xi) \neq 0$, a contradiction. Hence (1.11) is verified.

We claim that this process must terminate at some finite step $k = N$, for which $M = m^0 + \sum_{i=1}^{N} m^i$. Indeed, if $m^i > 0$ for all $i \in \mathbb{N}$, since $M \geq \sum_{i=0}^{k} m^i$ for all $k$, we have $\lim_{k \to \infty} m^k = 0$. By (A2) we conclude that $\lim_{j \to \infty} \omega(\{u_n^j\}) = 0$, ie, the remaining mass after $k$ steps, $(M - \sum_{i=0}^{k} m^i)$ may be made arbitrarily small. However, by the concavity of $I_0(M)$ for small (see Appendix or [13, Lemma 9 (iii)]), there exists $M_c > 0$ such that minimizing sequences for $I_0$ do not split for $M < M_c$. This proves statements (1.8), (1.9), and (1.10).

For $V \neq 0$, we now show that $m^0 > 0$, and hence the translations $x_n^0 = 0$ are trivial in this case. Indeed, if $m^0 = 0$, consider the sequence $\tilde{u}_n = u_n(x - x_n^1)$. As $\mathcal{E}_0$ is translation invariant, and $\mathcal{E}_V(u^1) < \mathcal{E}_0(u^1)$, a simple calculation shows $\lim_{n \to \infty} \mathcal{E}_V(\tilde{u}_n) < I_V$, which is not possible. For $V \equiv 0$, the functional $\mathcal{E}_0$ is translation invariant. Hence, we may begin the process at the Step $k = 1$, defining $\omega(\{u_n\})$ and identifying a first set of translates $\{x_n^0\}$ as above. By translation invariance, $\tilde{u}_n = u_n(\cdot - x_n^1)$ is also a minimizing sequence for $I_0(M)$,
and the weak limit \( u^0 = w - \lim_{n \to \infty} \tilde{u}_n \) will be nontrivial. The rest of the proof continues as in the case of nontrivial \( V \).

It remains to show that each \( u^i \) solves the Euler-Lagrange equation with the same Lagrange multiplier \( \mu \). By the Ekeland Variational Principle \([5]\) (see also \([14, \text{Corollary 5.3}]\)) we may find a minimizing sequence \( \{v_n\} \), with \( \|v_n\|_2 = M \) and \( \|v_n - u_n\| \to 0 \), for which the Euler-Lagrange equation is solved up to an small error in \( \mathcal{H}^{-1}(\mathbb{R}^3) \). That is, \( \exists \mu_n \in \mathbb{R} \) with

\[
D\mathcal{E}_V(v_n) - \mu_n v_n \to 0 \quad \text{in } \mathcal{H}^{-1} \text{ norm.}
\]

The Lagrange multipliers may be expressed as:

\[
\mu_n M = (D\mathcal{E}_V(v_n), v_n) + o(1)\|v_n\|_{\mathcal{H}^1(\mathbb{R}^3)} = (D\mathcal{E}_V(v_n), v_n) + o(1),
\]

as minimizing sequences are bounded. By Lemma \([11,3]\) \( |\mu_n| \) is uniformly bounded, and hence (after extracting a sequence) we may assume \( \mu_n \to \mu \) for some \( \mu \in \mathbb{R} \). As \( u_n(\cdot - x_n^i) \to u^i \) weakly in \( \mathcal{H}^1(\mathbb{R}^3) \), the same is true for \( \tilde{v}_n := v_n(\cdot - x_n^i) \to u^i, \ i = 0, \ldots, N \). Hence, for every \( \varphi \in C_0^\infty(\mathbb{R}^3) \),

\[
(D\mathcal{E}_V(u^0) - \mu u^0, \varphi) = \lim_{n \to \infty} (D\mathcal{E}_V(\tilde{v}_n) - \mu_n \tilde{v}_n, \varphi) = 0,
\]

and similarly, \( D\mathcal{E}_0(u^i) - \mu u^i = 0, \ i = 1, \ldots, N \).

\[\square\]

B. Appendix: Concavity for small mass

We show that \( I_0(M) \) is concave for small values of \( M \). This is another property which the TFDW-type functionals share with Gamow's liquid drop model.

**Proposition B.1.** \( I_0(M) \) is strictly concave for \( M \) sufficiently small.

**Proof.** Nam and Van Den Bosch \([13]\) showed \( I_0(M) \) is attained for \( M \) small enough by exploiting

\[
I_0(M) = \inf \{ F_u(M); u \in \mathcal{H}^1(\mathbb{R}^3), \|u\|_2 = 1 \}, \ \forall M > 0,
\]

where

\[
F_u(M) := -\frac{M^\frac{5}{2} \left( C_u - M^\frac{4}{3} D_u \right)^2}{4 \left( A_u + M^\frac{2}{3} B_u \right)},
\]

with

\[
A_u := \int_{\mathbb{R}^3} |\nabla u(x)|^2 dx, \quad B_u := c_1 \int_{\mathbb{R}^3} |u(x)|^{10} dx, \quad C_u := c_2 \int_{\mathbb{R}^3} |u(x)|^8 dx, \quad D_u := \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{u^2(x)u^2(y)}{|x-y|} dxdy.
\]
Indeed, they proved $M \ll 1 \mapsto I_0(M)$ is strictly subadditive by showing that $M \ll 1 \mapsto F_u(M)/M$ is strictly increasing, uniformly in $u$. The latter was established by making use of the inequalities

$$B_u \leq CM^{\frac{2}{3}}A_u, \quad D_u \leq CM^{\frac{2}{3}}C_u, \quad \forall u \in \mathcal{H}^1(\mathbb{R}^3).$$

(B1) follow from Hölder’s inequality, Sobolev’s inequality, Hardy-Littlewood’s inequality, and the interpolation inequality in Lebesgue spaces.

Then, let us fix any $\alpha \in (0, 1)$, and $M_1, M_2 \ll 1$. By (B1),

$$\frac{d^2F}{dM^2} = \frac{d^2}{dM^2} \left[ \frac{-M^{\frac{2}{3}} (C_u - M^{\frac{2}{3}} D_u)^2}{4 \left( A_u + M^{\frac{2}{3}} B_u \right)} \right] = -\frac{2G_u(M)}{9M^{\frac{2}{3}}(A_u + M^{\frac{2}{3}} B_u)^3}, \quad \forall M \ll 1,$$

where

$$G_u(M) := 14M^{\frac{2}{3}} B_u^2 D_u^2 + M^2(37A_u B_u D_u^2 - 10B_u^2 C_u D_u) + M^{\frac{2}{3}}(27A_u^2 D_u^2 - 30A_u B_u C_u D_u)
$$

$$+ M^{\frac{2}{3}}(-28A_u^2 C_u D_u + A_u B_u C_u^2) + 5A_u^2 C_u^2
$$

$$> A_u^2 C_u^2(-10M^2 - 30M^{\frac{2}{3}} - 28M^{\frac{2}{3}} + 5) > 0,$$

uniformly in $u$. Therefore, $F_u(M)$ is strictly concave for $M \ll 1$ uniformly in $u$. In consequence, for some $u^* = u^*, \alpha, M_1, M_2$

$$I_0(\alpha M_1 + (1 - \alpha)M_2) = F_{u^*}(\alpha M_1 + (1 - \alpha)M_2)
$$

$$> \alpha F_{u^*}(M_1) + (1 - \alpha)F_{u^*}(M_2)
$$

$$\geq \alpha I_0(M_1) + (1 - \alpha)I_0(M_2).$$

Since $\alpha, M_1,$ and $M_2$ were arbitrary, we conclude that $I_0$ is strictly concave for $M \ll 1$.  \(\square\)
