LOCAL RIGIDITY OF MANIFOLDS WITH HYPERBOLIC CUSPS
II. NONLINEAR THEORY

YANNICK GUEDES BONTHONNEAU AND THIBAULT LEFEUVRE

ABSTRACT. This paper is the second in a series of two articles whose aim is to extend a recent result of Guillarmou-Lefeuvre [GL19b] on the local rigidity of the marked length spectrum from the case of compact negatively-curved Riemannian manifolds to the case of manifolds with hyperbolic cusps. In this second paper, we deal with the nonlinear version of the problem and prove that such manifolds are locally rigid for nonlinear perturbations of the metric that decrease sufficiently at infinity. Our proof relies on the linear theory addressed in [GBL] and on two new ingredients: an approximate version of the Livsic Theorem and a careful analytic study of the operator $\Pi_2$, the generalized X-ray transform. In particular, we prove that the latter fits into the microlocal theory introduced in [Bon16] and developed in [GW17, GBL].

1. INTRODUCTION

1.1. Main results. A central problem in spectral theory is to identify an operator from its spectrum. A widely studied example is the Laplacian, and led to the question of Kac [Kac66], *can one hear the shape of the drum?* Several negative answers were given (even before the question was asked [Mil64]!). However in the case of negatively curved compact manifolds, whether the spectrum of the Laplacian determined the metric up to isometries remained open until Vignéras gave a negative answer [Vig80]. Since this spectrum also determines also the set of lengths of periodic geodesics, a refined version of the question was stated by Burns and Katok [BK85]. Instead of considering the set of lengths, one can consider the map that associates to each free homotopy class of curves the length of the corresponding unique closed geodesic. This is the *marked length spectrum*. Burns and Katok wondered whether this map determines the metric up to isometries.

Several authors, using various techniques, have made advances on this question. Katok [Kat88] proved the result when the two metrics are conformal. A few years later, Croke [Cro90] and Otal [Ota90] independently proved the conjecture for compact surfaces. Then, Hamenstädt [Ham99], using the work of Besson-Courtois-Gallot [BCG95], proved the conjecture when one of the metrics is a locally symmetric space.
The problem did not really evolve until the recent analytical proof of a local version of the conjecture by Guillarmou and the second author [GL19b]. For further references, we refer to the surveys of Croke [Cro04] and Wilkinson [Wil14].

We will be interested in the marked length spectrum rigidity question on noncompact manifolds whose ends are real hyperbolic cusps. More precisely, the case we will consider will be that of a complete negatively-curved Riemannian manifold \((M, g)\) with a finite numbers of ends of the form

\[ Z_{a,\Lambda} = [a, +\infty]_y \times (\mathbb{R}^d / \Lambda)_\theta, \]

where \(a > 0\), and \(\Lambda\) is a cristallographic group with covolume 1. On this end, we have the metric

\[ g = \frac{dy^2 + d\theta^2}{y^2}. \]

The sectional curvature of \(g\) in the cusp is constant equal to \(-1\), and the volume of \(Z_{a,\Lambda}\) is finite. In dimension two, all the cusps are the same (we must have \(\Lambda = \mathbb{Z}\)). However, in higher dimensions, if \(\Lambda\) and \(\Lambda'\) are not in the same orbit of \(SO(d, \mathbb{Z})\), \(Z_{a,\Lambda}\) and \(Z_{a',\Lambda'}\) are never isometric. In the following, we will call \textit{cusp manifolds} such manifolds.

Observe that in general \(\Lambda \subset O(d) \ltimes \mathbb{R}^d\); however, according to Bieberbach’s theorem, taking a finite cover we can assume that \(\Lambda\) is actually a lattice of translations in \(\mathbb{R}^d\). As a consequence, instead of dealing directly with the non-lattice case, we will consider the case of manifold with cusps, whose cusps are defined with lattices, and posit the existence of a finite group of isometries (acting freely).

We will denote by \(\mathcal{C}\) the set of hyperbolic free homotopy classes on \(M\), which is in one-to-one correspondent with the set of hyperbolic conjugacy classes of \(\pi_1(M, \cdot)\). From elementary Riemannian geometry, since the flow is Anosov, we know that for each such class \(c \in \mathcal{C}\) of \(C^1\) curves on \(M\), there is a unique representant \(\gamma_g(c)\) which is a \textit{geodesic} for \(g\) (see Lemma A.1 for a more extensive discussion about this). This is still true for small perturbations \(g'\) of a cusp metric of reference \(g\). The marked length spectrum of such a manifold \((M, g')\) is then defined as the map

\[ L_g : \mathcal{C} \rightarrow \mathbb{R}_+, \quad L_g(c) = \ell_g(\gamma_g(c)). \]

This map is invariant under the action of the group of diffeomorphisms that are homotopic to the identity, namely if \(\phi\) is a smooth diffeomorphism on \(M\) (satisfying some mild assumptions at infinity), one has \(L_{\phi^*g'} = L_{g'}\). The \textit{marked length rigidity problem} is to understand whether this is the only obstruction to the injectivity of the map \(g' \mapsto L_g\). In the case of a smooth compact manifold, given a fixed metric \(g\), the space of isometry classes of metrics (that is the orbits under the action of the group of diffeomorphisms homotopic to the identity) in a neighbourhood of \(g\) can be easily described (see [GL19b, Lemma 4.1] and [Ebi68] for the historical result): there
exists a small $C^{k,\alpha}$-neighbourhood $U$ (here $k \geq 2, \alpha \in (0,1)$) around $g$ such that for any metric $g' \in U$, there exists a unique $C^{k+1,\alpha}$-diffeomorphism close to the identity in this topology such that $\phi^*g' - g$ is solenoidal, also called divergence-free, where the divergence $D^*_g$ is the canonical one induced by $g$ and defined on 2-tensors (see Section §1.3.2 for a proper definition). For the sake of simplicity, we will now write $C^{k+\alpha}_*$ instead of $C^{k,\alpha}$ for the regularity spaces. Thus, isometry classes in a neighbourhood around $g$ are in 1-to-1 correspondence with (small) divergence-free symmetric 2-tensors. In the case of a cusp manifold, this is no longer the case and we will prove (see Proposition 4.1) that for $N \geq 1$ large enough, isometry classes of metrics $g'$ such that $\|g' - g\|_{y^{-N}_C} C_N$ is small (these are metrics $g'$ which differ from $g$ by a fast-decaying term, $y$ being a height function in the cusp) are in 1-to-1 correspondence with almost solenoidal (also called almost divergence-free) symmetric 2-tensors in $y^{-N}C^*_N$, which are tensors $f$ such that $(1 - P)D^*_gf = 0$, $P$ being a finite rank operator of rank 1. For the sake of simplicity, given a metric $g'$ close to $g$, we will denote by $[g']$ its class in the set of isometry classes identified with its almost solenoidal symmetric 2-tensor given by this correspondance (see Section §4.1 for further details). The main Theorem of this article is the following local rigidity result.

**Theorem 1.** Let $(M^{d+1},g)$ be a negatively-curved complete manifold whose ends are real hyperbolic cusps. There exists $N \geq 1$ large enough, $\varepsilon > 0$ small enough and a 1-codimensional submanifold $N_{\text{iso}}$ of the space of isometry classes such that the following holds. Let $g'$ be a metric such that $\|g' - g\|_{y^{-N}_C} < \varepsilon$, $[g'] \in N_{\text{iso}}$ and assume that the marked length spectrum of $g$ and $g'$ coincide i.e. $L_g = L_{g'}$. Then $g'$ is isometric to $g$.

A proper definition of the space $N_{\text{iso}}$ is given in (23). While we have not tracked down precisely the number $N$ it should be possible to express it in terms of the Lyapunov exponents of the metric $g$, so it should be controlled by uniform bounds on the sectional curvature of $g$. We strongly believe that the introduction of the
finite codimensional submanifold emerges as an artifact from the proof (which is of very analytical nature, whereas the problem is essentially geometric) but we were unable to relax this assumption.

If the Theorem is proved in the case of cusps defined with lattices, it follows for the general case. Indeed, we can take a finite cover for which the Theorem applies. We then have on this finite cover a finite group acting freely by isometries. Since all constructions are geometric, everything is appropriately equivariant. In particular, starting from an invariant metric $g'$ close to $g$, its almost solenoidal reduction will still be invariant.

For surfaces of finite area, following the works of [Cro90, Ota90], the conjecture of Burns-Katok was globally addressed by [Cao95] and our result is not new. However, in dimension $\geq 3$, this is the first non-linear result concerning the conjecture obtained allowing variable curvature on non-compact manifolds. As in [GL19b], the previous Theorem is actually a corollary of a stronger result which quantifies the distance between isometry classes in terms of the marked length spectrum in a neighborhood of a metric of reference $g$. This statement is new even in dimension 2.

**Theorem 2.** Let $(M^{d+1},g)$ be a negatively-curved complete manifold whose ends are real hyperbolic cusps. There exists $N \geq 1$ large enough, $C > 0$, $\varepsilon, s > 0$ small enough, $\gamma > 0$ and a 1-codimensional submanifold $\mathcal{N}_{iso}$ of the space of isometry classes such that the following holds. Let $g'$ be a metric such that $\|g' - g\|_{y^{-N}C_N} < \varepsilon$, $[g'] \in \mathcal{N}_{iso}$. Then, there exists a diffeomorphism $\phi : M \to M$ such that:

$$\|\phi^* g' - g\|_{H^{-1-s}} \leq C \|L_{g'} / L_g - 1\|_{\ell^\gamma(\mathcal{C})} \|g' - g\|_{y^{-N}C_N}^{1-\gamma}.$$ 

The diffeomorphism $\phi$ is of the form $\phi = e_V \circ T_u$, where $e_V(x) := \exp_x (V(x))$, for some vector field $V \in y^{-N}C_1^{N+1}(M, TM)$ close to 0 and $T_u(y, \theta) := (y, \theta + \chi u \cdot \partial_{\theta})$, for some $u \in \mathbb{R}^d$ close to 0.

Of course, assuming that $L'_{g'} = L_g$, one recovers the statement of Theorem 1. As a closing remark, observe that we are able to perturb only metrics with curvature exactly $-1$ in some neighbourhood of the cusp, because we are using the meromorphic continuation of the resolvent of the geodesic flow of $g$; this is only available when $g$ has curvature $-1$ outside of a compact set.

**1.2. Strategy of proof.** Let us give a word on the structure of the proof of Theorem 1. If one could apply the Inverse Function Theorem to $g' \mapsto L_{g'}$, one would obtain directly our local result. However, that is not possible, and we will circumvent this in several steps. The key ingredient of the proof is a detailed study of the X-ray transform $I^2_{g}$ acting on symmetric 2-tensors:

$$I^2_{g} h(c) := \frac{1}{\ell(\gamma_g(c))} \int_0^{\ell(\gamma_g(c))} h_{\gamma(t)}(\dot{\gamma}(t), \dot{\gamma}(t)) dt,$$
where \( c \in C \) is a free homotopy class and \( \gamma \) is a unit-speed parameterization of the unique (with respect to the metric \( g \)) closed geodesic in the free homotopy class \( c \). In [GBL], it was proved that the X-ray transform is \textit{solenoidal injective} in the sense that it is injective when restricted to \textit{solenoidal tensors} or \textit{divergence-free tensors} (see Definition 1.2). We will observe (see Lemma A.1) that, given \( g' \) close enough to \( g \):

\[
\frac{L'_{g'}(c)}{L_g(c)} - 1 = \frac{1}{2} I^g_2 f(c) + O(\|f\|_{C^3}^2),
\]

where \( f := g' - g \). In particular, if the two marked length spectrum agree, then

\[
(1) \quad \|I^g_2 f\|_{\ell^\infty(C)} \leq C\|f\|_{C^3}^2.
\]

The functional spaces on which \( I^g_2 \) acts are not practical for PDE analysis, so we need another operator that captures its essential features. In [Gui17], Guillarmou introduced a new operator \( \Pi_2 \) — which would correspond to \( "(I^g_2)^* I^g_2" \), mimicking the usual operator defined on a manifold with boundary, if that made sense. This operator turns out to be a pseudodifferential operator of order \(-1\), elliptic and injective on solenoidal tensors. What is important here is that this operator fits into the definition of \textit{admissible operators} introduced in [GBL]. We will then make a gauge transformation (see Proposition 4.1) so that \( g' \) becomes solenoidal in the new coordinates and for that to be possible, we will have to assume that \([g']\) lives in a 1-codimensional submanifold of the space of isometry classes (otherwise, \( g' \) would only be almost solenoidal which would not be enough to conclude). Then, as in [GL19b], the elliptic theory will allow us to invert \( \Pi_2 \) (see Theorem 6) and thus obtain a stability estimate, of the form \( \|h\|_{H^s} \leq C\|\Pi_2 h\|_{H^{s+1}}, h \in H^s \).

Then, we will link \( \Pi_2 \) to \( I_2 \) using an \textit{approximate Livsic Theorem} (see Theorem 5) which will give a stability inequality of the form \( \|f\|_{H^{-1-s}} \lesssim \|I_2\|^{\theta}\|f\|_{C^0}^{1-\theta} \) (see Theorem 7). Using (1), we will eventually lose some derivatives and obtain the inequality of the form

\[
\|y^N f\|_{C_N^s} \geq C,
\]

for some constants \( N, C > 0 \), depending only on \( g \). Taking \( g' \) close enough to \( g \) in the \( y^{-N} C_N^s \)-topology, we will obtain a contradiction, meaning that the first gauge transformation carried out to set ourselves in the solenoidal coordinates was actually the isometry we were looking for.

To close this introduction, we observe that in dimension \( \geq 3 \), there are non-isometric hyperbolic cusps, but we can only deal with a perturbed metric \( g' \) that is \textit{asymptotically} isometric to \( g \). We expect that this limitation is artificial. We hope that a detailed study of the polyhomogeneous expansion of the resolvent of the geodesic flow at 0 should suffice, but we leave this for future investigation.
1.3. Main results of the previous paper. In this paragraph, we recall the main results of [GBL].

1.3.1. Constructing parametrices. In [GBL], techniques of inversion of elliptic pseudodifferential operators have been developed for cusp manifolds, mainly inspired by the work of Melrose [Mel93]. The main obstacle to the construction of parametrices is that smoothing operators are no longer compact since the manifold is not compact. The setting we will be working with is that of the microlocal calculus introduced in [Bon16] and further expanded in [GW17]. One of the main results of [GBL] was the construction of parametrices for pseudodifferential operators on Hölder-Zygmund spaces $C^*_s$ (see [GBL, Section 4] and this will be used in Proposition 4.1 in order to obtain a gauge-fixing Lemma. This calculus was also used in [GW17] in order to invert the infinitesimal generator $X$ of the geodesic flow on the unit tangent bundle $SM$ which is not an elliptic operator. This will appear in Section §3, where the analytic properties of the meromorphic resolvents $(X \pm \tau)^{-1}$ at $\tau = 0$ will be investigated.

Since we want to state results in some generality, we will consider the following setup: we are given a non-compact manifold $N$ with a finite number of ends $N_\ell$, which take the form $Z_\ell \times F_\ell$, where $Z_\ell = \{ z \in Z_\ell \mid y(z) > a \}$, and $Z_\ell = [0, +\infty] \times \mathbb{R}^d / \Lambda_\ell$, $\Lambda_\ell \subset \mathbb{R}^d$ being a lattice and the slice $(F_\ell, g_{F_\ell})$ is a compact Riemannian manifold. We will use the variables $(z, \zeta) \in Z_\ell \times F_\ell$ and $z = (y, \theta) \in [a, +\infty) \times \mathbb{R}^d / \Lambda_\ell$. We assume that $N$ is endowed with a metric $g$, equal over the cusps to

$$\frac{dy^2 + d\theta^2}{y^2} + g_{F_\ell}.$$

We also have a vector bundle $L \to N$, and we assume that for each $\ell$, there is a vector bundle $L_\ell \to F_\ell$, so that

$$L|_{N_\ell} \simeq Z_\ell \times L_\ell.$$

Whenever $L$ is a hermitian vector bundle with metric $g_L$, a compatible connection $\nabla^L$ is one that satisfies

$$X g_L(Y, Z) = g_L(\nabla^L_X Y, Z) + g_L(Y, \nabla^L_X Z).$$

Taking advantage of the product structure, we impose that when $X$ is tangent to $Z$,

$$\nabla_X Y(z, \zeta) = d_z Y(X) + A_z(X) \cdot Y,$$
where the connection form $A_z(X)$ is an anti-symmetric endomorphism depending linearly on $X$, and $A(y\partial_y), A(y\partial_\theta)$ do not depend on $y, \theta$. In particular, we get that the curvature of $\nabla^L$ is bounded, as are all its derivatives. Such data $(L \to N, g, g_L, \nabla^L)$ will be called an admissible bundle. Given a cusp manifold $(M, g)$, the bundle of differential forms over $M$ is an admissible bundle. Since the tangent bundle of a cusp is trivial, any linearly constructed bundle over $M$ is admissible. For example, the bundle of forms over the Grassmann bundle of $M$, or over the unit cosphere bundle $S^*M$.

In the functional spaces, it will be important to consider the behaviour at infinity. In particular, we are led to study spaces of the form $y^\rho H^s$. Since the operators we consider preserve almost exactly the Fourier modes in the $\theta$ variable in the cusps, we introduce spaces $H^{s, \rho_0, \rho_\perp}$, which behave locally as $H^s$, and in the cusps, as $y^\rho_0 H^s$ for the zeroth Fourier mode, and as $y^\rho_{\perp} H^s$ in the other Fourier modes (see [GBL, Definition 3.1]). One of the main results of [GBL] is the following Theorem.

**Theorem 3.** Let $L$ be an admissible bundle. Assume that $L$ is endowed with a pseudo-differential operator $P$. Assume that it is $(\rho, \rho') - L^2$ (resp. $-L^\infty$)-admissible in the sense of [GBL, Definitions 3.2, 3.3, 4.3]. Also assume that it is uniformly elliptic in the sense of [GBL, Definition 2.3]. Then then there is a discrete set $S \subset (\rho, \rho')$ such that for each connected component $I \subset (\rho, \rho') \setminus S$, there is an operator $Q_I$ such that

$$PQ_I - 1 \quad \text{and} \quad Q_I P - 1$$

are compact operators on $H^{s, \rho'' - d/2, \rho_\perp}(L)$ (resp. $y^\rho'' C^s_*$) for $\rho'' \in I$, $s, \rho_\perp \in \mathbb{R}$. In particular, $P$ is Fredholm on these spaces, and the index does not depend on the space.

Roughly speaking, an admissible pseudodifferential operator $P$ does not make zero and non-zero Fourier modes in the $\theta$-variable interfere. We refer to [GBL] for further details and the precise definitions. The Hölder-Zygmund spaces $C^s_*(L)$ (for $s \in \mathbb{R}$) are defined thanks to a Paley-Littlewood decomposition (see [GBL, Section 4]). For $s \in \mathbb{R}_+ \setminus \mathbb{N}$, they coincide with the usual Hölder spaces induced by the metric. In [GBL, Section 4], boundedness of pseudodifferential operators on such spaces was established.

**1.3.2. X-ray transform and symmetric tensors.** For a general function $f \in C^0(SM)$, we define its X-ray transform by

$$I^g f(c) = \frac{1}{\ell(\gamma_g(c))} \int_0^{\ell(\gamma_g(c))} f(\gamma(t), \dot{\gamma}(t))dt,$$

where $c \in C$, $\gamma$ is a unit-speed parametrisation of the unique closed $g$-geodesic in $c$. Although we will mostly use 1- and 2-tensors, it is convenient to introduce notations
for general symmetric tensors. We will be using the injection
\[ \pi_m : v \in C^\infty(M, SM) \to v \otimes \cdots \otimes v \in C^\infty(M, SM^{\otimes m}). \]
Given a symmetric \( m \)-tensor \( h \in C^\infty(M, S^m(T^*M)) \), we can define a function on \( SM \) by pulling it back via \( \pi_m \):
\[ \pi_m^* h : (x, v) \mapsto h_x(v \otimes \cdots \otimes v). \]

**Definition 1.1.** The X-ray transform on symmetric \( m \)-tensors is defined in the same way as for \( C^0 \) functions on \( SM \): if \( h \) is a symmetric \( m \)-tensor,
\[ I^m_g h(c) = \frac{1}{\ell(\gamma_g(c))} \int_0^{\ell(\gamma_g(c))} \pi_m^* h(\gamma(t), \dot{\gamma}(t)) dt, \]
where \( t \mapsto \gamma(t) \) is a parametrization by arc-length, \( c \in C \).

Given a symmetric \( m \)-tensor \( h \), we can consider its covariant derivative \( \nabla h \), which is a section of \( T^*M \otimes S^m(T^*M) \to M \).

If \( \sigma \) denotes the symmetrization operator from \( \otimes^{m+1} T^*M \) to \( S^{m+1}(T^*M) \), we define the symmetric derivative as
\[ Dh = \sigma(\nabla h) \in C^\infty(M, S^{m+1}(T^*M)). \]

Given \( x \in M \), the pointwise scalar product for tensors in \( \otimes^m T^*_xM \) is defined by
\[ \langle v_1^* \otimes \cdots \otimes v_m^*, w_1^* \otimes \cdots \otimes w_m^* \rangle_x = \prod_{j=1}^m g(v_j, w_j), \]
where \( v_j, w_j \in T_x M \) and \( v_j^*, w_j^* \) denotes the dual vector given by the musical isomorphism. We can then endow the spaces \( C^\infty(M, S^m(T^*M)) \) with the scalar product
\[ \langle h_1, h_2 \rangle = \int_M \langle h_1(x), h_2(x) \rangle_x d\text{vol}(x) \]
We obtain a global scalar product on \( C^\infty(M, S^m(T^*M)) \) by declaring that whenever \( m \neq m' \), \( C^\infty(M, S^m(T^*M)) \) is orthogonal to \( C^\infty(M, S^{m'}(T^*M)) \). Following conventions we denote by \(-D^*\) the adjoint of \( D \) with respect to this scalar product. One can compute that for a tensor \( T \), for any orthogonal frame \( e_1, \ldots, e_{d+1} \),
\[ D^* T(\cdot) = \text{Tr}(\nabla T)(\cdot) = \sum_i \nabla_{e_i} T(e_i, \cdot). \]
The operator \( D^* \) is called the **divergence**, and one can check that it maps symmetric tensors to symmetric tensors.

**Definition 1.2.** Let \( f \) be a tensor so that \( D^* f = 0 \). Then we say that \( f \) is **solenoidal**.
We proved in [GBL, Lemma 5.5] that

**Lemma 1.1.** The $L^2$-orthogonal projection $\pi_{\ker D^*}$ on the kernel of $D^*$ is well defined, and is $(\lambda_d^-, \lambda_d^+)$-$L^2$ admissible with

$$\lambda_d^\pm = d/2 \pm \sqrt{d + d^2/4}.$$

One can check that $-1 < \lambda_d^- < -1/2 < d + 1/2 < \lambda_d^+ < d + 1$.

We can also define $\pi_{m*}$, which is the formal adjoint of $\pi_m^*$ — with respect to the usual scalar product on $L^2(SM)$. Moreover, one can check that

$$\pi_{m+1}^* D = X \pi_m^*.$$

Through $\pi_m^*$ we obtain another scalar product on symmetric tensors:

$$[u, v] = \int_{SM} \pi_m^* u \pi_m^* v.$$

Representing $[u, v] = \langle Au, v \rangle$, one can check that there are universal constants $C_m > 0$ such that $\|A\| \leq C_m$, $\|A^{-1}\| \leq C_m$ when restricted to $m$-tensors.

Using the microlocal framework developed in the first article, it was proved in [GBL] that any symmetric 2-tensor $f \in H^s(M, S^2(T^*M))$, $s \in \mathbb{R}$, can be uniquely decomposed as

$$f = Dp + h,$$

where $p \in H^{s+1}(M, S^1(T^*M))$, $h \in H^s(M, S^2(T^*M))$ and $D^* h = 0$. The following theorem was one of the main results of [GBL]

**Theorem 4.** Let $(M^{d+1}, g)$ be a negatively-curved complete manifold whose ends are real hyperbolic cusps. Let $-\lambda^2$ be the maximum of the sectional curvature. Then, for all $\alpha \in (0, 1)$ and $\beta \in [0, \lambda)$, the X-ray transform $I_2^\beta$ is injective on

$$y^\beta C^\alpha (M, S^2 T^* M) \cap H^1(M, S^2 T^* M) \cap \ker D^*.$$

**1.4. Outline of the paper.** In Section §2, we prove an approximate version of Livsic theorem in the same spirit as the one proved in [GL19a]. Section §3 is devoted to the introduction of the normal operator $\Pi_2$ which generalizes the X-ray transform. There, we prove that it is an admissible pseudodifferential operator (in our class) of order $-1$ which is elliptic on solenoidal tensors and we invert $\Pi_2$ modulo a compact remainder. Eventually, in Section §4.2, we gather all the previous results in order to prove the main theorems.

**Acknowledgements:** We thank Viviane Baladi, Sébastien Gouëzel, Colin Guillarmou, Sergiu Moroianu, Davi Obata, Frédéric Paulin, Frédéric Rochon for helpful remarks and useful discussions. T.L. also thanks the reading group on b-calculus in Orsay for sharing their knowledge and enthusiasm. T.L. has received funding from
2. Approximate Livsic theorem

The approximate version of the Livsic theorem will be crucial in the proof of our main Theorem. In the case of a closed manifold with Anosov flow, this result was recently proved by Gouëzel and the second author [GL19a] together with a finite version of the Livsic Theorem and successfully applied to quantifying the solenoidal injectivity of the X-ray transform.

**Theorem 5** (Approximate Livsic theorem). There exists $s_0 \in (0, 1)$, and $\nu > 0$ such that the following holds. For all $f \in C^1(SM)$, one can find $u, h \in H^{s_0}(SM)$ so that $f = Xu + h$ and for every $0 < \delta \leq d/2$, there exists a constant $C := C(\delta) > 0$, such that

$$\|h\|_{H^{s_0,-d/2+\delta,0}} \leq C\|f\|_{C^1}^{1-\nu\delta}\|I^g f\|_{\ell^\infty}^{\nu\delta}.$$

If we can prove this result with the additional condition that $\|I^g f\|_{\ell^\infty} \leq \varepsilon_0\|f\|_{C^1}$, then the full result is proved, because in the case $\|I^g f\|_{\ell^\infty} > \varepsilon_0\|f\|_{C^1}$, taking $h = f$, this lemma is a consequence of $C^1 \hookrightarrow H^{s_0,-d/2+\delta,0}$. From now on, we can and will thus assume that $\|f\|_{C^1} \leq 1$, and $\|I^g\|_{\ell^\infty}$ is small.

Let us briefly explain the mechanism behind the proof. The idea is to divide the manifold $M := SM$ into a compact part $M_\varepsilon$ and a non-compact part $M \setminus M_\varepsilon$ whose volume is controlled by some power of $\varepsilon > 0$. In the compact part, the arguments roughly follow that given in [GL19a], to prove the approximate Livsic theorem on a closed manifold. The idea is to construct a coboundary $Xu$ by defining $u$ (as a primitive of $f$) on an orbit which is both sufficiently dense and sufficiently “separated” (see the definition in §2.2.3) so that one can control the Hölder norm of the difference $h := f - Xu$. In the non-compact part, however, the control of the $H^s$-norm of $h$ is obtained thanks to the estimate on the volume of $M \setminus M_\varepsilon$. One could be much more precise on the exponents appearing, however, there does not seem to be anything to be gained by such precision.

2.1. General remarks on cusps. Since we will be considering the geodesic flow on cusp manifolds, it is convenient to introduce some coordinates on $SZ$. Given a vector in $TZ$,

$$v = v_y y \partial_y + v_\theta \cdot y \partial_\theta,$$
one has that \( |v|^2 = v_y^2 + v_{\theta}^2 \). In particular, we can take spherical \((\phi, u)\) coordinates in \(SZ\). Here, \( \phi \in [0, \pi] \) and \( u \in S^{d-1} \), and \((y, \theta, \phi, u)\) denotes the point \( \cos \phi y \partial_y + \sin \phi y \partial_{\theta} + y \sin \phi u \cdot \partial_{\theta} \).

The geodesic vector field over \(Z\) is then given by

\[
X = \cos \phi y \partial_y + \sin \phi \partial_{\phi} + y \sin \phi u \cdot \partial_{\theta}.
\]

Observe that \(u\) is invariant under the geodesic flow of the cusp.

\[2.1.1. \; \text{Hyperbolic dynamics.}\] Since the curvature is globally assumed to be negative, the geodesic flow \(\varphi_t\) on \(M := SM\) is Anosov, in the sense that there exists a continuous flow-invariant splitting

\[
T_z(M) = \mathbb{R}X(z) \oplus E_u(z) \oplus E_s(z),
\]

where \(E_s(z)\) (resp. \(E_u(z)\)) is the stable (resp. unstable) vector space at \(z \in M\), such that

\[
|d\varphi_t(z) \cdot \xi_{\varphi_t(z)}| \leq Ce^{-\lambda|t|}|\xi|_z, \quad \forall t > 0, \xi \in E_s(z),
\]

\[
|d\varphi_t(z) \cdot \xi_{\varphi_t(z)}| \leq Ce^{-\lambda|t|}|\xi|_z, \quad \forall t < 0, v \in E_u(z),
\]

for some uniform constants \(C, \lambda > 0\). The norm, here, is given in terms of the Sasaki metric on \(M = SM\). Observe that the Sasaki metric is uniformly equivalent on \(SZ\) to the product metric given by \(SZ \simeq Z \times S^d\). We define the global stable and unstable manifolds \(W_s(z), W_u(z)\) by:

\[
W_s(z) = \{z' \in M, d(\varphi_t(z), \varphi_t(z')) \to_{t \to +\infty} 0\}
\]

\[
W_u(z) = \{z' \in M, d(\varphi_t(z), \varphi_t(z')) \to_{t \to -\infty} 0\}
\]

For \(\varepsilon > 0\) small enough, we define the local stable and unstable manifolds \(W_{s}^{\varepsilon}(z) \subset W_s(z), W_{u}^{\varepsilon}(z) \subset W_u(z)\) by:

\[
W_{s}^{\varepsilon}(z) = \{z' \in W_s(z), \forall t \geq 0, d(\varphi_t(z), \varphi_t(z')) \leq \varepsilon\}
\]

\[
W_{u}^{\varepsilon}(z) = \{z' \in W_u(z), \forall t \geq 0, d(\varphi_{-t}(z), \varphi_{-t}(z')) \leq \varepsilon\}
\]

We fix once for all such an \(\varepsilon_0\) small enough.

**Example 2.1.** In the cusp \(Z_\ell\), in the usual coordinates \((y, \theta, \phi, u) \in [a, +\infty) \times T^d \times [0, \pi] \times S^d\), we consider a point \(z = (y_0, \theta_0, 0, 0)\). Then, \(W_s(z) = \{(y_0, \theta, 0, 0), \theta \in T^d\}\).
2.1.2. Exit time in the cusp. It is convenient to think of cusps as (non-compact) manifolds with (geodesically) strictly convex boundary. We will denote by 
\[ \partial_-SZ = \{(a, \theta, \phi, u), \theta \in \mathbb{T}^d, \phi \in [0, \pi/2], u \in S^d\}, \]
the incoming boundary and correspondingly \( \partial_+SZ \) the outgoing boundary. Given \( z \in SZ \), \( \ell_+ (z) \leq +\infty \) will denote its exit time from the cusp in the future, and \( -\infty \leq \ell_- (z) \) its exit time in the past.

From the expression of \( X \) in \( SZ \), we see that the angle \( \phi \) evolves according to the ODE
\[ \dot{\phi} = \sin(\phi). \]
Given \( z := (x, \phi, u) \in \partial_-SZ \), its exit angle satisfies \( \phi(\varphi_{\ell_+}(z)) = \pi - \varphi \). Thus, a direct integration of the ODE, gives that:
\[ z \in \partial_-SZ, \quad \ell_+(z) = -2 \ln |\tan(\phi/2)| \]

2.2. Covering a cusp manifold.

2.2.1. Transverse sections in the cusps. We now fix \( \eta > 0 \) small enough so that the closing lemma is satisfied at this scale. For the sake of simplicity, we will write the proof as if there were a single cusp: this is just a matter of notation and does not affect the content of the proof. By this means, we hope to simplify the reading.

We consider on the cusp the following transverse sections to the geodesic flow:
\[ \Sigma_{\text{out}} = \{(a, \theta, \phi, u), \theta \in \mathbb{T}^d, \phi \in [0, \pi/4], u \in \mathbb{S}^{d-1}\}, \]
\[ \Sigma_{\text{in}} = \{(a, \theta, \phi, u), \theta \in \mathbb{T}^d, \phi \in [3\pi/4, \pi], u \in \mathbb{S}^{d-1}\}. \]

Note that, up to taking a larger \( a' > a \) and readjusting the constants, we can always assume that \( \Sigma_{\text{out,in}} \) have diameter less than \( \eta \). We consider the flowboxes
\[ U_{\text{out}} = \{\varphi_t z, \ z \in \Sigma_{\text{out}}, \ t \geq -\eta, \ \phi(\varphi_t z) \leq \pi/2 + \eta\}, \]
\[ U_{\text{in}} = \{\varphi_t z, \ z \in \Sigma_{\text{in}}, \ t \leq \eta, \ \phi(\varphi_t z) \geq \pi/2 - \eta\}. \]

Their union covers the whole cusp. It will also be convenient to give a name to the incoming unstable manifold
\[ D_\infty := \{(y, \theta, \pi, u), \ y \geq a, \ \theta \in \mathbb{T}^d, \ u \in \mathbb{S}^{d-1}\}. \]

In \( U_{\text{out}} \) (resp. \( U_{\text{in}} \)), we denote by \( \pi \) the map \( \pi(z) = \varphi_{\ell_-(z)}(z) \) (resp. \( \pi(z) := \varphi_{\ell_+(z)}(z) \)).

**Lemma 2.1.** There exists a constant \( C > 0 \) such that for any point \( z \in U_{\text{out}} \),
\[ \|\nabla \ell_-(z)\| \leq C \text{ and } \|d_z \pi\| \leq C e^{\ell_-(z)}. \]

**Proof.** Let \( z \in U_e \). By construction, one has: \( y(\varphi_{\ell_-(z)}(z)) = a \). Thus, by differentiating with respect to z, one gets for any \( Z \in T_zM \):
\[ dy (d_z \varphi_{\ell_-(z)}(Z) + (\nabla \ell_-(z) \cdot Z) X(\varphi_{\ell_-(z)}(z))) = 0 \]
In other words, if we write \( \varphi_{\ell}(z) = (a, \theta, \varphi, u) \) and use the expression (4):

\[
|\langle \nabla \ell(z) \cdot Z \rangle| = |\cos(\varphi)|^{-1} \left| \frac{dy}{y} \left( d_{z} \varphi_{\ell}(z) \right) \right|
\]

Now, by definition of the section \( \Sigma_{\text{out}} \), there exists a uniform lower bound 
\( |\cos(\varphi)| \geq \cos(\pi/4) = 1/\sqrt{2} > 0 \).

Since the equation for \( y_t := y(\varphi_t(z)) \) is

\[
\dot{y} = y \cos \phi,
\]

we deduce that

\[
\frac{dy_t}{y_t} = \frac{dy_0}{y_0} + \int_0^t \frac{\partial \cos \phi_s}{\partial \phi_0} \, ds \, d\phi_0.
\]

For \( \phi_0 < \pi/2 + \eta \), and in negative time, \( |\partial \phi_s/\partial \phi_0| \leq Ce^{-Cs} \), so that (since \( dy/y \) is unitary with respect to the dual metric) we get:

\[
\forall Z \in T_z \mathcal{M}, \quad |\langle \nabla \ell(z) \cdot Z \rangle| \leq C|Z|
\]

This provides the desired result.

As to the differential of the projection \( \pi \), one has to write \( \pi(z) = \varphi_{\ell}(z) \) and differentiate with respect to \( z \). The result then follows from the previous arguments. \( \square \)

### 2.2.2. Covering the unit tangent bundle.

We now choose a finite number of smooth transverse sections \( \langle \Sigma_i \rangle_{1 \leq i \leq N} \) to the flow of diameter less than \( \eta \) so that the flowboxes

\[
\mathcal{U}_{\text{out}} \cup \mathcal{U}_{\text{in}} \cup \bigcup_{i=1}^{N} \mathcal{U}_i
\]

form a cover of \( \mathcal{M} \), where \( \mathcal{U}_i = \varphi_{(-\eta,\eta)}(\Sigma_i) \). We then fix a partition of unity \( 1 = \sum_i \theta_i \) associated to this cover. Note that this can be done so that the function \( \theta_{\text{out}} \) is such that \( X \theta_{\text{out}} \) is \( C^\infty \)-bounded. Indeed, one first picks a cutoff \( \chi_{\text{out}} \) on \( \Sigma_{\text{out}} \) (equal to 1 in a neighborhood of \( \mathcal{N} := \{(a, \theta, 0, u), \theta \in \mathbb{T}^d, u \in \mathbb{S}^{d-1}\} \)) and then pushes this function by the flow in order to obtain a function \( \chi_{\text{out}} \) on \( \mathcal{U}_{\text{out}} \). It remains to multiply \( \chi_{\text{out}} \) by a smooth functions \( \chi_{\text{out}}^{\text{height}}(y) \) and \( \chi_{\text{out}}^{\text{angle}}(\varphi) \), equal to 1 respectively for \( y \geq a \) and \( \varphi \leq \pi/2 \). A similar construction is available for \( \mathcal{U}_{\text{in}} \) and \( \theta_{\text{in}} \).

We set \( \mathcal{M}_0 := S \mathcal{M}_0 \) and

\[
\mathcal{M}_\varepsilon = \mathcal{M} \setminus \left\{ \varphi_t z \mid 0 \leq t \leq \ell_+(z), z = (a, \theta, \phi, u) \in \Sigma_{\text{out}}, \phi \in [0, \varepsilon^{2\nu}] \right\} \cup D_\infty
\]

where \( \nu, \varepsilon > 0 \) will be chosen small enough at the end. We will pay attention to the fact that the different constants appearing in the following paragraphs do not depend on \( \nu \), unless explicitly stated. Note that by construction, using (7), any point in \( \mathcal{M}_\varepsilon \) will exit the cusp (either in the future or in the past) by a time which is bounded above by \( C + 2\nu |\log \varepsilon| \), which we state as a

**Lemma 2.2.** There exists a constant \( C > 0 \) such that for all \( z \in \mathcal{M}_\varepsilon \), there exists a time \( t \) such that \( |t| \leq C + 2\nu |\log \varepsilon| \) and \( \varphi_t z \in \mathcal{M}_0 \).
2.2.3. A well-designed periodic orbit. As mentioned in the introduction to this Section, the proof heavily relies on the fact that one can find a suitable orbit, which will be used in order to define an approximate coboundary. In the following, we will denote by $W_\theta(z) = \bigcup_{w \in W_\theta^u(z)} W_\theta^s(w)$ for $\theta > 0$. This is a Hölder section which is transverse to the flow. We will say that a segment of orbit $S$ is $\theta$-transversally separated if for all $z \in \mathcal{M}$, $S$ intersects $W_\theta(z)$ at most in one point. We also say that a segment of orbit is $\eta > 0$ dense in $\Omega$ if its $\eta$-neighbourhood contains $\Omega$.

**Lemma 2.3.** There are constants $\beta_1 > 1 > \beta_d > 0$ such that for all $\varepsilon > 0$ small enough, there exists a periodic point $z_0$ with period $T \leq \varepsilon^{-1/2}$, such that in $\mathcal{M}_\varepsilon$ its orbit is $\varepsilon^{\beta_1}$-transversally separated and $(\varphi_t z_0)_{0 \leq t \leq T-1}$ is $\varepsilon^{\beta_d}$-dense. Moreover, there exists a segment of length $\leq C$ which is $\eta$-dense in $\mathcal{M}_0$.

**Proof.** The proof is rather identical to that of [GL19a] so we skip it. The main difference is that, for any $z, w \in \mathcal{M}_\varepsilon$, the non-compactness does not allow to find a segment of orbit $\gamma_{z,w}$ joining a ball of radius $\rho$ around $z$ to a ball of radius $\rho$ around $w$ in a time $T(\rho)$ which is independent of $\varepsilon$. However, thanks to Lemma 2.2, one can prove that this time $T(\rho, \varepsilon)$ is bounded by $C + 2\nu|\log \varepsilon|$, which is harmless for the rest of the proof. We refer to the proof in [GL19a] for further details. \qed
2.3. Proof of the approximate Livsic Theorem. We first construct the coboundary $Xu$ and then show that it satisfies the required estimate. Recall that $\|f\|_{C^1} \leq 1$, and $\varepsilon := \|I^\theta f\|_{L^\infty}$ is assumed to be small. It will only be required to be small enough so that we can apply Lemma 2.3, and get a corresponding good orbit $\varphi_t z_0$.

2.3.1. Construction of the coboundary. On the periodic orbit of $z_0$, we define the function $\tilde{u}$ by $\tilde{u}(\varphi_t z_0) = \int_0^t f(\varphi_s z_0)ds$. Note that it may not be continuous at $z_0$. To circumvent this problem, we will rather define $\tilde{u}$ only on the set $\mathcal{O}(z_0) := (\varphi_t x_0)_{0 \leq t \leq T-1}$ (which satisfies the desired properties of density and transversality).

Lemma 2.4. Assume $\beta := (2\beta_t)^{-1} < 1/2$. Then, there exists $C > 0$, independent of $\varepsilon$, such that $\|\tilde{u}\|_\beta \leq C$.

Here $\|f\|_\beta := \sup_{z,z'} |\frac{f(z) - f(z')}{d(z,z')^\beta}|$ denotes the Hölder part of the $C^\beta$-norm.

Proof. If $z, z'$ are close enough and on the same piece of local orbit, the result is obvious. We can thus assume $z, z' \in \mathcal{O}(z_0)$ and $z' \in W_\eta(z)$. Then, by separation of the orbit, we know that $d(z, z') \geq \varepsilon^{\beta_t}$. Without loss of generality, we can assume that $z' = \varphi_z z_0$ and $z = \varphi_t z_0$ with $t > t'$ and thus

$$\tilde{u}(z) - \tilde{u}(z') = \int_0^t f(\varphi_s z')ds.$$ 

By the Anosov closing lemma, we can close the segment of orbit $(\varphi_s z')_{0 \leq s \leq t}$, that is there exists a periodic point $z_p$ such that $d(z, z_p) \leq C d(z, z')$ and of period $t_p = t + \tau$, where $|\tau| \leq C d(z, z')$ which shadows the segment. Then:

$$|\tilde{u}(z') - \tilde{u}(z)| \leq \left| \int_0^t f(\varphi_s z')ds - \int_0^{t_p} f(\varphi_s z_p)ds \right| + \left| \int_0^{t_p} f(\varphi_s z_p)ds \right| = (I) + (II)$$

The first term (I) is bounded by $C d(z, z')^\beta$ by hyperbolicity, with $C$ depending only on the global hyperbolicity of the flow. The second term (II) is bounded — by assumption — by $\varepsilon t_p$. But

$$\varepsilon t_p \leq 2\varepsilon t \leq 2\varepsilon T \leq 2\varepsilon^{1/2} \leq 2d(z, z')^{1/(2\beta_t)}.$$ 

This finishes the proof. $\blacksquare$

We consider $i \in \{\text{out}, \text{in}, 1, \ldots, N\}$. Given $z \in \Sigma_i \cap \mathcal{O}(z_0)$, we define $\tilde{u}_i(z) := \tilde{u}(z)$. We have the

Lemma 2.5. There exists a constant $C > 0$ such that $\|\tilde{u}_i\|_{C^\beta} \leq C$. 

Lemma 2.6. Proof. Of course, since \( u \in S \), the terms (I) and (III) are controlled by a constant \( C \), using the Hölder regularity provided by the previous Lemma. The control of the term (II) follows from the fact that \( S \) has length \( \leq C \) and that \( \| f \|_{C^0} \leq \| f \|_{C^1} \leq 1 \).

For \( i \in \{ \text{out}, \text{in}, 1, \ldots, N \} \), we then extend \( \tilde{u}_i \) to \( \Sigma_i \) by the formula

\[
\tilde{u}_i(x) := \sup \{ \tilde{u}(y) - \| u \|_{C^0(\mathcal{O}(z_0))} d(x, y)^\beta \mid y \in \mathcal{O}(z_0) \cap \Sigma_i \}.
\]

One finds that \( \| u_i \|_{C^\beta} \leq C \| \tilde{u}_i \|_{C^\beta} \leq C \). We then push the function \( u_i \) by the flow in order to define it on \( U_i \) by setting for \( z \in \Sigma_i, \varphi_i z \in U_i \):

\[
u_i(\varphi_i z) := u_i(z) + \int_0^t f(\varphi_s z) ds.
\]

We now set \( u := \sum_i u_i \theta_i \) and \( h := f - Xu = -\sum_i u_i X \theta_i \).

2.3.2. Regularity of the coboundary. By construction, the functions \( X \theta_i \) are uniformly bounded in \( C^\infty \), independently of \( \varepsilon \). Thus, for \( i \in \{ 1, \ldots, N \} \), the functions \( u_i X \theta_i \) are in \( C^\beta \) with a Hölder norm independent of \( \varepsilon > 0 \). However, this is not the case of the function \( u_{\text{out}} X \theta_{\text{out}} \), \( u_{\text{in}} X \theta_{\text{in}} \). We have local results. First, let us introduce \( \overline{u} \) and \( \overline{h} \) the averages with respect to the \( \theta \) variable in the cusps.

Lemma 2.6. We have the following estimates in the cusps:

\[
\sup_{d(z, z') \leq 1} \frac{|u(z)|}{d(z, z')^\beta}, \quad \frac{|h(z) - h(z')|}{d(z, z')^\beta} \leq C y^\beta.
\]

\[
\sup_{d(z, z') \leq 1} \frac{|\overline{u}(z) - \overline{u}(z')|}{d(z, z')^\beta}, \quad \frac{|\overline{h}(z) - \overline{h}(z')|}{d(z, z')^\beta} \leq C.
\]

Proof. Of course, since \( \theta_{\text{in, out}} \) do not depend on \( \theta \), the estimates on \( u \) imply those on \( h \). It is thus sufficient to control \( u_{\text{out}} \). We first control the \( C^0 \)-norm. For \( z \in \Sigma_{\text{out}}, \)
t \geq -\eta, \phi(\varphi_{t}z) < \pi + \eta, we have:

\[ |u_{out}(\varphi_{t}z)| = \left| u_{out}(z) + \int_{0}^{t} f(\varphi_{s}z)ds \right| \leq \|u_{e}|_{C_{e}}\|_{C^{0}} + |t|\|f\|_{C^{0}} \leq C + (|\ell_{-}(z)| + \eta)\|f\|_{C^{0}}. \]

As to the \(\beta\)-Hölder norm, we have for \(z, z' \in \mathcal{U}_{out}\) (such that \(d(z, z') \leq 1\) assuming without loss of generality that \(|\ell_{-}(z')| \geq |\ell_{-}(z)|\):

\[ |u_{out}(z) - u_{out}(z')| \leq |u_{out}(\pi(z)) - u_{out}(\pi(z'))| \]

\[ + \int_{0}^{\ell_{-}(z)} |f(\varphi_{s}(z)) - f(\varphi_{s+\ell_{-}(z')-\ell_{-}(z)}(z'))|ds + 2|\ell_{-}(z) - \ell_{-}(z')|\|f\|_{C^{0}} : = (I) \]

\[ + \int_{0}^{\ell_{-}(z)} \|f\|_{C^{0}}|\varphi_{s}, \varphi_{s+\ell_{-}(z')-\ell_{-}(z)}(z')|^{\beta}ds \leq C \int_{0}^{\ell_{-}(z)} e^{\lambda_{max}\beta s} d(z, \varphi_{\ell_{-}(z')-\ell_{-}(z)}z')^{\beta} ds \leq \frac{C}{\lambda_{max}^{\beta}} e^{\lambda_{max}\beta|\ell_{-}(z)|} d(z, z')^{\beta}, \]

and:

\[ (III) \leq Cd(z, z'). \]

By Lemma 2.1, successively, using that \(|\ell_{-}(z)| \leq C + |\log y|:

\[ (I) \leq \|u_{out}|_{C_{out}}\|_{C^{0}}d(\pi(z), \pi(z'))^{\beta} \leq Ce^{\ell_{-}(z)|\beta} d(z, z')^{\beta}, \]

\[ (II) \leq \int_{0}^{\ell_{-}(z)} \|f\|_{C^{0}}d(\varphi_{s}, \varphi_{s+\ell_{-}(z')-\ell_{-}(z)}z')^{\beta}ds \]

\[ \leq C \int_{0}^{\ell_{-}(z)} e^{\lambda_{max}\beta s} d(z, \varphi_{\ell_{-}(z')-\ell_{-}(z)}z')^{\beta} ds \leq \frac{C}{\lambda_{max}^{\beta}} e^{\lambda_{max}\beta|\ell_{-}(z)|} d(z, z')^{\beta}, \]

and:

\[ (III) \leq Cd(z, z'). \]

Here, \(\lambda_{max}\) is the maximal Lyapunov exponent of the flow in the cusp, which is just 1.

Let us now deal with \(\pi(y, \varphi)\) and \(\eta\). Since the flow is equivariant with respect to translations in the \(\theta\) variable, denoting by \(\pi(y, \varphi)\) the point \((a, \varphi_{0})\) with \(\sin \varphi_{0} = a \sin \varphi/y\), we find that

\[ \pi = \pi_{0}(y, \varphi) + \int_{-\ell_{-}(y, \varphi)}^{0} f(\varphi_{t}(y, \varphi))dt. \]

In particular, the argument above carries out again except that it is much better because the life.

Then, in (8), terms (I) and (II) become much better. Indeed, we can assume that \(\theta(z) = \theta(z')\). Since \(z, z' \in \mathcal{U}_{out}\), they must thus be in the same weak unstable manifold of the geodesic flow of the full cusp, and \(\varphi_{|\ell_{-}(z')-\ell_{-}(z)}(z')\) is in the strong stable manifold of \(z\). In that case, without loss of generality, we can assume that \(\ell_{-}(z) =
As a consequence, taking \( |\ell(z)| \leq Ce^{-|\ell(z)|}d(z,z') \), we obtain
\[
d(\varphi_s(z), \varphi_s(z')) \leq Ce^{-s}d(z,z').
\]

Now, we claim that \( h \) vanishes on \( \mathcal{O}(z_0) \): indeed, for \( i \in \{\text{out, in, 1, \ldots, N}\} \), on \( \mathcal{U}_i \cap \mathcal{O}(z_0) \) one has \( u_i \equiv \tilde{u} \) and thus \( h = -\tilde{u} \sum_i X_i \theta_i = -\tilde{u} X \sum_i \theta_i = -\tilde{u} X 1 = 0 \). Next, recall that \( y \leq C\varepsilon^{-2\nu} \) in \( \mathcal{M}_\varepsilon \), so that by Lemma 2.6, \( \|h\|_{\mathcal{M}_\varepsilon} \|C^{\beta} \leq C\varepsilon^{-2\beta \nu} \). Combining this with the fact that \( \mathcal{O}(z_0) \) is \( \varepsilon^{\beta_d} \)-dense in \( \mathcal{M}_\varepsilon \), we deduce:

**Lemma 2.7.** The coboundary satisfies
\[
\|h\|_{\mathcal{M}_\varepsilon} \|C^{0} \leq C\varepsilon^{\beta(\beta_d - 2\nu)}.
\]

We can now end the proof of Theorem 5.

**Proof of Theorem 5.** By Lemma 2.6, we have that \( u, h \in \psi^{\beta} C^{\beta} (SM) \subset H^{s}(SM) \) for \( 0 < s < \beta \) (since \( \beta < 1/2 < d/2 \)). On the other hand, the zeroth Fourier mode is much better, with \( C^{\beta} \) estimates. Using [GBL, Lemma 4.7], we deduce that \( u, h, Xu \in H^{s-a/2+\delta_0,0} (SM) \), for any \( \delta > 0 \) small enough, \( 0 < s < \beta \). We take now some \( 0 < \delta < d \), and decompose
\[
\|y^{d/2-\delta} h\|_{L^2(SM)}^2 = \int_{\mathcal{M}_\varepsilon} y^{d-2\delta} h^2 d\mu + \int_{\mathcal{M}_\varepsilon \setminus \mathcal{M}_\varepsilon} y^{d-2\delta} h^2 d\mu,
\]
where \( |(I)| \leq C\varepsilon^{\beta(\beta_d - 2\nu)} \) by Lemma 2.7 as long as \( \delta > 0 \).

For \( |(II)| \), using the logarithmic bound on \( h \) given by Lemma 2.6, we get
\[
| (II) | \leq C \int_0^{\pi/2} \sin^{d-1} \phi d\phi \int_{\frac{\pi}{y} \sin \phi < \varepsilon^{2\nu}, y > a} \frac{(1 + \log y)}{y^{1+2\delta}} dy
\]
\[
\leq C \int_0^{\pi/2} \sin^{d-1} \phi d\phi \left( \frac{a}{\varepsilon^{2\nu}} \right) -2\delta \log \frac{a \sin \phi}{\varepsilon^{2\nu}}
\]
\[
\leq C (\varepsilon^{2\nu d} + \varepsilon^{4\nu \delta} |\log \varepsilon|).
\]
As a consequence, taking \( \nu > 0 \) small enough so as to ensure that \( \beta(\beta_d - \nu) \geq \nu d \), we obtain
\[
\|y^{d/2-\delta} h\|_{L^2} \leq C\varepsilon^{2\nu \delta} |\log \varepsilon|.
\]

Then, we take \( s > 2\beta/3 \) (to absorb the log term) and we interpolate between \( H^{0,-d/2+\delta_0} \) and \( H^{s,-d/2+\delta_0} \):
\[
\|h\|_{H^{\beta/3,-d/2+\delta_0}} \leq C\varepsilon^{\nu \delta}.
\]
Here, recall that $\beta = 1/(2\beta_t)$.

3. The normal operator

3.1. Definition and results. The X-ray transform is not a very convenient operator for PDE analysis, and we would like to replace it with an operator that acts on distributions in some sense. We will be able to do this in a weak sense, and this was the center of the paper [GL19b]. Given $f, g \in H^s(SM)$, with $s > 0$, and so that $\int f = \int g = 0$, we denote

$$\langle \Pi f, g \rangle := \int_{\mathbb{R}} \langle f \circ \varphi_t, g \rangle dt.$$  

We also require that $\langle \Pi 1, 1 \rangle = 1$. Once a proper meaning has been given to this formula, the proof of the following proposition is similar to that of [Gui17, Theorem 1.1]:

**Proposition 3.1.** There exists a constant $C > 0$ such that for any $s > 0$, $\rho \in (-d/2, d/2)$, $|\rho_\perp| \leq |\rho|$, the operator $\Pi$ is bounded from $H^{s+C|\rho|, \rho, \rho_\perp}(SM)$ to $H^{-s-C|\rho|, \rho, \rho_\perp}(SM)$. It is symmetric with respect to the $L^2$ duality, and

1. $\forall f \in H^{s, \rho, \rho_\perp}(SM)$, $X\Pi f = 0$.
2. $\forall f \in H^{s, \rho, \rho_\perp}(SM)$ such that $Xf \in H^{s, \rho, \rho_\perp}(SM)$, $\Pi Xf = 0$.
3. If $f \in H^{s, \rho, \rho_\perp}(SM)$, $\langle f, 1 \rangle_{L^2} = 0$ then: $f \in \ker \Pi$ if and only if there exists a solution $u \in H^{s, \rho, \rho_\perp}(SM)$ to the cohomological equation $Xu = f$ (such a $u$ is unique modulo constants).
4. The operator $\Pi$ is positive in the sense of quadratic forms, that is for all $s > 0$, $f \in H^{s, 0, 0}(SM)$, $\langle \Pi f, f \rangle_{L^2(SM)} \geq 0$.

The operator $\Pi$ will play the role of the so-called normal operator $I^* I$ in the case of X-ray transform on manifolds with boundary. While $\Pi$ is not a very regular operator, its action on 2-tensors is very convenient for our purposes. Indeed, we let:

$$\Pi_2 := \pi_2 \Pi \pi_2^*.$$  

A priori, $\Pi_2$ is defined as an operator from the spaces $H^{s, \rho, \rho_\perp}(M, S^2(T^*M)) \to H^{-s, \rho, \rho_\perp}(M, S^2(T^*M))$, but we will prove:

**Theorem 6.** $\Pi_2$ is pseudo-differential: it is a $(0, d)$-$L^2$ admissible operator of order $-1$. It is invertible on solenoidal tensors, in the sense that there exists another $(0, d)$-$L^2$-admissible operator $Q_2$, of order 1, such that:

$$Q_2 \Pi_2 = \Pi_2 Q_2 = \pi_{\ker D^*},$$  

where $\pi_{\ker D^*}$ is the $L^2$-orthogonal projection on the kernel of $D^*$. 

The proof of this central theorem will be given in the second half of this section. For now, let us just observe the following. Since $\pi^*_2 D = X \pi^*_1$, we get that $\Pi_2 D = 0$, and $D^* \Pi_2 = 0$. In particular, $\Pi_2$ can be seen as a map from $\ker D^*$ to itself. We also obtain a stability estimate

**Theorem 7.** There exist $s_0, \theta \in ]0,1[$ such that for all $0 < s < s_0$,

$$\forall f \in C^1(M, S^2(T^*M)) \text{ with } D^* f = 0, \quad \|f\|_{H^{-s,1,0,0}} \leq C\|I_2 f\|_{L^\infty}^{\nu d/2} \|f\|^{1-\theta}_{C^1}.$$  

We can also consider the action of functions instead of 2-tensors:

$$\Pi_0 = \pi_0 \Pi \pi_0^*.$$

This is also a pseudo-differential operator of order $-1$. We will see (in Remark 3.1) that a similar statement as Theorem 6 holds, and so does a stability estimate for Hölder functions.

**Proof.** Let $f \in C^1(M, S^2(T^*M))$ be such that $D^* f = 0$ and $\|f\|_{C^1} \leq 1$. By Theorem 5, we can write $\pi^*_2 f = Xu + h$, with $\|h\|_{H^{s,0,0}} \lesssim \|I_2 f\|_{L^\infty}^{\nu d/2}$ for some $1 > \nu > 0$. Thus for $0 < s < s_0$,

$$\|f\|_{H^{-s,1,0,0}} \lesssim \|\Pi_2 f\|_{H^{-s,0,0}} \lesssim \|\pi_2 \Pi h\|_{H^{-s,0,0}} \lesssim \|h\|_{H^{s,0,0}} \lesssim \|I_2 f\|_{L^\infty}^{\nu d/2}$$

where the first inequality follows from Theorem 6 and the last one from Theorem 5. Observe that $\nu < 2/d$, so that $\theta = \nu d/2 \in (0,1)$. $\square$

Let us now explain the precise meaning of formula (9). In the article [GW17], a scale of anisotropic Hilbert spaces $H^{m,\rho}(SM)$ was introduced to analyze the meromorphic continuation of the resolvent $R^\pm(\tau) = (X \pm \tau)^{-1}$ of $X$. This scale took the form

$$H^{m,\rho}(SM) = \text{Op}(e^{rG})^{-1} H^{0,\rho,0}(SM).$$

Here, $G$ is a log order symbol of the form $G \sim m \log |\xi|$, where $m$ is an order 0 symbol. To obtain the meromorphic continuation of $(X - \tau)^{-1}$, as usual, the criterion is a sign condition on the subprincipal symbol of $X$ acting on thoses spaces (there was also a special ingredient relating to inversion of an indicial operator). In particular, the arguments from [GW17] apply to the spaces $H^{m,\rho,\rho,\perp}(SM)$, and we find that $(X - \tau)^{-1}$ continues from $\Re s > 0$ to $\Re s > -\delta$ as a bounded operator on $H^{m,\rho,\rho,\perp}(SM)$ if $Cr > \max(|\rho|, |\rho,\perp|) + \delta$, for some constant $C > 0$ depending only on $m$.

Since one has some $C > 0$,

$$H^{s,\rho,\rho,\perp}(SM) \subset H^{Cm,\rho,\rho,\perp}(SM) \subset H^{-s,\rho,\rho,\perp}(SM),$$

we obtain the following:
Lemma 3.1. Let \((M, g)\) be a cusp manifold. Given \(s > 0, \rho \in (-d/2, d/2)\) and \(|\rho_\perp| \leq |\rho|\), there is a \(\delta > 0\) such that seen as an operator from \(H^{s+C[|\rho_\perp|, \rho, \rho_\perp]}(SM)\) to \(H^{-s-C[|\rho_\perp|, \rho, \rho_\perp]}(SM)\), \(R^\pm(\tau)\) has a meromorphic continuation from \(\{\tau \in \mathbb{C} \mid \Re \tau > 0\}\) to \(\{\tau \in \mathbb{C} \mid \Re \tau > -\delta\}\).

Since \(X\), seen as a differential operator, is antiself-adjoint on its domain in \(L^2(SM)\), the poles of its resolvent on the imaginary axis \(i\mathbb{R}\) are of order 1 (see [Gui17, Lemma 2.4]). Moreover, the geodesic flow of a cusp manifold is mixing (see [Moo87] for constant curvature manifolds, [DP98] in the general case) and this implies that there is a single pole at 0 (see [Gui17, Lemma 2.5]). Actually, 0 is an embedded discrete eigenvalue of multiplicity 1 and the absolute spectrum is \(i\mathbb{R}\); there is no singular continuous spectrum.

The holomorphic part of \(R^\pm(\tau)\) at \(\tau = 0\), denoted by \(R_0^\pm\), is a well defined operator, bounded from \(H^{s+C[|\rho_\perp|, \rho, \rho_\perp]}(SM)\) to \(H^{-s-C[|\rho_\perp|, \rho, \rho_\perp]}(SM)\) for all \(s > 0\) and \(\rho \in (-d/2, d/2), |\rho_\perp| \leq |\rho|\). Additionally, whenever \(Xu \in H^{s+C[|\rho_\perp|, \rho, \rho_\perp]}(SM)\) and \(\int_{SM} ud\mu = 0\),

\[
R_0^\pm Xu = u.
\]

Using the spectral theorem, and the Stone theorem, we can identify the spectral measure of \(X\), and deduce that on the subspace \(\{f \in H^s \mid \int f = 0\} \subset L^2\), it is a smooth function. This implies that

\[
\lambda \mapsto \int e^{it\lambda} \langle f \circ \varphi_t, g \rangle dt,
\]

originally defined as an element of \(S'\), is a smooth function, and its value at 0 is given by

\[
R_0^+ - R_0^-.
\]

(in particular \((R_0^+)^* = -R_0^-\)). This shows that Formula (9) makes sense and we define

(11) \[
\Pi := R_0^+ + R_0^- + |1 \times 1|.
\]

3.2. Inverting the normal operator on tensors. Let us start by some preliminary arguments. Consider \(f \in y^{-d/2+\epsilon}H^N\), such that \(\Pi_2 f = D^* f = 0\). Then using the positivity of \(\Pi\), we deduce that \(\Pi \pi_2^* f = 0\), and thus \(\pi_2^* f = Xu\) with \(u \in y^{-d/2+\epsilon}H^N\). This implies that \(I_2^3 f = 0\). If \(N\) is large enough, we get also that \(f \in y^\epsilon C^1\) by the embedding lemma of [GBL, Lemma 4.8], and assuming \(\epsilon\) is small enough, we can then apply Theorem 4, and deduce that \(f = 0\).

Following this observation, it would be convenient if we could prove that the kernel of \(\Pi_2\) can only contain elements of \(y^{-d/2+\epsilon}H^N\). Next, we would also like to deduce from the injectivity, the fact that \(\Pi_2\) is invertible; that is, we want to prove that \(\Pi_2\) is Fredholm on some spaces, with index 0. We will show that indeed it is Fredholm with
constant index on a range of spaces which includes $L^2$. Since $\Pi_2$ is $L^2$-symmetric, its index will have to be 0. This will rely the machinery of [GBL, Section 3.6].

To obtain Theorem 6, it will thus suffice to build a parametrix with a good remainder. To this end, we will prove

**Lemma 3.2.** *The normal operator $\Pi_2$ is $(0,d)$-$L^2$ admissible of order $-1$.*

This will be the most technical part of the proof. Next, according to Lemma 1.1, $\pi_{\ker D^*}$ itself is $(0,d)$-$L^2$ admissible. Its principal symbol $\sigma(\pi_{\ker D^*})$ is a projector. We will find that the symbol $\sigma(\Pi_2)$ of $\Pi_2$ is elliptic on the range of $\sigma(\pi_{\ker D^*})$, in the sense that we can factorize

$$q\sigma(\Pi_2) = \sigma(\pi_{\ker D^*}),$$

with $q$ a symbol of order 1. For Theorem 4 to apply, we would need $\Pi_2$ to be elliptic in the usual sense. However, we will check that the ellipticity on the range of $\sigma(\pi_{\ker D^*})$ is sufficient to obtain the same result. Finally, it will remain to compute the indicial roots of $\Pi_2$, and check that there are none in $(0,d)$.

### 3.2.1. Local part of the operator.

As suggested by (9), we first pick a cutoff $\chi$ equal to 1 in $[-t_0,t_0]$, and define

$$\Pi_{2,\chi} f = \pi_{2,*} \int_{\mathbb{R}} \chi(t) (\pi_{2,*} f) \circ \varphi_t dt.$$

This operator commutes with local isometries in the cusp, and is properly supported. Additionally, one can check in local coordinates that it is pseudo-differential (it is the case at the bottom of the cusp, invariance by isometries guarantees that it is still the case for large $y$). Given $(x,\xi) \in T^*M$, we can decompose the space of tensor

$$S^2(T^*_x M) = \ker \sigma(D^*)(x,\xi) \oplus \text{ran} \sigma(D)(x,\xi)$$

$$= \ker i_\xi \oplus \text{ran} \sigma j_\xi,$$

where $i_\xi$ is the contraction by $\xi^2$, $\sigma j_\xi : u \mapsto \sigma(\xi \otimes u)$. We denote by $\pi_{\ker i_\xi}$ the projection on the left space, parallel to the right space. Note in particular that $\sigma(\pi_{\ker D^*}) = \pi_{\ker i_\xi}$. Then, since the principal symbol of an operator is obtained by a local computation, one gets, just as in the compact setting that the principal symbol of $\Pi_{2,\chi}$ is

$$\frac{2\pi}{B_d} |\xi|^{-1} \pi_{\ker i_\xi} \pi_{2,*} \pi_{2,*} \pi_{\ker i_\xi},$$

where $B_d = \int_0^\pi \sin^{d+3}(\phi) d\phi$.

We conclude that $\Pi_{2,\chi}$ is a $L^2$ admissible operator, elliptic on $\ker i_\xi$. It remains to study the difference $\Pi_2 - \Pi_{2,\chi}$, and prove that it is a smoothing, $L^2$ admissible.
operator. Since we can write
\[ \Pi_2 - \Pi_2,\chi = \left[ 1 - \int_\mathbb{R} \chi \right] |1 \times 1| \]
\[ + \pi_{2*} \left[ \int_0^{+\infty} \chi'(t) \phi_t^* R_0^- \ dt \right] \pi_2^* + \pi_{2*} \left[ \int_{-\infty}^0 \chi'(t) \phi_t^* R_0^+ \ dt \right] \pi_2^*, \]
we can concentrate our study on:
\[ U := \int_{t_0}^{+\infty} \chi'(t)\pi_{2*} \phi_t^* R_0^- \pi_2^* \ dt \]

3.2.2. Regularity properties. We will show in this section that \( U \) is a smoothing \((0,d)\)-\( L^2 \) admissible operator. Before explaining how one can use the symmetries of the flow to prove that it is admissible, let us recall why it should be smoothing. This part of the argument is very similar to the compact case.

The space \( T(SM) \) decomposes as the sum \( T(SM) = \mathbb{R}X \oplus \mathbb{V} \oplus \mathbb{H} \), where \( \mathbb{V} := \ker d\pi \) (\( \pi : SM \to M \) being the canonical projection) is the vertical space and \( \mathbb{H} \) is the horizontal space. We denote by \( \mathbb{V}^*, \mathbb{H}^* \) the dual vector bundles such that
\[ \mathbb{H}^*((\mathbb{V}) = 0, \mathbb{V}^*(\mathbb{H} \oplus \mathbb{R}X) = 0. \]

As soon as there are no conjugate points, the vertical bundle \( \mathbb{V} \) is transverse to the Green bundles, so that we have \( \mathbb{H}^* \oplus E_u^* = \mathbb{H}^* \oplus E_s^* = T(SM) \); for a proof, see [Kli74, Proposition 6]. The map \( d\pi^T : T^*M \to \mathbb{H}^* \) is an isometry and \( d\pi : \mathbb{H} \oplus \mathbb{R}X \to TM \) is an isometry too. We have:
\[ WF(\pi_2* f) \subset \{(x,\xi) \mid \exists v \in S_xM, ((x,v),d\pi^T \xi,0) \in WF(f)\}. \]
\[ WF(\pi_2^* f) \subset \{((x,v),d\pi^T \xi,0) \mid (x,\xi) \in WF(f)\} \subset \mathbb{H}^*. \]

Since the curvature of the manifold is negatively pinched, there are no conjugate points. It follows that \( \phi_t(\mathbb{H}^*) \cap \mathbb{H}^* \cap \{\xi, X = 0\} = \{0\} \) for all \( t \neq 0 \). Recall from [GW17, Theorem 3] that
\[ WF'(R_0^-) \subset \Delta(T^*SM) \cup \{((x,\xi),\phi_t(x,\xi)) \mid t \geq 0, \langle \xi, X \rangle = 0\} \cup E_u^* \times E_s^*. \]

Since averaging along the flow is smoothing in that direction, we deduce
\[ WF' \left[ \int \chi'(t)\phi_t^* R_0^- \right] \subset \{((x,\xi),\phi_t(x,\xi)) \mid t \geq t_0, \langle \xi, X \rangle = 0\} \cup E_u^* \times E_s^*. \]

As a consequence,
\[ (12) \quad WF'(U) = \{0\}. \]
All the arguments that we have exposed, and indeed, [GW17, Theorem 3], are based on propagation of singularities. We will have to come back to these more precise estimates to conclude. For the sake of simplicity, we now write \( H^{s,\rho} := H^{s,\rho,\rho} \) for spaces with the same weight on the zero and non-zero modes. Following [GBL, Section 3.2], what we need to prove are the following properties of admissibility:

1. \( U \) is bounded from \( H^{-N,\rho} \) to \( H^{N,\rho} \) for all \( \rho \in (-d/2, d/2) \), \( N \in \mathbb{N} \).
2. \( [\partial_\theta, U] \) is bounded from \( H^{-N,d/2-\epsilon} \) to \( H^{N,-d/2+\epsilon} \) for all \( \epsilon > 0 \), \( N \in \mathbb{N} \).
3. There is a smoothing convolution operator \( I_Z(U) \) such that \( P_ZU \mathcal{E}_Z - I_Z(U) \) is bounded from \( e^{r(d-\epsilon)}H^{-N} \) to \( e^{r\epsilon}H^{N} \) for all \( \epsilon > 0 \), \( N \in \mathbb{N} \). Here \( P_Z \) is the projection on the zero Fourier mode and \( \mathcal{E}_Z \) is the extension to the cusp manifold by setting the non-zero Fourier modes to zero (see [GBL, Section 3]).

Before going on with the proof, it is convenient to recall that the scale of spaces \( H^{m,\rho}(SM) \) was built as
\[
H^{m,\rho}(SM) := \text{Op}(e^m \log(\langle \xi \rangle))H^{0,\rho}(SM),
\]
where \( m \) is an order 0 symbol. It was important to impose its value on \( E_u^* \), and \( E_s^* \). However, in its construction, one can always impose that it is arbitrarily large or small on \( \mathbb{H}^* \). In particular for any \( s \in \mathbb{R} \) and \( \epsilon > 0 \), we can choose \( m \) such that
\[
\pi_2^*(H^{s,\rho}(M,S^2(T^*M))) \subset H^{m,\rho}(SM), \text{ and } \pi_2^*H^{m,\rho}(SM) \subset H^{s-\epsilon,\rho}(M,S^2(T^*M)).
\]

Let us start with property (1). In the compact case, the proof of this fact in [GL19b] relies on the propagation of singularities estimates from [DZ16]. In [GW17], it was proved that these estimates apply almost verbatim in the case of cusp manifolds, if one uses the relevant pseudo-differential calculus. In particular, the estimates that lead to (12), which are a priori local, are actually uniform over the whole manifold. While we reproduce the proof below, the reader familiar with [GL19b] will see nothing new.

We work with \( h\)-semi-classical quantization. We consider the following microlocal decomposition:
\[
\pi_{2s} = \pi_{2s}A_{\text{reg}} + \pi_{2s}A_{\text{ell}} + \pi_{2s}A_{\text{prop}} + O_{H^{-N,\rho} \rightarrow H^{N,\rho}(h^{N})},
\]
with \( A_{\text{reg,ell,prop}} \), \( \mathbb{R}-L^2 \) admissible operators of order 0, such that \( A_{\text{reg}} \) is microlocally supported around the zero section. \( A_{\text{ell}} \) is microsupported in the region of ellipticity of the flow. And finally, \( A_{\text{prop}} \) is microsupported in a small conical neighbourhood of \( \{ (\xi, X) = 0 \} \cap \{ |\xi| > 1 \} \cap \mathbb{H}^* \).

Since
\[
-X \int \chi'(t)\varphi^*_t dt = \int \chi''(t)\varphi^*_t dt,
\]
we can use a parametrix construction to find that

\[ A_{\text{eff}} \int \chi(t) \varphi_t^* dt = A_{\text{eff}}^N \int \chi^{(N+1)} \varphi_t^* dt + \mathcal{O}_{H^{-N,\rho} \to H^{N,\rho}}(h^N), \]

with \( A^N \) of order \(-N\). We deduce that

\[ \left\| \pi_{2*} A_{\text{eff}} \int \chi'(t) \varphi_t^* R_0^* \pi_{2*} u dt \right\|_{H^{N,\rho}} \leq C \| u \|_{H^{-N,\rho}}, \]

(the constant may explode as \( h \to 0 \)). Next, since \( \varphi_t(\text{WF}_h(A_{\text{prop}})) \) is eventually in a neighbourhood of \( E_u^\ast \), and since \( \varphi_t H^* \) is always transverse with \( H^* \), uniformly as \( t \to +\infty \), we deduce from the propagation of singularities [GW17, Propositions A.21, A.23] that there is \( C \in \Psi^0 \) whose wavefront set does not encounter \( H^* \), and such that for \( u \in H^{m,\rho}(SM) \), and \( t \geq t_0 \),

\[ \| A_{\text{prop}} \varphi_t^* u \|_{H^{m,\rho}} \leq C t h^{-1} \| CX u \|_{H^{m,\rho}} + \mathcal{O}(h^N \| u \|_{H^{-N,\rho}}). \]

(the constants are locally uniform in \( t \)). As a consequence, we get that

\[ \left\| \pi_{2*} A_{\text{prop}} \varphi_t^* R_0^* \pi_{2*} u \right\|_{H^{N,\rho}} \leq C t \| C \pi_{2*} u \|_{H^{m,\rho}} + \mathcal{O}(h^N \| u \|_{H^{-N,\rho}}) \leq \mathcal{O}(h^N \| u \|_{H^{-N,\rho}}). \]

Finally, for fixed \( h \), \( A_{\text{reg}} \) is bounded from \( H^{-N,\rho} \) to \( H^{N,\rho} \) (with norm \( \sim h^{-2N} \)). We conclude that

\[ \| U u \|_{H^{N,\rho}} \leq C \| u \|_{H^{-N,\rho}}, \]

by taking \( h > 0 \) small enough. In all the arguments above, the only limitation on \( \rho \) is that we require that \( R_0^* \) is bounded on \( H^{m,\rho} \), hence the restriction \( \rho \in (-d/2, d/2) \).

Let us now turn to the item (2). Consider a cutoff \( \chi_1 \) supported in the cusp, constant for large \( y > 0 \). Pick \( u \in C_0^\infty(SM) \), with \( \int u = 0 \). Then

\[ [\chi_1(y) \partial_\theta, R_0^-] u = \chi_1(y) \partial_\theta R_0^- u - R_0^- \chi_1(y) \partial_\theta u, \]

\[ = R_0^- [X, \chi_1(y) \partial_\theta] R_0^- u, \]

\[ = R_0^- (y \cos \varphi \chi_1'(y) \partial_\theta) R_0^- u \]

(and the commutator vanishes on constant functions). From there, since \( \pi_{2*} \) commutes with \( \partial_\theta \), and since the flow \( \varphi_t \) commutes with \( \partial_\theta \) for small times, and \( \chi_1' \) is compactly supported, if \( \chi_1 \) is only supported for \( y > 0 \) large enough, we get

\[ [\chi_1(y) \partial_\theta, U] = \int_{t_0}^{+\infty} \chi'(t) \pi_{2*} \varphi_t^* [\chi_1(y) \partial_\theta, R_0^-] \pi_{2*} dt, \]

\[ = \int_{t_0}^{+\infty} \chi'(t) \pi_{2*} \varphi_t^* R_0^- (y \cos \varphi \chi_1'(y) \partial_\theta) R_0^- \pi_{2*} dt \]

The arguments from the point (1) apply, and, using the fact that \( \chi_1' \) is compactly supported, we deduce that the commutator is bounded from \( H^{-N,d/2-\epsilon} \) to \( H^{N,-d/2+\epsilon} \) for all \( N, \epsilon > 0 \).
We now prove the third item (3). Denote by $R_0^{-}$ the inverse of $I(X)$, acting on $\mathbb{R} \times \mathbb{S}^d$, or equivalently, on functions on the full cusp that do not depend on $\theta$. Its existence [GW17, Theorem 2, Lemma 5.5] is the foundation of the proof of [GW17, Theorem 3]. It is a convolution operator bounded on the anisotropic spaces $H^{\rho} \times \mathbb{S}^d, e^{-rd}drd\zeta$, for $\rho \in (-d/2, d/2)$. Let us observe that

\[
\pi_2^* \left[ P_Z \chi \varphi_1^* R_0^\ast \chi \mathcal{E}_Z - \varphi_1^* R_0^{-} \right] \pi_2^* = \\
\pi_2^* \varphi_1^* R_0^{-} \left[ P_Z (\varphi_1^*[X, \chi]) R_0^\ast \chi \mathcal{E}_Z + \varphi_1^*(\chi') \chi - 1 \right] \pi_2^*.
\]

Then, we observe that

\[
\left[ P_Z (\varphi_1^*[X, \chi]) R_0^\ast \chi \mathcal{E}_Z + \varphi_1^*(\chi') \chi - 1 \right] \pi_2^*
\]

maps $e^{(d-c)r}H^{-N}(\mathbb{R})$ to $H^{\rho} \times \mathbb{S}^d, e^{-rd}drd\zeta$ for all $\epsilon > 0$, mapping the wavefront set to $\cup_{t>0}\varphi_t H^*$. Then, we can apply the arguments from point (1) directly to $R_0^{-}$ to conclude. The indicial operator of $U$ is thus found to be

\[
\int_{t_0}^{+\infty} \chi'(t) \pi_2^* \varphi_1^* R_0^{-} \pi_2^* dt.
\]

This in turn implies that the indicial operator of $\Pi_2$ is (as one would hope) the $\Pi_2$ operator associated to the full cusp, restricted to the zeroth Fourier mode in $\theta$, i.e.

\[
I(\Pi_2)f = \pi_2^* \int_{\mathbb{R}} (\pi_2^* f) \circ \varphi dt.
\]

This finishes the proof of Lemma 3.2. \hfill \square

3.2.3. Parametrix construction for range ellipticity. So far, we have found that $\Pi_2$ is a $L^2$ admissible pseudo-differential operator, and that it is elliptic on $\ker \sigma(D^*)$. However, we cannot directly apply the arguments of [GBL] because $\ker D^*$ is not a space of sections of a fixed bundle. We will see that this is not actually a problem.

By definition of range ellipticity, we have a symbol $q_0$ such that

\[
\operatorname{Op}(q_0) \Pi_2 = \pi_{\ker D^*} + \mathcal{O}((\Psi^{-1}).
\]

However, $\Pi_2 = \Pi_2 \pi_{\ker D^*}$, so the principal symbol of the remainder can be written $r\sigma(\pi_{\ker D^*}) + \mathcal{O}(S^{-2})$. Then, we can find $q_1$ so that $q_1 \sigma(\Pi_2) = r\sigma(\pi_{\ker D^*})$, and improve the parametrix to $\mathcal{O}((\Psi^{-2})$. By induction, we obtain a formal solution $\tilde{q} \sim q_0 + q_1 + \ldots$, for which we can build a Borel sum $q \in S^1$, and we get

\[
\pi_{\ker D^*} \operatorname{Op}(q) \Pi_2 = \pi_{\ker D^*} (1 + R) \pi_{\ker D^*},
\]

where, $\operatorname{Op}(q)$ and $R$ are $(0, d)-L^2$ admissible, of order $1$, $-\infty$ respectively. In the next section, we will prove
Lemma 3.3. The indicial operator of $\Pi_2$ does not have indicial roots in $(0, d) + i\mathbb{R}$. In particular, there is an indicial resolvent $S(\Pi_2) = S_{(0, d)}(\Pi_2)$ so that $S(\Pi_2)$ is bounded from $e^{(d/2 + \rho)r}H^s(\mathbb{R})$ to $e^{(d/2 + \rho)r}H^{s+1}(\mathbb{R})$ for $s \in \mathbb{R}$ and $\rho \in (-d/2, d/2)$, and
\[
S(\Pi_2)I(\Pi_2) = I(\pi_{\ker D^*}).
\]

Now, we follow the arguments from [GBL, Section 3.4]. We replace $\pi_{\ker D^*}$ Op$(q)$ by
\[
Q = \pi_{\ker D^*} \left[ \text{Op}(q) + \sum \chi E_{\ell} [S(\Pi_2) - I(\pi_{\ker D^*} \text{Op}(q))] P_{\ell} \chi \right],
\]
for some cutoff function $\chi$ equal to 1 in the cusps. This is an operator such that $Q\Pi_2 = \pi_{\ker D^*}(1 + R)\pi_{\ker D^*}$, with $R$ mapping $H^{-N,d/2-\epsilon}$ to $H^{N,-d/2+\epsilon}$ for all $N, \epsilon > 0$. According to the discussion at the start of Section §3.2, this closes the proof of Theorem 6.

3.2.4. Finding the roots. It remains to prove Lemma 3.3. First off, since $\pi_{\ker D^*} = 1 - D\Delta^{-1}D^*$, with $\Delta = D^*D$, we get that
\[
I(\pi_{\ker D^*}) = \pi_{\ker I(D^*)},
\]
this being an orthogonal projection on $e^{rd/2}L^2(\mathbb{R}, dr)$. In particular, we only need to invert $I(\Pi_2)$ on the kernel of the indicial operator of $D^*$. On the other hand, if we look for $S(\Pi_2)$ in the form of a Fourier multiplier, we must have
\[
S(\Pi_2, \lambda)I(\Pi_2, \lambda) = \pi_{\ker I(D^*, \lambda)}.
\]
Thus, we will need that for $\Re \lambda \in [0, d]$, $I(\Pi_2, \lambda)$ (which is now just a matrix) is invertible on ker $I(D^*, \lambda)$. Denoting the inverse $\tilde{S}(\Pi_2, \lambda)$, we will consider $\tilde{S}(\Pi_2)$, the convolution operator on $\mathbb{R}$ whose Fourier multiplier is $\tilde{S}(\Pi_2, \lambda)$, as in [GBL, section 3.3]. There may appear to be a small difficulty in the fact that so far, we have only defined $\tilde{S}(\Pi_2, \lambda)$ on ker $I(D^*, \lambda)$; We will complete this by requiring that is just 0 on ker$(\pi_{\ker I(D^*, \lambda)})$. The operator defined in this way will satisfy suitable bounds because $\pi_{\ker D^*}$ is itself admissible.

After these preliminary discussion, it only remains to compute the indicial family of $\Pi_2$, and prove that it is invertible. Consider a symmetric 2-tensor
\[
f = a \frac{dy^2}{y^2} + \sum_i \frac{b_i}{2} \left( \frac{dy\,d\theta_i}{y} + \frac{d\theta_i\,dy}{y} \right) + \sum_{i,j} c_{i,j} \frac{d\theta_i\,d\theta_j}{y},
\]
where $a = a_{\infty}y^\rho, b_i = b^i_{\infty}y^\rho, c_{i,j} = c_{i,j}^\rho y^\rho$, $c$ being a symmetric matrix. Then:
\[
D^*f = (a(\rho - d) + \text{Tr}(c)) \frac{dy}{y} + \frac{1}{2}(\rho - (d + 1)) \sum_i b_i \frac{d\theta_i}{dy}.
\]
If $\Re(\rho) \in (0, d)$, we get that $f$ is solenoidal if and only if $b_i \equiv 0$ for all $i \in \{1, \ldots, d\}$ and:

\begin{equation}
(14)
  a_\infty (\rho - d) + \Tr(c_\infty) = 0.
\end{equation}

From now on, we assume that these conditions hold. We now compute $\Pi \pi_2^* f$.

Given $z = (y_0, \theta_0, \phi_0, u_0)$ a point in $[0, +\infty[ \times \mathbb{T}^d \times ]0, \pi[ \times S^{d-1}$, we write $\varphi_t(z) = (y_t, \theta_t, \phi_t, u_t)$ and we have:

\[\Pi \pi_2^* f \left( a \frac{dy^2}{y^2} \right) (y_0, \theta_0, \phi_0, u_0) = \Pi (a_\infty y^\rho \cos^2 \phi)(y_0, \phi_0)\]

\[= a_\infty \int_{-\infty}^{+\infty} y_t^\rho \cos^2(\phi_t) dt\]

\[= a_\infty \left( \frac{y_0}{\sin \phi_0} \right)^\rho \int_{-\infty}^{+\infty} \sin^\rho(\phi_t) (1 - \sin^2(\phi_t)) dt\]

\[= a_\infty \left( \frac{y_0}{\sin \phi_0} \right)^\rho (H(\rho) - H(\rho + 2)),\]

where $H(\rho) := \int_{-\infty}^{+\infty} \sin^\rho(\phi_t) dt$. This is independent of $\phi_0 \neq 0 (\pi)$ and one can check that:

\begin{equation}
(15)
  H(\rho) = \sqrt{\pi} \frac{\Gamma(\rho/2)}{\Gamma((\rho + 1)/2)}
\end{equation}

Thus $H(\rho) - H(\rho + 2) = \frac{H(\rho)}{\rho + 1}$ and we get:

\begin{equation}
(16)
  \Pi \pi_2^* \left( a_\infty y^\rho \frac{dy^2}{y^2} \right) = a_\infty \left( \frac{y}{\sin(\phi)} \right)^\rho \frac{H(\rho)}{\rho + 1}
\end{equation}

In the same fashion:

\begin{equation}
(17)
  \Pi \pi_2^* \left( \sum_{i,j} y^\rho c_{ij}^\infty \frac{d\theta_i d\theta_j}{y^2} \right) = \left( \frac{y}{\sin(\phi)} \right)^\rho \frac{\rho H(\rho)}{\rho + 1} \sum_{i,j} c_{ij}^\infty u_i u_j
\end{equation}

Since $\pi_2^*$ and $\pi_2$ are formally adjoint operators on the $d$-dimensional sphere, it is sufficient to check that:

\[\langle y^{-\rho} \Pi \pi_2^* f, y^{-\rho} \pi_2^* f \rangle_{L^2(S^d)} \neq 0\]
Now, this is equal to:

\[
\langle y^{-\rho} \Pi_2^* f, y^{-\rho} \Pi_2^* f \rangle_{L^2(S^d)} = \frac{H(\rho)}{\rho + 1} \int_{S^d} \left| a_\infty \right|^2 \cos^2(\phi) + \sum_{kl} a_{\infty}^{kl} u_k u_l \sin^2(\phi) + \rho \sum_{ij} c_{\infty}^{ij} u_i u_j \cos^2(\phi) + \\
\rho \sum_{ijkl} c_{\infty}^{ij} c_{\infty}^{kl} u_i u_j u_k u_l \sin^2(\phi) \right) \frac{d\mu_{S^d}}{\sin^\rho(\phi)},
\]

where \(d\mu_{S^d} = \sin^{d-1}(\phi) d\phi d\mu_{S^{d-1}}(u)\) is the usual measure on the sphere. After some (non-trivial) simplifications, and using the fact that \(a_\infty(\rho - d) + \text{Tr}(c_\infty) = 0\), we obtain:

\[
\frac{1}{\text{vol}(S^{d-1})} \langle y^{-\rho} \Pi_2^* f, y^{-\rho} \Pi_2^* f \rangle_{L^2(S^d)} = \frac{H(\rho) H(d - \rho)}{(\rho + 1)(d + 1 - \rho)} \left| a_\infty \right|^2 \left( 1 + \frac{|d - \rho|^2}{d} + \frac{\rho(d - \rho)}{d} + \frac{\rho(d - \rho)^2}{d(d + 2)} \right) + 2 \text{Tr} |c_\infty|^2 \frac{\rho(d - \rho)}{d(d + 2)}
\]

\[
= \frac{\pi}{(\rho + 1)(d + 1 - \rho)} \frac{\Gamma \left( \frac{\rho}{2} \right) \Gamma \left( \frac{d - \rho}{2} \right)}{\Gamma \left( \frac{\rho + 1}{2} \right) \Gamma \left( \frac{d + 1 - \rho}{2} \right)} \times \left| a_\infty \right|^2 \left( 1 + \frac{|d - \rho|^2}{d} + \frac{\rho(d - \rho)}{d} + \frac{\rho(d - \rho)^2}{d(d + 2)} \right) + 2 \text{Tr} |c_\infty|^2 \frac{\rho(d - \rho)}{d(d + 2)}
\]

On the strip \(\{0 < \Re(\rho) < d\}\), the cross-ratio of \(\Gamma\) functions is holomorphic and does not vanish (in particular, it is a positive real number on the line \(\rho = d/2 + i\lambda\)). The term between parenthesis can be written in the form \(\lambda(\rho) + \rho(d - \rho)\mu(\rho) = -\mu(\rho)\rho^2 + \rho d\mu(\rho) + \lambda(\rho)\), where \(\lambda(\rho), \mu(\rho) \geq 0\) when \(\rho \in (0, d)\). The roots of this equation must then satisfy \(\rho = d/2 \pm \sqrt{d^2/4 + \lambda(\rho)/\mu(\rho)}\) so they are outside the strip \(\{0 < \Re(\rho) < d\}\).

Remark 3.1. It also has an interest on its own to compute the indicial roots of the operator \(\Pi_0\) to determine on which spaces it will be invertible. Considering a function on the whole cusp \(f = a_\infty y^\rho\) for \(\rho \in \mathbb{C}\) and carrying the same sort of computations
as before, one finds out that:
\[
\langle y^{-\rho}\Pi_0^*(a_\infty y^\rho), y^{-\rho}\Pi_0^*(a_\infty y^\rho) \rangle_{L^2(S^d)} = |a_\infty|^2 \pi \frac{\Gamma \left( \frac{d}{2} \right) \Gamma \left( \frac{d-\rho}{2} \right)}{\Gamma \left( \frac{\rho+1}{2} \right) \Gamma \left( \frac{d-\rho+1}{2} \right)}
\]

In particular, it has no roots for \(0 < \Re(\rho) < d\), as \(\Pi_2\). This may be true for tensors of higher order \(m \in \mathbb{N}\) but we did not do the general computation.

4. **Proof of the main Theorems**

4.1. **Reduction to solenoidal perturbations.** In our setting, there is an obvious group of gauge transformation, the diffeomorphisms of the manifold. It is thus necessary to fix a gauge. Since we will use the operator \(\Pi_2\), which has good analytic properties – it is elliptic and invertible – on solenoidal tensors, we will work in the solenoidal gauge (as in the compact case of [GL19b]). This means that we will be looking for a diffeomorphism \(\psi\) so that \(\psi^* g' - g\) is solenoidal. The modern procedure to do this is explained in [GL19b, Lemma 4.1] but the ideas go back to [Ebi68]. The main idea is to consider the map
\[
(\psi, g) \mapsto D^*_g(\psi^* g').
\]

Its derivative at 0 with respect to \(\psi\) is invertible when the Laplacian \(\Delta = D^* D\) acting on 1 forms is invertible. One can then use the Implicit Function Theorem.

In our case, we have to give a special treatment to the ends. Basically, the reason for this is that at the end of our argument, we will need that after this gauge fixing, \(g' - g\) decays very fast when \(y \to +\infty\); this enters in the contradiction with the fact that \(\Delta\) is not invertible on spaces of the type \(y^{-\rho} L^2\) for \(\rho\) too large. Indeed, consider a cutoff function \(\chi\) equal to 1 in the cusps and \(\rho < -1, s \geq 0\) large enough. We introduce the finite-dimensional space
\[
H := \text{Span}(\chi y^{-1} d\theta_i/y, \chi y^\lambda d \gamma/y).
\]

We then have the

**Lemma 4.1.** The operator
\[
\Delta_g : y^\rho C^{s+1}_*(M, T^* M) \oplus H \to y^\rho C^{s-1}_*(M, T^* M),
\]
is an isomorphism for all \(\rho < -1, s \in \mathbb{R}\).

**Proof.** The proof mainly relies on [GBL, Lemmas 3.5, 5.4]. First of all, it is clear that \(y^\rho C^{s+1}_* \oplus H \subset C^{s+1}_*\) and \(\Delta_g\) is injective on this space by [GBL, Lemma 5.4]. As to the surjectivity, we know by [GBL, Lemma 3.5], that there exists \(S \in \Psi^{-2}\) which is \((-\infty, -1)\) admissible on both \(L^2\) and \(L^\infty\) such that
\[
(19) \quad \Delta^{-1} = S + \chi \mathcal{E}_Z(\Pi_{\lambda_+} + \Pi_{\lambda_-})(\mathcal{P}_Z \chi + G),
\]
where $G$ maps into $e^{\rho t}H^{\infty}$ for all $\rho \in \mathbb{R}$. Here, the matrices $\Pi_{\Delta'}, \Pi_{-1}$ are completely explicit: they are obtained from the residues at $\lambda_d^{-}$ and $-1$ of the matrices $I(\Delta, \lambda)^{-1}$ computed in the proof of [GBL, Lemma 5.4] (they can be obtained by anti-clockwise integration of $I(\Delta, \lambda)^{-1}$ on small circles surrounding the indicial roots). More precisely, in the orthonormal basis $(dy/y, d\theta_i/y)$, one has

$$\text{Res}_{\lambda_d^{-}}(I(\Delta, \lambda)^{-1}) = \begin{pmatrix} (\lambda_d^{-} - \lambda_d^{+})^{-1} & 0 & \cdots & 0 \\ 0 & \ddots & \cdots & \vdots \\ \vdots & \cdots & \ddots & 0 \\ 0 & \cdots & 0 & 0 \end{pmatrix} = (\lambda_d^{-} - \lambda_d^{+})^{-1}\langle \cdot, dy/y \rangle,$$

where $\langle \cdot, \cdot \rangle$ denotes the metric on 1-forms induced by the hyperbolic metric. As a consequence, considering the formal vector bundle $E \to \mathbb{R}$, where $E = \text{Span}(dy/y, d\theta_i/y)$ and given a section $f \in C^\infty_c(\mathbb{R}, E)$, one obtains

$$\Pi_{\lambda_d^{-}} f = \langle f, e^{-\lambda_d^{-}r}dy/y \rangle_{L^2(E \to \mathbb{R}, dr)} dy/y e^{\lambda_d^{-}r} = \left( \int_{\mathbb{R}} \langle f(r'), e^{-\lambda_d^{-}r}dy/y \rangle dr' \right) e^{\lambda_d^{-}r} dy/y$$

Thus, in the usual coordinates $(y, \theta)$, one can write

$$\chi E_Z \Pi_{\lambda_d^{-}} f = \langle f, y^{-\lambda_d^{-}d+1} dy/y \rangle_{L^2(dy^d \theta^d+1)} \chi y^{\lambda_d^{-}} dy/y$$

Observe that $d - \lambda_d^{-} = \lambda_d^{+}$, the “symmetric” indicial root for the Laplacian (with respect to the line $\{\Re(\lambda) = d/2\}$). In the same fashion, one has

$$\text{Res}_{-1}(I(\Delta, \lambda)^{-1}) = \begin{pmatrix} 0 & 0 & \cdots & 0 \\ 0 & -2/d & \cdots & \vdots \\ \vdots & \cdots & \ddots & 0 \\ 0 & \cdots & 0 & -2/d \end{pmatrix},$$

and

$$\chi E_Z \Pi_{-1} f = \sum_i \langle f, y^{d+1} d\theta_i/y \rangle_{L^2(dy^d \theta^d+1)} \chi y^{-1} d\theta_i/y.$$
Proposition 4.1.\textit{ In order to prevent this polyhomogeneous development to appear, restrict ourselves to a codimension one operator }\( P := \langle \cdot, k' \rangle_{L^2_k} k \text{, where we have } k \in y^{-\infty} C^\infty(M, T^*M) \text{, } k' \in y^{\lambda_d^2} C^\infty(M, T^*M) \text{ which is } (-\infty, \lambda_d^2) \text{-admissible both on } L^2 \text{ and on } L^\infty \text{ such that the following holds. For all } s \geq 2, \rho < -1, \text{ there exists a small } y^s C^s \text{-neighbourhood of } g, \text{ such that for any metric } g' \text{ in this neighbourhood, there exists a (unique) diffeomorphism } \phi := T_u \circ e_V, \text{ where } V \in y^\rho C^{s+1}_s(M, TM), \text{ such that } \\
\phi^* g' - g \in y^\rho C^s_s \cap \ker(1 - P) D_g^* \text{.}\

\text{map. Since in the compact part, one can show directly that it is injective, it is then a global diffeomorphism.}
We call this gauge the almost solenoidal gauge.

Proof. The operator $\Delta_g$ acting on $y^\rho C_s^\infty(M,T^*M)$ for $\rho' > \lambda^d_+$, $s \in \mathbb{R}$ is no longer injective (but it is still surjective). In particular, using [GBL, Lemma 3.4], for $\lambda^d_- < \rho' < d+1$, the kernel of $\Delta_g$ on $y^\rho C_s^\infty(M,T^*M)$ is one-dimensional, given by $\text{Span}(k')$ for some $k' \in y^{\lambda^d_+}C^\infty(M,T^*M)$. Using Lemma 4.1, we write for $\rho < -1$:

$$\Delta(\text{Span}(\chi y^{\lambda^d_-}dy/y)) \ominus \Delta(\text{Span}(\chi y^{-1}d\theta_i/y) \ominus y^\rho C_s^{s-1}) = y^\rho C_s^{s-1}$$

Given $f = \Delta_g f_0 + \Delta_g e \in y^\rho C_s^{s-1}$ with $f_0 = c\chi y^{\lambda^d_-}dy/y, c \in \mathbb{R}, e \in E$, one has:

$$\langle f, k' \rangle_{L^2} = \langle \Delta_g f_0 + \Delta_g e, k' \rangle_{L^2} = \langle \Delta_g f_0, k' \rangle_{L^2},$$

since $\langle \Delta_g e, k' \rangle_{L^2} = \langle e, \Delta_g k' \rangle_{L^2} = 0$ by duality. Since $k'$ is non-trivial, $\langle \Delta_g, k' \rangle_{L^2}$ induces a non-trivial linear form on all the spaces $H^{s,\rho-d/2,\rho_\perp}, s \in \mathbb{R}, \rho < -1, \rho_\perp \in \mathbb{R}$ and in particular, there exists a tensor $f_0 = c\chi y^{\lambda^d_-}dy/y$ such that $\langle \Delta_g f_0, k' \rangle_{L^2} = 1$. We write $k := \Delta_g f_0 \in y^{-\infty}C^\infty$ and define $P := \langle k', \cdot \rangle_{L^2}$ and one has $P^* = \langle k, \cdot \rangle_{L^2}$.

It satisfies the relation $\Delta_g P^* = 0$ on all the spaces $y^\rho C_s^\infty(M,T^*M)$ for $s \in \mathbb{R}, \rho > \lambda^d_-$. By duality it also satisfies $P\Delta_g = 0$ on the spaces with $\rho < \lambda^d_-$, $s \in \mathbb{R}$ and thus

$$\langle 1 - P \rangle\Delta_g : y^\rho C_s^{s+1} \ominus \text{Span}(\chi y^{-1}d\theta_i/y) \sim \Delta_g(y^\rho C_s^{s+1} \ominus \text{Span}(\chi y^{-1}d\theta_i/y))$$

is an isomorphism. In the formalism developed in [GBL], the operator $P \in \Psi^{-\infty}$ is a $(-\infty, \lambda^d_-)$-admissible operator both in $L^2$ and in $L^\infty$ whereas $P^* \in \Psi^{-\infty}$ is $(\lambda^d_+\infty)$-admissible.

We now consider for $\rho < -1$ the map

$$F : y^\rho C_s^{s+1}(M,T^*M) \times \mathbb{R}^d \times y^\rho C_s^\infty(M,\otimes^2_T^sT^*M) \to (1 - P)\left(y^\rho C_s^{s-1}(M,T^*M)\right),$$

defined by $F(V, u, g') := (1 - P)D_\overline{g}(e_V^*T_u^s g')$, for $g'$ in a neighbourhood of $g$ and $V, u$ in a neighbourhood of 0. This is a $C^1$ map in both variables. Observe that

$$d_{(V,u)}F_{(0,0,0)}(W, v) = \Delta_g \left(W^b + \sum_i v_i \chi y^{-1}d\theta_i/y\right),$$

where $b$ denotes the musical isomorphism, $W \in y^\rho C_s^{s+1}(M,T^*M), v \in \mathbb{R}^d$, and this is an isomorphism by Lemma 4.1. One then concludes by the implicit function theorem.

**Remark 4.1.** Observe that since $T$ is $C^1$, the implicit function theorem also tells us that the map $g' \mapsto e_V(g') =: \phi(g')$ is $C^1$ and we thus have an estimate $\|\phi^* g' - g\|_{y^\rho C^1_2} \lesssim \|g' - g\|_{y^\rho C^2_2}$. 

□
Lemma 4.2. There exists a linear form \( A : y^\rho C^s_\ast(M, \otimes_3^2 T^* M) \to \mathbb{R} \), defined for all \( \rho < \lambda_\ast^d, s \in \mathbb{R} \) such that
\[
\ker(1 - P)D_g^* \cap \ker A \cap y^\rho C^s_\ast(M, \otimes_3^2 T^* M) = \ker D_g^* \cap y^\rho C^s_\ast(M, \otimes_3^2 T^* M).
\]

Proof. The inclusion from the right to the left being trivial, it remains to prove the other one. For \( \rho < \lambda_\ast^d \), assume \( f \in y^\rho C^s_\ast(M, \otimes_3^2 T^* M) \leftrightarrow C^0_\ast(M, \otimes_3^2 T^* M) \) and \((1 - P)D_g^* f = 0\). Then \( f = D_g p + h \) where \( p \in C^s_\ast^+ \hookrightarrow T^* M, h \in C^s_\ast(M, \otimes_3^2 T^* M) \) and \( D_g^* h = 0 \) by standard solenoidal decomposition. Thus \( D_g^* f = D_g^* D_g p \) and by (19), we get
\[
p = SD_g^* f + \tilde{A}(D_g^* f) y^{-\lambda_\ast^d} d\rho d\gamma + \sum_i \tilde{B}_i(D_g^* f) y^{-1} d\theta_i/y,
\]
where the linear forms \( \tilde{A}, \tilde{B}_i \) are given respectively by (20) and (21). We set \( A := \tilde{A}D_g^* \). Assuming \( f \in \cap \ker A \), one obtains \( p \in y^\rho C^s_\ast^+ \hookrightarrow T^* M, p \otimes \text{Span}(y^{-1} d\theta_i/y) \).

But \((1 - P)D_g^* f = 0 = (1 - P)\Delta_g p \) and using (22), we get \( p = 0 \), that is \( f = h \in \ker D_g^* \). \( \square \)

As a consequence, the 1-codimensional submanifold of isometry classes on which we are going to prove the theorem is a neighbourhood of \( g \) intersected with
\[
\mathcal{N}_{\text{iso}} := \ker(1 - P)D_g^* \cap \ker A \cap y^{-N} C^N_\ast(M, \otimes_3^2 T^* M),
\]
or, equivalently, Theorem 2 will hold in a neighbourhood around \( g \) on the submanifold
\[
\mathcal{N}_{\text{met}} := \{ \phi^* f \mid f \in \mathcal{N}_{\text{iso}}, \phi = T_u \circ e_V, V \in y^{-N} C^{N+1}_\ast(M, T^* M), u \in \mathbb{R}^d \}.
\]

Eventually, let us observe as a last remark that the normal operator \( \Pi_2 \) is still injective on the almost solenoidal gauge. Thus, it is very likely that one could carry out the interpolation argument of the following paragraph in this gauge. However, since \( P \) is only \((-\infty, \lambda_\ast^d)\) admissible and \( \Pi_2 \) is \((0, d)\) admissible (and these two intervals do not overlap!), one cannot obtain a parametrix such that \( Q\Pi_2 = \pi_{\ker(1 - P)D^*} + \text{compact} \).
4.2. End of the proof. Since Theorem 1 follows directly from Theorem 2, we focus on the latter. We are given \( g \) a cusp metric, and \( g' \) another metric, such that \( \| g - g' \|_{y^{-N}} < \epsilon \), with \( N \in \mathbb{N} \) large enough (chosen at the end), and \( \epsilon > 0 \) small enough (chosen at the end) and \( g' \in \mathcal{N}_{\text{met}} \). If we assume that \( \epsilon \) is small enough, we can apply Proposition 4.1 and obtain a diffeomorphism \( \phi' := \phi^* g' \) is genuinely solenoidal, and \( \phi \) is \( \epsilon \)-close to the identity (in the topology given by Proposition 4.1).

We now apply a similar interpolation argument to [GL19b]. For the sake of simplicity, we now denote by \( H^{s,\rho} \) the Sobolev spaces \( H^{s,\rho,\rho} \), meaning that the \( y \)-weight in the zero and non-zero Fourier modes is the same. We first estimate the norm of \( g' - g \) and for that we can apply the stability estimate Theorem 7. We fix \( s > 0 \) arbitrarily small, then there exists \( \gamma > 0 \) such that,

\[
\| g'' - g \|_{H^{-1-s,0}} \lesssim \| g'' - g \|_{C^{1,\gamma}}^{1/2} \| g'' - g \|_{C^{1,\gamma}}^{1/2} \| I_2^s (g'' - g) \|_{L^\infty}.
\]

From Lemma A.3, we know that

\[
L_{g'/L_g} = L_{g''/L_g} = 1 + I_2^s (g'' - g) + \mathcal{O}(\| g'' - g \|_{C^3}),
\]

and we deduce that

\[
\| I_2^s (g'' - g) \|_{L^\infty} \lesssim \| g'' - g \|_{C^3} + \| L_{g'/L_g} - 1 \|_{L^\infty}.
\]

In particular, we get

\[
\| g'' - g \|_{H^{-1-s,0}} \lesssim \| g'' - g \|_{C^3} + \| g'' - g \|_{H^{s,0}} \lesssim \| g'' - g \|_{H^{s,0}}.
\]

Then, we use the Sobolev embedding [GBL, Lemma 4.8]: for \( r := (d+1)/2 + 3 + s \),

\[
\| g'' - g \|_{C^3} \lesssim \| g'' - g \|_{H^{r,-d/2}}.
\]

Next, we see \( H^{r,-d/2} \) as the \( \gamma/(1 + \gamma) \) complex interpolation of \( H^{-1-s,0} \) and \( H^{N_1,-N_2} \), so that

\[
\| g'' - g \|_{H^{r,-d/2}} \lesssim \| g'' - g \|_{H^{-1-s,0}} \| g'' - g \|_{H^{N_1,-N_2}},
\]

where

\[
N_1 := (1 + 1/\gamma)(3 + (d+1)/2 + s + 1 + s) - 1 - s, \quad N_2 := (1 + 1/\gamma)d/2.
\]

We deduce that

\[
\| g'' - g \|_{H^{-1-s,0}} \lesssim \| g'' - g \|_{H^{-1-s,0}} \| g'' - g \|_{H^{N_1,-N_2}} + \| g'' - g \|_{C^1} \| L_{g'/L_g} - 1 \|_{L^\infty}
\]

and taking \( \| g'' - g \|_{H^{N_1,-N_2}} \lesssim \| g'-g \|_{H^{N_1,-N_2}} < \epsilon \) small enough (the first inequality follows from Remark 4.1), the first term on the right-hand side can get swallowed in the left-hand side, which yields:

\[
\| g'' - g \|_{H^{-1-s,0}} \lesssim \| g'' - g \|_{C^1} \| L_{g'/L_g} - 1 \|_{L^\infty}.
\]

Taking \( N > \max(N_1, N_2 - d/2) \) and using the injection \( y^{-NC^s} \hookrightarrow C^1 \), we obtain the desired result.
Appendix A. Perturbation of the marked length spectrum

In this appendix we give some results regarding the perturbation of the marked length spectrum with somewhat more general assumptions than the ones we make in the rest of article. They are probably regarded as classical by the community, but we have not been able to locate a proof of exactly what was needed.

If $(N,g)$ is a complete manifold without boundary, such that its curvature tensor and all its covariant derivatives are bounded, we say that $g$ has bounded local geometry. If $X$ is a vector field on $N$ which is bounded as well as all its covariant derivatives, we say that it is $C^\infty$-bounded. If the flow $(\varphi_t)_{t \in \mathbb{R}}$ of $X$ on $N$ is hyperbolic in the sense of §2.1.1, we say $X$ is an Anosov vector field. Consider a manifold $(M,g)$ which has bounded local geometry. Then, so does $(SM,g_S)$, where $g_S$ denotes the Sasaki metric. We say that $(M,g)$ is an Anosov manifold if its geodesic vector field is an Anosov vector field on $SM$. In that case, $(M,g)$ has no conjugate points, and $E^u, E^s$ can be identified with respectively $E^+$ and $E^-$ — the Green’s bundles. In particular, by definition, a cusp manifold is an Anosov manifold.

Lemma A.1. Let $(N,g)$ be a manifold with bounded local geometry, endowed with an Anosov vector field $X$. There is a constant $C_X > 0$ such that whenever $Y$ is a $C^\infty$-bounded vector field, and $\|Y - X\|_{C^1} < C_X$, $Y$ also is Anosov. Additionally, if $x \in N$ is a periodic point for $X$ with orbit $\gamma$, there is a point $x' \in N$ such that $x'$ is periodic for $Y$, with an orbit freely homotopic to $\gamma$. Denoting by $L$ the period of the orbit, we finally have

$$L(Y) - L(X) = \sum_{k=1}^{N} \frac{1}{k!} D_Y^k L \cdot (Y - X) + O(L(X)\|Y - X\|_{C^{N+1}}),$$

where the constants on the right-hand side are independent of $\gamma$.

This follows from the fact that sufficiently close Anosov flows are conjugated by homeomorphisms. We will give a proof in our context, based on the proof of de la Llave-Marco-Moryon [dlLMM86]. In that article, in the case of compact manifolds, they use the structure of Banach manifold of $C^0_X(N,N)$, the set of maps from $N$ to itself that are continuously differentiable along $X$. In our case, since we do not assume that the radius of injectivity is positive, there is a slight difficulty in proving that this is a Banach manifold.

However, we can use our assumption that the local geometry is bounded to circumvent this. Indeed, there is a global $r > 0$ such that $\exp_x$ is a local diffeomorphism on $B(x,r)$ for all $x$. This suggests to consider maps of the form

$$f : x \mapsto \exp_x(u(x)).$$
Then $D_X f$ is the value at $\exp_x(u(x))$ of the Jacobi field along $t \mapsto \exp_x(tu(x))$, such that $J(0) = X(x)$, and $J'(0) = \nabla_X u$. In particular, the relevant space is

$$\mathcal{B} := \{ u \in C^0(N, TN) \mid |\nabla_X u| \in C^0 \}$$

This is a Banach space when endowed with $\|u\| = \max(r^{-1}\|u\|_{L^\infty}, \|\nabla_X u\|_{L^\infty})$. We consider its unit ball:

$$\mathcal{D} := \{ u \in \mathcal{B} \mid |u| < r, \ |\nabla_X u| < 1 \}.$$  

It is an open set of a Banach space, so it is a smooth Banach manifold. For $u \in \mathcal{D}$, let $f^u(x) := \exp_x(u(x))$. Then $f^u$ is continuous, and $D_X f^u$ also is.

**Theorem 8.** In the space of $C^k$ vector fields on $N$, one can define $C^k$ maps $Y \mapsto u_Y, F_Y$ for $\|Y - X\|_{C^1(N)} < \delta(X)$, with $(u, F)$ valued in $\mathcal{D} \times C^0(N)$, so that for $x \in N$,

$$f^{uv}(\varphi_t^X(x)) = \varphi_t^Y(f^{uv}(x)),$$

with

$$\alpha_Y(t) := \int_0^t F_Y(\varphi_t^X(x))dt.$$

First, let us deduce the Lemma from the Theorem. Indeed, assume that $x$ is a periodic point for $X$ with period $L$. Then

$$\varphi_{\alpha_Y(L)}(f^{uv}(x)) = f^{uv}(\varphi_L^X(x)) = f^{uv}(x),$$

so $f^{uv}(x)$ is periodic with period

$$L(Y) = \int_0^L F_Y(\varphi_t^X(x))dt.$$

Since $F_Y$ is a $C^k$ map, we deduce that $Y \mapsto L(Y)$ depends on $Y$ in a $C^k$ fashion as announced. Now, we turn to the proof of Theorem 8.

**Proof.** We will follow the proof of [dlLMM86]. Start by considering

$$\mathcal{B}_1 := \{ u \in \mathcal{B} \mid \forall x, \ u(x) \in E^u \oplus E^s \}.$$  

Since the bundles $E^u, E^s$ are uniformly Hölder, this is a closed linear subspace of $\mathcal{B}$. Since $E^u \oplus E^s$ is $C^\infty$ along $X$, it is not trivial, and this will be using this indirectly. We will also consider $\mathcal{D}_1 = \mathcal{B}_1 \cap \mathcal{D}$.

Next, consider the map $\Psi$ defined by

$$\Psi(Y, u, F) : x \mapsto (d_u \exp_x)^{-1} [D_X f^u - F(x)(\exp_x(u(x)))] \in T_x N.$$  

If $Y$ is a $C^k$ vector field, $u \in \mathcal{D}_1$ and $F \in C^0(N)$, $\Psi(Y, u, F)$ is a $C^0$ vector field (i.e. in $\Gamma^0(TN)$). Additionally, $\Psi$ is $C^k$ from $C^k(N, TN) \times \mathcal{D}_1 \times C^0(N)$ to $C^0(N, TN)$. Here we use the fact that the multiplication is $C^\infty$ on $C^0$ spaces, and the composition $(Y, f^u) \mapsto Y \circ f^u$ is $C^k$ as a map $C^k \times C^0 \to C^0$. 

Assume that for each $Y$ we can find $u_Y$, $F_Y$ such that $\Psi(Y, u, F) = 0$ (the 0 section). Then for $x \in N$, let $x_t = \varphi^{X}_t(x)$, and $y_t = f^u(x_t)$.

$$\frac{d}{dt} y_t = (D_X f^u)(x_t) = F(x_t)Y(y_t),$$

so that $y_t$ is a reparametrized trajectory of $Y$; this proves the theorem.

We are left with finding solutions to $\Psi = 0$. For this, we will apply the Local Inversion Theorem. We need to compute $d_{u,F} \Psi(X, 0, 1)$.

For fixed $x$, consider $u(x) \in E^u_x \oplus E^s_x$, and the Jacobi fields $J_1$, $J_2$ the Jacobi fields along $\exp_x(tu/|u|)$ that satisfy

$$J_1(0) = 1, J'_1(0) = 0, J_2(0) = 0, J'_2(0) = 1.$$  

Then

$$d_u \exp_x \cdot w = \frac{1}{|u|} J_2(|u|) \cdot w.$$  

We also have

$$D_X f^u = J_1(|u|) \cdot X(x) + \frac{1}{|u|} J_2(|u|) \cdot \nabla_X u.$$  

In particular,

$$\Psi(X, tu, 1 + sF) = t\nabla_X u + t|u| J_2^{-1}(t|u|) \left[ J_1(t|u|) \cdot X(x) - (1 + sF(x))X(\exp_x(tu)) \right]$$

$$= t(\nabla_X u - \nabla_u X) - sFX(x) + o(s, t)$$

$$= tL_{X}u - sFX + o(s, t).$$

The theorem will thus be proved if we can prove

**Lemma A.2.** The map

$$u, F \mapsto L_{X}u - FX$$

is a linear isomorphism between

$$\mathcal{B}_1 \times C^0(N) \text{ and } \Gamma^0(TN).$$

The proof of this Lemma follows closely the lines of [dlLMM86, Lemma A.7, p597]. First, recall that there is an $\alpha_0 > 0$ such that the angle between $E^u$ and $X$ is at least $\alpha_0$. Indeed, since $X$ is $C^1$, there is a constant $\Lambda > 0$ such that $||d\varphi_t|| \leq e^{\Lambda|t|}$. Then, if the angle between $E^u$ and $X$ at some point is $\alpha'$, then we can find $v \in E^u$ such that $||v|| = 1$ and, with $\lambda = 1/|X|$, we have

$$||v + \lambda X||^2 = 2(1 - \cos \alpha') \simeq_{\alpha' \to 0} \alpha'^2.$$
Next, we observe that for $t > 0$,
\[
e^{\lambda t} \alpha' \geq \|d\varphi_t(\lambda X + v)\| = \|\lambda X_t + d\varphi_t v\| \geq \frac{1}{C} e^{\beta t} - \frac{|X_t|}{|X|}.
\]
From this, we deduce that the projection on $E^u \oplus E^s$ along $X$ is uniformly bounded.

Now, assume that $L_X u = FX$. Then, since $E^u \oplus E^s$ is invariant by the flow, we obtain $F = 0$, and $L_X u = 0$. But then, since $u$ is bounded, the hyperbolicity of the flow implies that $u$ has to be directed along $X$, so it has to vanish. On the other hand, consider $V$ a continuous vector field, and let us find $u, F$ such that $L_X u - FX = V$. Decompose $V = \lambda X + V^u + V^s$. Then $V^u$ and $V^s$ are bounded thanks to the uniformity of the projection. We deduce that necessarily, $F = \lambda$, and $L_X u = V^u + V^s$. To solve this last equation, we let
\[
u = \int_{\infty}^{\infty} (\varphi_t)^* V^s dt - \int_{-\infty}^{0} (\varphi_t)^* V^u dt.
\]
the definition of the stable/unstable subspaces implies that this is a continuous bounded vector field, differentiable in the direction of the flow. This finishes the proof of the Lemma, and the Theorem.

In practice, we will use the following consequence:

**Lemma A.3.** Let $(M, g)$ be an Anosov manifold. Then, there exists $\epsilon := \epsilon(g) > 0$ such that if $(M, g')$ is also an Anosov manifold with $\|g' - g\|_{C^3} < \infty$, and $\|g' - g\|_{C^2} \leq \epsilon$, there is actually in any free homotopy class $c$ of a given closed geodesic $\gamma_g$ for $g$, exactly one closed geodesic $\gamma_{g'}$ for $g'$. We denote the length by $L_g(c)$. Additionally, we have
\[
\frac{L_{g'}(c)}{L_g(c)} - 1 = D_g L(c) \cdot (g' - g) + \mathcal{O}(\|g' - g\|^2_{C^3}),
\]
where the remainder is uniform in $c \in \mathcal{C}$.

**Proof.** Let us assume that the uniqueness has been proved. Then, using Lemma A.1, we deduce that
\[
\frac{L_{g'}(c)}{L_g(c)} - 1 = D_g L(c) \cdot (g' - g) + \mathcal{O}(\|X_{g'} - X_g\|^2_{C^2}),
\]
Since $X_g$ can be expressed in terms of the first order derivatives of $g$, it now suffices to compute the first order differential of the length. For this, let $g_t = tg' + (1 - t)g$ and write the equation
\[
L_{g_t}(c) = \int g_t(c_g(s)) ds.
\]
Differentiating with respect to $t$, we get
\[
d_{g_t}L(c) \cdot (g' - g) = \int (g' - g)(\dot{c}_{g_t}(s))ds + 2\int g_t \left( \dot{c}_{g_t}(s), \frac{d}{dt}[\dot{c}_{g_t}(s)] \right) ds.
\]
However, since $g_t(\dot{c}_{g_t}(s))$ is a constant, the second term has to vanish.

We are only left to prove that in each free homotopy class, there can be at most one closed geodesic. In the case of negative curvature, this is a consequence of the Toponogoff comparison theorem. However, in this section, we are working with only the assumption that the flow is uniformly hyperbolic.

Since the geodesic flow is uniformly hyperbolic, there can be no conjugate points, so that the exponential map at any given point is a universal cover of $M$. In particular, the distance on the universal cover is uniquely geodesic. Given $\gamma \in \pi_1(M)$, and $x \in \tilde{M}$, we denote by $L_\gamma(x)$ the length of the geodesic between $x$ and $\gamma x$. This geodesic projects to a loop in $M$. The following lemma is sufficient to conclude the proof.

**Lemma A.4.** For each $\gamma$, there exists a unique geodesic curve $c_\gamma$ such that the critical points of $L_\gamma$ are the points of $c_\gamma$. For each point $x \in c_\gamma$, $c_\gamma$ is the geodesic through $x$ and $\gamma x$.

**Proof of Lemma A.4.** Let us call $c_x$ the geodesic through $x$ and $\gamma x$. Then we have the relations
\[
c_x(0) = x, \quad c_x(L_\gamma(x)) = \gamma x, \quad |\dot{c}_x| = 1.
\]
If we fix $x \in \tilde{M}$, given $\delta x \in T_x \tilde{M}$, one has
\[
d_xL_\gamma(\delta x) = -\langle \dot{c}_x(0), \delta x \rangle + \langle \dot{c}_x(L_\gamma(x)), dx\gamma \cdot \delta x \rangle.
\]
We denote by $\alpha(\gamma, x)$ the angle between $\dot{c}_x(L_\gamma(x))$ and $dx\gamma \cdot \dot{c}_x(0)$. Let $h$ be a unitary vector orthonormal to $dx\gamma \cdot \dot{c}_x(0)$ in the plane $\text{Span}(dx\gamma \cdot \dot{c}_x(0), \dot{c}_x(L_\gamma(x)))$. Since $\gamma$ is an isometry, there exists $\tilde{h} \in T_{x_0} \tilde{M}$ such that $dx\gamma \cdot \tilde{h} = h$ and $\tilde{h}$ is perpendicular to $\dot{c}_x(0)$. Then, applying (25) with $\delta x = \tilde{h}$, we deduce that there is a uniform constant $C > 0$, (independent of $\gamma$) such that $|\alpha| \leq C|\nabla L_\gamma|$.

Let us now consider a point $x$ such that $|\nabla L_\gamma|$ is small. Then, the geodesic from $x$ to $\gamma x$ corresponds in the base to an almost closed trajectory of the geodesic flow. In particular we can apply the Anosov closing Lemma and lift the periodic orbit upstairs: there exist $L_0, C > 0$, and $\epsilon_0 > 0$ such that whenever $L_\gamma(x) > L_0$, and $|\nabla_x L_\gamma| < \epsilon_0$, there is a critical point of $L_\gamma$ at distance at most $C|\nabla_x L_\gamma|$ of $x$.

Then, let us turn to the hessian of $L_\gamma$ at a critical point $x_0$. If we perturb around $x_0$, we obtain a family $c_{x(s)}$ and the variation $\partial_x c_{x(s)}$ is a matrix Jacobi field $J$ along $c_{x_0}$, with
\[
J(0) = 1, \quad J(L_\gamma(x_0)) = dx_0 \gamma.
\]
Variations in the direction of \( c_{x_0} \) are just translations along the closed geodesic so we can assume that \( J \) is a perpendicular Jacobi field. The hessian of \( L_\gamma \) at \( x_0 \) is then given by

\[
d_{x_0}^2 L_\gamma(\delta x, \delta x) = \int_0^{L_\gamma(x_0)} \left( |\dot{J}|^2 - \langle KJ, J \rangle \right) dt,
\]

\( K \) being the symmetric matrix encoding the sectional curvatures appearing in the equation for Jacobi fields.

We consider \( J^u \) (resp. \( J^s \)) the unstable (resp. stable) matrix Jacobi field with \( J^u(L_\gamma(x_0)) = d_{x_0} \gamma^\perp \) (resp. \( J^s(0) = 1 \)). Recall that \( U^u := J^u(J^s)^{-1} \) solves the Ricatti equation, and is defined for all times, so that according to [Ebe73, Lemma 2.8], \( |U^u| \leq k_{\text{max}} \), where \( K \geq -k_{\text{max}}^2 \). The same applies to \( J^s \). Additionally, since the stable and unstable distributions are uniformly transverse, \((U^u - U^s)\) is invertible, with a globally bounded inverse.

We let \( A_{u,s} := \dot{J} - U^{u,s}J \). Then, integrating by parts in the second line, we get

\[
\int |\dot{J}|^2 - \langle KJ, J \rangle = \int |\dot{J}|^2 + \langle (\dot{U}^{u,s} + (U^{u,s})^2)J, J \rangle,
\]

\[
= \int |\dot{J} - U^{u,s}J|^2 = \int |A^{u,s}|^2.
\]

There are no boundary terms because \( U^{u,s} \) are periodic. On the other hand,

\[
|J| \lesssim |(U^u - U^s)J| \leq |A^u - A^s| \leq |A^u| + |A^s|
\]

And \( \dot{J} = A^u + U^uJ \) so \( |\dot{J}| \leq |A^u| + |U^u| \leq |A^u| + k_{\text{max}}|J| \leq C(|A^u| + |A^s|) \). In particular,

\[
d_{x_0}^2 L_\gamma(\delta x, \delta x) \geq C \int (|J|^2 + |\dot{J}|^2) \geq C|\delta x|^2,
\]

for some uniform constant \( C > 0 \).

Take \( x \in \bar{M} \) such that \( L_\gamma(x) > L_0 \), and \( |\nabla_x L_\gamma| < \epsilon \). Then there is a critical point \( x_0 \) at distance \( \leq C|\nabla_x L_\gamma| \) from \( x \), and we have that \( L_\gamma(x) - L_\gamma(x_0) \geq C d(x, c_{x_0})^2 \).

Now, consider the vector field \( X = \nabla L_\gamma \) on \( \bar{M}/\langle \gamma \rangle \). It is uniformly bounded, so the corresponding flow \( w_t \) is globally defined. Moreover, if \( |X(x)| < \epsilon \), then \( x \) is close to a critical point (more precisely, to a 1-parameter family of critical points) and the trajectory of \( x \) in negative time is asymptotic to that critical point. If \( x_0 \) is a critical point with \( L_\gamma(x_0) > L_0 \), we consider \( V \) the boundary of a uniform, global tubular neighbourhood of the associated geodesic \( c_{x_0} \). Then, we define a map \( w : \mathbb{R}^+ \times V \to \bar{M}/\langle \gamma \rangle \) with \( w(t, x) = w_t(x) \). Since this is a gradient flow, \( L_\gamma(w(t, x)) \) increases with \( t \). To be more precise, for \( t \) large, we get that

\[
\partial_t L_\gamma(w(t, x)) = |X(w(t, x))|^2 > \epsilon^2.
\]
In particular, the pull back of $L_\gamma$ to $\mathbb{R}^+ \times V$ is proper. Since $L_\gamma$ is continuous on $\tilde{M}/\langle \gamma \rangle$, this implies that the map $w$ is also proper. Since it is also open, it is surjective. This proves that there can be no other critical point of $L_\gamma$.

Finally, we have to deal with the case that $L_\gamma$ has a critical point $x_0$, with $L_\gamma(x_0) \leq L_0$. In that case, we can consider $\gamma^n$, with large enough. Then $x_0$ is a critical point of $L_{\gamma^n}$, with length $nL_\gamma(x_0)$, which is eventually larger than $L_0$. We can apply the argument to $L_{\gamma^n}$. Since each critical point of $L_\gamma$ is a critical point of $L_{\gamma^n}$, this closes the proof.

This also concludes the proof of Lemma A.3. □
