Abstract

We introduce the Mutual Information Machine (MIM), an autoencoder model for learning joint distributions over observations and latent states. The model formulation reflects two key design principles: 1) symmetry, to encourage the encoder and decoder to learn consistent factorizations of the same underlying distribution; and 2) mutual information, to encourage the learning of useful representations for downstream tasks. The objective comprises the Jensen-Shannon divergence between the encoding and decoding joint distributions, plus a mutual information term. We show that this objective can be bounded by a tractable cross-entropy loss between the true model and a parameterized approximation, and relate this to maximum likelihood estimation and variational autoencoders. Experiments show that MIM is capable of learning a latent representation with high mutual information, and good unsupervised clustering, while providing data log likelihood comparable to VAE (with a sufficiently expressive architecture).

1 Introduction

Mutual information is a natural indicator of the quality of a learned representation [15], along with other characteristics, such as the compositionality of latent factors that are expected to be useful in downstream tasks, like transfer learning [4]. Mutual information is, however, computationally difficult to estimate for continuous high-dimensional random variables. As such, it can be hard to optimize when learning latent variable models [3, 7].

This paper formulates a new class of probabilistic autoencoder model that is motivated by two key design principles, namely, the maximization of mutual information, and the symmetry of the encoder-decoder components. Symmetry captures our desire for both the encoder and decoder to effectively and consistently model the underlying observation and latent domains. This is particularly useful for downstream tasks in which either one or both of the encoder and decoder play a central role. These properties are formulated in terms of the symmetric Jensen-Shannon Divergence between the encoder and decoder, combined with an objective term to maximize mutual information. We refer to the resulting model as the mutual information machine, or MIM.

We contrast MIM with models trained using (approximate) maximum likelihood, the canonical example being the variational autoencoder, or VAE [19, 29]. The VAE comprises a probabilistic decoder and an approximate encoder, learned via optimization of an evidence-based lower bound (ELBO) on the log marginal data distribution. In contrast to MIM it is asymmetric in its formulation, and while often producing excellent representations, VAEs sometimes produce pathological results in which the encoder, or approximate posterior, conveys relatively little information between observations and latent states. This behavior, often referred to as posterior collapse, results in low mutual information between observations and inferred latent states [6, 8, 27, 33, 35].

We formulate the MIM model, and a learning algorithm that minimizes an upper bound on the desired loss. The resulting objective can be viewed as a symmetrized form of KL divergence, thereby closely

Preprint. Under review.
With amortized posterior inference, we take expectation over the observation distribution, \( V AE \) loss with respect to \( \theta \).

\( V AE \)s are normally thought of as maximizing a lower bound on the data log-likelihood, however it \( V AE \) learning entails optimization of a variational lower bound on the log-marginal likelihood of the data, which can also be expressed as minimizing the divergence between two joint distributions over \( x \) and \( z \) in terms of posterior collapse, mutual information, data log likelihood, and clustering. Experiments show that \( MIM \) offers favourable mutual information, better clustering in the latent representation, and similar reconstruction, at the expense of sampling quality and data log likelihood when compared to a \( V AE \) with the same architecture. We also demonstrate that for a sufficiently powerful architecture, \( MIM \) can match sampling quality and log likelihood of a \( V AE \) with the same architecture.

\section{Variational Autoencoders}

\( V AE \) learning entails optimization of a variational lower bound on the log-marginal likelihood of the data, \( \log P(x) \), to estimate the parameters \( \theta \) of an approximate posterior \( q_\theta(z|x) \) over latent states \( z \) (i.e., the encoder) and a corresponding decoder, \( p_\theta(x|z) \) [19, 29]. A prior over the latent space, \( P(z) \), often assumed to be an isotropic Gaussian, serves as a prior for \( q_\theta(z|x) \) in the evidence-lower-bound (ELBO) on the marginal likelihood:

\[
\log P(x) \geq E_{z \sim q_\theta(z|x)} \left[ \log p_\theta(x|z) \right] - D_{KL}(q_\theta(z|x) \parallel P(z)) ,
\]

Here, we use the notation \( P(x) \) and \( P(z) \) to emphasize that these priors are given, and that we can draw random samples from them, but not necessarily evaluate the log-likelihood of samples under them. In what follows we often refer to them as \textit{anchors} to further emphasize their role.

With amortized posterior inference, we take expectation over the observation distribution, \( P(x) \), to obtain the \( V AE \) objective:

\[
\mathcal{R}_{V AE} (\theta) = E_{x \sim P(x)} \left[ E_{z \sim q_\theta(z|x)} \left[ \log p_\theta(x|z) \right] - D_{KL}(q_\theta(z|x) \parallel P(z)) \right]
= E_{x \sim P(x), z \sim q_\theta(z|x)} \left[ \log p_\theta(x|z) + \log P(z) - \log q_\theta(z|x) \right] , \tag{1}
\]

Gradients of Eqn. (1) are estimated through MC sampling from \( q_\theta(z|x) \) with reparameterization, yielding unbiased low-variance gradient estimates [19, 29].

\( V AE \)s are normally thought of as maximizing a lower bound on the data log-likelihood, however it can also be expressed as minimizing the divergence between two joint distributions over \( x \) and \( z \). To see this, we first subtract \( \log P(x) \) from (1), which does not change the gradients of the objective with respect to \( \theta \). We then negate the result, as we will be performing minimization. This yields a \( V AE \) loss

\[
\mathcal{L}_{V AE} (\theta) = -\mathcal{R}_{V AE} (\theta) + E_{x \sim P(x)} \left[ \log P(x) \right] = D_{KL}(q_\theta(z|x)P(x) \parallel p_\theta(x|z)P(z)) . \tag{2}
\]

The \( V AE \) optimization is therefore equivalent to minimizing the KL divergence between an encoding distribution \( q_\theta(z|x)P(x) \) and a decoding distribution \( p_\theta(x|z)P(z) \).

\section{Symmetry and Mutual Information}

Our goal is to find a consistent encoder-decoder pair, representing a joint distribution over the observation and latent domains, with high mutual information between observations and latent states. By consistent, we mean that the encoding and decoding distributions, \( q_\theta(z|x)P(x) \) and \( p_\theta(x|z)P(z) \), define the same joint distribution. Figure 1 depicts this basic idea, in which the same distribution is identical under both the encoding and decoding factorizations. Effectively, we estimate

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{A MIM model learns two factorizations of a joint distribution: (a) encoding; (b) decoding factorizations; and (c) the estimated joint distribution (an undirected graphical model).}
\end{figure}
an undirected graphical model with two valid factorizations. We note that consistency is achievable in the VAE when the approximate posterior \( q_\theta (z|x) \) is capable of representing the posterior under the decoding distribution \( p_\theta (z|x) \). In the general case, however, consistency is not usually achieved.

In contrast to the asymmetric divergence between encoding and decoding distributions in the VAE objective \((2)\), here we consider a symmetric measure, namely, the well-known Jensen-Shannon divergence (JSD),

\[
\text{JSD}\left(\theta\right) = \frac{1}{2} \left( D_{\text{KL}}(p_\theta(x|z) P(z) \parallel M_S) + D_{\text{KL}}(q_\theta(z|x) P(x) \parallel M_S) \right),
\]

(3)

where \( M_S \) is an equally weighted mixture of the encoding and decoding distributions; i.e.,

\[
M_S = \frac{1}{2} \left( p_\theta(x|z) P(z) + q_\theta(z|x) P(x) \right).
\]

(4)

In addition to encoder-decoder consistency, to learn useful latent representations we also want high mutual information between \( x \) and \( z \). Indeed, the link between mutual information and representation learning has been explored in recent work [3, 7, 15]. Here, to emphasize high mutual information, we add a particular regularizer of the form

\[
R_H(\theta) = \frac{1}{2} \left( H(p_\theta(x|z) P(z)) + H(q_\theta(z|x) P(x)) \right).
\]

(5)

This is the average of the joint entropy over \( x \) and \( z \) according to the encoding and decoding distributions. This is related to mutual information by the identity \( H(x, z) = H(x) + H(z) - I(x; z) \). That is, minimizing joint entropy encourages the minimization of the marginal entropy and maximization of the mutual information. In addition to encouraging high mutual information, one can show that this particular regularizer has a deep connection to JSD and the entropy of \( M_S \), i.e.,

\[
\text{JSD}\left(\theta\right) + R_H(\theta) = H(M_S).
\]

(6)

The derivation for Eqn. \((6)\) is given in Appendix A.1.

4 Mutual Information Machine

The loss function in Eqn. \((6)\) reflects our desire for model symmetry and high mutual information. Nevertheless, it is difficult to optimize directly since we do not know how to evaluate \( \log P(x) \) in the general case \( i.e., \) we do not have an exact closed-form expression for \( P(x) \). As a consequence, we introduce parameterized approximate priors, \( q_\theta(x) \) and \( p_\theta(z) \), to derive tractable bounds on the penalized Jensen-Shannon divergence. This is similar in spirit to VAEs, which introduce a parameterized approximate posterior. These parameterized priors, together with the conditional encoder and decoder, \( q_\theta(z|x) \) and \( p_\theta(x|z) \), comprise a new pair of joint distributions, i.e.,

\[
q_\theta(x, z) \equiv q_\theta(z|x) q_\theta(x)
\]

\[
p_\theta(x, z) \equiv p_\theta(x|z) p_\theta(z).
\]

These joint distributions allow us to formulate a new, tractable loss that bounds \( H(M_S) \). That is,

\[
\mathcal{L}_{\text{CE}}(\theta) \equiv H(M_S, M_\theta) = D_{\text{KL}}(M_S \parallel M_\theta) + H(M_S) \geq H(M_S),
\]

(7)

where

\[
M_\theta = \frac{1}{2} \left( p_\theta(x, z) + q_\theta(x, z) \right),
\]

(8)

and \( H(M_S, M_\theta) \) denotes the cross-entropy between \( M_S \) and \( M_\theta \).

We refer to \( \mathcal{L}_{\text{CE}} \) as the cross-entropy loss. It aims to match the model prior distributions to the anchors, while also minimizing \( H(M_S) \). A key advantage of this formulation is that the cross-entropy loss can be trained by Monte Carlo sampling from the anchor distributions with reparameterization [19, 29].

At this stage it might seem odd to introduce a parametric prior for \( P(z) \). Indeed, setting it directly is certainly an option. Nevertheless, in order to achieve consistency between \( p_\theta(x, z) \) and \( q_\theta(x, z) \) it can be advantageous to allow \( p_\theta(z) \) to vary. Essentially, we trade-off latent prior fidelity for increased model consistency. We provide more insights about this in Appendix D.3.
One issue with $L_{CE}$ is that, while it will try to enforce consistency between the model and the anchored distributions, i.e., $p_\theta(x, z) \approx p_\theta(x|z)p(z)$ and $q_\theta(x, z) \approx q_\theta(z|x)p(x)$, it will not directly try to achieve model consistency: $p_\theta(x, z) \approx q_\theta(x, z)$. To remedy this, we bound $L_{CE}$ using Jensen’s inequality, i.e.,

$$L_{MIM}(\theta) = \frac{1}{2}(H(M_S, q_\theta(x, z)) + H(M_S, p_\theta(x, z))) \geq L_{CE}(\theta).$$  \hspace{1cm} (9)

Equation (9) gives us the loss function for the Mutual Information Machine (MIM). It is an average of cross entropy terms between the mixture distribution $M_S$ and the model encoding and decoding distributions respectively. To see that this encourages model consistency, it can be shown that $L_{MIM}$ is equivalent to $L_{CE}$ plus a non-negative model consistency term; i.e.,

$$L_{MIM}(\theta) = L_{CE}(\theta) + R_{MIM}(\theta).$$  \hspace{1cm} (10)

The non-negativity of $R_{MIM}$ is a simple consequence of $L_{MIM}(\theta) \geq L_{CE}(\theta)$ in (9). One can further show (see Appendix A.2) that $R_{MIM}(\theta)$ satisfies

$$R_{MIM}(\theta) = \frac{1}{2}(D_{KL}(M_S \| p_\theta(x, z)) + D_{KL}(M_S \| q_\theta(x, z))) - D_{KL}(M_S \| M_\theta)$$ \hspace{1cm} (11)

$$= \mathbb{E}_{x,z \sim M_S} \left[ -\log \frac{\sqrt{q_\theta(x, z) \cdot p_\theta(x, z)}}{\frac{1}{2}(q_\theta(x, z) + p_\theta(x, z))} \right] \geq 0.$$ \hspace{1cm} (12)

One can conclude from Eqn. (11) that $R_{MIM}$ is zero only when the two joint model distributions, $q_\theta(x, z)$ and $p_\theta(x, z)$, are identical under fair samples from the joint sample distribution $M_S(x, z)$. In practice we find that encouraging model consistency also helps to stabilize learning.

To understand the MIM objective in greater depth, we find it helpful to express $L_{MIM}$ as a sum of fundamental terms that provide some intuition for its expected behavior. In particular, as derived in the Appendix A.3,

$$L_{MIM}(\theta) = R_H(\theta) + \frac{1}{4}(D_{KL}(P(z) \| p_\theta(z)) + D_{KL}(P(x) \| q_\theta(x)))$$
$$+ \frac{1}{4}(D_{KL}(q_\theta(z|x)P(x) \| p_\theta(x, z)) + D_{KL}(p_\theta(x|z)P(z) \| q_\theta(x, x)))$$ \hspace{1cm} (13)

The first term in Eqn. (13) encourages high mutual information between observations and latent states. The second shows that MIM directly encourages the model priors to match the anchor distributions. Indeed, the KL term between the data anchor and the model prior is the maximum likelihood objective. The third term encourages consistency between the model distributions and the anchored distributions, in effect fitting the model decoder to samples drawn from the anchored encoder (cf. VAE), and, via symmetry, fitting the model encoder to samples drawn from the anchored decoder (both with reparameterization). As such, MIM can be seen as simultaneously training and distilling a model distribution over the data into a latent variable model. The idea of distilling density models has been used in other domains, e.g., for parallelizing auto-regressive models [34].

In summary, the MIM loss provides an upper bound on the joint entropy of the observation and latent states under the mixture distribution $M_S$:

$$L_{MIM}(\theta) = \frac{1}{2}(H(M_S, q_\theta(x, z)) + H(M_S, p_\theta(x, z)))$$
$$= H(M_S, M_\theta) + R_{MIM}(\theta)$$
$$\geq H(M_S, M_\theta)$$
$$\geq H(M_S)$$
$$= H_{M_S}(x) + H_{M_S}(z) - I_{M_S}(x; z).$$ \hspace{1cm} (14)

Through the MIM loss and the introduction of the parameterized model distribution $M_\theta$, we are pushing down on the entropy of the anchored mixture distribution $M_S$, which is the sum of marginal entropies minus the mutual information. Minimizing the MIM bound yields consistency of the model encoder and decoder, and high mutual information under $M_S$ between observations and latent states.
Another useful model with high dimensional data, following [5], is to define VampPrior’s effect over gradient estimation.

VampPrior

As an alternative, for image data, we make use of the when dealing with high dimensional data (31), which models the latent prior as a mixture of posteriors, i.e., \( p_\theta (z) = \sum_{k=1}^{K} q_\theta (z|x = u_k) \) with learnable pseudo-inputs \( \{u_k\}_{k=1}^{K} \). This is effective and allows one to avoid the need for additional parameters (see [31] for details on VampPrior’s effect over gradient estimation).

Algorithm 1 specifies the corresponding training procedure. The algorithm makes no assumptions on the form of the parameterized distributions (e.g., discrete, or continuous). In practice, for gradient-based optimization, we would like an unbiased gradient estimator without the need to accurately approximate the full expectations per se (i.e., in the cross entropy terms). This is particularly important when dealing with high dimensional data (e.g., images), where it is computationally expensive to estimate the value of the expectation. We next discuss practical considerations for the continuous case and the discrete case.

5 Learning

Here we provide a detailed description of MIM learning, with algorithmic pseudo-code. In addition we offer practical considerations regarding the choice of priors’ parameterization, and gradient estimation. The empirical upper bound objective, \( \mathcal{L}_{\text{MIM}} \) in Eq. (9), is expressed in terms of two cross-entropy terms. Given \( N \) fair samples, \( \{x_i, z_i\}_{i=1}^{N} \) drawn from the anchored (sample) distribution, \( \mathcal{M}_S(x, z) \) in (4), the empirical loss is

\[
\hat{\mathcal{L}}_{\text{MIM}} (\theta; \{x_i, z_i\}_{i=1}^{N}) = - \frac{1}{2N} \sum_{i=1}^{N} \log (q_\theta (z_i|x_i) q_\theta (x_i)) + \log (p_\theta (x_i|z_i) p_\theta (z_i)) , \tag{15}
\]

where samples from \( \mathcal{M}_S \) comprise equal numbers of points from \( p_\theta (x|z) P(z) \) and \( q_\theta (z|x) P(x) \). Samples from the anchors, \( P(x) \) and \( P(z) \), are treated as external observations; i.e., we assume we can sample from them but not necessarily evaluate the density of points under the anchor distributions.

Algorithm 1 specifies the corresponding training procedure. The algorithm makes no assumptions on the form of the parameterized distributions (e.g., discrete, or continuous). In practice, for gradient-based optimization, we would like an unbiased gradient estimator without the need to accurately approximate the full expectations per se (i.e., in the cross entropy terms). This is particularly important when dealing with high dimensional data (e.g., images), where it is computationally expensive to estimate the value of the expectation. We next discuss practical considerations for the continuous case and the discrete case.

5.1 MIM Parametric Priors

There are several effective ways to parameterize the priors. For the 1D experiments in Appendix D we model \( p_\theta (z) \) using linear mixtures of isotropic Gaussians. With complex, high dimensional data one might also consider more powerful models (e.g., autoregressive, or flow-based priors). Unfortunately, the use of complex models typically increases the required computational resources, and the training and inference time.

As an alternative, for image data, we make use of the VampPrior [31], which models the latent prior as a mixture of posteriors, i.e., \( p_\theta (z) = \sum_{k=1}^{K} q_\theta (z|x = u_k) \) with learnable pseudo-inputs \( \{u_k\}_{k=1}^{K} \). This is effective and allows one to avoid the need for additional parameters (see [31] for details on VampPrior’s effect over gradient estimation).

Another useful model with high dimensional data, following [5], is to define \( q_\theta (x) \) as the marginal of the decoding distribution; i.e.,

\[
q_\theta (x) = \mathbb{E}_{z \sim p_\theta (z)} \left[ p_\theta (x|z) \right] . \tag{16}
\]

Like the vampprior, this entails no new parameters. It also helps to encourage consistency between the encoding and decoding distributions. In addition it enables direct empirical comparison between MIM and VAE as we can then use identical parameterizations and architectures for both. During learning, when \( q_\theta (x) \) is defined as the marginal (16), we evaluate \( \log q_\theta (x) \) with a single sample and
reparameterization. When \( z \) is drawn directly from the latent prior:
\[
\log q_\theta(x) = \log E_{z \sim p_\theta(x)}[p_\theta(x|\tilde{z})] \approx \log p_\theta(x|\tilde{z}).
\]

When \( z \) is drawn from the encoder, given a sample observation, we use importance sampling:
\[
\log q_\theta(x) = \log E_{z \sim q_\theta(z|x)} \frac{p_\theta(x|\tilde{z})}{q_\theta(\tilde{z}|x)} \approx \log p_\theta(x|\tilde{z}) + \log p_\theta(\tilde{z}) - \log q_\theta(\tilde{z}|x)
\]
Algorithm 2 provides algorithm details with the marginal prior.

5.2 Gradient Estimation

Optimization is performed through minibatch stochastic gradient descent. To ensure unbiased gradient estimates of \( \hat{L}_{MM} \) we use the reparameterization trick \([19, 29]\) when taking expectation with respect to continuous encoder and decoder distributions, \( q_\theta(z|x) \) and \( p_\theta(x|z) \). Reparameterization entails sampling an auxiliary variable \( \epsilon \sim p(\epsilon) \), with known \( p(\epsilon) \), followed by a deterministic mapping from sample variates to the target random variable, that is \( p(\epsilon) = q_\theta(\epsilon) \) and \( q_\theta(z|x) = h_\theta(\epsilon, x) \) for prior and conditional distributions. In doing so we assume \( p(\epsilon) \) is independent of the parameters \( \theta \). It then follows that
\[
\nabla_\theta E_{\epsilon \sim p(\epsilon)}[f_\theta(\epsilon)] = \nabla_\theta E_{\epsilon \sim p(\epsilon)}[f_\theta(h_\theta(\epsilon, x))] = E_{\epsilon \sim p(\epsilon)}[\nabla_\theta f_\theta(h_\theta(\epsilon, x))]
\]
where \( f_\theta(\epsilon) \) is the loss function with parameters \( \theta \). It is common to let \( p(\epsilon) \) be standard normal, \( \epsilon \sim \mathcal{N}(0, 1) \), and for \( z|x \) to be Gaussian with mean \( \mu_\theta(x) \) and standard deviation \( \sigma_\theta(x) \), in which case \( z = \sigma_\theta(x) \epsilon + \mu_\theta(x) \). A more generic exact density model can be learned by mapping a known base distribution (e.g., Gaussian) to a target distribution with normalizing flows \([9, 10, 28]\).

For discrete distributions, e.g., with discrete data, reparameterization is not readily applicable. There exist continuous relaxations that permit reparameterization (e.g., \([24, 32]\)), but current methods are rather involved, and require adaptation of the objective function or the optimization process. Here we simply use the REINFORCE algorithm \([30]\) for unbiased gradient estimates, as follows
\[
\nabla_\theta E_{z \sim q_\theta(z|x)}[f_\theta(z)] = E_{z \sim q_\theta(z|x)}[\nabla_\theta f_\theta(z) + f_\theta(z) \nabla_\theta \log q_\theta(z|x)].
\]

The derivation for Eqn. (17) is as follows:
\[
\nabla_\theta E_{z \sim q_\theta(z|x)}[f_\theta(z)] = \int q_\theta(z|x) \nabla_\theta f_\theta(z) \, dz + \int f_\theta(z) \nabla_\theta q_\theta(z|x) \, dz
\]
\[
= \int q_\theta(z|x) \nabla_\theta f_\theta(z) \, dz + \int f_\theta(z) q_\theta(z|x) \nabla_\theta \log q_\theta(z|x) \, dz
\]
\[
= E_{z \sim q_\theta(z|x)}[\nabla_\theta f_\theta(z) + f_\theta(z) \nabla_\theta \log q_\theta(z|x)].
\]
while the MIM objective explicitly encourages high mutual information between observations and 

for which the step from the first line to the second line makes use of the well-known identity,

\[ \nabla_q q_\theta(z|x) = q_\theta(z|x) \nabla_q \log q_\theta(z|x) \]. This relation is essential as it enables a Monte Carlo approximation to the integral.

5.3 Training Time

Training times of MIM models are comparable to training times for VAEs with comparable architectures. One important difference concerns the time required for sampling from the decoder during training. This is particularly significant for models like auto-regressive decoders (e.g., [20]) for which sampling is very slow. In such cases, we find that we can also learn effectively with a sampling approximation to the integral.

Training continues until the loss \( (i.e., \ \beta = 1) \) on a held-out validation set has not improved for the same number of epochs as the warm-up steps \( (i.e., \ \text{defmed per experiment}) \). We have found the number of epochs to convergence of MIM learning to be between 2 to 5 times greater than a VAE with the same architecture. (Code is available from [https://github.com/seraphlabs-ca/MIM](https://github.com/seraphlabs-ca/MIM)).

6 Experiments

In what follows we examine MIM empirically, with the VAE as a baseline. We consider synthetic datasets and well-known image datasets, namely MNIST [23], Fashion-MNIST [38] and Omniglot [22]. All models were trained using Adam optimizer [17] with a learning rate of \( 10^{-3} \), and a mini-batch size of 128. Following [1], we anneal the loss to stabilize the optimization. To this end we linearly increase \( \beta \) from 0 to 1 in the following expression for a number of 'warm-up' epochs:

\[
\hat{L}_{\text{MIM}}(\theta; \{x_i, z_i\}^{N}_{i=1}, \beta) = - \frac{1}{2N} \sum_{i=1}^{N} \log (p_\theta(x_i|z_i) p_\theta(z_i)) + \beta \log (q_\theta(z_i|x_i) \log q_\theta(x_i)).
\] (18)

Training continues until the loss \( (i.e., \ \beta = 1) \) on a held-out validation set has not improved for the same number of epochs as the warm-up steps \( (i.e., \ \text{defined per experiment}) \). We have found the number of epochs to convergence of MIM learning to be between 2 to 5 times greater than a VAE with the same architecture. (Code is available from [https://github.com/seraphlabs-ca/MIM](https://github.com/seraphlabs-ca/MIM)).

6.1 Relation to VAE and Posterior Collapse

Before turning to empirical results, it is useful to briefly revisit similarities and differences between MIM and the canonical VAE formulation. To that end, one can show from Eqns. (1) and (2) that the VAE loss can be expressed in a form that bears similarity to the MIM loss in Eqn. (9). In particular, following the derivation in Appendix C,

\[
L_{\text{VAE}} = \frac{1}{2} \left( H(\mathcal{M}_{S}^{\text{VAE}}; q_\theta(z|x) P(x)) + H(\mathcal{M}_{S}^{\text{VAE}}; p_\theta(x|z) P(z)) \right) \]

\[- H_{\mathcal{M}_{S}^{\text{VAE}}}(x) - H_{\mathcal{M}_{S}^{\text{VAE}}}(z) + I_{\mathcal{M}_{S}^{\text{VAE}}}(x; z) \]. (19)

where \( \mathcal{M}_{S}^{\text{VAE}}(x, z) = q_\theta(z|x) P(x) \). Like the MIM loss, the first term in Eqn. (19) in the average of two cross entropy terms, between a sample distribution and the encoding and decoding distributions. Unlike the MIM loss, these terms are asymmetric as the samples are drawn only from the encoding distribution. Also unlike the MIM loss, the VAE loss includes the last three terms in Eqn. (19), the sum of which comprise the negative joint entropy \(-H(x, z)\) under the sample distribution \(\mathcal{M}_{S}^{\text{VAE}}\).

While the MIM objective explicitly encourages high mutual information between observations and corresponding latent embeddings, this VAE loss includes a term that encourages a reduction in the mutual information. We posit that this plays a significant role in the phenomena often referred to as posterior collapse, in which the variance of the variational posterior grows large and the latent embedding conveys relatively little information about the observations (e.g., see [8] and others).

6.2 Posterior Collapse in Low Dimensional Data

To empirically support the expression in Eqn. (19), we begin with synthetic data comprising 2D observations \( x \in \mathbb{R}^2 \), with a 2D latent space, \( z \in \mathbb{R}^2 \). In 2D one can easily visualize the model and measure quantitative properties of interest (e.g., mutual information). Observations are drawn from
Figure 2: VAE and MIM models with 2D inputs, a 2D latent space, and 5, 20 and 500 hidden units. Top row: Black contours depict level sets of $P(x)$; red dots are reconstructed test points. Bottom row: Green contours are one standard deviation ellipses of $q_\theta(z|x)$ for test points. Dashed black circles depict one standard deviation of $P(z)$. The VAE predictive variance remains high, regardless of model expressiveness, an indication of various degrees of posterior collapse, while MIM produces lower predictive variance and lower reconstruction errors, consistent with high mutual information (see inset quantities).

(a) MI (b) NLL (c) Recon. Error (d) Classif. (5-NN)

Figure 3: Test performance for MIM (blue) and VAE (red) for the 2D GMM data (cf. Fig. 2), all as functions of the number of hidden units (on x-axis). Plots show (a) mutual information, (b) negative log-likelihood of test points, (c) test reconstruction error, and (d) K-NN mode classification performance. Each plot shows the mean and standard deviation of 10 experiments.

anchor $P(x)$, a Gaussian mixture model with five isotropic components with standard deviation 0.25 (Fig. 2, top row). The latent anchor $P(z)$ is an isotropic standard Normal (Fig. 2, bottom row). The encoder and decoder conditional distributions are Gaussian, the means and variances of which are regressed from the input using two fully connected layers and $\tanh$ activation. The parameterized data prior, $q_\theta(x)$, is defined to be the marginal of the decoding distribution (16), and the model prior $p_\theta(z)$ is defined to be $P(z)$, so the only model parameters are those of the encoder and decoder. We can thus learn models with MIM and VAE objectives, but with the same architecture and parameterization. We used a warm-up scheduler [37] for the learning rate, with a warm-up of 3 steps, and with each epoch comprising 10000 samples. Training and test sets are drawn independently from the GMM.

Figure 2 depicts three models for VAE (odd columns) and MIM (even columns), with increasing numbers of hidden units (from left to right) to control model expressiveness. The top row depicts observation space where black contours are levels sets of constant density $P(x)$, and red points are reconstructed samples, i.e., one point drawn from $q_\theta(x|x')$ where $z'$ is drawn from the encoder $q_\theta(z'|x')$, given a test point $x'$ from $P(x)$. In each case we also report the mutual information and the root-mean-squared reconstruction error, with MIM producing superior results.

The bottom row of Fig. 2 depicts latent space behavior. The dashed black circle depicts one standard deviation of $P(z)$. Each green curve depicts a one standard deviation ellipse of the encoder posterior $q_\theta(z'|x')$ given a test point $x'$ from $P(x)$. For the weakest architecture (a), with 5 hidden units, VAE and MIM posterior variances are similar to the prior in one dimension, a sign of posterior collapse. As the number of hidden units increases (b,c), the VAE posterior variance remains large, preferring lower mutual information while matching the aggregated posterior to the prior. In contrast, the MIM
encoder produces tight posteriors, and yields higher mutual information and lower reconstruction errors at the expense of somewhat worse data log likelihoods.

To quantify this behavior Fig. 3 shows mutual information, the average negative log-likelihood (NLL) of test points under the model \( q_\theta \), the mean reconstruction error of test points, and 5-NN classification performance\(^1\) (predicting which of 5 GMM components each test point was drawn from). The auxiliary classification task provides a proxy for representation quality. Following [3], we estimate mutual information using the KSG estimator [21, 13], based on 5-NN neighborhoods.

Mutual information and classification accuracy for test data under the MIM model are higher than for VAE models. One can also see that mutual information is saturated for MIM, as it effectively learns an (approximate) invertible mapping. The encoder and decoder approach deterministic mappings, reflected in the near-zero reconstruction error. Interestingly, MIM learning finds near-invertible mappings with unconstrained architectures (demonstrated here for the 2D case), when the dimensionality of the latent representation and the observations is the same. (See Sec. D of the supplementary material for experiments on variants of MIM and VAE that tease apart the impact of specific terms of the respective objectives.)

Next we consider synthetic 20D data from a 5-component GMM, with independent training and test sets, and with latent dimensionalities between 2 and 20. This ensures that the distribution is well modeled with a relatively simple architecture. This experiment extends the experiment in Fig. 3 by adding a bottleneck. The experimental setup was otherwise similar to that used in Fig. 3.

Results are shown in Fig. 4. MIM produces higher mutual information and better classification as the latent dimensionality increases. VAE mutual information and classification accuracy deteriorate with increasing latent dimensionality, due to stronger posterior collapse for higher dimensional latent. The test NLL scores for MIM are not as good as those for VAEs in part because the MIM encoder produces very small posterior variance, approaching a deterministic encoder. Nevertheless, MIM produces lower test reconstruction errors. These results are consistent with those in Fig. 3.

To further investigate MIM learning in low dimensional data, we project 784D images from Fashion-MNIST onto a 20D linear subspace using PCA (capturing 78.5% of total variance), and repeat the

\(^1\)We experimented with 1-NN,3-NN,5-NN,10-NN and found the results to be consistent.
experiment in Fig. 4. The training and validation sets had 50,000 and 10,000 images respectively. We trained for 200 epochs, well past convergence, and then selected the model with the lowest validation loss. Fig. 5 summarizes the results, with MIM producing high mutual information and classification accuracy, at all but very low latent dimensions. MIM and VAE yield similar test reconstruction errors, with VAE having better negative log likelihoods for test data.

We conclude that the VAE is prone to posterior collapse for a wide range of models’ expressiveness and latent dimensionality, with latent embeddings exhibiting low mutual information. In contrast, MIM was empirically robust to posterior collapse, and showed higher mutual information, converging to an encoder with small variance. As a result the learned marginal data likelihood for MIM is worse. In this regard, we note that several papers have described ways to mitigate posterior collapse in VAE learning, e.g., by lower bounding, or annealing the KL divergence term in the VAE objective [1, 27], or by limiting the expressiveness of the decoder (e.g., [8]). We posit that MIM does not suffer from this problem as a consequence of the objective design principles that encourage high mutual information between observations and the latent representation.

### 6.3 Image Data

We next consider MIM and VAE learning with image data (Fashion-MNIST, MNIST, Omniglot). Unfortunately, with high dimensional data we cannot reliably compute mutual information [3]. Instead, for model assessment we focus on negative log-likelihood, reconstruction, and the quality of random samples. In doing so we also explore multiple architectures, including the top performing

models from [31], namely, \textit{convHVAE} (L = 2) and \textit{PixelHVAE} (L = 2), with Standard (S) priors\(^2\), and \textit{VampPrior} (VP) priors\(^3\). The VP pseudo-inputs are initialized with training data samples. All the experiments below use the same experimental setup as in [31], and the same latent dimensionality \( z \in \mathbb{R}^{80} \). Here we also demonstrate that a powerful prior (e.g., PixelHVAE (VP)) allows MIM to learn models with competitive sampling and NLL performance.

Sampling from an auto-regressive decoder (e.g., PixelHVAE) is very slow. To reduce training time, as discussed above in Sec. 5.3, we learn with a sampling distribution comprising just the encoding distribution, i.e., \( \mathcal{P}(x)q_\theta(z|x) \), rather than the mixture, a MIM variant we refer to as asymmetric-MIM (or A-MIM).

Table 1 reports test NLL scores. One can see that VAE models yield better NLL, but with a small gap for more expressive models (i.e., PixelHVAE (VP)). We also show qualitative results for the most expressive models (i.e., PixelHVAE). Fig. 6 depicts reconstruction\(^4\) and sampling for Fashion-MNIST, MNIST, and Omniglot, for the top performing model (PixelHVAE (VP)), with MIM and VAE being comparable. The top three rows depict data samples, VAE reconstructions, and A-MIM reconstructions, respectively. The bottom row depicts random samples. Note that, while MIM with a weak prior (Standard) suffers from poor sampling, increasing the expressiveness results in comparable samples and reconstruction. See Appendix E for additional results.

The poor NLL and hence poor sampling for MIM with a weak prior model can be explained by the tightly clustered latent representation (e.g., Fig. 2). A more expressive, learnable prior can capture such clusters more accurately, and as such, also produces good samples (e.g., VampPrior). In other words, while VAE opts for better NLL and sampling at the expense of lower mutual information, MIM provides higher mutual information at the expense of the NLL for a weak prior, and comparable NLL and sampling with more expressive priors. In Sec. 6.4 we probe the effect of higher mutual information on the quality of the learned representation.

6.4 Clustering and Classification

Finally, following [15], we consider an auxiliary classification task as a further measure of the quality of the learned representations. We opted for K-NN classification, being a non-parametric method which relies on semantic clustering in latent space without any additional training. Given

\[^2\] \( p_\theta(z) = \mathcal{N}(z; \mu = 0, \sigma = \mathbb{I}) \), a standard Normal distribution, where \( \mathbb{I} \) is the identity matrix.

\[^3\] \( p_\theta(z) = \frac{1}{K} \sum_{k=1}^{K} q_\theta(z|u_k) \), a mixture model of the encoder conditioned on optimized pseudo-inputs \( u_k \).

\[^4\] Test data in the top row of Fig. 6 are binary, while reconstructions depict the probability of each pixel being 1, following [31].
representations learned above in Sec. 6.3, a simple 5-NN classifier\(^5\) was applied to test data to predict one of 10 classes for MNIST and Fashion-MNIST. Table 2 shows that in all but one case, MIM yields more accurate classification results. We attribute the performance difference to higher mutual information of MIM representations, combined with low entropy of the marginals. Figures (7, 8, 9, and 10) provide a qualitative visualization of the latent clustering, for which t-SNE [36] was used to project the latent space down to 2D for Fashion-MNIST, and MNIST data. One can see that MIM learning tends to cluster classes in the latent representation more tightly, while VAE clusters are more diffuse and overlapping, consistent with the results in Table 2.

7 Related Work

Given the vast literature on generative models, here we only touch on the major bodies of work related to MIM.

VAEs [19] are widely used as latent variable models for representation learning. The VAE provides a strong sampling capability (e.g., [27]), considered as a proxy for representation quality, in addition to auxiliary tasks such as classification [4]. Nevertheless, it has been observed that a powerful decoder can suffer from posterior collapse [6, 8, 27, 33, 35], where the decoder effectively ignores the encoder in some dimensions, and the learned representation has low mutual information with the observations. While several attempts to mitigate the problem have been proposed [1, 27], the root cause has not been identified.

As mentioned above, mutual information, together with disentanglement, is considered to be a cornerstone for useful representations [3, 15]. Normalizing flows [28, 9, 10, 18, 16] directly maximizes mutual information by restricting the architecture to be invertible and tractable. This, however, requires the latent dimension to be the same as the dimension of the observations (i.e., no bottleneck). As a consequence, normalizing flows are not well suited to learning a concise representation of high dimensional data (e.g., images). Here, MIM often yields mappings that are approximately invertible, with high mutual information and low reconstruction errors.

The Bidirectional Helmholtz Machine [5] shares some of the same design principles as MIM, i.e., symmetry and encode/decoder consistency. However, their formulation models the joint density in terms of the geometric mean between the encoder and decoder, for which one must compute an

\(^5\)We omitted results for \(k \in \{1, 3, 10\}\) as we find them similar.
expensive partition function. [25] focus on minimizing symmetric KL, but must use an adversarial learning procedure, while MIM can be minimized directly.

GANs [14], which focus mainly on decoder properties, without a proper inference model, have been shown to minimize JSD between the data anchor $P(x)$ and the model generative process $q_\theta(x)$ (i.e., the marginal of the decoding distribution in MIM terms). In particular, prior work recognizes the importance of symmetry in learning generative models with reference to symmetric discriminators on $x$ and $z$ [2, 11, 12]. In contrast, here we target JSD between the joint encoding and decoding distributions, together with a regularizer to encourage high mutual information.

8 Conclusions

We introduce a new representation learning framework, named the mutual information machine (MIM), that defines a generative model which directly targets high mutual information (i.e., between the observations and the latent representation), and symmetry (i.e., consistency of encoding and decoding factorizations of the joint distribution). We derive a variational bound that enables the maximization of mutual information in the learned representation for high dimensional continuous data, without the need to directly compute it. We then provide a possible explanation for the phenomena of posterior collapse, and demonstrate that MIM does not suffer from it. Empirical comparisons to VAEs show that MIM learning leads to higher mutual information and better clustering (and classification) in the latent representation, given the same architecture and parametrization. In addition, we show that MIM can provide reconstruction error similar to a deterministic auto-encoder, when the dimensionality of the latent representation is equal to that of the observations. Such behaviour can potentially allow approximate invertibility when the dimensionality differs, with a stochastic mapping that is defined through consistency and high mutual information.

In future work, we intend to focus on utilizing the high mutual information mapping provided by MIM, by exploiting the clustered latent representation to further improve the resulting generative model.

Acknowledgements

Many thanks to Ethan Fetaya, Jacob Goldberger, Roger Grosse, Chris Maddison, and Daniel Roy for interesting discussions and for their helpful comments. We are especially grateful to Sajad Nourozi for extensive discussions and for his help to empirically validate the formulation and experimental work. This work was financially supported in part by the Canadian Institute for Advanced Research (Program on Learning in Machines and Brains), and NSERC Canada.

## A Derivations for MIM Formulation

In what follows we provide detailed derivations of key elements of the formulation in the paper, namely, Equations (6), (10), (12), and (13). We also consider the relation between MIM based on the Jensen-Shannon divergence and the symmetric KL divergence.

### A.1 JSD and Entropy Objectives

First we develop the relation in Eqn. (6), between Jensen-Shannon divergence of the encoder and decoder, the average joint entropy of the encoder and decoder, and the joint entropy of the mixture distribution \( \mathcal{M}_S \).

The Jensen-Shannon divergence with respect to the encoding distribution \( q_\theta(z|x) \mathcal{P}(x) \) and the decoding distribution \( p_\theta(x|z) \mathcal{P}(z) \) is defined as

\[
\text{JSD}(\theta) = \frac{1}{2} (D_{\text{KL}}(p_\theta(x|z) \mathcal{P}(x) \| \mathcal{M}_S) + D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \| \mathcal{M}_S))
\]

\[
= \frac{1}{2} \left( H(p_\theta(x|z) \mathcal{P}(z), \mathcal{M}_S) - H(p_\theta(x|z) \mathcal{P}(z))
+ H(q_\theta(z|x) \mathcal{P}(x), \mathcal{M}_S) - H(q_\theta(z|x) \mathcal{P}(x)) \right)
\]

Where \( \mathcal{M}_S = \frac{1}{2}(p_\theta(x|z) \mathcal{P}(z) + q_\theta(z|x) \mathcal{P}(x)) \) is a mixture of the encoding and decoding distributions. Adding \( R_{\text{H}}(\theta) = \frac{1}{2}(H(p_\theta(x|z) \mathcal{P}(z)) + H(q_\theta(z|x) \mathcal{P}(x))) \) to the JSD term gives

\[
\text{JSD}(\theta) + R_{\text{H}}(\theta) = \frac{1}{2} (H(p_\theta(x|z) \mathcal{P}(z), \mathcal{M}_S) + H(q_\theta(z|x) \mathcal{P}(x), \mathcal{M}_S))
\]

\[
= H(\mathcal{M}_S)
\]
A.2 MIM Consistency

Here we discuss in greater detail how the learning algorithm encourages consistency between the encoder and decoder of a MIM model, beyond the fact that they are fit to the same sample distribution. To this end we expand on several properties of the model and the optimization procedure.

A.2.1 MIM consistency objective

In what follows we derive the form of the MIM consistency term, $R_{\text{MIM}}(\theta)$, given in Eqn. (10). Recall that we define $\mathcal{M}_\theta = \frac{1}{2}(p_\theta(x, z) + p_\theta(x, z))$. We can show that $\mathcal{L}_{\text{MIM}}$ is equivalent to $\mathcal{L}_{\text{CE}}$ plus a regularizer by taking their difference.

\[
R_{\text{MIM}}(\theta) = \mathcal{L}_{\text{MIM}}(\theta) - \mathcal{L}_{\text{CE}}(\theta)
\]

\[
= \frac{1}{2}(H(\mathcal{M}_S, p_\theta(x, z)) + H(\mathcal{M}_S, p_\theta(x, z))) - H(\mathcal{M}_S, \mathcal{M}_\theta)
\]

\[
= \frac{1}{2}(\mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel p_\theta(x, z)) + H(\mathcal{M}_S) + \mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel p_\theta(x, z)) + H(\mathcal{M}_S))
\]

\[
- \mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel \mathcal{M}_\theta) - H(\mathcal{M}_S)
\]

\[
= \frac{1}{2}(\mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel p_\theta(x, z)) + \mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel p_\theta(x, z))) - \mathcal{D}_{\text{KL}}(\mathcal{M}_S \parallel \mathcal{M}_\theta)
\]

where $R_{\text{MIM}}(\theta)$ is non-negative, and is zero only when the encoding and decoding distributions are consistent (i.e., they represent the same joint distribution). To prove that $R_{\text{MIM}}(\theta) \geq 0$ and to derive Eqn. (12), we now construct Eqn. (10) in terms of expectation over a joint distribution, which yields

\[
R_{\text{MIM}}(\theta) = \frac{1}{2}(H(\mathcal{M}_S, p_\theta(x, z)) + H(\mathcal{M}_S, p_\theta(x, z))) - H(\mathcal{M}_S, \mathcal{M}_\theta)
\]

\[
= E_{x, z \sim \mathcal{M}_S} \left[ -\frac{1}{2} \log p_\theta(x, z) - \frac{1}{2} \log p_\theta(x, z) + \log \frac{1}{2} (q_\theta(x, z) + p_\theta(x, z)) \right]
\]

\[
= E_{x, z \sim \mathcal{M}_S} \left[ -\log \sqrt{q_\theta(x, z) \cdot p_\theta(x, z)} + \log \frac{1}{2} (q_\theta(x, z) + p_\theta(x, z)) \right]
\]

\[
= E_{x, z \sim \mathcal{M}_S} \left[ -\log \sqrt{q_\theta(x, z) \cdot p_\theta(x, z)} \right] \geq 0
\]

where the inequality follows Jensen’s inequality, and equality holds only when $q_\theta(x, z) = p_\theta(x, z)$ (i.e., encoding and decoding distributions are consistent).

A.2.2 Self-Correcting Gradient

One important property of the optimization follows directly from the difference between the gradient of the upper bound $\mathcal{L}_{\text{MIM}}$ and the gradient of the cross-entropy loss $\mathcal{L}_{\text{CE}}$. By moving the gradient operator into the expectation using reparametrization, one can express the gradient of $\mathcal{L}_{\text{MIM}}(\theta)$ in terms of the gradient of $\log \mathcal{M}_\theta$ and the regularization term in Eqn. (10). That is, with some manipulation one obtains

\[
\frac{\partial}{\partial \theta} \left( \log q_\theta + \log p_\theta \right) = \frac{\partial}{\partial \theta} \log \left( \frac{q_\theta + p_\theta}{2} \right) + \frac{1}{2} \left( \log \frac{p_\theta}{q_\theta} - 1 \right) \frac{\partial}{\partial \theta} q_\theta + \left( \log \frac{q_\theta}{p_\theta} - 1 \right) \frac{\partial}{\partial \theta} p_\theta,
\]

(20)

which shows that for any data point where a gap $q_\theta > p_\theta$ exists, the gradient applied to $p_\theta$ grows with the gap, while placing correspondingly less weight on the gradient applied to $q_\theta$. The opposite is true when $q_\theta < p_\theta$. In both case this behaviour encourages consistency between the encoder and decoder. Empirically, we find that the encoder and decoder become reasonably consistent early in the optimization process.

A.2.3 Numerical Stability

Instead of optimizing an upper bound $\mathcal{L}_{\text{MIM}}$, one might consider a direct optimization of $\mathcal{L}_{\text{CE}}$. Earlier we discussed the importance of the consistency regularizer in $\mathcal{L}_{\text{MIM}}$. Here we motivate the use of
\( \mathcal{L}_{\text{MIM}} \) from a numerical perspective point of view. In order to optimize \( \mathcal{L}_{\text{CE}} \) directly, one must convert \( \log q_\theta \) and \( \log p_\theta \) to \( q_\theta \) and \( p_\theta \). Unfortunately, this is has the potential to produce numerical errors, especially with 32-bit floating-point precision on GPUs. While various tricks can reduce numerical instability, we find that using the upper bound eliminates the problem while providing the additional benefits outlined above.

### A.2.4 Tractability

A linear mixture via the JSD is not the only way one might combine the encoder and decoder in a symmetric fashion. An alternative to MIM, explored in [5], is to use a product; i.e.,

\[
\mathcal{M}_\theta = \frac{1}{\beta} \sqrt{q_\theta p_\theta},
\]

where \( \beta = \int \sqrt{q_\theta p_\theta} \, dx \, dz \) is the partition function. One can then define the objective to be the cross-entropy as above with a regularizer to encourage \( \beta \) to be close to 1, and hence to encourage consistency between the encoder and decoder. This, however, requires a good approximation to the partition function. Our choice of \( \mathcal{M}_\theta \) avoids the need for a good value approximation by using reparameterization, which results in unbiased low-variance gradient, independent of the accuracy of the approximation of the value.

### A.3 MIM Loss Decomposition

Here we show how to break down the \( \mathcal{L}_{\text{MIM}} \) into the set of intuitive components given in Eqn. (13). To this end, first note the definition of \( \mathcal{L}_{\text{MIM}} \):

\[
\mathcal{L}_{\text{MIM}}(\theta) = \frac{1}{2} (H(\mathcal{M}_S, p_\theta(x, z)) + H(\mathcal{M}_S, q_\theta(x, z)))
\]

(22)

We will focus on the first half of Eqn. (22) for now,

\[
\frac{1}{2} H(\mathcal{M}_S, p_\theta(x, z)) = \frac{1}{4} \left( H(p_\theta(x|z) \mathcal{P}(z), p_\theta(x, z)) + H(q_\theta(z|x) \mathcal{P}(x), p_\theta(x, z)) \right)
\]

(23)

It will be more clear to write out the first term of Eqn. (23), \( \frac{1}{4} H(p_\theta(x|z) \mathcal{P}(z), p_\theta(x, z)) \) in full

\[
\frac{1}{4} H(p_\theta(x|z) \mathcal{P}(z), p_\theta(x, z)) = -\frac{1}{4} \int_{x,z} p_\theta(x|z) \mathcal{P}(z) \log(p_\theta(x, z)) \, dx \, dz
\]

\[
= -\frac{1}{4} \int_{x,z} p_\theta(x|z) \mathcal{P}(z) \log(p_\theta(x|z)) \, dx \, dz
\]

\[
- \frac{1}{4} \int_{x,z} p_\theta(x|z) \log(p_\theta(z)) \, dx \, dz
\]

We then add and subtract \( \frac{1}{4} H(\mathcal{P}(z)) \), where

\[
\frac{1}{4} H(\mathcal{P}(z)) = -\frac{1}{4} \int_{x,z} \mathcal{P}(z) \log(\mathcal{P}(z)) \, dx \, dz = -\frac{1}{4} \int_{x,z} p_\theta(x|z) \mathcal{P}(z) \log(\mathcal{P}(z)) \, dx \, dz
\]

Then expanding \( \frac{1}{4} H(p_\theta(x|z) \mathcal{P}(z), p_\theta(x, z)) + \frac{1}{4} H(\mathcal{P}(z)) - \frac{1}{4} H(\mathcal{P}(z)) \) into constituent parts and combining terms, we obtain

\[
\frac{1}{4} H(p_\theta(x|z) \mathcal{P}(z), p_\theta(x, z)) = H(p_\theta(x|z) \mathcal{P}(z)) + D_{\text{KL}}(\mathcal{P}(z) \parallel p_\theta(z))
\]

(24)

The second term in Eqn. (23) can then be rewritten as

\[
\frac{1}{4} H(q_\theta(z|x) \mathcal{P}(x), p_\theta(x, z)) = \frac{1}{4} D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x, z)) + \frac{1}{4} H(q_\theta(z|x) \mathcal{P}(x))
\]

(25)

Combining Eqns. (24) and (25), we get the interpretable form for Eqn. 23, i.e.,

\[
\frac{1}{2} H(\mathcal{M}_S, p_\theta(x, z)) = \frac{1}{4} (H(p_\theta(x|z) \mathcal{P}(z)) + H(q_\theta(z|x) \mathcal{P}(x)))
\]

\[
+ \frac{1}{4} D_{\text{KL}}(\mathcal{P}(z) \parallel p_\theta(z)) + \frac{1}{4} D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x, z))
\]

\[
= \frac{1}{2} R_H(\theta) + \frac{1}{4} D_{\text{KL}}(\mathcal{P}(z) \parallel p_\theta(z)) + \frac{1}{4} D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x, z))
\]

(26)
We can use the same basic steps to derive an analogous expression for $H(\mathcal{M}_S, p_\theta(x, z))$ in Eqn. (22) and combine it with Eqn. (26) to get the final interpretable form:

$$L_{\text{MIM}}(\theta) = R_{\text{II}}(\theta) + \frac{1}{4} \left( D_{\text{KL}}(\mathcal{P}(z) \parallel p_\theta(z)) + D_{\text{KL}}(\mathcal{P}(x) \parallel q_\theta(x)) \right)$$

$$+ \frac{1}{4} \left( D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x, z)) + D_{\text{KL}}(p_\theta(x|z) \mathcal{P}(z) \parallel q_\theta(z, x)) \right)$$

### B MIM in terms of Symmetric KL Divergence

As discussed above, the VAE objective can be expressed as minimizing the KL divergence between the joint anchored encoding and anchored decoding distributions. Below we consider a model formulation using the symmetric KL divergence (SKL),

$$\text{SKL}(\theta) = \frac{1}{2} \left( D_{\text{KL}}(p_\theta(x|z) \mathcal{P}(z) \parallel q_\theta(z|x) \mathcal{P}(x)) + D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x|z) \mathcal{P}(z)) \right),$$

the second term of which is the VAE objective. The mutual information regularizer $R_{\text{II}}(\theta)$ given in Eqn. (5) can be added to SKL to obtain a cross-entropy objective that looks similar to MIM:

$$\frac{1}{2} \text{SKL}(\theta) + R_{\text{II}}(\theta) = \frac{1}{2} (H(\mathcal{M}_S, p_\theta(x|z) \mathcal{P}(z)) + H(\mathcal{M}_S, q_\theta(z|x) \mathcal{P}(x)))$$

When the model priors are equal to the anchors, this regularized SKL and MIM are equivalent. In general, however, the MIM loss is not a bound on the regularized SKL.

In what follows we explore the relation between SKL and JSD. In Section A.1 we showed that the Jensen-Shannon divergence can be written as

$$\text{JSD}(\theta) = \frac{1}{2} \left( H(p_\theta(x|z) \mathcal{P}(z), \mathcal{M}_S) - H(p_\theta(x|z) \mathcal{P}(z)) \right)$$

$$+ H(q_\theta(z|x) \mathcal{P}(x), \mathcal{M}_S) - H(q_\theta(z|x) \mathcal{P}(x)) \right)$$

$$= \frac{1}{2} \left( H(p_\theta(x|z) \mathcal{P}(z), \mathcal{M}_S) + H(q_\theta(z|x) \mathcal{P}(x), \mathcal{M}_S) \right) - R_{\text{II}}(\theta)$$

Using Jensen’s inequality, we can bound JSD$(\theta)$ from above,

$$\text{JSD}(\theta) \leq \frac{1}{4} \left( H(p_\theta(x|z) \mathcal{P}(z)) + H(p_\theta(x|z) \mathcal{P}(z), q_\theta(z|x) \mathcal{P}(x)) \right)$$

$$+ \frac{1}{4} \left( H(q_\theta(z|x) \mathcal{P}(x)) + H(q_\theta(z|x) \mathcal{P}(x), p_\theta(x|z) \mathcal{P}(z)) \right) - R_{\text{II}}(\theta)$$

$$= \frac{1}{4} \left( H(p_\theta(x|z) \mathcal{P}(z), q_\theta(z|x) \mathcal{P}(x)) + H(q_\theta(z|x) \mathcal{P}(x), p_\theta(x|z) \mathcal{P}(z)) \right)$$

$$+ 2R_{\text{II}}(\theta) - R_{\text{II}}(\theta)$$

$$= \frac{1}{4} \left( D_{\text{KL}}(p_\theta(x|z) \mathcal{P}(z) \parallel q_\theta(z|x) \mathcal{P}(x)) + D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x|z) \mathcal{P}(z)) \right)$$

$$+ 4R_{\text{II}}(\theta) - R_{\text{II}}(\theta)$$

$$= \frac{1}{4} \left( D_{\text{KL}}(p_\theta(x|z) \mathcal{P}(z) \parallel q_\theta(z|x) \mathcal{P}(x)) + D_{\text{KL}}(q_\theta(z|x) \mathcal{P}(x) \parallel p_\theta(x|z) \mathcal{P}(z)) \right)$$

$$= \frac{1}{2} \text{SKL}(\theta)$$

From Eqn. (27), if we add $R_{\text{II}}(\theta)$ and simplify, we get

$$\frac{1}{2} \text{SKL}(\theta) + R_{\text{II}}(\theta) = \frac{1}{2} (H(\mathcal{M}_S, q_\theta(z|x) \mathcal{P}(x)) + H(\mathcal{M}_S, p_\theta(x|z) \mathcal{P}(z)))$$
Interestingly, we can write this in terms of KL divergence,
\[
\frac{1}{2} \text{SKL}(\theta) + R_H(\theta) = \frac{1}{2} \left( D_{KL}(\mathcal{M}_S \| q_\theta(z|x) \mathcal{P}(x)) + D_{KL}(\mathcal{M}_S \| p_\theta(x|z) \mathcal{P}(z)) \right) + H(\mathcal{M}_S)
\]
\[
= \frac{1}{2} \left( D_{KL}(\mathcal{M}_S \| q_\theta(z|x) \mathcal{P}(x)) + D_{KL}(\mathcal{M}_S \| p_\theta(x|z) \mathcal{P}(z)) \right) + JSD(\theta) + R_H(\theta)
\]

which gives the exact relation between JSD and SKL.
\[
\frac{1}{2} \text{SKL}(\theta) = \frac{1}{2} \left( D_{KL}(\mathcal{M}_S \| q_\theta(z|x) \mathcal{P}(x)) + D_{KL}(\mathcal{M}_S \| p_\theta(x|z) \mathcal{P}(z)) \right) + JSD(\theta)
\]
\[
= \frac{1}{2} \left( D_{KL}(\mathcal{M}_S \| q_\theta(z|x) \mathcal{P}(x)) + D_{KL}(\mathcal{M}_S \| p_\theta(x|z) \mathcal{P}(z)) \right) + JSD(\theta) + R_H(\theta)
\]

\[+ \frac{1}{2} \left( D_{KL}(q_\theta(z|x) \mathcal{P}(x) \| \mathcal{M}_S) + D_{KL}(p_\theta(x|z) \mathcal{P}(z) \| \mathcal{M}_S) \right)\]

C Posterior Collapse in VAE

Here we discuss a possible root cause for the observed phenomena of posterior collapse, and show that VAE learning can be viewed as an asymmetric MIM learning with a regularizer that encourages the appearance of the collapse. We further support that idea in the experiments in Section 6.2. As discussed earlier, VAE learning entails maximization of a variational lower bound (ELBO) on the log-marginal likelihood, or equivalently, given Eqn. (1), the VAE loss in terms of expectation over a joint distribution:
\[
-\mathbb{E}_{x \sim \mathcal{P}(x), z \sim q_\theta(z|x)} \left[ \log p_\theta(x|z) + \log \mathcal{P}(z) - \log q_\theta(z|x) \right].
\]

(28)

To connect the loss in Eqn. (28) to MIM, we first add the expectation of \( \log \mathcal{P}(x) \), and scale the loss by a factor of \( \frac{1}{2} \), to obtain
\[
\mathbb{E}_{x \sim \mathcal{P}(x), z \sim q_\theta(z|x)} \left[ -\frac{1}{2} \left( \log(p_\theta(x|z)\mathcal{P}(z)) + \log(q_\theta(z|x)\mathcal{P}(x)) \right) + \log \mathcal{P}(x) + \log q_\theta(z|x) \right]
\]

(29)

where \( \mathcal{P}(x) \) is the data distribution, which is assumed to be independent of model parameters \( \theta \) and to exist almost everywhere (i.e., complementing \( \mathcal{P}(z) \)). Importantly, because \( \mathcal{P}(x) \) does not depend on \( \theta \), the gradients of Eqs. (28) and (29) are identical up to a multiple of \( \frac{1}{2} \), so they share the same stationary points.

Combining IID samples from the data distribution, \( x^i \sim \mathcal{P}(x) \), with samples from the corresponding variational posterior, \( z^i \sim q_\theta(z|x^i) \), we obtain a joint sampling distribution; i.e.,
\[
\mathcal{M}^{\text{VAE}}_S(x, z) = \mathcal{P}(x)q_\theta(z|x)
\]

where \( \mathcal{M}^{\text{VAE}}_S \) comprises the encoding distribution in \( \mathcal{M}_S \). With it one can then rewrite the objective in Eqn. (29) in terms of the cross-entropy between \( \mathcal{M}^{\text{VAE}}_S \) and the parametric encoding and decoding distributions; i.e.,
\[
\frac{1}{2} \left( H(\mathcal{M}^{\text{VAE}}_S, p_\theta(x|z)\mathcal{P}(z)) + H(\mathcal{M}^{\text{VAE}}_S, q_\theta(z|x)\mathcal{P}(x)) \right) +
\]
\[
- H_{\mathcal{M}^{\text{VAE}}_S}(x) - H_{\mathcal{M}^{\text{VAE}}_S}(z) + I_{\mathcal{M}^{\text{VAE}}_S}(x; z).
\]

(30)

The sum of the last three terms in Eqn. (30) is the negative joint entropy \( -H(z, x) \) under the sample distribution \( \mathcal{M}^{\text{VAE}}_S \).

Equations (1) and (30), the VAE objective and VAE as regularized cross entropy objective respectively, define equivalent optimization problems, under the assumption that \( \mathcal{P}(x) \) and samples \( x \sim \mathcal{P}(x) \) do not depend on the parameters \( \theta \), and that the optimization is gradient-based. Formally, the VAE objectives (1) and (30) are equivalent up to a scalar multiple of \( \frac{1}{2} \) and an additive constant, namely, \( H_{\mathcal{M}^{\text{VAE}}_S}(x) \).

Equation (30) is the average of two cross-entropy objectives (i.e., between sample distribution \( \mathcal{M}^{\text{VAE}}_S \) and the model decoding and encoding distributions, respectively), along with a joint entropy
(a) $h \in \mathbb{R}^5$

(b) $h \in \mathbb{R}^{20}$

(c) $h \in \mathbb{R}^{500}$

Figure 11: Effects of entropy as a mutual information regularizer in 2D $x$ and 2D $z$ synthetic problem. VAE and MIM models with 2D inputs, a 2D latent space, and 5, 20 and 500 hidden units. Top row: Black contours depict level sets of $P(x)$; red dots are reconstructed test points. Bottom row: Green contours are one standard deviation ellipses of $q_\theta(z|x)$ for test points. Dashed black circles depict one standard deviation of $P(z)$. Here we added $H_q(x,z)$ to VAE loss, and subtracted $H_{M_\theta}(x,z)$ from MIM loss, in order to demonstrate the effect of entropy on mutual information. Posterior collapse in VAE is mitigated following the increased mutual information. MIM, on the other hand, demonstrates a severe posterior collapse as a result of the reduced mutual information (i.e., posterior matches prior over $z$ almost perfectly). (see inset quantities).

D Additional Experiments

Here we provide additional experiments that further explore the characteristics of MIM learning.

D.1 Entropy as Mutual Information Regularizer

Here we examine the use of entropy as a mutual information regularizer. We repeat the experiment in Section 6.2 with added entropy regularizer. Figure 11 depicts the effects of an added $H_{q_\theta}(x,z)$ to the VAE loss, and a subtracted $H_{M_\theta}(x,z)$ from MIM. The corresponding quantitative values are presented in Figure 12. Adding the entropy regularizer leads to increased the mutual information, and subtracting it results in a strong posterior collapse, which in turn is reflected in the reconstruction quality. While such an experiment does not represent a valid probabilistic model, it supports our use of entropy as a regularizer (cf. Eq. (5)) for JSD in order to define a consistent model with high mutual information.

D.2 Consistency regularizer in $\mathcal{L}_{MIM}$

Here we explore properties of models for 1D $x$ and $z$, learned with $\mathcal{L}_{MIM}$ and $\mathcal{L}_{CE}$, the difference being the model consistency regularizer $R_{MIM}(\theta)$. All model priors and conditional likelihoods $(q_\theta(x), q_\theta(z|x), p_\theta(z), p_\theta(x|z))$ are parameterized as 10-component Gaussian mixture models, and optimized during training. Means and variances for the conditional distributions were regressed with 2 fully connected layers ($h \in \mathbb{R}^{10}$) and a swish activation function [26].
While both models offer similar reconstruction (a-b), and similar consistency w.r.t. the anchors (c-d), anchor consistency is depicted in Fig. 13(c,d), where Green histograms are marginal distributions (cf. Fig. 11), all as functions of the number of hidden units (on x-axis). Each plot shows the mean and standard deviation of 10 experiments. Adding encoding entropy regularizer to VAE loss leads to high mutual information (i.e., prevent posterior collapse), low reconstruction error, and better classification accuracy. Subtracting sample entropy regularizer from MIM loss results in almost zero mutual information (severe collapse), which leads to poor reconstruction error and classification accuracy.

Figure 13: We explore the influence of consistency regularizer \( R_\theta \). CE and MIM indicate the loss, \( \mathcal{L}_{\text{CE}} \) or \( \mathcal{L}_{\text{MIM}} \) (the regularized objective), respectively. Top row shows anchor \( \mathcal{P}(x) \) (dashed), prior \( q_\theta(x) \) (red), and reconstruction distribution \( x_i \sim \mathcal{P}(x) \rightarrow z_i \sim q_\theta(z|x_i) \rightarrow x'_i \sim p_\theta(x|z_i) \) (green). Bottom row mirrors the top row, with anchor \( \mathcal{P}(z) \) (dotted), prior \( p_\theta(z) \) (blue), and reconstruction distribution \( z_i \sim \mathcal{P}(z) \rightarrow x_i \sim p_\theta(x|z_i) \rightarrow z'_i \sim q_\theta(z|x) \) (yellow). In (c-d) the reconstruction is replaced with decoding from anchors \( z_i \sim \mathcal{P}(z) \rightarrow x'_i \sim p_\theta(x|z_i) \) (green), and encoding \( x_i \sim \mathcal{P}(x) \rightarrow z'_i \sim q_\theta(z|x) \) (yellow). In (e-f) the reconstruction is replaced with decoding from priors \( z_i \sim p_\theta(z) \rightarrow x'_i \sim p_\theta(x|z_i) \) (green), and encoding \( x_i \sim q_\theta(x) \rightarrow z'_i \sim q_\theta(z|x) \) (yellow). While both models offer similar reconstruction (a-b), and similar consistency w.r.t. the anchors (c-d), only MIM finds a consistent model (e-f). See text for details.

Top and bottom rows in Fig. 13 depict distributions in the observation and latent spaces. Dashed black curves are anchors, \( \mathcal{P}(x) \) on top, and \( \mathcal{P}(z) \) below (GMMs with up to 3 components). Learned model priors, \( q_\theta(x) \) and \( p_\theta(z) \), are depicted as red (top) and blue (bottom) curves.

Green histograms in Fig. 13(a,b) depict reconstruction distributions, computed by passing fair samples from \( \mathcal{P}(x) \) through the encoder to \( z \) and then back through the decoder to \( x \). Similarly the yellow histograms show samples from \( \mathcal{P}(z) \) passed through the decoder and then back to the latent space. For both losses these reconstruction histograms match the anchor priors well. In contrast, only the priors that were learned with \( \mathcal{L}_{\text{CE}} \) loss approximates the anchor well, while the \( \mathcal{L}_{\text{MIM}} \) priors do not. To better understand that, we consider two generative procedures: sampling from the anchors, and sampling from the priors.

Anchor consistency is depicted in Fig. 13(c,d), where Green histograms are marginal distributions over \( x \) from the anchored decoder (i.e., samples from \( \mathcal{P}(z)p_\theta(x|z) \)). Yellow are marginals over \( z \) from the anchored encoders \( \mathcal{P}(x)q_\theta(z|x) \). One can see that both losses results in similar quality of matching the corresponding opposite anchors.

Priors consistency is depicted in Fig. 13(e,f), where Green histograms are marginal distributions over \( x \) from the model decoder \( p_\theta(z)p_\theta(x|z) \). Yellow depicts marginals over \( z \) from the model encoder \( q_\theta(x)q_\theta(z|x) \). Importantly, with \( \mathcal{L}_{\text{MIM}} \) the encoder and decoder are consistent; i.e., \( q_\theta(x) \) (red curve)
matches the decoder marginal, while $p_\theta(z)$ (blue) matches the encoder marginal. The model trained with $L_{CE}$ (i.e., without consistency prior) fails to learn a consistent encoder-decoder pair. We note that in practice, with expressive enough priors, $L_{MIM}$ will be a tight bound for $L_{CE}$.

D.3 Parameterizing the Priors

Here we explore the effect of parameterizing the latent and observed priors. A fundamental idea in MIM is the concept of a single model, $M_\theta$. As such, parameterizing a prior increases the global expressiveness of the model $M_\theta$. Fig. 14 depicts the utilization of the added expressiveness in order to increase the consistency between the encoding and decoding model distribution, in addition to the consistency of $M_\theta$ with $M_S$.

D.4 Effect of Consistency Regularizer on Optimization

Here we explore whether a learned model with consistent encoding-decoding distributions (i.e., trained with $L_{MIM}$) also constitutes an optimal solution of a CE objective (i.e., trained with $L_{CE}$). Results are depicted in Fig. 15. In order to distinguish between the effects of the optimization from the consistency regularizer we initialize a MIM model by pre-training it with $L_{CE}$ loss followed by $L_{MIM}$ training in Fig. 15(i), and vice versa in Fig. 15(ii). (a-b,e-f) All trained models in Fig. 15 exhibit similarly good reconstruction (green matches dashed black). (c-d,g-h) However, only models that were trained with $L_{MIM}$ exhibit encoding-decoding consistency (green matches red, yellow matches blue). While it is clear that the optimization plays an important role (i.e., different initialization leads to different local optimum), it is also clear that encoding-decoding consistency is not necessarily an optimum of $L_{CE}$, as depicted in a non-consistent model (h) which was initialized with a consistent model (g). Not surprisingly, without the consistency regularizer training with $L_{CE}$ results in better fit of priors to anchors (f) as it is utilizing the expressiveness of the parametric priors in matching the sample distribution.
Figure 15: Effects of MIM consistency regularizer and optimization on encoding-decoding consistency. (i) and (ii) differ in initialization order. Odd rows: anchor $P(x)$ (dashed), prior $q_\theta(z)$ (red). Even rows: anchor $P(z)$ (dotted), prior $p_\theta(z)$ (blue). (a-b,e-f) Reconstruction $x_i \sim P(x) \rightarrow z_i \sim q_\theta(z|x_i) \rightarrow x'_i \sim p_\theta(x|z_i)$ ($x'_i$, green, $z_i$, yellow). (c-d,g-h) Prior decoding $z_i \sim p_\theta(z) \rightarrow x'_i \sim p_\theta(x|z_i)$ (green), and prior encoding $x_i \sim q_\theta(x) \rightarrow z_i \sim q_\theta(z|x_i)$ (yellow). See text for details.

E Additional Results

Here we provide additional visualization of various MIM and VAE models.

E.1 Reconstruction and Samples for MIM and A-MIM

In what follows we show samples and reconstruction for MIM (i.e., with convHVAE architecture), and A-MIM (i.e., with PixelHVAE architecture). We demonstrate, again, that a powerful enough encoder allows for generation of samples which are comparable to VAE samples.
Figure 16: MIM and VAE learning with PixelHVAE for Fashion MNIST. The top three rows (from top to bottom) are test data samples, VAE reconstruction, A-MIM reconstruction. Bottom: random samples from VAE and MIM. (c-d) We initialized all pseudo-inputs with training samples, and used the same random seed for both models. As a result, the samples order is similar. We note that with a standard prior, MIM provides better reconstructions, whereas with VampPrior MIM offers comparable reconstructions. We consider that a result of VampPrior being a non-ideal match for MIM, as MIM tends to learn posteriors with low variance. Using VampPrior leads to increased variance, and thus a degradation in the quality of reconstructions.

Figure 17: MIM and VAE learning with convHVAE for Fashion MNIST. The top three rows (from top to bottom) are test data samples, VAE reconstruction, MIM reconstruction. Bottom: random samples from VAE and MIM.
Figure 18: MIM and VAE learning with PixelHVAE for MNIST. Top three rows are test data samples, followed by VAE and A-MIM reconstructions. Bottom: random samples from VAE and MIM. (c-d) We initialized all pseudo-inputs with training samples, and used the same random seed for both models. As a result the samples order is similar. We note that with a standard prior, MIM provides better reconstructions, whereas with VampPrior MIM offers comparable reconstructions. We consider that a result of VampPrior being a non-ideal match for MIM, as MIM tends to learn posteriors with low variance. Using VampPrior leads to increased variance, and thus a degradation in the quality of reconstructions.
