SMOOTH FACTORIAL AFFINE SURFACES OF LOGARITHMIC KODAIRA DIMENSION ZERO WITH TRIVIAL UNITS

GENE FREUDENBURG, HIDEO KOJIMA, AND TAKANORI NAGAMINE

Abstract. This paper considers the family \( S_0 \) of smooth affine factorial surfaces of logarithmic Kodaira dimension 0 with trivial units over an algebraically closed field \( k \). Our main result (Theorem 4.1) is that the number of isomorphism classes represented in \( S_0 \) is at least countably infinite. This contradicts the earlier classification of Gurjar and Miyanishi [5] which asserted that \( S_0 \) has at most two elements up to isomorphism when \( k = \mathbb{C} \). Thus, the classification of surfaces in \( S_0 \) for the field \( \mathbb{C} \), long thought to have been settled, is an open problem.

1. Introduction

Let \( k \) be an algebraically closed field \( k \), and let \( \mathcal{S} \) denote the family of smooth affine factorial surfaces with trivial units over \( k \). Then \( \mathcal{S} \) is partitioned according to logarithmic Kodaira dimension:

\[ \mathcal{S} = \mathcal{S}_2 \cup \mathcal{S}_1 \cup \mathcal{S}_0 \cup \mathcal{S}_{-\infty} \]

where \( S \in \mathcal{S}_d \) means \( \bar{\kappa}(S) = \bar{\kappa} \). Surfaces in \( \mathcal{S}_2 \) are said to be of general type. It is known that \( \mathcal{S}_{-\infty} \) consists of one element (up to isomorphism), namely, the affine plane \( \mathbb{A}^2_k \); see [7].

In their 1988 paper [5], Gurjar and Miyanishi studied elements of \( \mathcal{S} \) of non-general type in the case \( k = \mathbb{C} \). For \( \mathcal{S}_0 \), they claim that “there are only two types of surfaces in this case” (p.99). Specifically, Theorem 2 asserts that any element of \( \mathcal{S}_0 \) is isomorphic to one of the surfaces \( S \) or \( S' \), defined as follows. Let \( x, y \) be a system of coordinate functions in the complex plane \( \mathbb{C}^2 \).

- \( S \) is obtained by blowing up \( \mathbb{C}^2 \) at the points \((0, 1)\) and \((1, 0)\), and removing the proper transform of the degenerate conic defined by \( xy = 0 \).
- \( S' \) is obtained by blowing up \( \mathbb{C}^2 \) the point \((1, 1)\), and removing the proper transform of the smooth conic \( xy = 1 \).

In this paper, we will show the following.

1. \( S \cong \mathbb{C} S' \) (Theorem 4.4)
2. For any algebraically closed field \( k \), the number of isomorphism classes represented in \( \mathcal{S}_0 \) is at least countably infinite.

In fact, even the number of stable isomorphism classes represented in \( \mathcal{S}_0 \) is at least countably infinite (see Theorem 5.1). Thus, the classification of surfaces in \( \mathcal{S}_0 \) for the field \( \mathbb{C} \), long thought to have been settled, is an open problem.

The surface \( S' \) is the affine modification of the plane along the curve \( xy = 1 \) with center \((1, 1)\); see [6]. For any algebraically closed field \( k \), the curve \( xy = 1 \) is isomorphic to the affine line over \( k \) with one point removed, denoted \( \mathbb{A}^1_k \). But this is just one of many ways to embed \( \mathbb{A}^1_k \) in \( \mathbb{A}^2_k \), and each of these embeddings, together with a point on the curve, yields an affine modification \( X \) of \( \mathbb{A}^2_k \). Theorem 3.1 gives conditions on the embedding which imply that \( X \in \mathcal{S} \), and Theorem 3.2 gives further conditions which imply \( X \in \mathcal{S}_0 \).

We consider the family of embeddings $x^ny = 1, n \geq 1$. Specifically, let $V_n$ be the affine modification of $A_k^d$ along the curve $\Gamma_n$ defined by $x^ny = 1$ with center $(1,1)$. We show that $V_n \in \mathcal{F}_0$ for each $n \geq 1$, and that $V_m \not\equiv V_n$ if $m \neq n$, and more generally, for cylinders over these surfaces, $V_m \times A_k^d \not\equiv V_n \times A_k^d$ if $m \neq n$ and $d \geq 0$; see Theorem 5.1.

For each $n$, we have $\Gamma_n \cong A_k^1$, but it is not hard to show that the complements $A_k^2 \setminus \Gamma_m$ and $A_k^2 \setminus \Gamma_n$ are not isomorphic when $m \neq n$. Consequently, there is no automorphism of $A_k^2$ transforming $\Gamma_m$ to $\Gamma_n$ when $m \neq n$. For the field $k = \mathbb{C}$, the closed embeddings of $\mathbb{C}^n$ in $\mathbb{C}^2$ have been classified (see [2]), thus providing a rich family of surfaces to study, obtained by affine modification of $\mathbb{C}^2$.

2. Preliminaries

2.1. Some Notation. If $R$ is an integral domain, then $\text{frac}(R)$ is the field of fractions of $R$. Given $n \in \mathbb{N}$, $R^{[n]}$ is the polynomial ring in $n$ variables over $R$, and $R^[\pm n]$ is the ring of Laurent polynomials in $n$ variables over $R$. If $S$ is an integral domain containing $R$, then $\text{tr.deg}_RS$ is the transcendence degree of $\text{frac}(S)$ over $\text{frac}(R)$.

Assume that $k$ is algebraically closed. Given distinct $c_1, \ldots, c_n \in k$, let

$$A_k^1(c_1, \ldots, c_n) = \text{Spec} k[t, (t-c_1)^{-1}, \ldots, (t-c_n)^{-1}]$$

i.e., an affine line over $k$ with $n$ points removed. If $n = 1$, we also write $A_k^1(k)$. Given $d \in \mathbb{N}$, $A_k^d$ denotes affine space over $k$ of dimension $d$.

2.2. The Degree-Neutral Invariant. Let $R$ be an integral domain, and let $\deg: R \to \mathbb{Z} \cup \{-\infty\}$ be a degree function. We say deg is non-negative if $\deg$ is of the form $\deg: R \to \mathbb{N} \cup \{-\infty\}$, and trivial if $\deg(R \setminus \{0\}) = \{0\}$. The induced filtration is

$$R = \bigcup_{d \in \mathbb{Z}} \mathcal{F}_d$$

where the sets $\mathcal{F}_d = \{r \in R \mid \deg r \leq d\}$ are the associated degree modules. Note that deg can be extended to $K = \text{frac}(R)$ by letting $\deg(f/g) = \deg f - \deg g$ for $f, g \in R$, $g \neq 0$. Note also that, if $R$ is a field, then deg is a degree function on $R$ if and only if $(-\deg)$ is a discrete valuation of $R$.

Recall that a subalgebra $A \subset R$ is factorially closed in $R$ if $rs \in A$ for nonzero $r, s \in R$ implies $r \in A$ and $s \in A$.

Proposition 2.1. With the assumptions and notation above:

(a) $\mathcal{F}_0$ is a subring of $R$ which is integrally closed in $R$.
(b) $\mathcal{F}_d$ is an ideal of $\mathcal{F}_0$ for each $d \leq 0$.
(c) If $\deg$ is non-negative, then $\mathcal{F}_0$ is factorially closed in $R$. Consequently, $R^* \subset \mathcal{F}_0$.
(d) If $R$ is a normal ring, then $\mathcal{F}_0$ is a normal ring.
(e) If $R$ is a field, then $\mathcal{F}_0$ is a valuation ring of $R$ and $\text{frac}(\mathcal{F}_0) = R$.

Proof. Extend deg to $K$ and let $V = \{f \in K \mid \deg f \leq 0\}$. Then $V$ is a valuation ring of $K$, and $\mathcal{F}_0 = V \cap R$. This implies parts (a), (d) and (e), and part (b) is clear. For part (c), if $ab \in \mathcal{F}_0$ for nonzero $a, b \in R$, then $0 = \deg(ab) = \deg a + \deg b$ in $\mathbb{N}$ implies $\deg a = \deg b = 0$, so $a, b \in \mathcal{F}_0$.

Definition 2.2. The degree-neutral invariant of $R$ is the subring of $R$ defined by the intersection of all subrings of the form $\mathcal{F}_0$ for some non-negative degree function on $R$, denoted by $\Delta^0(R)$. We say that $R$ is degree-rigid if $\Delta^0(R) = R$, i.e., every non-negative degree function on $R$ is trivial.

The degree-neutral invariant has the following properties.

1. $\Delta^0(R)$ is a factorially closed subring of $R$, being the intersection of factorially closed subrings, and $\Delta^0(R)$ is an invariant subring of $R$. Therefore, $\Delta^0(R)$ is an algebraically closed subring of $R$, and if $R$ is a UFD, then $\Delta^0(R)$ is a UFD.
2. $R^* \subset \Delta^0(R)$.
3. If $S \subset R$ is a subring, then $\Delta^0(S) \subset \Delta^0(R)$, since any non-negative degree function on $R$ restricts to a non-negative degree function on $S$. 
(4) If \( R[x_1, \ldots, x_n] \cong R^{[n]} \), then by considering the degree functions \( \text{deg}_{x_i}, 1 \leq i \leq n \), it is clear that \( \Delta^0(R^{[n]}) \subset R \).

(5) The Makar-Limanov invariant \( ML(R) \) is defined by the intersection of subrings of the form \( \mathcal{F}_0 \) for certain non-negative degree functions; see [3, 4]. Therefore, \( \Delta^0(R) \subset ML(R) \). \( R \) is said to be rigid if \( ML(R) = R \). Thus, degree-rigid implies rigid.

Recall that \( R \) is **strongly invariant** if the following condition holds (see [1]).

For any integer \( n \geq 0 \) and subring \( S \subset R[x_1, \ldots, x_n] \cong R^{[n]} \), if there exist \( y_1, \ldots, y_n \) in \( R^{[n]} \) such that \( R[x_1, \ldots, x_n] = S[y_1, \ldots, y_n] \), then \( R = S \).

**Lemma 2.3.** Suppose that \( R \) is degree-rigid.

- (a) \( \Delta^0(R^{[n]}) = R \)
- (b) \( R \) is strongly invariant.

**Proof.** Let \( \delta \) be a non-negative degree function on \( R^{[n]} \) with induced filtration \( \bigcup_{i \in \mathbb{N}} \mathcal{F}_i \). Then \( \delta \) restricts to \( R \), so \( \delta(f) = 0 \) every \( f \in R \setminus \{0\} \), and \( R \subset \mathcal{F}_0 \). Therefore, \( R \subset \Delta^0(R^{[n]}) \subset R \), which implies \( \Delta^0(R^{[n]}) = R \). This shows part (a).

For part (b), assume that \( B \) is a ring containing \( R \), and \( B \cong_R R^{[n]} \) for some \( n \geq 0 \). Let \( S \subset B \) be a subring such that \( B \cong_S S^{[n]} \). Then \( R = \Delta^0(B) \subset S \subset R^{[n]} \). Therefore, \( \text{tr.deg}_RS \leq n \) and:

\[
n = \text{tr.deg}_RB = \text{tr.deg}_RS + \text{tr.deg}_SB = \text{tr.deg}_RS + n \implies \text{tr.deg}_RS = 0
\]

Since both \( S \) and \( R \) are algebraically closed in \( B \), it follows that \( R \) is algebraically closed in \( S \). Therefore, \( R = S \). \( \square \)

2.3. **Samuel’s Criterion.** A well known criterion for a ring to be a UFD is given by Samuel [8], Proposition 7.6. In an integral domain \( A \), elements \( a, b \in A \) are **relatively prime** if \( aA \cap bA = abA \).

**Proposition 2.4.** Assume that \( A \) is an integral domain and \( a, b \in A \) are relatively prime and nonzero. Let \( A[X] \cong A^3 \) and \( A' = A[X]/(aX - b) \).

- (a) \( aX - b \) is a prime element of \( A[X] \).
- (b) If \( A \) is a noetherian UFD and \( aA \) and \( aA + bA \) are prime ideals of \( A \), then \( A' \) is a noetherian UFD.

3. **Surfaces defined by \( A^1 \times \mathbb{A}^2 \) Embeddings**

In this section, we use certain closed embeddings of the punctured line \( A^1 \) in the plane \( A^2 \) to define surfaces belonging to \( \mathcal{S} \).

3.1. **A Family of Surfaces in \( \mathcal{S} \).**

**Theorem 3.1.** Let \( A = k[x, y] \cong k^{[2]} \) and let \( a, b \in A \) be such that:

\[
A/aA \cong k^{[i+1]} , \quad A/bA \cong k^{[i]} , \quad A/(aA + bA) \cong k
\]

Define the ring \( B \subset A_a \) by \( B = A[b/a] \).

- (a) \( B \) is a UFD and \( B^* = k^* \).
- (b) If \( k \) is algebraically closed and \( X = \text{Spec}(B) \), then \( X \in \mathcal{S} \).

**Proof.** We have \( B \cong A[X]/(aX - b) \), where \( A[X] \cong A^3 \). In addition, \( a \) and \( b \) are prime elements of \( A \), \( \gcd_A(a, b) = 1 \) and the ideal \( aA + bA \) is prime in \( A \). By Samuel’s Criterion, it follows that \( B \) is a UFD. Since \( A \subset B \subset A_a \) and \( B \neq A_a \), we see that \( B^* = A^* = k^* \). This proves part (a).

To prove part (b), let \( \Gamma \subset A^2 \) be the curve defined by \( a = 0 \), noting that \( \Gamma \cong A^1 \). Define the maximal ideal \( I = (a, b) \subset A \), and let \( P \in A^2 \) be the point defined by \( I \), noting that \( P \in \Gamma \). Let \( W \) be the blow-up of \( A^2 \) at \( P \). Then \( W \) is smooth. Let \( \Gamma' \subset W \) be the proper transform of \( \Gamma \). Then \( W \setminus \Gamma' \) is smooth, and the coordinate ring of \( W \setminus \Gamma' \) is the affine modification:

\[
A[a^{-1}I] = A[a^{-1}(a, b)] = A[b/a] = B
\]

Therefore, \( X = W \setminus \Gamma' \) is smooth, which implies \( X \in \mathcal{S} \). \( \square \)
3.2. Logarithmic Kodaira Dimension. Assume that the ground field $k$ is algebraically closed. Let $B = A[b/a]$ be a ring of the type described in Theorem 3.1 that is, $A = k[x, y] \cong k[2]$, and $a, b \in A$ are such that:

$$A/aA \cong k^{[2]}, \quad A/bA \cong k^{[1]}, \quad A/(aA + bA) \cong k$$

Let $X = \text{Spec}(B)$. By Theorem 3.1, $X \in \mathcal{Y}$.

**Theorem 3.2.** Let $\Gamma \subset \mathbb{A}^2_k$ be the curve defined by the ideal $aA$.

(a) $\bar{\kappa}(X) = \bar{\kappa}(\mathbb{A}^2_k \setminus \Gamma)$

(b) If $\Gamma$ has two places at infinity, then $\bar{\kappa}(X) \geq 0$.

(c) If the complement $\mathbb{A}^2_k \setminus \Gamma$ contains an open set isomorphic to $\mathbb{A}^1_k \times \mathbb{A}^1_k$, then $\bar{\kappa}(X) \leq 0$.

In order to prove the theorem, we need the following lemma, which is well-known.

**Lemma 3.3.** Let $V$ be a smooth projective surface defined over $k$ and let $C$ be a reduced curve on $V$. Let $\pi : W \to V$ be the blow-up at a point $P$ on $C$ and let $D$ be the proper transform of $C$ on $W$. If $P$ is a smooth point of $C$, then $\bar{\kappa}(W \setminus D) = \bar{\kappa}(V \setminus C)$.

**Proof.** We may assume that $C$ is an SNC-divisor, i.e., $C$ has only normal crossings and consists of smooth curves. Since $P$ is a smooth point of $C$, we have $K_W + D \sim \pi^*(K_V + C)$. So $H^0(W, C_W(n(K_W + D))) \cong H^0(V, O_V(n(K_V + C)))$ for any integer $n \geq 1$. Hence, $\bar{\kappa}(W \setminus D) = \bar{\kappa}(V \setminus C)$. \hfill \Box

**Proof of Theorem 3.2.** Let $S = \mathbb{A}^2_k \setminus \Gamma$, let $P \in \mathbb{A}^2_k$ be the point defined by the maximal ideal $(a, b)$, let $\pi : W \to \mathbb{A}^2_k$ be the blow-up at the point $P$, and let $\Gamma' \subset W$ be the proper transform of $\Gamma$. Then $X \equiv W \setminus \Gamma'$. Since $P$ is a smooth point of $\Gamma$, we infer from Lemma 3.3 that

$$\bar{\kappa}(X) = \bar{\kappa}(W \setminus \Gamma') = \bar{\kappa}(S).$$

This proves part (a).

For part (b), since $\Gamma$ is a smooth affine plane curve with two places at infinity, the log geometric genus of $S$ is positive; see, e.g., Chapter 2, Lemma 2.2.2 (p. 72) of [7]. Hence, $\bar{\kappa}(S) \geq 0$, so $\bar{\kappa}(X) \geq 0$.

For part (c), since $S$ contains an open set $U \cong \mathbb{A}^1_k \times \mathbb{A}^1_k$, we have $\bar{\kappa}(S) \leq \bar{\kappa}(\mathbb{A}^1_k \times \mathbb{A}^1_k) = 0$. Therefore, $\bar{\kappa}(X) \leq 0$. \hfill \Box

4. The Rings $B_n$

4.1. **Definition.** Let $A = k[x, y] \cong k[2]$. Given $n \in \mathbb{N}$, $n \geq 0$, define the ring:

$$B_n = A[(x - 1)/(x^n y - 1)]$$

By Theorem 3.1 we see that $B_n$ is a UFD and $B_n^* = k^*$. Let $u = (x - 1)/(x^n y - 1)$.

4.2. **Fibrations.** Assume that $k$ is algebraically closed, and fix the positive integer $n$. Let $V_n = \text{Spec}(B_n)$. Given $\lambda \in k$, consider the fibers $x - \lambda$, $u - \lambda$ and $y - \lambda$. There are three cases.

1. General fiber: $\lambda \notin \{0, 1\}$

   (i) $\text{Spec } B/(x - \lambda) \cong \text{Spec } k[y, u]/(u(y^n y - 1) + (1 - \lambda)) \cong \mathbb{A}^1_k$

   (ii) $\text{Spec } B/(u - \lambda) \cong \text{Spec } k[x, y]/(\lambda(x^n y - 1) - (x - 1)) \cong \mathbb{A}^1_k$

   (iii) $\text{Spec } B/(y - \lambda) \cong \text{Spec } k[x, u]/(u(\lambda x^n - 1) - (x - 1)) \cong \mathbb{A}^1_{k^n}$

2. Reducible fiber: $\lambda = 1$

   (i) $\text{Spec } B/(x - 1) \cong \text{Spec } k[y, u]/(u(y - 1)) \cong \mathbb{A}^1_k \cup \mathbb{A}^1_k$

   (ii) $\text{Spec } B/(u - 1) \cong \text{Spec } k[x, y]/(x(x^n y - 1)) \cong \mathbb{A}^1_k \cup \mathbb{A}^1_k$

   (iii) $\text{Spec } B/(y - 1) \cong \text{Spec } k[x, u]/((x - 1)(u(x^n - 1 + \cdots + x + 1) - 1)) \cong \mathbb{A}^1_k \cup \mathbb{A}^1_{k^{n-1}}$

3. Zero fiber: $\lambda = 0$

   (i) $\text{Spec } B/(x) \cong \text{Spec } k[y] \cong \mathbb{A}^1_k$

   (ii) $\text{Spec } B/(u) \cong \text{Spec } k[y] \cong \mathbb{A}^1_k$

   (iii) $\text{Spec } B/(y) \cong \text{Spec } k[x] \cong \mathbb{A}^1_k$
Note that the inclusions $k[x] \to B_m$ and $k[u] \to B_n$ induce $A_1^k$-fibrations of $V_n$. Note also that the ideals $(x - \lambda), (u - \lambda)$ and $(y - \lambda)$ are prime if and only if $\lambda \neq 1$.

4.3. $k$-Algebra Isomorphism Classes.

**Theorem 4.1.** Given $m, n \in \mathbb{N} \setminus \{0\}$, if $B_m \cong_k B_n$, then $m = n$.

**Proof.** It suffices to assume that $k$ is algebraically closed.

Assume that $B_m \cong_k B_n$ and that $n > m \geq 1$. Then there exists a subalgebra $B \subset k(x, y) \cong k^{(2)}$ and elements $u, X, Y, U$ such that:

$$B = k[x, y, u] = k[X, Y, U], \quad u(x^my - 1) = x - 1, \quad U(x^nY - 1) = X - 1$$

Let $A = k[x, y]$ and $t = x^my - 1$, noting that $A \cong k^{[2]}$ and $A \subset B \subset B_t = A_t$. Define a $Z$-grading of $A_t$ by letting $x, y$ be homogeneous with $\deg x = 1$ and $\deg y = -m$. It is easy to see that:

1. $h \in A_t$ and $\deg h < 0 \implies h \in yA_t$

The degree function restricts to $B$. Let $B = \bigcup_{d \in \mathbb{Z}} F_d$ be the filtration of $B$ by degree modules. We claim that the following two properties hold:

2. $h \in B$ and $\deg h < 0 \implies h \in yB$

and

3. $h \in B$ is prime and $\deg h < 0 \implies hB = yB$ and $k[h] = k[y]$

Consequently, when condition [3] holds, the general fiber of $h$ is $k_{sm}^1$ and $h$ has exactly one reducible fiber, that fiber being isomorphic to $A_{sn}^1 \cup A_{(m-1)}^1$.

To prove these implications, note that, since $B$ is a UFD, $y$ is prime in $B$ and $yB + tB = B$, it follows that $yB \cap B = yB$. Therefore, if $h \in B$ and $\deg h < 0$, then $h \in yB_t$ by the implication [2]. But then $h \in yB_t \cap B = yB$. So the implication [2] is confirmed.

Suppose $h \in B$ is prime and $\deg h < 0$. Then by [2] we have $hB = yB$, since $y$ is prime in $B$. Since $B^* = k^*$, it follows that $k[h] = k[y]$. So the implication [3] is confirmed.

Since $Y$ is prime and the general fiber of $Y$ is $A_{sn}^1$, and since $A_{sn}^1 \not\cong A_{sm}^1$, it follows that $\deg Y \geq 0$.

In addition, $U$ is prime, the general fiber of $U$ is $A_{sn}^1$, and the reducible fiber of $U$ is $A_{sn}^1 \cup A_{(m-1)}^1$. If $\deg U < 0$, then $A_{sn}^1 = A_{sm}^1$ implies $m = 1$. But then the reducible fibers give $A_{sn}^1 \cup A_{sn}^1 \not\cong A_{1}^1 \cup A_{1}^1$, a contradiction. So $\deg U \geq 0$.

Since $X^nY - 1$ is prime and has a reducible fiber with $n + 1 > 2$ components, it follows that $\deg(X^nY - 1) \geq 0$. Since $X - 1 = U(X^nY - 1)$, we also see that $\deg(X - 1) \geq 0$.

There are 2 cases to consider.

**Case 1:** $\deg X \geq 0$. Then

$$\deg X = \deg(X - 1 + 1) \leq \max\{\deg(X - 1), 0\} = \deg(X - 1) \leq \max\{\deg X, 0\} = \deg X$$

which implies $\deg X = \deg(X - 1)$. The same reasoning shows $\deg(X^nY) = \deg(X^nY - 1)$. Therefore:

$$\deg X = \deg(X - 1)$$
$$= \deg(U(X^nY - 1))$$
$$= \deg U + \deg(X^nY - 1)$$
$$= \deg U + \deg(X^nY)$$
$$= \deg U + n \deg X + \deg Y$$

Since $\deg X, \deg Y, \deg U \in \mathbb{N}$ and $n \geq 2$, this gives:

$$0 = \deg U + (n - 1) \deg X + \deg Y \implies \deg X = \deg Y = \deg U = 0$$

But then

$$k[X, Y, U] = F_0 \subset B = k[X, Y, U] \implies F_0 = B$$
which is a contradiction, since $x \not\in \mathcal{F}_0$. So the case $\deg X \geq 0$ cannot occur.

**Case 2:** $\deg X < 0$. Then (3) implies $XB = yB$ and $k[X] = k[y]$. So $X = cy$ for some $c \in k^*$. Since the general fiber of $X$ is $A^1$ and the general fiber of $y$ is $A^1_m$, it follows that $m = 1$.

Let $T = X^n Y - 1$, $K = k(X) = k(y)$ and $B_K = K \otimes k B$. Since the generic fiber of $X = cy$ is $A^1(K)$, we see that $B_K \cong K^{[d]}$. Specifically:

$$B_K = K[x, y, u] = K[x, u] = K[y^{-1}(t + 1), (y^{-1} - 1)t^{-1} + y^{-1}] = K[t, t^{-1}]$$

and

$$B_K = K[X, Y, U] = K[Y, U] = K[y^n(T + 1), (y - 1)T^{-1}] = K[T, T^{-1}]$$

It follows that $aT = bt^{k+1}$ for some $a, b \in k[y]$ with $\gcd(a, b) = 1$.

Assume $aT = bt$. Since $\gcd(a, b) = 1$, we see that either both $a$ and $b$ are prime in $B$, or $a, b \in B^* = k^*$. The case $a, b \in k^*$ is not possible, since the reducible fiber of $T$ has $n + 1 > 2$ components, and the reducible fiber of $t$ has $m + 1 = 2$ components. Therefore, both $a$ and $b$ are prime in $B$. But then $aB = tB$ implies $t = ra \in K$ for some $r \in k^*$, a contradiction, since $t$ is transcendental over $K$.

Assume $aTt = b$. Then $b \in aB$ implies $a \in k^*$, and $b$ has exactly two prime factors. One possibility is that $b$ has a root $\lambda \in k \setminus \{1\}$. But then either $T = r(y - \lambda) \in K$ or $t = r(y - \lambda) \in K$ for $r \in k^*$, which is a contradiction. The other possibility is that $b = s(y - 1)$ for $s \in k^*$. The equality $Tt = a^{-1}s(y - 1)$ shows $a^{-1}s = -1$. Since $X = cy$, we have:

$$Tt = (X^n Y - 1)(xy - 1) = 1 - y \quad \Rightarrow \quad X^n Y xy - X^n Y - xy = -y$$

$$\quad \Rightarrow \quad X^n Y eX^{-1}Y - x = -1$$

Since $n \geq 2$, we conclude that $XB + yB = B$, a contradiction since $XB + yB$ is a maximal ideal of $B$. So the case $\deg X < 0$ cannot occur.

The assumption that $m \neq n$ thus leads to contradiction. Therefore, $m = n$. 

4.4. **Degree-Rigidity of $B_n$.**

**Theorem 4.2.** $B_n$ is degree-rigid for each $n \geq 1$.

**Proof.** Let $B_n = k[x, y, (x - 1)/(x^n y - 1)]$, let $\delta : B_n \to \mathbb{N} \cup \{-\infty\}$ be a non-negative degree function, and let $B_n = \bigcup_{\delta \in \mathbb{N}} \mathcal{F}_\delta$ be the filtration induced by $\delta$. Given $\lambda, \mu \in k$ and $f \in B_n \setminus k$, since $k^* \subset \mathcal{F}_0$, we have:

$$0 \leq \delta(f - \lambda) = \delta((f - \mu) + (\mu - \lambda)) \leq \max\{\delta(f - \mu), \delta(\lambda - \mu)\} = \delta(f - \mu)$$

Therefore, $\delta(f - \lambda) = \delta(f - \mu)$ for all $f \in B \setminus k$ and $\lambda, \mu \in k$. It follows that

$$0 \leq \delta\left(\frac{x - 1}{x^n y - 1}\right) = \delta(x - 1) - \delta(x^n y - 1) = \delta(x) - \delta(x^n y) = \delta(x) - n\delta(x) - \delta(y)$$

which gives:

$$0 \leq (n - 1)\delta(x) \leq -\delta(y) \quad \Rightarrow \quad (n - 1)\delta(x) = \delta(y) = 0$$

If $n \geq 2$, we see that $\delta(x) = 0$. If $n = 1$, there is an automorphism $\alpha$ of $B_1$ such that $\alpha(y) = x$. Therefore, $\delta(x) = 0$ if $n = 1$.

So in all cases, $\delta(x) = \delta(y) = 0$, meaning that $k[x, y] \subset \mathcal{F}_0$. By Proposition 2.2, $\mathcal{F}_0$ is factorially closed, and thus algebraically closed, in $B_n$. Therefore, the algebraic closure of $k[x, y]$ in $B_n$ is contained in $\mathcal{F}_0$, which implies $B_n \subset \mathcal{F}_0$, i.e., $B_n = \mathcal{F}_0$. 

**Corollary 4.3.** Given integers $m, n, d \geq 1$, if $B_n[d] \cong_k B_n[d]$, then $m = n$.

**Proof.** By Theorem 4.2, $B_m$ is degree-rigid. Therefore, by Lemma 2.3, $B_m$ is strongly invariant. Since $B_n[d] \cong_k B_n[d]$, we have $B_m \cong_k B_n$. By Theorem 4.1, it follows that $m = n$. 

\[\square\]
4.5. Coordinate Rings for Two Surfaces of Gurjar and Miyanishi. Let \( k \) be a field. We consider the following two \( k \)-algebras \( C_1, C_2 \):
\[
C_1 = k[x,y,u,v]/(ux-(y-1), vy-(x-1))
\]
and
\[
C_2 = k[X,Y,U,V]/(U(XY-1) - (X-1), V(XY-1) - (Y-1))
\]
Observe that, for the surfaces \( S \) and \( S' \) defined in the Introduction, we have \( S = \text{Spec}(C_1) \) and \( S' = \text{Spec}(C_2) \) when \( k = \mathbb{C} \).

**Theorem 4.4.** For any field \( k \), the rings \( C_1, C_2 \) and \( B_1 \) are isomorphic as \( k \)-algebras.

**Proof.** Let \( B = k[x,y,u,v] \cong k[4] \) and define ideals:
\[
I = (ux-(y-1), vy-(x-1)) , \ J = (x(uv-1)+(v+1), y(uv-1)+(u+1))
\]
First of all, we show \( I = J \), that is, \( C_1 = B/J \).

In \( B/I \), we have:
\[
x(uv-1) + (v+1) = v(ux+1) - (x-1) \\
= vy - (x-1) \\
= 0
\]
Similarly we have that \( y(uv-1) + (u+1) = 0 \) in \( B/I \). Therefore \( J \subset I \).

On the other hand, in \( B/J \), we have:
\[
(uv-1)(1+ux) = uv-1+u(x(uv-1)) = uv-1-u(v+1) = -(u+1) = y(uv-1)
\]
Hence \( 1+ux = y \) in \( B/J \). Similarly we have that \( 1+vy = x \) in \( B/J \). Therefore, in \( B/J \), we have
\[
x(uv-1) + (v+1) = u(1+vy) - (y-1) = y(uv-1) + (u+1) = 0
\]
and \( vy-(x-1) = 0 \), which implies \( I \subset J \). Hence \( I = J \).

Define the \( k \)-isomorphism \( \varphi : B \to k[X,Y,U,V] \cong k[4] \) by \( \varphi(x,y,u,v) = (U,V,-Y,-X) \). Then:
\[
\varphi(x(uv-1) + (v+1), y(uv-1) + (u+1)) = (U(XY-1) - (X-1), V(XY-1) - (Y-1))
\]
Therefore we have \( C_1 \cong_k \varphi(B/J) = C_2 \).

Finally, in \( C_2 \) we have
\[
\frac{Y-1}{XY-1} = 1 - \frac{X-1}{XY-1}
\]
which shows \( C_2 = k[X,Y,\frac{X-1}{XY-1}] \cong B_1 \). \( \square \)

5. **Isomorphism Classes in \( S_0 \)**

Assume that \( k \) is algebraically closed. Given \( n \geq 1 \), let \( V_n = \text{Spec}(B_n) \). As observed above, \( B_n = A[b/a] \) satisfies the hypotheses of Theorem 3.1 for \( A = k[x,y] \) and elements \( a = x^n y-1 \) and \( b = x-1 \). Therefore, \( V_n \in \mathcal{S} \) for each \( n \geq 1 \).

Let \( \Gamma_n \subset \mathbb{A}^2_k \) be the curve defined by the ideal \( aA \). Then \( \Gamma_n \) has two places at infinity. By Theorem 3.2(b), \( \bar{\kappa}(V_n) \geq 0 \).

Consider the localization of the ring \( A_a \) at \( x \):
\[
A_a[x^{-1}] = k[x, x^{-1}, y, (x^n y - 1)^{-1}] = k[x, x^{-1}, x^n y - 1, (x^n y - 1)^{-1}] \cong k[\pm 2]
\]
Therefore, \( \mathbb{A}^2_k \setminus \Gamma_n \) contains an open subset isomorphic to \( \mathbb{A}^1_k \times \mathbb{A}^1_k \). By Theorem 3.2(c), \( \bar{\kappa}(V_n) \leq 0 \).
It follows that $\bar{\kappa}(V_n) = 0$. Moreover, Theorem 4.1 shows that $V_m \cong V_n$ implies $m = n$, and Corollary 4.3 shows that $V_m \times A^d_k \cong V_n \times A^d_k$ for some $d \geq 0$ implies $m = n$. These results are summarized below.

**Theorem 5.1.** For the surfaces $V_n$, $n \geq 1$, the following properties hold.

(a) $V_n \in \mathcal{I}_0$ for each $n \geq 1$

(b) Given positive integers $m, n$, if $V_m \times A^d_k \cong_k V_n \times A^d_k$ for some $d \in \mathbb{N}$, then $m = n$.

**Question.** Over the field $k = \mathbb{C}$, are the surfaces $V_n$, $n \geq 1$, pairwise analytically isomorphic (respectively, pairwise homeomorphic)?
