ON THE FIBRATION METHOD FOR RATIONAL POINTS

DASHENG WEI

Abstract. We study weak approximation on rationally connected varieties under an assumption of strong approximation for a "simple" variety or under Schinzel’s hypothesis. We also get some unconditional results.

1. Introduction

Let $X$ denote a smooth proper algebraic variety over a number field $k$. It is customary to embed the set $X(k)$ of rational points of $X$ diagonally into the space of adelic points $X(A_k)$. In 1970, Manin ([Man71], [Man86]) showed that an obstruction based on the Brauer group of varieties, now referred to as the Brauer–Manin obstruction, can often explain failures of the Hasse principle and weak approximation. Further work (see [Wit18] for a survey) has shown that for some classes of rationally connected varieties the Brauer–Manin obstruction is the only obstruction to the Hasse principle and weak approximation.

Let $X$ be a smooth proper and geometrically irreducible variety over a number field $k$, and let $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rationally connected geometric generic fiber. Weak approximation on $X$ has been studied extensively. There are two approaches to study this problem. The first approach is to study weak approximation for its universal torsors by descent theory developed in [CTSS87], see for example [CTSS87], [SD99], [CTSa89] by geometric methods; see [HBS02], [Jo13] by the circle method; see [BHB12], [DSW14], [Irv14] by the sieve method; and see [HSW14], [BMS14], [BM17] by additive combinatorics.

Another approach is the fibration method which can be traced back to Hasse’s proof about the local-global principle of quadratic forms. Under Schinzel’s hypothesis, weak approximation was first studied by Colliot-Thélène and Sansuc in [CTS82]. Such a conditional result (Under Schinzel’s hypothesis) was largely extended in [CTSD94], [CTSS98], [Wit07], [Wei14a] and so on.

Harpaz and Wittenberg (see [HW16, Theorem 9.17]) further improved the fibration method such that most of the above mentioned results can be covered. They proposed a conjecture (Conjecture 9.1) in [HW16] which implies that a large class of rationally varieties satisfy weak approximation with the Brauer–Manin obstruction.

Let $k$ be a number field, let $P_1(t), \ldots, P_n(t)$ be pairwise distinct irreducible polynomials in $k[t]$. Let $k_i = k[t]/(P_i(t))$ and $a_i$ the class of $t$ in
Let $F_i$ be the singular locus of $R_{L_i}(\mathbb{A}^1_{L_i}) \setminus R_{L_i}(\mathbb{G}_{m,L_i})$, this is a codimension 2 closed subset of the affine space $R_{L_i}(\mathbb{A}^1_{L_i})$. Let $W$ be the closed subvariety of $\mathbb{A}^2_{\mathbb{Q}} \times \prod_{i=1}^n (R_{L_i}((\mathbb{A}^1_{L_i}) \setminus F_i))$ with coordinates $(\lambda, \mu, z_1, \cdots, z_n)$ defined by the system of equations

$$
\begin{align*}
  b_1(\lambda - a_1\mu) &= N_{L_1/k_1}(z_1), \\
  \cdots &
\end{align*}
$$

where $N_{L_1/k_1}$ is the norm form of the extension $L_1/k_1$. We call such $W$ to be a variety associated to the pairs $(P_1(t), L_1), \cdots, (P_n(t), L_n)$.

Varieties closely related to $W$ (in fact, partial compactifications of $W$) first appeared in the context of descent in [Sko90, §3.3] named vertical torsors, see also [CTS00, p. 391], [Sko01, §4.4]. By an easy computation, one obtains $k[W] = k^\times$ and Pic($W$) = 0, then Br$_1(W) = Br_0(W)$.

The following conjecture was first mentioned in [HW16, §9] and [Wit18, §3.4], and it implies Harpaz and Wittenberg’s Conjecture 9.1 (see [HW16, Corollary 9.10]).

**Conjecture 1.1.** The variety $W$ satisfies strong approximation off any place $v_0$ of $k$.

A scheme of finite type over a field is split if it contains a geometrically irreducible component of multiplicity 1. Recall here that the rank of a fibration $f : X \to \mathbb{P}^1_k$ is defined to be the sum of degrees of closed points of $\mathbb{P}^1_k$ above which the fiber of $f$ is not split. The definition of split fibers can be found in work of Skorobogatov [Sko96], which is where the notion was originally introduced to the subject.

Let $X$ be a smooth, proper and geometrically integral variety over a number field $k$ and let $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rational connected geometrical generic fiber. Let $U_0 \subset \mathbb{P}^1_k$ be the dense open subset over which the fiber of $f$ is split and $\infty \in U_0$. Let $\Psi = \mathbb{P}^1_k \setminus U_0$. Let $P_1(t), \cdots, P_n(t) \in k[t]$ denote the irreducible monic polynomials which vanish at the points of $\Psi$. Let $P_1(t), \cdots, P_n(t) \in k[t]$ denote irreducible monic polynomials which vanish at the points of $\Psi$. For $i \in \{1, \cdots, n\}$, let $k_i = k[t]/(P_i(t))$, let $D_i$ be a component over $k$ of multiplicity one over the point corresponding to $P_i(t)$, and let $L_i$ be the algebraic closure of $k_i$ in the function field $k(D_i)$.

Now we state the main results of this paper (see Theorem 2.5 and 3.5).

**Theorem 1.2.** Let $X$ be a smooth, proper and geometrically integral variety over a number field $k$ and let $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rational connected geometrical generic fiber. Let $P_i(t)$ and $L_i$ be as above.

Assume that:

- $X_c(k)$ is dense in $X_c(\mathbb{A}_k^{Br(X_c)})$ for every rational point $c$ of a Hilbert subset of $\mathbb{P}^1_k$;

and one of the following two conditions holds:

i) strong approximation off $v_0$ holds for any variety $W$ associated to the pairs $(P_1(t), L_1), \cdots, (P_n(t), L_n)$, where $v_0$ runs through almost all finite places of $k$;
ii) Hypothesis (HH$_i$) holds for $P_1(t), \ldots, P_n(t)$, and field extensions $L_i/k_i$ are cyclic for all $i$.

Then $X(k)$ is dense in $X(A_k)^{Br(X)}$.

We may compare Theorem 1.2 with Harpaz and Wittenberg’s fibration theorem ([HW16, Theorem 9.17]). On one hand, there is a technical condition (9.9) in [HW16, Theorem 9.17], which will hold under the assumption that $k$ is totally imaginary or that a non-split fiber of $f$ lies over a rational point of $\mathbb{P}_k^1$ (see [HW16, Remark 9.18 ii]); on the other hand, if there is the Brauer–Manin obstruction on smooth fibers of $f$, [HW16, Theorem 9.17] requires that [HW16, Conjecture 9.1] holds for larger fields $L_i$ than defined in Theorem 1.2 for all points in $\Psi$, such $L_i$’s depend on the Brauer group of the generic fiber of $f$ and on all non-split fibers. Since the Brauer group are wildly open in general, the $L_i$’s are hard to be controlled; on the other hand, in general, [HW16, Conjecture 9.1] is more difficult to be established if the $L_i$’s are larger. Therefore, an effective version of [HW16, Theorem 9.17] is requiring that [HW16, Conjecture 9.1] holds for each $L_i$, see all unconditional results in [HW16, §9.4] and [BS19, Theorem 1.1].

There are two approaches to prove [HW16, Conjecture 9.1]. The first approach is by Schinzel’s hypothesis (H) under the assumption that all $L_i/k_i$ in [HW16, Conjecture 9.1] are abelian (or slightly more general, almost abelian, see [HW16, §9.2]). There should be no Brauer–Manin obstructions to weak approximation on smooth fibers of $f$ for [HW16, Theorem 9.17] to be applicable, which should be compared with the case ii) in Theorem 1.2.

Another approach is by Conjecture 1.1, see [HW16, Corollary 9.10]. For example, if $k = \mathbb{Q}$, Conjecture 1.1 holds for each of the following two cases:

1. $\deg(m_i) = 1$ for all $i \in \{1, \ldots, n\}$, $v_0$ is a finite place of $\mathbb{Q}$;
2. $\sum \deg(m_i) \leq 3$ and $\deg(m_i) = 1$ for at least one $i \in \{1, \ldots, n\}$.

The case (1) is due to Matthiesen by [Mat18, Theorem 1.3] and its remark; it uses additive combinatorics and builds on the work of Browning and Matthiesen [BM17]. The case (2) is a recent result of Browning and Schindler [BS19], which, similarly, builds on the work of Browning and Heath-Brown [BHB12]. Combining these analytic results with Theorem 1.2, we cover the unconditional results in [HW16, §9.4] (e.g., Theorem 9.28, Corollary 9.29, Theorem 9.31) and [BS19, Theorem 1.1]. Our proof needs to combine descent theory ([CTS87, Wei16] and [CDX19]) with the fibration method in [Har94], this idea may also be applied to study strong approximation on some non-proper varieties (e.g., [CWX19, Theorem 4.4]).

Furthermore, we get some unconditional results (see Corollary 2.3, 2.9 and 3.7).

**Theorem 1.3.** Let $X$ be a smooth, proper, geometrically integral variety over a number field $k$ and $f : X \to \mathbb{P}_k^1$ be a dominant morphism with rationally connected geometric generic fiber. Assume that one of following condition holds:

1. $\text{rank}(f) \leq 2$;
Let $S$ be endowed with a morphism $f : X \to \mathbb{P}^1_k$ such that the algebraic closure of $k(m)$ in the function field $k(D_m)$ is quadratic over $k(m)$;

$(3) \ k = \mathbb{Q}$, and $\text{rank}(f) \leq 3$, and every non-split fiber $X_m$ contains a multiplicity one component $D_m$ such that the algebraic closure of $k(m)$ in the function field $k(D_m)$ is cyclic over $k(m)$.

If $X_c(k)$ is dense in $X_c(A_k)^{\text{Br}(X)}$ for every rational point $c$ of a Hilbert subset of $\mathbb{P}^1_k$, then $X(k)$ is dense in $X(A_k)^{\text{Br}(X)}$.

Under the assumption that the fibers above a Hilbert set of rational points satisfy weak approximation, the case (1) and (2) were also proved in [CTSS98, Theorem 2.2], [CTS00, Theorem A,B]; the case (1) had also been dealt with in [HW16, Theorem 9.31] under the assumption that $k$ is totally imaginary or that the non-split fibers of $f$ lie over rational points of $\mathbb{P}^1_k$, they also mentioned that the technical assumption is superfluous in the footnote.

**Terminology.** Notation and terminology are standard. Let $k$ be a number field, $\Omega$ the set of all places of $k$ and $\infty_k$ the set of all archimedean places of $k$. Write $v < \infty_k$ for $v \in \Omega_k \setminus \infty_k$. Let $\mathcal{O}_k$ be the ring of integers of $k$ and $\mathcal{O}_S$ the $S$-integers of $k$ for a finite set $S$ of $\Omega$ containing $\infty_k$. For each $v \in \Omega$, the completion of $k$ at $v$ is denoted by $k_v$, the completion of $\mathcal{O}_k$ at $v$ by $\mathcal{O}_v$ and the residue field at $v$ by $k(v)$ for $v < \infty_k$. Let $A_k$ be the adele ring of $k$.

Let $Z$ be a smooth variety over $k$. Denote $Z(A_k)^B$ to be the set of all $(z_v)_v \in Z(A_k)$ satisfying $\sum_{v \in \Omega_k} \text{inv}_v(A(z_v)) = 0$ for each $A$ in the subgroup $B$ of the Brauer group $\text{Br}(Z) = H^2_{\text{et}}(Z, \mathbb{G}_m)$ of $Z$, where the map $\text{inv}_v : \text{Br}(k_v) \to \mathbb{Q}/\mathbb{Z}$ is the invariant map from local class field theory. The subgroup $\text{Br}_0(Z)$ of constant elements in the Brauer group is the image of the natural map $\text{Br}(k) \to \text{Br}(Z)$. The algebraic Brauer group $\text{Br}_1(Z)$ is the kernel of the natural map $\text{Br}(Z) \to \text{Br}(\overline{Z})$, where $\overline{Z} = Z \times_k \overline{k}$.

We say that strong approximation holds for $Z$ off a (finite or infinite) set $S$ of places of $k$ if the image of the set $Z(k)$ of rational points on $Z$ is dense in the space $Z(A_k)^S$ of adelic points on $Z$ outside $S$. In particular, $Z$ satisfies strong approximation off $\Omega \setminus S$ for each finite subset $S$ of $\Omega$, which is equivalent to that $Z$ satisfies weak approximation. If $S_1 \subset S_2$ be two subsets of $\Omega$, then strong approximation off $S_1$ holds for $Z$ implies strong approximation off $S_2$ holds for $Z$.

2. **Under Conjecture 1.1 and some unconditional results**

Let $k$ be a number field, $F$ a finite field extension of $k$, and denote $\Omega_{F/k}$ to be the set of finite places of $k$ at which $F/k$ is totally split.

**Proposition 2.1.** Let $X$ be a smooth, geometrically integral variety over $k$, endowed with a morphism $f : X \to \mathbb{P}^1_k$ with smooth geometrically integral generic fiber. Assume that every fiber of $f$ contains an irreducible component of multiplicity 1 and that the fibration $f$ acquires a rational $k$-section, and
that $\bar{k}[X]^\times = \kbar^\times$. Let $U_0, \Psi, P_1(t), D_i, k_i, L_i$ and $k(D_i)$ be as in Theorem 1.2. Let $U'_0 \subset U_0$ be an open subset, and $\infty \in U'_0$. Let $B \subset \text{Br}(f^{-1}(U'_0))$ be a finite set.

Let $(x_v)_v \in X(A_k)$ be orthogonal to $B \cap \text{Br}(X) + \text{Br}_1(X)$ with respect to the Brauer–Manin pairing. Assume that:

a) strong approximation off $\Omega_{F/k} \setminus T$ holds for any $W$ associated to the pairs $(P_1(t), L_1), \cdots, (P_n(t), L_n)$, where $T$ runs through all finite subsets of $\Omega_{F/k}$ and $F$ is a finite extension of $k$ depending on $X$.

Then there exists $c \in U'_0(k)$ and $(x'_v)_v \in X_c(A_k)$ such that $X_c$ is smooth and $(x'_v)_v$ is orthogonal to $B$ with respect to the Brauer–Manin pairing and is arbitrary closed to $(x_v)_v$ in $X(A_k)$.

Remark 2.2. Let $F'$ be any finite extension of $k$ and $n$ any fixed positive integer. Note that $\Omega_{F'F'/k}$ is an infinite subset of $\Omega_{F/k}$, then $\Omega_{F'F'/k} \setminus T$ is an infinite set. Therefore, $\Omega_{F'F'/k} \setminus T$ contains infinitely many subsets of $\Omega_{F'/k}$ of cardinality $n$. So, if $W$ satisfies strong approximation off $S$ where $S$ runs through almost all subsets of $\Omega_{F'/k}$ of cardinality $n$, then the condition a) in Proposition 2.1 holds.

Let $V_0 = U_0 \setminus \infty$ and let $V = f^{-1}(V_0) \subset X$. Let $P$ be the $k$-group of multiplicative type dual to the $\Gamma_k$-module $\hat{P} = \ker[\text{Pic}(X) \to \text{Pic}(\bar{V})]$. We have the exact sequence

$$0 \to \bar{k}[V]^\times / \kbar^\times \xrightarrow{\text{div}} \text{Div}_{X/\bar{V}}(X) \to \hat{P} \to 0.$$ 

Let $\hat{M}$ be the free $\Gamma_k$-module generated by all divisors

$$\overline{D}_\infty, \overline{D}_{11}, \cdots, \overline{D}_{r_1}, \cdots, \overline{D}_{n1}, \cdots, \overline{D}_{nr},$$

where $\overline{D}_{ij} \subset \overline{D}_i$ and $1 \leq j \leq r_i$. Then $\hat{M}$ is a permutation submodule of $\text{Div}_{X/\bar{V}}(X)$, its dual

$$M \cong \mathbb{G}_m \times R_{L_1/k_1}(\mathbb{G}_{m,L_1}) \times \cdots \times R_{L_n/k_n}(\mathbb{G}_{m,L_n}).$$

We have another exact sequence

$$0 \to \bar{k}[V_0]^\times / \kbar^\times \xrightarrow{\text{div}} \hat{M} \to \hat{Q} \to 0,$$

where $\hat{Q}$ is the quotient of the morphism $\text{div}$. Obviously $\hat{Q}$ is a finitely generated free $\mathbb{Z}$-module since all $\overline{D}_i$ are of multiplicity 1, hence its dual $\hat{Q}$ is a torus. Let $\hat{R} = \bar{k}[V_0]^\times / \kbar^\times$, $\hat{R}$ is a permutation module and its dual $R$ is isomorphic to $\prod_{i=1}^n R_{k_i/k}(\mathbb{G}_{m,k_i})$. Then we have a commutative diagram

$$
\begin{array}{cccccc}
0 & \longrightarrow & \hat{R} & \xrightarrow{\text{div}} & \hat{M} & \longrightarrow & \hat{Q} & \longrightarrow & 0 \\
\rho \downarrow & & \eta \downarrow & & \lambda \downarrow & & \\
0 & \longrightarrow & \bar{k}[V]^\times / \kbar^\times & \xrightarrow{\text{div}} & \text{Div}_{X/\bar{V}}(X) & \longrightarrow & \hat{P} & \longrightarrow & 0,
\end{array}
$$

where $\rho$ and $\eta$ are the natural morphism and $\lambda$ is induced by $\eta$. The morphism $\lambda$ induces an element in $\text{Hom}_k(\hat{Q}, \text{Pic}(X))$, we also denote it by $\lambda$.

Since $\bar{k}[X]^\times = \kbar^\times$, by descent theory ([CTS87 Corollary 2.3.4], [Sko01 Proposition 4.4.1]), the torsors of type $\lambda$ over $X$ always exist.
The dual of the morphism $\text{div} : \hat{R} \to \hat{M}$ is then given by the morphism of $k$-tori

$$d : M \to R = \prod_{i=1}^{n} R_{k_i/k}(\mathbb{G}_{m,k_i}), \quad z \mapsto (z_{\infty}N_{L_1/k_1}(z_1), \ldots, z_{\infty}N_{L_n/k_n}(z_n)),$$

where $z = (z_\infty, z_1, \cdots, z_n) \in M$.

We have an exact sequence of tori

$$1 \to Q \to M \to R \to 1.$$ 

This makes $M$ into a $R$-torsor under the torus $Q$.

We now describe the map $V \to R$ induced by the splitting $\phi : \kappa[V]^\times / \kappa^\times \to \kappa[V]^\times$. Then

$$\phi \circ \rho : \hat{R} = \kappa[V_0]^\times / \kappa^\times \to \kappa[V]^\times, t \mapsto b(t - a_i),$$

where $b_i \in k_i$. The induced map $V \to R$ is induced by

$$V_0 \to R = \prod_{i=1}^{n} R_{k_i/k}(\mathbb{G}_{m,k_i}), \quad t \mapsto (b_1(t - a_1), \cdots, b_n(t - a_n)).$$

By [CTS87, Theorem 2.3.1, Corollary 2.3.4], any torsor $T_V$ over $V$ of type $\lambda$ is the pullback of a torsor $M$ from $R$ to $V$, hence it is isomorphic to this variety $V \times_R M$. Since

$$V \times_R M \equiv V \times_{V_0} V_0 \times_R M \equiv V \times_{V_0} g^{-1}(V_0) \subset X \times_{P^1_k} W,$$

where $W$ is the variety in Conjecture 1.1 and $g : W \to P^1_k$, $(\lambda, \mu) \mapsto [\lambda : \mu]$ is the natural projection. Let $p' : X \times_{P^1_k} W \to W$ be the natural projection, then $T_V = p'^{-1}(V_0)$. Therefore, we have the commutative diagram

$$\begin{array}{ccc}
T_V & \xrightarrow{\rho} & V \\
p & \downarrow & \downarrow g \\
V & \xrightarrow{f} & V_0.
\end{array}$$

We extend the commutative diagram (2.1) to the following commutative diagram

$$\begin{array}{ccc}
X \times_{P^1_k} W & \xrightarrow{p'} & W \\
p & \downarrow & \downarrow g \\
X & \xrightarrow{f} & P^1_k,
\end{array}$$

in which we denote morphisms by same notations for simplicity as in (2.1).

The following Lemma is in fact [Sko96, Theorem 3.3.3], it is not directly used in the latter part. However, the original idea is inspired by combining it with [Har94, Theorem 4.2.1].

**Lemma 2.3.** All fibers of the morphism $p' : X \times_{P^1_k} W \to W$ are split.
Proof. Let $y$ be a geometrical point of $W$. Suppose $g(y) \in U_0$. The fiber of $g$ over $y$ is geometrically integral, and the fiber

$$p^{-1}(y) = f^{-1}(g(y)) \times_{k(g(y))} k(y)$$

by the diagram (2.2). Since $f^{-1}(g(y))$ is split by the definition of $U_0$, the fiber $p^{-1}(y)$ is split. If $g(y) \notin U_0$, then $g(y)$ is a closed point. Without loss of generality, we may assume $g(y)$ be the point in $\mathbb{P}_k^1 \setminus U_0$ corresponding to the irreducible polynomial $P_1(t)$, hence $y \in D_1$, where $D_1$ be the divisor of $W$ defined by $P_1(t) = 0$. By the definition of $W$, $D_1$ is a disjoint union of the prime divisors, which implies that $L_1 \subset k[D_1]$. Hence we have $L_1 \subset k(y)$. By the diagram (2.2), the fiber

$$p^{-1}(y) = f^{-1}(g(y)) \times_{k(g(y))} k(y) = f^{-1}(g(y)) \times_{k_1} k(y) \supset D_1 \times_{k_1} k(y).$$

Since $L_1$ is the algebraic closure of $k_1$ in $k[D_1]$, the fiber of $p'$ over $y$ is split. 

Proof of Proposition 2.7. Let $(x_v)_v \in X(A_k)$ be orthogonal to $B \cap \text{Br}(X) + \text{Br}_1(X)$. Let $V = f^{-1}(V_0)$, and $B \subset \text{Br}(V)$. By descent theory (see [Wei16, Theorem 1.7], [CDX19, Corollary 4.3]), there exists a $T$ with $p : T \to X$ which is a torsor of type $\lambda$ such that $(x_v)_v$ is the image of a point $(y_v)_v \in T(A_k)^{\text{Br}_1(T)}$. Since $T$ is a torsor over $X$ under the torus $Q$, all fibers are geometrically integral, hence we have

$$p^*(B \cap \text{Br}(X)) = p_T^*(B) \cap \text{Br}(T),$$

where $p_T$ is the restriction of $p$ on $V$. Therefore $(y_v)_v$ is orthogonal to $p_T^*(B) \cap \text{Br}(T)$ by the functority of Brauer–Manin pairing, hence

$$(y_v)_v \in T(A_k)^{p_T^*(B) \cap \text{Br}(T) + \text{Br}_1(T)}, \quad (2.3)$$

Let $\Psi = \{m_1, \ldots, m_n\}$, $\Psi' = U_0 \setminus U_0' = \{m_{n+1}, \ldots, m_N\}$, and then $\mathbb{P}_k^1 \setminus U_0' = \{m_1, \ldots, m_N\}$. For $i \in \{1, \ldots, n\}$, let $D_i$ just be the divisor over $m_i$ in our assumption. For $i = n + 1, \ldots, N$, let $P_i(t)$ be the irreducible polynomial which vanishes at $m_i$, we may choose $D_i$ to be a geometrically integral divisor of multiplicity 1 over $k_i$ since the fiber of $f$ is split at $m_i$. For $i \in \{1, \ldots, n\}$ choose a finite abelian extension $E_i/k(D_i)$ such that the residue of any element of $B$ at the generic point of $D_i$, belongs to the kernel of the restriction map $H^1(k(D_i), \mathbb{Q}/\mathbb{Z}) \to H^1(E_i, \mathbb{Q}/\mathbb{Z})$. Let $K_i$ be the algebraic closure of $L_i$ in $E_i$, hence $K_i/L_i$ is a finite abelian extension. For $i \in \{n+1, \ldots, N\}$, since $f$ is split at $m_i$, we have $L_i = k_i$, hence $K_i/k_i$ is a finite abelian extension.

The subvariety $W_0 := g^{-1}(V_0)$ of $W$ satisfies the equations (1.1). Recall $\mathcal{T}_V$ to be the restriction of $\mathcal{T}$ on $V$. Then $p'$ maps $\mathcal{T}_V$ onto $W_0$. Let

$$B' = \{\text{Cor}_{L_i/k}(\chi, z_i) : 1 \leq i \leq n, \chi \in H^1(K_i/L_i, \mathbb{Q}/\mathbb{Z})\},$$

obviously $B' \subset \text{Br}_1(W_0)$. Write $A_k^1 = \text{Spec } k[t] := \mathbb{P}_k^1 \setminus \{\infty\}$. Let

$$B'' = \{\text{Cor}_{K_i/k}(\chi, t - a_i) : n + 1 \leq i \leq N, \chi \in H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})\},$$

obviously $B'' \subset \text{Br}_1(U_0')$.
Since $B$, $B'$ and $B''$ are finite groups, $p^*_v(B)$ is a finite subgroup of $\Br(\mathcal{T}_V)$, $p^*_{V_0}(B')$ and $p^*(f^*(B''))$ are finite subsets of $\Br_1(\mathcal{T}_V)$. Let $A$ be the finite subgroups of $\Br(\mathcal{T}_V)$ generated by $p^*_v(B)$, $p^*_{V_0}(B')$ and $p^*(f^*(B''))$. Thus, according to [2,3], by Harari’s formal lemma (see [CT03, Theorem 1.4], [Har94]), there exists $(y'_v)_{v} \in \mathcal{T}_V(\mathbb{A}_k)$ orthogonal to $A$ and arbitrarily close to $(y_v)_{v}$ in $\mathcal{T}(\mathbb{A}_k)$, hence $(p(y'_v))_v$ arbitrarily close to $(x_v)_v$ in $X(\mathbb{A}_k)$. Furthermore, by the implicit function theorem, we may assume $p(y'_v)$ belongs to a smooth fiber of $f$ over $V_0$ for each $v$.

Let $S$ be a finite set of places of $k$ containing the infinite places of $k$, the places at which we want to approximate $(x_v)_v$ and the finite places above which, for $i \in \{1, \ldots, n\}$, either $a_i$ or $b_i$ is not a unit or $K_i/k_i$ is ramified, for $i \in \{n + 1, \ldots, N\}$, $a_i$ is not a unit. We choose $S$ large enough that the order of $A$ is invertible in $\mathcal{O}_S$, that $\beta(y'_v) = 0$ for all $v \notin S$ and for all $\beta \in A$, that $\mathcal{T}$, $X$ and $W$ extends to smooth schemes $\mathcal{T}$, $X$ and $W$ over $\mathcal{O}_S$, and $f : X \to \mathbb{P}^1_k$, $p : \mathcal{T} \to X$ and $g : W \to \mathbb{P}^1_{\mathcal{O}_S}$ extends to flat morphisms $f : X \to \mathbb{P}^1_{\mathcal{O}_S}$, $p : \mathcal{T} \to X$ and $g : W \to \mathbb{P}^1_{\mathcal{O}_S}$. Let $\mathcal{W}_0$, $\mathcal{U}_0$ and $\mathcal{U}'_0$ be the open subscheme of $W$ and $\mathbb{P}^1_{\mathcal{O}_S}$ which extends $W_0$, $U_0$ and $U'_0$, respectively.

For $m \in \mathbb{P}^1_{\mathcal{O}_S}$, let $\tilde{m}$ denote the Zariski closure of $m$ in $\mathbb{P}^1_{\mathcal{O}_S}$. Then $\{\tilde{m}_1, \ldots, \tilde{m}_N\} = \mathbb{P}^1_{\mathcal{O}_S} \setminus \mathcal{U}'_0$. For each $i \in \{1, \ldots, N\}$, let $\mathcal{D}_i$ denote the Zariski closures of $D_i$ in $\mathcal{X}$, endowed with the reduced scheme structure, let $\mathcal{D}^0_i \subseteq \mathcal{D}_i$ be a dense open subset and let $\mathcal{E}_i$ denote the normalization of $\mathcal{D}^0_i$ in the finite extension $E_i/k(D_i)$. By shrinking $\mathcal{D}^0_i$, we may assume that $\mathcal{E}_i$ is finite and étale over $\mathcal{D}^0_i$ and that $\mathcal{D}^0_i$ is smooth over $\mathcal{O}_S$. Finally, for $i \in \{1, \ldots, N\}$, let $G_i = \text{Gal}(E_i/k(D_i))$ and $H_i = \text{Gal}(E_i/k(D_i)K_i) \subseteq G_i$.

After enlarging $S$, we may assume that $B \subset \text{Br}(f^{-1}(\mathcal{U}'_0))$, that $B' \subset \text{Br}(\mathcal{W}_0)$, that $B'' \subset \text{Br}(\mathcal{U}'_0)$, that the Zariski closure $\overline{\Psi}$ and $\overline{\Psi}'$ of $\Psi$ and $\Psi'$ in $\mathbb{P}^1_{\mathcal{O}_S}$ are étale over $\mathcal{O}_S$ and, by the Lang–Weil–Nisnevich bounds [LW54] [Nis54] and by a geometric version of Chebotarev’s density theorem [Eke90, Lemma 1.2], that the following statements hold:

- the fiber of $f$ above any closed point of $\mathcal{U}'_0$ contains a smooth rational point;
- for any $i \in \{1, \ldots, N\}$, if $L_i$ possesses a place of degree 1 over $w$ then the closed fibers of $\mathcal{D}^0_i \to \tilde{m}_i$ contain rational points;
- for any $i \in \{1, \ldots, N\}$ and any place $w$ of $k_i$ which splits completely in $L_i$ and which does not lie above a place of $S$, any element of $H_i$ can be realized as the Frobenius automorphism of the irreducible abelian étale cover $\mathcal{E}_i \to \mathcal{D}^0_i$ at some rational point of the fiber of $\mathcal{D}^0_i \to \tilde{m}_i$ above the closed point corresponding to $w$.

Using Chebotarev’s density theorem, we fix pairwise distinct places $v_1, \ldots, v_N$ in $\Omega \setminus S$ such that $v_i$ splits completely in $K_i$ for each $i$. For each $i \in \{1, \ldots, N\}$, we also fix a place $w_i$ of $k_i$ lying over $v_i$ and an element $t_{v_i} \in k_{w_i}$ such that $w_i(t_{v_i} - a_i) = 1$.

Let $S' = S \cup \{v_1, \ldots, v_N\}$. Let $F'$ be a finite field containing $F$ and all $K_i$ and large enough such that the rational $\overline{\mathbb{F}}$-section is defined over $F'$. By our assumption, $W$ satisfies strong approximation off $\Omega_{F'/k} \setminus S'$. Therefore, there exists a point $c' = (\lambda_0, \mu_0, z_0) \in W(k)$ such that $c'$ is very close to $p'(y'_v) \in W_0(\mathbb{A}_k)$ for $v \in S'$ and $c' \in W(\mathcal{O}_v)$ for $v \notin (\Omega_{F'/k} \setminus S')$, in
For each $v \in S$, we may choose $x'_v \in X_c(k_v)$ arbitrarily close to $x_v$. Let us now construct $x'_v$ for $v \notin S$.

Suppose $v \notin S' \cup \Omega_{F'/k}$ and $g(c) \cap \mathbb{P}^1_{k(v)} \in \tilde{m}_i$ for $i \in \{1, \ldots, N\}$, it is clear that $L_i$ contains a place of degree 1 above $v$ by [HW16, Corollary 9.10].

For $v \notin S$, let $w \in \mathbb{P}^1_{\mathcal{O}_S}$ denote the closed point $w = g(\tilde{c}) \cap \mathbb{P}^1_{k(v)}$. For $i \in \{1, \ldots, N\}$, we define $\Omega_i$ to be the set of places $v \in \Omega \setminus S$ such that $w \in \tilde{m}_i$. The sets $\Omega_i$ are finite and pairwise disjoint. When $v \in \Omega_i$, we may view $w$ as a place of $k_i$ dividing $v$: we then have $w(t_v - a_i) > 0$. We may assume that $w_i(t_v - a_i) = 1$, and hence that $v_i \in \Omega_i$, by choosing $t_v$ close enough to $t_v$.

For each $v \in \Omega \setminus S$ which does not belong to any $\Omega_i$, we use Hensel's lemma to lift an arbitrary smooth rational point of $f^{-1}(w)$ to a $k_v$-point $x'_v$ of $X_c$.

For each $v \in \Omega_{F'/k} \setminus S'$, we can choose a rational point $x'_v$ of $X_c$ by the rational $\mathbb{k}$-section (in fact, $F'$-section). For each $i \in \{1, \ldots, N\}$ and each $v \in \Omega_i \setminus \{v_i\}$ and $v \notin \Omega_{F'/k}$, we fix an arbitrary rational point $\xi_{v,i}$ of the fiber of $D_i^0 \to \tilde{m}_i$ above $w$ and again lift it to a $k_v$-point $x'_v$ of $X_c$ since $L_i/k$ contains a place of degree 1 above $v$ by an easy argument similar as in [HW16, Corollary 9.10].

We have now defined $x'_v$ for all $v \in \Omega \setminus \{v_1, \ldots, v_N\}$. Let us finally construct $x'_v$ at the remaining places. For $i \in \{1, \ldots, N\}$ and $v \in \Omega_i$, let $n_{w,i} = \text{ord}_w(t_v - a_i)$.

Let $\sigma_i = \sum_{v \in \Omega \setminus \{v_i\}} n_{w,i} \text{Fr}_{\xi_{w,i}} \in G_i$, where $\text{Fr}_{\xi_{w,i}}$ denotes the Frobenius automorphism of the irreducible abelian étale cover $\mathcal{E}_i \to D_i^{0}$ at $\xi_{w,i}$.

**Lemma 2.4.** For each $i \in \{1, \ldots, N\}$, we have $\sigma_i \in H_i$.

**Proof.** Suppose $i \in \{1, \ldots, n\}$. For any $\gamma = \text{Cor}_{L_i/k}(\chi, z_i) \in B'$, as $c$ is arbitrarily close to $p'(y'_v)$ for $v \in S$, as $\sum_{v \in \Omega} \text{inv}_v \gamma(p'(y'_v)) = 0$ and as $\gamma(p'(y'_v)) = 0$ for $v \in \Omega \setminus S$, we have $\sum_{v \in \Omega} \text{inv}_v \gamma(c') = 0$. Furthermore, we have $\text{inv}_v \gamma(c) = 0$ for $v \notin S \cup \Omega_i$. If $v = v_i$ or $v \in (\Omega_{F'/k} \setminus S')$, by our choice, we have $K_i/k_i$ is totally split, hence

$$\text{inv}_v \gamma(c) = 0$$

where $\text{Fr}_w \in \text{Gal}(K_i/L_i)$ denotes the Frobenius at $w$.

By the global reciprocity law, we deduce that

$$\sum_{v \in \Omega_i \setminus (\Omega_{F'/k} \cup \{v_i\})} \text{inv}_v \gamma(c) = 0.$$
since $\gamma \in \text{Br}(\mathcal{W}_0)$, where $\text{Fr}_w \in \text{Gal}(K_i/L_i)$ denotes the Frobenius at $w$. Therefore

$$\chi(\sigma_i) = \sum_{v \in \Omega_i \setminus (\Omega_{F'/k} \cup \{v_0\})} n_{w,i} \chi(\text{Fr}_w) = \sum_{v \in \Omega_i \setminus (\Omega_{F'/k} \cup \{v_0\})} \text{inv}_v \gamma(c) = 0.$$ 

Note that $\chi$ can run through $H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})$, we have $\sigma_i \in H_i$.

Suppose $i \in \{n+1, \ldots, N\}$. For arbitrary character $\chi \in H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})$. Let $\gamma = \text{Cor}_{k_i/k}(\chi, t - a_i)$, then $\gamma \in B^\sigma$. As $(\lambda_0, \mu_0, \mathbf{z}_0)$ is arbitrarily close to $p(y_i')$ for $v \in S$, as $\sum_{v \in \Omega} \text{inv}_v \gamma(p(y_i')) = 0$ and as $\gamma(p(y_i')) = 0$ for $v \in \Omega \setminus S$, we have $\sum_{v \in S} \text{inv}_v \gamma(t_0) = 0$. Furthermore, we have $\text{inv}_v \gamma(t_0) = 0$ for $v \not\in S \cup \Omega_i$. If $v = v_j$ or $v \in (\Omega_{F'/k} \setminus S')$, by our choice, we have $K_i/k_i$ is totally split, hence $\text{inv}_v \gamma(t_0) = 0$ and $\chi(\text{Fr}_w) = 0$. For $v \in \Omega_i \setminus \Omega_{F'/k}$, we have

$$\text{inv}_v \gamma(t_0) = n_{w,i} \chi(\text{Fr}_w),$$

where $\text{Fr}_w \in \text{Gal}(K_i/k_i)$ denotes the Frobenius at $w$, since $\gamma \in \text{Br}(\mathcal{U}_0')$. By the global reciprocity law, we deduce that

$$\chi(\sigma_i) = \sum_{v \in \Omega_i \setminus (\Omega_{F'/k} \cup \{v_0\})} n_{w,i} \chi(\text{Fr}_w) = \sum_{v \in \Omega_i \setminus (\Omega_{F'/k} \cup \{v_0\})} \text{inv}_v \gamma(c) = 0.$$ 

Note that $\chi$ can run through $H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})$, we have $\sigma_i \in H_i$.  

By Lemma 2.4 and our hypotheses on $S$, we can choose, for each $i \in \{1, \ldots, N\}$, a rational point $\xi_{w,i}$ of the fiber of $T_i^0 \to \tilde{m}_i$ above $w_i$ such that $\text{Fr}_{\xi_{w,i}} = -\sigma_i$ and hence

$$\sum_{v \in \Omega_i} n_{w,i} \text{Fr}_{\xi_{w,i}} = 0 \quad (2.4)$$

in $G_i$. We then lift $\xi_{w,i}$ to a $k_{v_i}$-point $x_{v_i}$ of $X_{K_i}$.

We have thus constructed an adelic point $(x_v')_{v \in \Omega} \in X_v(A_k)$ arbitrarily close to $(x_v)_{v \in \Omega}$ in $X(A_k)$. It remains to check that $(x_v')_{v \in \Omega}$ is orthogonal to $B$ with respect to the Brauer–Manin pairing. By the orthogonality of $(p(y_i'))_v$ to $B$ and by the definition of $S$, we have $\sum_{v \in S} \text{inv}_v \beta(p(y_i')) = 0$ for all $\beta \in B$. On the other hand, as $x_v'$ is arbitrarily close to $p(y_i')$ for $v \in S$, we have $\beta(x_v') = \beta(p(y_i'))$ for all $v \in S$ and all $\beta \in B$, so that $\sum_{v \in S} \text{inv}_v \beta(x_v') = 0$ for all $\beta \in B$. For $v \in \Omega \setminus (S \cup \Omega_1 \cup \cdots \cup \Omega_N)$ we have $\beta(x_v') = 0$ for all $\beta \in B$ since $B \subseteq \text{Br}(f^{-1}(\mathcal{U}_0'))$. Thus

$$\sum_{v \in \Omega} \text{inv}_v \beta(x_v') = \sum_{i=1}^N \sum_{v \in \Omega_i} \text{inv}_v \beta(x_v')$$

for all $\beta \in B$. Now, as $\beta \in \text{Br}(f^{-1}(\mathcal{U}_0'))$, we have

$$\text{inv}_v \beta(x_v') = n_{w,i} \partial_{\beta,D_i}(\text{Fr}_{\xi_{w,i}})$$

for any $\beta \in B$, any $i \in \{1, \ldots, N\}$ and any $v \in \Omega_i$, if $\partial_{\beta,D_i} \in \text{Hom}(G_i, \mathbb{Q}/\mathbb{Z}) \subset H^1(k(D_i), \mathbb{Q}/\mathbb{Z})$ denotes the residue of $\beta$ at the generic point of $D_i$ (see [Har94 Corollaire 2.4.3]). In view of (2.4), we conclude that $\sum_{v \in \Omega} \text{inv}_v \beta(x_v') = 0$ for all $\beta \in B$.  

\qed
Theorem 2.5. Let $X$ be a smooth, proper, geometrically integral variety over a number field $k$ and let $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rationally connected geometric generic fiber. Let $F_1(t)$ and $L_i$ be as in Theorem 1.2. Assume that:

1. strong approximation off $\Omega_{F/k} \setminus T$ holds for any $W$ associated to $(P_1(t), L_1), \cdots, (P_n(t), L_n)$, where $T$ runs through all finite subsets of $\Omega_{F/k}$ and $F$ is a finite extension of $k$ depending on $X$;

2. there exists a Hilbert subset $H \subset \mathbb{P}^1_k$ such that $X_c(k)$ is dense in $X_c(\mathbb{A}_k)^{Br(X)}$ for every rational point $c$ of $H$.

Then $X(k)$ is dense in $X(\mathbb{A}_k)^{Br(X)}$.

Proof. Let $U_0$ be as in Theorem 1.2. After shrinking $U_0$, we may assume that there exists a finite subgroup $B \subset Br(f^{-1}(U_0))$ such that $B + f^*_n Br(\eta) = Br(X_\eta)$. Indeed, $Br(X_\eta)/f^*_n Br(\eta)$ is finite and $f$ has a $\mathfrak{T}$-section since the generic fiber of $f$ is rationally connected (see [HW16, Lemma 8.6] and [GHS03, Theorem 1.1]). By [HW16, Proposition 4.1], there exists a Hilbert subset $H' \subset U$ such that the natural map $B \to Br(X_\eta)/f^*_c Br(k)$ is surjective for all $c \in H'$.

By Proposition 2.1, we have

$$\bigcup_{c \in U_0(k)} X_c(\mathbb{A}_k)^B$$

is dense in $X(\mathbb{A}_k)^{Br(X)}$; \hspace{1cm} (2.5)

as in [Sk09], the same proof shows that $c$ can be required in rational points in $U_0 \cap H \cap H'$ in (2.5) (this uses Ekedahl’s version of Hilbert’s irreducibility theorem [Eke90]). In view of (2), we may approximate in the fiber $X_c$ to conclude the proof. \hfill \Box

Corollary 2.6. Let $X$ be a smooth, proper, geometrically integral variety over a number field $k$ and $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rationally connected geometric generic fiber. Assume that $\text{rank}(f) \leq 2$. If $X_c(k)$ is dense in $X_c(\mathbb{A}_k)^{Br(X)}$ for every rational point $c$ of a Hilbert subset of $\mathbb{P}^1_k$, then $X(k)$ is dense in $X(\mathbb{A}_k)^{Br(X)}$.

Proof. Corollary 2.6 is due to Harari [Har94, Har97] when $\text{rank}(f) \leq 1$. If $\text{rank}(f) = 2$, the variety $W$ (see Conjecture 1.1) is isomorphic to the complement of an affine space by a close subset of codimension 2, by [CXT14, Wei16]. $W$ satisfies strong approximation off a place $v_0$, the proof follows from Theorem 2.5. \hfill \Box

Remark 2.7. Fibrations over $\mathbb{P}^1_k$ with rank 2 had been dealt with (using the descent method) in [CTS00, Theorem A] under the assumption that the fibers above a Hilbert set of rational points satisfy weak approximation. It had also been dealt with in [HW16, Theorem 9.31] when $k$ is totally imaginary or the non-split fibers of $f$ lie over rational points of $\mathbb{P}^1_k$.

Lemma 2.8. Let $Y_n$ is the punctured affine cone over a smooth projective quadric of dimension $n \geq 1$, let $Z$ be a smooth open subvariety of $Y_n$ and $Y_n \setminus Z$ has codimension $\geq 2$ in $Y_n$. Then $Z$ satisfies strong approximation with algebraic Brauer–Manin obstruction off $v_0$, where $v_0$ can run through almost all finite places of $k$. Furthermore,
Proof. We may assume $Y_n \subset \mathbb{A}^{n+2}_k$ defined by the equation
\[
a_1x_1^2 + \cdots + a_{n+2}x_{n+2}^2 = 0
\]
with all $a_i \neq 0$. By an easy computation, we have $\bar{k}[Z]^x = \bar{k}^x$ and
\[
\text{Pic}(\mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}/2\mathbb{Z} & \text{if } n = 1; \\
\mathbb{Z} & \text{if } n = 2; \\
0 & \text{if } n \geq 3.
\end{cases}
\]

Then, by Hochschild-Serre’s spectral sequence, one obtains
\[
\text{Br}(\mathbb{Z})/\text{Br}(\mathbb{Z}) = \begin{cases} 
\infty & \text{if } n = 1; \\
\text{finite} & \text{if } n = 2; \\
0 & \text{if } n \geq 3.
\end{cases}
\]

We always assume $Z(A_k)^{\text{Br}(\mathbb{Z})} \neq \emptyset$. Suppose $n = 1$ or $2$, then $Y_n \setminus \{(0, \cdots, 0)\}$ is a smooth toric variety, hence $Z$ satisfies strong approximation with algebraic Brauer–Manin obstruction off any places $v_0$ by [Wei14b, Theorem 1.1].

Now we suppose $n \geq 3$. We argue by induction on $n$. Let $Z'$ be the complement of the closed subsets $\{x_{n+1} = x_{n+2} = 0\}$ and $\{x_1 = \cdots = x_n = 0\}$ in $Z$. Obviously $Y \setminus Z'$ also has codimension $\geq 2$ in $Y$. We only need to prove $Z'$ satisfies strong approximation off $v_0$ since $Z \setminus Z'$ has codimension $2$. Define a morphism $f : Z' \to \mathbb{P}^1_k(x_1, \cdots, x_{n+2}) \to [x_{n+1} : x_{n+2}]$. It is clear that any geometrical fiber of $f$ is geometric integral, and that there exists a dense open subset $U_0$ of $\mathbb{P}^1_k$ at which any fiber is the complement of a codimension at least 2 closed subset in some $Y_{n-1}$. Let $v_0$ be a place such that $a_1x_1^2 + a_2x_2^2 + a_3x_3^2 = 0$ has a nontrivial resolution at $v_0$. Obviously $v_0$ can run through almost all finite places of $k$. If any fiber over a rational point of $U_0$ satisfies strong approximation with algebraic Brauer–Manin obstruction off $v_0$, by [2.7] and an easy argument similar as in Proposition [2.1] or as in [Har94, CTH16], $Z'$ satisfies strong approximation off $v_0$. □

Corollary 2.9. Let $X$ be a smooth, proper, geometrically integral variety over a number field $k$ and $f : X \to \mathbb{P}^1_k$ be a dominant morphism with rationally connected geometric generic fiber. Assume that $\text{rank}(f) \leq 3$. Suppose every non-split fiber $X_m$ contains a multiplicity one component $D_m$ such that the algebraic closure of $k(m)$ in the function field $k(D_m)$ is a quadratic field of $k(m)$.

If $X_c(k)$ is dense in $X_c(A_k)^{\text{Br}(X)}$ for every rational point $c$ of a Hilbert subset of $\mathbb{P}^1_k$, then $X(k)$ is dense in $X(A_k)^{\text{Br}(X)}$.

Proof. If $\text{rank}(f) \leq 2$, it follows from Corollary [2.6]. Suppose $\text{rank}(f) = 3$, the variety $W$ (see Conjecture [1.1]) is the punctured affine cone over the complement of a closed subset of codimension 2 in a smooth projective...
quadric of dimension 4, the proof follows from Theorem 2.5 and Lemma 2.8.

Remark 2.10. Corollary 2.3 had been dealt with (using the descent method) in [CTS00, Theorem B] under the assumption that the fibers above a Hilbert set of rational points satisfy weak approximation.

3. SCHINZEL’S HYPOTHESIS AND AN UNCONDITIONAL RESULT

Many results on rational points are based on Schinzel’s hypothesis (H) (see CTSS98, [Wit07] and [Wei14a]). We refer to [SD11, Lemma 7.1] for a proof that Schinzel’s hypothesis (H) implies the following Hypothesis (HH").

**Hypothesis (HH”).** Let \( k \) be a number field, \( n \geq 1 \) be an integer and \( P_1, \ldots, P_n \in k[\lambda, \mu] \) be irreducible homogeneous polynomials. Let \( S \) be a finite set of places of \( k \) containing the archimedean places, large enough that for any \( v \notin S \), there exists \( (\lambda_v, \mu_v) \in \mathcal{O}_v \times \mathcal{O}_v \) such that \( v(P_1(\lambda_v, \mu_v)) = \cdots = v(P_n(\lambda_v, \mu_v)) = 0 \). Suppose given \( (\lambda_v, \mu_v) \in k_v \times k_v \) with \( (\lambda_v, \mu_v) \neq (0, 0) \) for \( v \in S \). There exists \( (\lambda_0, \mu_0) \in k \times k \) such that

1. \( [\lambda_0 : \mu_0] \) is arbitrarily close to \( [\lambda_v : \mu_v] \) in \( \mathbb{P}^1(k_v) \) for each place \( v \in S \);
2. \( \lambda_0 \) and \( \mu_0 \) are integral outside \( S \);
3. for each \( i \in \{1, \ldots, n\} \), the element \( P_i(\lambda_0, \mu_0) \in k \) is a unit outside \( S \) except at one place, at which it is a uniformizer.

**Remark 3.1.** From the work of Heath-Brown and Moroz [HBM04, Theorem 2] on primes represented by binary cubic forms, it is easy to deduce the validity of (HH") when \( k = \mathbb{Q} \), \( n = 1 \) and \( \deg(P_i) = 3 \), see [HW16, Remark 9.7].

Let \( X \) be a smooth and geometrically integral variety over a number field \( k \) and let \( f : X \to \mathbb{P}^1_k \) be a dominant morphism. Let \( \text{Br}^\text{vert}(X) := f^*(\text{Br}(k(\eta))) \cap \text{Br}_1(X) \) be the vertical Brauer group of \( X \), where \( \eta \) is the generic point of \( \mathbb{P}^1_k \).

**Proposition 3.2.** Let \( X \) be a smooth and geometrically integral variety over \( k \) and let \( f : X \to \mathbb{P}^1_k \) be a dominant morphism with smooth geometrically integral generic fiber. Assume that every fiber of \( f \) contains an irreducible component of multiplicity 1. Let \( U_0, \Psi, P_i(t), D_i, k(D_i), \delta_i \) and \( L_i \) be as in Theorem 7.2. Let \( U_0' \subset U_0 \) be an open subset, and \( \infty \in U_0 \), and let \( \text{Br}^\text{vert}(f^{-1}(U_0')) \) be a finite set.

Assume that

1. For each \( i \in \{1, \ldots, n\} \), \( L_i \) is cyclic over \( k_i \).
2. Hypothesis (HH") holds for \( P_1(t), \ldots, P_n(t) \).

Then

\[
\bigcup_{c \in U_0'(k)} X_c(A_k)^B \text{ is dense in } X(A_k)^{\text{Br}(X) + \text{Br}^\text{vert}(X)}
\]

where \( X_c \) is the fiber of \( f \) over \( c \in U_0'(k) \).

**Proof.** For any \( (x_v)_v \in X(A_k)^{\text{Br}(X) + \text{Br}^\text{vert}(X)} \), since \( X \) is smooth and geometrically integral over \( k \), any \( v\)-adic neighborhood of \( x_v \in X(k_v) \) is
Zariski dense on $X$, by implicit function theorem, hence we may assume that $x_v \in V(k_v)$ is a smooth point by shrinking $x_v$, where $V = f^{-1}(U'_0)$.

Let $\Psi = \{m_1, \cdots, m_n\} = \mathbb{P}^1 \setminus U_0$ and $\Psi' = U_0 \setminus U'_0 := \{m_{n+1}, \cdots, m_N\}$. Then $\mathbb{P}^1_k \setminus U'_0 = \{m_1, \cdots, m_N\}$. For $i \in \{1, \cdots, n\}$, let $D_i$ just be the divisor in our assumption. For $i = n + 1, \cdots, N$, let $P_i(t)$ be the irreducible polynomial which vanishes at $m_i$, we may choose $D_i$ to be a geometrically integral divisor of multiplicity 1 over $k_i$ since the fiber of $f$ is split at $m_i$.

For $i \in \{1, \cdots, N\}$, choose a finite abelian extension $E_i/k(D_i)$ such that the residue of any element of $B$ at the generic point of $D_i$ belongs to the kernel of the restriction map $H^1(k(D_i), \mathbb{Q}/\mathbb{Z}) \to H^1(E_i, \mathbb{Q}/\mathbb{Z})$. Let $K_i$ be the algebraic closure of $k(D_i)$ in $E_i$, hence $K_i/L_i$ is a finite abelian extension. For $i \in \{1, \cdots, n\}$, we can furthermore assume that $K_i/k$ is Galois. For $i \in \{n+1, \cdots, N\}$, since $f$ is split at $m_i$, we have $L_i = k_i$, hence $K_i/k_i$ is a finite abelian extension. Finally, for $i \in \{1, \cdots, N\}$, let $G_i = \text{Gal}(E_i/k(D_i))$ and $H_i = \text{Gal}(E_i/k(D_i))$ and $H_i = \text{Gal}(E_i/k(D_i))$.

Let $S$ be a finite set of places of $k$ containing the infinite places of $k$, the places at which we want to approximate $(x_v)_v$. We can enlarge $S$ large enough that we can apply Hypothesis (HH1) for $P_1(t), \cdots, P_n(t)$ and that the following conditions hold:

(a) The morphism $f : X \to \mathbb{P}^1_k$, the open immersions $U_0 \to \mathbb{A}^1_k$, $U'_0 \to \mathbb{A}^1_k$ and $f^{-1}(U'_0) \to X$ are extended to morphisms of their corresponding integral models $X, \mathbb{P}^1 \setminus U_0$ and $U'_0$ over $\mathcal{O}_S$.

(b) The morphism $D_i \to m_i$ is extended to their integral models $\mathcal{D}_i \to \tilde{m}_i$ over $\mathcal{O}_S$ such that

$$\tilde{m} = \text{Spec}(\mathcal{O}_S[t]/(P_1(t)))$$

is smooth over $\mathcal{O}_S$ for $1 \leq i \leq N$. Moreover,

$$\mathbb{P}^1_{\mathcal{O}_S} \setminus U'_0 = \{\tilde{m}_1, \cdots, \tilde{m}_N\}$$

(c) For each $i \in \{1, \cdots, N\}$, let $\mathcal{D}^0_i \subseteq \mathcal{D}_i$ be a dense open subset and let $\mathcal{E}_i$ denote the normalization of $\mathcal{D}^0_i$ in the finite extension $E_i/k(D_i)$. By shrinking $\mathcal{D}^0_i$, we may assume that $\mathcal{E}_i$ is finite and étale over $\mathcal{D}^0_i$ and that $\mathcal{D}^0_i$ is smooth over $\mathcal{O}_S$.

After enlarging $S$, we may assume, by the Lang–Weil–Nisnevich bounds [LW54, Nis54] and by a geometric version of Chebotarev’s density theorem [Eke90, Lemma 1.2], that the following statements hold:

- the fiber of $f$ above any closed point of $U'_0$ contains a smooth rational point;
- for any $i \in \{1, \cdots, N\}$, if $L_i$ possesses a place of degree 1 over $w$ then the closed fibers of $\mathcal{D}^0_i \to \tilde{m}_i$ contain rational points;
- for any $i \in \{1, \cdots, N\}$ and any place $w$ of $k_i$ which splits completely in $L_i$ and which does not lie above a place of $S$, any element of $H_i$ can be realized as the Frobenius automorphism of the irreducible abelian étale cover $\mathcal{E}_i \to \mathcal{D}^0_i$ at some rational point of the fiber of $\mathcal{D}^0_i \to \tilde{m}_i$ above the closed point corresponding to $w$.

For $i \in \{1, \cdots, n\}$, by the Chebotarev density theorem, there is a finite set $T_i$ of places in $L_i$ of degree 1 over $k$ such that

1. for each $\sigma \in \text{Gal}(K_i/L_i)$, there are exactly one element $q \in T_i$ with sufficiently large cardinalities of the residue fields and $\text{Frob}(q) = \sigma$;
(2) the set $S_i = \{q \cap k : q \in T_i\}$ has $|\text{Gal}(M_i/L_i)|$ elements with $S \cap S_i = \emptyset$ and $S_i \cap S_j = \emptyset$ for $i \neq j$.

For each $v \in S_i$ with $i \in \{1, \cdots, n\}$, we also fix a place $w$ of $k_i$ lying over $v$ and an element $t_v \in k_v$ such that $\text{ord}_w(t_v - \alpha_i) = 1$.

For $i \in \{1, \cdots, n\}$, let $v \in S_i$. Since all primes in $T_i$ are of degree 1 over $k$, one concludes that $(L_i)_q = k_v$ for each $q \in T_i$ with $v = q \cap k \in S_i$. Moreover, the scheme $D_i \times_{\mathcal{O}_v} \mathcal{O}_v$ splits into geometrically irreducible components $\{\sigma D_{i,v} : \sigma \in \text{Gal}(L_i/k_i)\}$ over $\mathcal{O}_v$ by (b) and (c), where $D_{i,v}$ is a fixed geometrically irreducible component of $D_i \times_{\mathcal{O}_v} \mathcal{O}_v$ for $v \in S_i$ with $1 \leq i \leq n$. Since the polynomial $P_i(t)$ has a root over $\mathcal{O}_v$ for each $v \in S_i$ by (b) and (c), one obtains $t_v \in \mathcal{O}_v'(\mathcal{O}_v)$ with $\text{ord}_v(P_i(t_v)) = 1$ such that there is $x''_v \in X_{t_v}(\mathcal{O}_v)$ satisfying

$$x''_v \mod v \in D_i^0(\kappa(v)).$$

We replace $x_v$ by $x''_v$ for each $v \in S_i, 1 \leq i \leq n$.

Let $\alpha_i$ be the image of $t$ in $k[t]/(P_i(t)) = k_i$. Let

$$B' = \{\text{Cor}_{k_i/k}(t - \alpha_i, \chi) : 1 \leq i \leq n, \chi \in H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})\},$$

$$B'' = \{\text{Cor}_{k_i/k}(t - \alpha_i, \chi) : n + 1 \leq i \leq N, \chi \in H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})\}.$$

Obviously $(B' \cup B'') \subset \text{Br}_{\text{vert}}(f^{-1}(U'_0))$. Let $A$ be the finite subgroups of $\text{Br}(X)$ generated by $B, B'$ and $B''$.

After enlarging $S$, we may assume that $S \supset \bigcup_{i=1}^n S_i$. Thus, according to \cite{2.3}, by Harari's formal lemma (see \cite{CT03} Theorem 1.4, \cite{Har94}), there exists $(x''_v)_v \in f^{-1}(U'_0)(\mathbb{A}_k)$ orthogonal to $A$ and arbitrarily close to $(x_v)_v$ in $X(\mathbb{A}_k)$. Thus, each $x''_v$ belongs to a smooth fiber of $f$ for each $v$. We enlarge $S$ such that $A \subset \text{Br}(f^{-1}(U'_0))$ and that $\beta(x''_v) = 0$ for all $v \notin S$ and for all $\beta \in A$; hence

$$\sum_{v \in S} \beta(x''_v) = 0. \quad (3.1)$$

Similarly, using Chebotarev’s density theorem, we fix pairwise distinct places $v'_1, \cdots, v'_N$ which are not contained in $S$, such that $v'_i, v'_i$ splits completely in $K_i$ for each $i$. For each $i \in \{1, \cdots, N\}$, we also fix a place $v'_i$ of $k_i$ lying over $v'_i$ and an element $t_{v'_i} \in k_{v'_i}$ such that $\text{ord}_{v_i}(t_{v'_i} - \alpha_i) = 1$.

For $i \in \{1, 2, \cdots, n\}$, let $P_i(\lambda, \mu)$ be the corresponding homogeneous polynomial of $P_i(t)$. By Hypothesis (HH1), there is $(\lambda_0, \mu_0) \in \mathcal{O}_S^2$ such that $[\lambda_0 : \mu_0]$ is very close to $f(x_v) \in \mathbb{P}^1(k_v)$ for $v \in S$ and $\text{ord}_v(P_i(\lambda_0, \mu_0)) = 0$ for all $v \notin S$ except one prime $v_i$ of $k$ with

$$\text{ord}_{v_i}(P_i(\lambda_0, \mu_0)) = 1 \text{ for } 1 \leq i \leq n. \quad (3.2)$$

We may assume that $\mu_0 \neq 0$, then let $t_0 := \lambda_0/\mu_0$.

As at least one $x''_v$ belongs to a smooth fiber of $f$ above $U'_0$, we may assume that $X_{t_0}$ is smooth. By the inverse function theorem, for each $v \in S$, we can choose $x''_v \in X_{t_0}(k_v)$ arbitrarily close to $x''_v$.

Let us now construct $x'_v$ for $v \notin S$.

Write

$$P_i(t) = \prod_{j=1}^g Q_j(t)$$

on the Fibration Method for Rational Points 15
where $Q_j(t)$ are irreducible polynomials over $O_{v_i}$ for $1 \leq j \leq g$. Let $Q_j(\lambda, \mu)$ be the corresponding homogeneous polynomial of $Q_j(t)$. There are $g$ primes $w_1, \cdots, w_g$ of $k_t$ above $v_i$ corresponding to irreducible polynomials $Q_1(t), \cdots, Q_g(t)$ respectively. Since $\text{ord}_{v_i}(P(\lambda_0, \mu_0)) = 1$ by (3.2), there is $1 \leq j_0 \leq g$ such that

$$\text{ord}_{v_i}(Q_{j_0}(\lambda_0, \mu_0)) = 1 \quad \text{and} \quad \text{ord}_{v_i}(Q_j(\lambda_0, \mu_0)) = 0 \quad \text{for all} \; j \neq j_0. \quad (3.3)$$

If $\text{ord}_{v_i}(\mu_0) > 0$, then $\text{ord}_{v_i}(P(t_0)) \leq 0$, hence $[\lambda_0 : \mu_0] \notin \tilde{m}_i$. We can choose $x'_{v_i} \in X_{t_0}(k_{v_i})$.

We suppose $\text{ord}_{v_i}(\mu_0) = 0$, then $\text{ord}_{v_i}(Q_{j_0}(t_0)) = 1$, hence $Q_{j_0}(t)$ is of degree $1$ by (b) and Hensel’s lemma and $w_{j_0}$ is a place of degree $1$ over $v_i$.

For $\text{Cor}_{k_i/k}(\chi, t - a_i) \in B'$, we have

$$0 = \sum_{v \in \Omega_k} \text{Cor}_{k_i/k}(\chi, t_0 - a_i)_v = \sum_{v \in S} \text{Cor}_{k_i/k}(\chi, t_0 - a_i)_v + \sum_{v \in S} \text{Cor}_{k_i/k}(\chi, t_v - a_i)_v$$

by the reciprocity law, (b) and (c), one concludes that

$$\sum_{j=1}^{g}(\chi, t_v - a_i)_{w_j} = -\sum_{v \in S} \text{Cor}(\chi, t_v - a_i)_v = 0$$

by (3.1). By (3.3), one obtains that

$$(\chi, t_0 - a_i)_{w_{j_0}} = 0 \quad \text{for all} \; \chi \in H^1(L_i/k_i, \mathbb{Q}/\mathbb{Z}).$$

Since $L_i/k_i$ is abelian, one concludes that $w_{j_0}$ splits completely in $L_i/k_i$. There is

$$x'_{v_i} \in X_{t_0}(O_{v_i}) \quad \text{such that} \quad x'_{v_i} \mod v_i \in D^0_i(k(v_i)) \subset X_{t_0}^0(k(v_i))$$

by Hensel’s lemma and (a) and (c) for $1 \leq i \leq n$.

For $v \notin S$, Let $\tilde{t}_0$ be the closed closure of the rational point $[u_0 : v_0]$ in $\mathbb{P}^1_{\Omega_k}$, let $w \in \mathbb{P}^1_{\Omega_k}$ denote the closed point $w = \tilde{t}_0 \cap \mathbb{P}^1_{\Omega_k}(v)$. For $i \in \{1, \ldots, N\}$, we define $\Omega_i$ to be the set of places $v \in \Omega \setminus S$ such that $w \in \tilde{m}_i$. The sets $\Omega_i$ are finite and pairwise disjoint. Obviously $t_0 \in O_v$ for any $v \in \Omega_i$.

For each $v \in \Omega \setminus S$ which does not belong to any $\Omega_i$, we use Hensel’s lemma to lift an arbitrary smooth rational point of $f^{-1}(t_0)$ to a $k_v$-point $x_v'$ of $X_{t_0}$. For each $i \in \{1, \ldots, N\}$ and each $v \in \Omega_i \setminus \{v_i\}$, we fix an arbitrary rational point $\xi_{w, i}$ of the fiber of $D^0_i \to \tilde{m}_i$ above $w$ and again lift it to a $k_v$-point $x_v'$ of $X_{t_0}$.

When $v \in \Omega_i$, we may view $w$ as a place of $k_i$ dividing $v$; then we have $w(t_0 - a_i) > 0$. We may assume that $w_i(t_0 - a_i) = 1$, and hence that $v'_i \in \Omega_i$, by choosing $t_0$ close enough to $t_v'$.

For $i \in \{1, \ldots, N\}$ and $v \in \Omega_i$, and let $n_{w, i} = \text{ord}_{w}(t_0 - a_i)$, let $\text{Fr}_{\xi_{w, i}}$ to denote the Frobenius automorphism of the irreducible abelian étale cover $\varepsilon_i \to D^0_i$ at $\xi_{w, i}$.

**Lemma 3.3.** (1) For each $i \in \{1, \ldots, n\}$, we have $\Omega_i = \{v'_i\}$ or $\{v_i, v'_i\}$.

Then

(a) if $\Omega_i = \{v'_i\}$, let $\sigma_i = 1_{G_i}$;

(b) if $\Omega_i = \{v_i, v'_i\}$, there exists $p_i \in S_i$ and $z_{p_i} \in X_{t_0}^0(O_{p_i})$ such that $\sigma_i \in H_i$, where

$$\sigma_i = \text{Fr}_{\xi_{w, i}} \circ \text{Frob}(x'_{p_i})^{-1} \circ \text{Frob}(z_{p_i}) \in G_i. \quad (3.4)$$
(2) For each \(i \in \{n+1, \ldots, N\}\), let \(\sigma_i = \sum_{v \in \Omega \setminus \{v'\}} n_{w,i} \text{Fr}_w, i \in G_i\), we have \(\sigma_i \in H_i\).

**Proof.** Suppose \(i \in \{n+1, \ldots, N\}\). For arbitrary character \(\chi \in H^1(K_i/k_i, \mathbb{Q}/\mathbb{Z})\), let \(\gamma = \text{Cor}_{k_i/k}(\chi, t - a_i)\), then \(\gamma \in B''\). As \(t_0\) is arbitrarily close to \(f(x''_v)\) for \(v \in S\), as \(\sum_{v \in \Omega} \text{inv}_v \gamma(f(x''_v)) = 0\) and as \(\gamma(f(x''_v)) = 0\) for \(v \in \Omega \setminus S\), we have \(\sum_{v \in S} \text{inv}_v \gamma(t_0) = 0\). If \(v = v'_i\), by our choice, we have \(K_i/k_i\) is totally split, hence \(\text{inv}_{v'_i} \gamma(t_0) = 0\). Furthermore, we have \(\text{inv}_v \gamma(t_0) = 0\) for \(v \not\in S \cup \Omega_i\). For \(v \in \Omega_i\), by [Har94, Corollary 2.4.3], we have
\[
\text{inv}_v \gamma(t_0) = n_{w,i} \chi(\text{Fr}_w),
\]
where \(\text{Fr}_w \in \text{Gal}(K_i/k_i)\) denotes the Frobenius at \(w\), since \(\gamma \in \text{Br}(\mathbb{U})\). By the global reciprocity law, we deduce that
\[
\chi(\sigma_i) = \sum_{v \in \Omega \setminus \{v'\}} n_{w,i} \chi(\text{Fr}_w) = 0.
\]
Note that \(\chi\) can run through \(H^1(K_i/L_i, \mathbb{Q}/\mathbb{Z})\), we have \(\sigma_i \in H_i\).

Suppose \(i \in \{1, \ldots, n\}\). We have \(\Omega_i = \{v'_i\}\) or \(\{v_i, v'_i\}\). Suppose \(\Omega_i = \{v'_i\}\), (1) obviously holds.

Now we assume \(\Omega_i = \{v_i, v'_i\}\), hence \(t_0 \in \mathcal{O}_{v_i}\). By [Har94, Corollary 2.4.3] and the choice of \(x'_v\), we have
\[
\beta(x'_v) = \partial_{\beta, D}(\text{Fr}_{\xi_{v,i}})
\]
for all \(\beta \in (B + B')\). By global class field theory, we
\[
\sum_{v \in \Omega} \gamma(x''_v) = \sum_{v \in \Omega} \text{Cor}_{L_i/k}(\chi, t_0 - a_i)_v = 0
\]
for all \(\gamma = \text{Cor}_{L_i/k}(\chi, t - a_i) \in B'\). One obtains
\[
\gamma(x'_v) = -\sum_{v \in S} \gamma(x''_v) = 0,
\]

hence
\[
\chi(\text{Fr}_{\xi_{v,i}}) = 0 \quad \text{for all} \quad \chi \in H^1(M_i/k_i, \mathbb{Q}/\mathbb{Z}).
\]

For any \(\sigma \in G_i\), denote \(\overline{\sigma}\) to be its image in \(\text{Gal}(k(D_i)K_i/k(D_i)) \cong \text{Gal}(K_i/L_i)\).

This implies that \(\text{Fr}_{\xi_{v,i}} \in [\text{Gal}(K_i/k_i), \text{Gal}(K_i/k_i)],\) the commutator of \(\text{Gal}(K_i/k_i)\).

Write
\[
[\text{Gal}(L_i/k_i), \text{Gal}(K_i/L_i)] = \{ \prod_{\gamma \in \text{Gal}(L_i/k_i)} (\gamma \circ \sigma_\gamma) \cdot \sigma_\gamma^{-1} : \sigma_\gamma \in \text{Gal}(M_i/L_i) \}.
\]

Then
\[
[\text{Gal}(L_i/k_i), \text{Gal}(M_i/L_i)] \subseteq [\text{Gal}(M_i/k_i), \text{Gal}(M_i/k_i)] \subseteq [\text{Gal}(M_i/L_i)].
\]

Since \(\text{Gal}(L_i/k_i)\) is cyclic, one has
\[
H^2(L_i/k_i, \mathbb{Q}/\mathbb{Z}) = H^3(L_i/k_i, \mathbb{Z}) = H^1(L_i/k_i, \mathbb{Z}) = 0.
\]

This implies the restriction map
\[
H^1(M_i/k_i, \mathbb{Q}/\mathbb{Z}) \to H^1(M_i/L_i, \mathbb{Q}/\mathbb{Z})^{\text{Gal}(L_i/k_i)}
\]
is surjective. Therefore the natural map
\[
\text{Gal}(M_i/L_i)/[\text{Gal}(L_i/k_i), \text{Gal}(M_i/L_i)] \to \text{Gal}(M_i/k_i)/[\text{Gal}(M_i/k_i), \text{Gal}(M_i/k_i)]
\]
is injective by the duality. One concludes that
\[\text{Gal}(L_i/k_i), \text{Gal}(M_i/L_i)] = [\text{Gal}(M_i/k_i), \text{Gal}(L_i/k_i)].\]
Since \(\text{Gal}(L_i/k_i)\) is cyclic, we have
\[\text{Gal}(L_i/k_i), \text{Gal}(K_i/L_i)] = \{(\gamma_i \circ \tau) \cdot \tau^{-1} : \tau \in \text{Gal}(M_i/L_i)\}\]
by an easy computation, where \(\gamma_i\) is a generator of \(\text{Gal}(L_i/k_i)\). Then
\[\overline{\beta_{\text{Fr},i}} = (\gamma_i \circ \tau_i) \cdot \tau_i^{-1}\]
for some \(\tau_i \in \text{Gal}(K_i/L_i)\). \hspace{1cm} \hspace{1cm} (3.7)
For \(\tau_i\) in (3.7), there is \(q_i \in T_i\) such that
\[\tau_i^{-1} = \text{Frob}(q_i) \quad \text{and} \quad (L_i)_{q_i} = k_{p_i} \quad \text{with} \quad p_i = q_i \cap k.\]
For \(v = p_i\), define \(z_{p_i} = \gamma(x_{p_i}) \in X_{t_0}(k_{v_i})\). Then \(\text{Frob}(z_{p_i}) = \gamma_i \circ \tau_i^{-1}\).
We have
\[\xi_i = \overline{\beta_{\text{Fr},i}}^{-1} \cdot \text{Frob}(x_{p_i}) \cdot \text{Frob}(z_{p_i}) = (\gamma \circ \tau_i) \cdot \tau_i^{-1} \cdot (\gamma_i \circ \tau_i^{-1}) = 1_{\text{Gal}(K_i/L_i)},\]
hence \(\sigma_i \in H_i\).
One has
\[\beta(z_{p_i}) = \beta(\gamma_i(x_{p_i})) = \partial_{\beta,D_i}(\gamma_i \circ \tau_i^{-1}) = -\partial_{\beta,D_i}(\gamma_i \circ \tau_i) \quad \text{for all} \quad \beta \in B.\]
Let \(I = \{i: 1 \leq i \leq n\}\) and \(\Omega_i = \{v_i, v'_i\}\) and let \(S' = \{p_i : i \in I\} \subset S.\)

**Lemma 3.4.** For any \(\beta \in B\), we have
\[\sum_{v \notin S' \cup \{v'_1, \ldots, v'_n\}} \beta(x'_v) + \sum_{v \in S'} \beta(z_v) = \sum_{i=1}^N \partial_{\beta,D_i}(\sigma_i).\]

**Proof.** We have
\[\sum_{v \in S' \setminus S'} \beta(x'_v) = \sum_{v \in S} \beta(x'_v) - \sum_{v \in S'} \beta(x'_v) = - \sum_{v \in S'} \beta(x'_v).\]
Since \(\beta(x'_v) = 0\) for any \(v \notin \bigcup \Omega_i \bigcup S\), one obtains
\[\sum_{v \notin S' \cup \{v'_1, \ldots, v'_n\}} \beta(x'_v) + \sum_{v \in S'} \beta(z_v) = \sum_{v \in S'} \beta(x'_v) + \sum_{i=1}^N \sum_{v \in \Omega_i \setminus \{v'_i\}} \beta(x'_v) + \sum_{v \in S'} \beta(z_v)\]
\[= - \sum_{v \in S'} \beta(x'_v) + \sum_{i \in I} \partial_{\beta,D_i}(\text{Fr}_{\xi_{v_i}}) + \sum_{i=n+1}^N \partial_{\beta,D_i}(\sigma_i) - \sum_{i \in I} \partial_{\beta,D_i}(\gamma \circ \tau_i)\]
\[= \sum_{i \in I} \partial_{\beta,D_i}(\tau_i) + \sum_{i \in I} \partial_{\beta,D_i}(\text{Fr}_{\xi_{v_i}}) + \sum_{i=n+1}^N \partial_{\beta,D_i}(\sigma_i) - \sum_{i \in I} \partial_{\beta,D_i}(\gamma \circ \tau_i)\]
\[= \sum_{i \in I} \partial_{\beta,D_i}(\sigma_i) + \sum_{i=n+1}^N \partial_{\beta,D_i}(\sigma_i)\]
\[= \sum_{i=1}^N \partial_{\beta,D_i}(\sigma_i).\]
by (3.1), (3.8) and (3.9).

For \( i \in I \), we replace \( x'_i \) by \( z_{p_i} \), we also denote it by \( x'_i \). By Lemma 3.3 and 3.4 and our hypotheses on \( S \), we can choose, for each \( i \in \{1, \ldots, N\} \), a rational point \( \xi_{w_i,i} \) of the fiber of \( D_i^0 \to \tilde{m}_i \) above \( w_i \) such that \( \text{Fr}_{\xi_{w_i,i}} = -\sigma_i \) and hence

\[
\sum_{v \in \Omega_i} n_{w_i,i} \text{Fr}_{\xi_{w_i,i}} = 0
\]

in \( G_i \). We then lift \( \xi_{w_i,i} \) to a \( k_{w_i} \)-point \( x'_{w_i} \) of \( X_{f_0} \). By a similar argument as in the last paragraph of the proof in Theorem 2.1, we conclude that \( \sum_{v \in \Omega} \text{inv}_v \beta'(x'_v) = 0 \) for all \( \beta \in B \).

**Theorem 3.5.** Let \( X \) be a smooth, proper and geometrically integral variety over \( k \) and let \( f : X \to \mathbb{P}^1_k \) be a dominant morphism with smooth geometrically integral generic fiber \( X_\eta \). Let \( P_i(t), k_i, L_i \) be as in Theorem 2.5.

Assume that

1. \( H^1(X_\eta, \mathbb{Q}/\mathbb{Z}) = 0 \) and \( H^2(X_\eta, \mathcal{O}_{X_\eta}) = 0 \);
2. for \( i \in \{1, \ldots, n\} \), \( L_i \) is a cyclic extension of \( k_i \);
3. Hypothesis \((\text{HH}_1)\) holds for \( P_1(t), \ldots, P_n(t) \);
4. there exists a Hilbert subset \( H \subset \mathbb{P}^1_k \) such that \( X_r(k) \) is dense in \( X_r(A_k)^{\text{Br}(X)} \) for every rational point \( c \) of \( H \).

Then \( X(k) \) is dense in \( X(A_k)^{\text{Br}(X)} \).

**Proof.** The condition (1) implies \( \text{Br}(X_\eta)/f_0^* \text{Br}(\eta) \) is finite (see [HW16 Lemma 8.6]). By Proposition 5.2 the proof follows from a similar argument as in Theorem 2.6.

**Remark 3.6.** (1) Suppose \( k = \mathbb{Q} \) and all non-split fibers lie over rational points of \( \mathbb{P}^1_{\mathbb{Q}} \). By [GT10 Corollary 1.9], Hypothesis \((\text{HH}_1)\) holds (see [HSW14 Proposition 1.2]), then Theorem 3.5 covers the main results of [BMS14] and [HSW14]. In fact, under these assumptions and condition (2), Theorem 3.5 covers a special case of [HW16 Theorem 1.6] which is proved by another approach.

(2) Let \( X \) be a smooth proper model of the smooth locus of the affine variety over \( k \) defined by

\[
N_{K/k}(z) = P_1(t)^{c_1} \cdots P_n(t)^{c_n},
\]

where \( K/k \) is a finite field extension and the \( P_i(t) \)'s are irreducible polynomials. Let \( L_i = k[t]/(P_i(t)) \). Suppose \( K L_i/L_i \) is cyclic for any \( i \in \{1, \ldots, n\} \), and \( [K : k] | \sum c_i | L_i : k \). Then conditions (1), (2) and (4) in Theorem 3.5 hold. Generally, the Brauer group of the generic fiber is non-trivial. So, Theorem 3.5 gives some new examples different from [CTSS98 Theorem 1.2].

By Theorem 3.5 and Remark 3.1 we immediately have the following unconditional result.

**Corollary 3.7.** Let \( k = \mathbb{Q} \). Let \( X \) be a smooth, proper, geometrically integral variety over a number field \( \mathbb{Q} \) and \( f : X \to \mathbb{P}^1_{\mathbb{Q}} \) be a dominant morphism with rationally connected geometric generic fiber. Assume that \( \text{rank}(f) \leq 3 \).
Suppose every non-split fiber \( X_m \) contains a multiplicity one component \( D_m \) such that the algebraic closure of \( k(m) \) in the function field \( k(D_m) \) is a cyclic extension of \( k(m) \).

If \( X_c(k) \) is dense in \( X_c(\mathbb{A}_k)^\text{Br}(X_c) \) for every rational point \( c \) of a Hilbert subset of \( \mathbb{P}^1_k \), then \( X(k) \) is dense in \( X(\mathbb{A}_k)^\text{Br}(X) \).

Proof. This theorem has been proved (see [HW16, BS19]) when there is a non-split fiber over a rational point of \( \mathbb{P}^1_{\mathbb{Q}} \). In fact, if there is a non-split fiber over a rational point of \( \mathbb{P}^1_{\mathbb{Q}} \), this theorem holds for all \( \text{rank}(f) \leq 3 \) without the cyclic assumption. Suppose there is not a non-split fiber over a rational point of \( \mathbb{P}^1_{\mathbb{Q}} \), then \( f \) is non-split over only one closed point \( m \in \mathbb{P}^1_{\mathbb{Q}} \) with \( \left[ \mathbb{Q}(m) : \mathbb{Q} \right] = 3 \). The proof follows from Theorem 3.5 and Remark 3.1. \( \square \)
