TILING A CIRCULAR DISC WITH CONGRUENT PIECES

ÁRPÁD KURUSA, LÁNGI ZSOLT, AND VIKTOR VÍGH

Abstract. In this note we prove that any monohedral tiling of the closed circular unit disc with \( k \leq 3 \) topological discs as tiles has a \( k \)-fold rotational symmetry. This result yields the first nontrivial estimate about the minimum number of tiles in a monohedral tiling of the circular disc in which not all tiles contain the center, and the first step towards answering a question of Stein appearing in the problem book of Croft, Falconer and Guy in 1994.

1. Introduction

A tiling of a convex body \( K \) in Euclidean \( d \)-space \( \mathbb{R}^d \) is a finite family of compact sets in \( \mathbb{R}^d \) with mutually disjoint interiors, called tiles, whose union is \( K \). A tiling is monohedral, if all tiles are congruent.

In this paper we deal with the monohedral tilings of the closed circular unit disc \( B^2 \) with center \( O \), in which the tiles are Jordan regions; i.e. are homeomorphic to a closed circular disc. The easiest way to generate such tilings, which we call rotationally generated tilings, is to rotate around \( O \) a simple, continuous curve connecting \( O \) to a point on the boundary \( S^1 \) of \( B^2 \). The following question, based on the observation that any tile of such a monohedral tiling of \( B^2 \) contains \( O \), seems to arise regularly in recreational mathematical circles [13]:

Question 1. Are there monohedral tilings of \( B^2 \) in which not all of the tiles contain \( O \)?

The answer to Question 1 is affirmative; the usual examples to show this are the first two configurations in Figure 1. The following harder variant is attributed to Stein by Croft, Falconer and Guy in [2, last paragraph on p. 87].

Question 2 (Stein). Are there monohedral tilings of \( B^2 \) in which \( O \) is in the interior of a tile?

A systematic investigation of monohedral tilings of \( B^2 \) was started in [6] by Hadley and Worsley. In their paper they called a monohedral tiling radially generated,
if every tile is \textit{radially generated}, meaning that its boundary is a continuous simple curve consisting of three parts: a circular arc of length $\alpha$ and two other curves one of which is the rotation of the other one about their common point by angle $\alpha$. The following ambitious conjecture appears in [6, Conjecture 6.1].

**Conjecture 1** (Haddley and Worsley). \textit{Every monohedral tiling is a subtiling of a radially generated tiling.}

A similar problem was investigated in [5] by Goncharov, who, for any $O$-symmetric convex body in $\mathbb{R}^d$, determined the smallest number of congruent copies of a subset of the body that cover the body. In the spirit of this approach we raise the following variant of Question 1:

**Question 3.** \textit{What is the minimum cardinality $n(B^2)$ of a monohedral tiling of $B^2$ in which not all of the tiles contain $O$?}

As the configurations in Figure 1 show, we have $n(B^2) \leq 12$. On the other hand, the lower bound $n(B^2) \geq 3$ is also relatively easy to prove: it was posed as a problem in 2000 on the Russian Mathematical Olympiads [14]. Presently, to the authors’ knowledge, the best bounds on $n(B^2)$ are still the trivial ones: $3 \leq n(B^2) \leq 12$.

![Figure 1](image)

**Figure 1.** A non-radially\(^1\), a radially, and a rotationally generated monohedral tiling of $B^2$. In contrast to these three, the rightmost, radially generated monohedral tiling is not rotationally invariant.

Our main result is the following.

**Theorem 1.1.** \textit{Any monohedral tiling of $B^2$ with at most three topological discs is rotationally generated.}

This result implies Conjecture 1 for tilings with at most 3 tiles, yields the first nontrivial lower bound for $n(B^2)$, and in particular proves that the answer for Question 2 is refuting for tilings with at most three tiles.

\(^1\) It may be worth noting that this configuration also appears regularly in various places: this was chosen, for example, as the logo of the MASS program at Penn State University, it appears on the front page of five issues of the Hungarian problem-solving mathematical journal Középiskolai Matematikai Lapok [10], and it can be found also in the book [2, Figure C8].
Corollary 1.2. We have $n(B^2) \geq 4$.

Corollary 1.3. There is no monohedral tiling of $B^2$ with at most three topological discs as tiles such that the center of $B^2$ is contained in exactly one of them.

In Section 2 we introduce the notions used in the paper, investigate the basic properties of monohedral tilings of $B^2$, and prove a series of lemmas that we use in the proof of Theorem 1.1. In Section 3 we prove Theorem 1.1.

Finally, in Section 4 we collect our additional remarks and propose some open problems.

2. Notations and preliminaries

Throughout the proof, we denote by $B^2$ the closed unit circular disc with the origin $O = (0, 0)$ as its center, and its boundary by $S^1 = \partial B^2$. We say that two points $P, Q \in S^1$ are antipodal if $d(P, Q) = 2$, where $d(\cdot, \cdot)$ denotes Euclidean distance. For points $P, Q \in \mathbb{R}^2$, the closed segment with endpoints $P, Q$ is denoted by $PQ$.

For any $P, Q \in \mathbb{R}^2$ with $d(P, Q) \leq 2r$, the $r$-spindle $\ominus_r P, Q$ of two points $P, Q$ is by definition (cf. [1] or [3]) the intersection of all Euclidean discs of radius $r > 0$ that contain $P$ and $Q$. In other words, $\ominus_r P, Q$ is the region bounded by the two circular arcs of radius $r > 0$ that connect $P$ and $Q$ and are not longer than a half-circle.

A set homeomorphic to $B^2$ is called a topological disc. The boundary of a topological disc is a simple, closed, continuous curve, called Jordan curve. On the other hand, the Jordan–Schoenflies theorem [17] yields that every Jordan curve is the boundary of a topological disc. We remark that since all topological discs are compact, they are Lebesgue measurable; we denote their measure by $\text{area}(\cdot)$. Nevertheless, there are topological discs (see, e.g. the Koch snowflake, or for more examples [16]) whose boundary is not rectifiable. Our next lemma, which we use in the proof, holds for these topological discs as well.

Lemma 2.1. Let $\Gamma$ be a Jordan curve and $C$ be a simple, continuous curve. Then $\Gamma$ contains finitely many congruent copies of $C$ which are mutually disjoint, apart from possibly their endpoints.

Proof. Assume for contradiction that $\Gamma$ contains infinitely many congruent copies $C_n$ ($n = 1, 2, \ldots$) of $C$ which are mutually disjoint, apart from possibly their endpoints. Let $P_n$ and $Q_n$ denote the endpoints of $C_n$. Since $\Gamma$ is compact, we may assume that $\lim_{n \to \infty} P_n = P$ and $\lim_{n \to \infty} Q_n = Q$ for some $P, Q \in \Gamma$. By the properties of congruence, $P \neq Q$. On the other hand, since $\Gamma$ is homeomorphic to $S^1$, the congruent copies of $C$ correspond to mutually nonoverlapping circular arcs on $S^1$. Clearly, this implies that $P = Q$, a contradiction.

Lemma 2.2. Let $D = D_1 \cup D_2$, where $D, D_1$ and $D_2$ are topological discs, and $\text{int} D_1 \cap \text{int} D_2 = \emptyset$. Then $S_1 = D_1 \cap \partial D$, $S_2 = D_2 \cap \partial D$, and $S = \partial D_1 \cap \partial D_2$ are simple continuous curves.
Proof. As $D$ is a topological disc, we have a homeomorphism $\chi$ such that $\chi(D) = \mathcal{B}^2$. Since the statement of the lemma is topologically invariant, it is sufficient to prove it in the case $D = \mathcal{B}^2$. Thus, we may assume that $S_i = S^1 \cap D_i$ for $i = 1, 2$, where we observe that since $D_i$ and $S^1$ are closed, so is $S_i$.

First, we show that $S_1$ and $S_2$ are connected. Assume, for example, that some $X_1, Y_1 \in S_1$ cannot be connected by an arc in $S_1$. Then there are some points $X_2, Y_2 \notin S_1$ that separate $X_1$ and $Y_1$ in $S^1$. Clearly, we have $X_2, Y_2 \in S_2$. For any $i = 1, 2$, since $D_i$ is a topological disc, there is a simple, continuous curve $\gamma_i$ with endpoints $X_i, Y_i$ such that apart from these points $\gamma_i$ is contained in int $S_i$. By continuity, $\gamma_1 \cap \gamma_2 \neq \emptyset$, implying that int $D_1 \cap$ int $D_2 \neq \emptyset$, a contradiction. Thus, $S_1$ and $S_2$ are connected, which yields that they are closed circular arcs in $S^1$. Let the (common) endpoints of these arcs be $P$ and $Q$.

The points $P, Q \in S_1 \cap S_2$ are also in $\partial D_1 \cap \partial D_2$, hence they are connected by a simple continuous curve in $\partial D_1 \setminus S_1$ and also in $\partial D_2 \setminus S_2$. These curves coincide because $D = D_1 \cup D_2$, hence it is $S$, and the proof of Lemma 2.2 is complete. □

Lemma 2.3. Let $\{D_1, D_2, D_3\}$ be a tiling of the topological disc $D$ where for $i = 1, 2, 3$, $D_i$ is a topological disc such that $S_i = D_i \cap \partial D$ is a nondegenerate simple continuous curve. Then $D_1 \cap D_2 \cap D_3$ is a singleton $\{M\}$, and for any $i \neq j$, $D_i \cap D_j$ is a simple continuous curve connecting $M$ and a point in $\partial D$.

Proof. Suppose for contradiction that there are two distinct points $M_1, M_2 \in D_i$ for $i = 1, 2, 3$. For any $i$, let $\Gamma_i$ be a simple, continuous curve connecting $M_1$ and $M_2$ which is contained in int $D_i$, apart from $M_1$ and $M_2$. Note that for any $i \neq j$, $\Gamma_i \cup \Gamma_j$ is a simple, closed, continuous curve. Thus, the union of a pair of the curves, say $\Gamma_1 \cup \Gamma_2$ encloses the third one. This implies that $\Gamma_1 \cup \Gamma_2$ encloses $D_3$. Since $M_1, M_2 \notin S^1$ by our conditions, it follows that $D_3$ is disjoint from $S^1$; a contradiction. Thus, $D_1 \cap D_2 \cap D_3$ contains at most one point. On the other hand, since the closure $X_1$ of $(\partial D_1) \setminus S_1$ is a simple, connected curve and it can be decomposed into the closed sets $X_1 \cap D_2$ and $X_1 \cap D_3$, it follows that these sets intersect, that is $D_1 \cap D_2 \cap D_3$ is not empty. Thus, $D_1 \cap D_2 \cap D_3 = \{M\}$ for some $M \in \operatorname{int} D$.

To prove the second part of Lemma 2.3, we may apply an argument like in the proof of Lemma 2.2. □

By the circumcircle of a topological disc $D$ we mean the unique smallest closed Euclidean circle encompassing $D$. The convex hull of the circumcircle is the circumdisc of $D$, the radius of the circumcircle is the circumradius of $D$. Observe that the center of the circumcircle $C$ of $D$ is in $\operatorname{conv}(C \cap D)$, as otherwise a smaller circle would encompass $D$. 
Lemma 2.4. Assume that $S^1$ is the common circumcircle of the non-overlapping congruent topological discs $D_1$ and $D_2$. Then there is a diameter $PQ$ of $B^2$ separating $S_1 = D_1 \cap S^1$ and $S_2 = D_2 \cap S^1$. Furthermore, any congruence $g$ with $g(D_1) = D_2$ is either the reflection about the line of $PQ$, or the reflection about $O$.

Proof. Using the idea of the proof of Lemma 2.2, it follows that there are no pairs of points $X_1, Y_1 \in S_1$ and $X_2, Y_2 \in S_2$ that strictly separate each other on $S^1$. In other words, there is a line $\ell$ separating $S_1$ and $S_2$. On the other hand, as $O \in \text{conv} \ S_1 \cap \text{conv} \ S_2$, $\ell$ contains $O$ and $\ell \cap S^1 \subseteq S_1 \cap S_2$, proving the first statement with $\{P, Q\} = \ell \cap S^1$. We note that from this argument it also follows that $S_1 \cap S_2 = \{P, Q\}$.

Consider some isometry $g$ with $g(D_1) = D_2$. The uniqueness of the circumscribed circle clearly implies that $g(S^1) = S^1$, and thus, $g(\{P, Q\}) = \{P, Q\}$. This implies that $g$ is either the reflection about the line of $PQ$, the reflection about the line bisecting $PQ$, or the reflection about $O$. We show that the conditions of the lemma exclude the second case: Consider a simple, continuous curve $\Gamma$ from $P$ to $Q$ such that $\Gamma \setminus \{P, Q\} \subset \text{int} \ D_1$. Then at least one point $R$ of $\Gamma$ lies on the line $\ell^\perp$ bisecting $PQ$. If $g$ is the reflection about $\ell^\perp$, then $g(R) = R$, and hence, $R \in \text{int} \ D_1 \cap \text{int} \ D_2$; a contradiction.

In the remaining part of Section 2, we deal only with a monohedral tiling of $B^2$, where the tiles $D_i$, $i = 1, 2, \ldots, n$, are congruent copies of a topological disc $D$. For any $j \neq 1$, we fix an isometry $g_{1j}$ mapping $D_1$ into $D_j$, and for any values of $i, j$, we set $g_{ij} = g_{1i}^{-1} \circ g_{ij}$. Then, by definition, we have $g_{ji} = g_{ij}^{-1}$ for all values of $i, j$. Finally, we set $S_i = D_i \cap S^1$ for all values of $i$.

Lemma 2.5. If $D$ contains two points at the distance 2, then $n = 1$ or $n = 2$, and the tiling is rotationally generated.

Proof. If $D$ contains two points at the distance 2, then each tile contains two antipodal points of $B^2$. Thus, $B^2$ is the circumscribed disc of each tile, which implies that $g_{ij}(B^2) = B^2$ for all values of $i, j$. Since $O \in D_i$ for some value of $i$, it also yields that $O \in D_i$ for all values of $i$. Then, by Lemma 2.4, there is a diameter $PQ$ of $B^2$ whose endpoints belong to every tile, and the congruence between any two of them is either a reflection about the line through $PQ$, or the reflection about the midpoint of $PQ$. This implies that there are at most two tiles.

To prove that the tiling is rotationally generated, assume that $n = 2$, and $D_2$ is a reflected copy of $D_1$ about the line through $PQ$. Since in this case $D_1$ and $D_2$ are the two closed half discs of $B^2$ containing $PQ$ in their boundaries, the statement follows. $\square$

Lemma 2.6. For all values of $i$, $S_i$ ($i = 1, \ldots, n$) is a closed, connected arc in $S^1$.

Proof. As $S_1$ is compact, there are points $P, Q \in S_1$ farthest from each other in $S_1$. If $P, Q$ are antipodal points of $S^1$, then every $D_i = g_{1i}(D_1)$ ($i = 1, \ldots$) contains...
antipodal points, hence $B^2$ is the circumscribed disc of every tile. Then Lemma 2.5 yields that $n = 1$ or $n = 2$. The case $n = 1$ is trivial, and if $n = 2$, then by Lemma 2.4, there is a diameter $PQ$ separating $S_1$ and $S_2$, which implies that $S_1$ and $S_2$ are closed half-circles. Thus, we may assume that $P, Q$ are not antipodal.

Let $\Gamma \subset S^1$ be the shorter arc connecting $P$ and $Q$. We show that $\Gamma \subset D_1$.

For contradiction, suppose that a point $X \in \Gamma$ does not belong to $D_1$. Then, without loss of generality, we may assume that $X \in D_2$, and that $X \neq P$, $X \neq Q$.

Let $r > 0$ be the radius of the circumscribed disc $B$ of $D_1$. Since $D_1$ is compact, and it does not contain antipodal points of $S^1$, we have $r < 1$, implying that $\varnothing_{P,Q}$ contains $\Gamma \setminus \{P, Q\}$ in its interior. Thus $\Gamma \subset B$, and $\Gamma \setminus \{P, Q\} \subset \text{int } B$. Let $\Gamma'$ be a continuous curve connecting $P$ and $Q$ such that $\Gamma' \setminus \{P, Q\} \subset \text{int } D_1$. This yields that $\Gamma \cup \Gamma'$ is a simple, continuous, closed curve in $B$ enclosing $D_2$, which, by the congruence of $D_1$ and $D_2$, implies that the $B$ is the circumscribed disc of $D_2$ as well. Hence, by Lemma 2.4 it follows that $\text{conv}(\partial B \cap D_1 \cap D_2)$ is a diameter $\delta$ of $B$. As $P, Q$ are the only points of $\Gamma \cup \Gamma'$ that may fall on $\partial B$, we have $\delta = PQ$.

From Lemma 2.4 it also follows that $g_{12}$ is the reflection about the line of $PQ$, or the reflection about the midpoint of $PQ$, and in particular $g_{21} = g_{12}$. On the other hand, observe that $g_{12}(\varnothing_{P,Q}) = \varnothing_{P,Q} = B^2 \cap g_{12}(B^2)$. Since $D_1 \subset B^2$ and $D_1 = g_{12}(D_2) \subset g_{12}(B^2)$, this implies that $D_1, D_2 \subset \varnothing_{P,Q}$. Now, if there is a point $R \in D_2 \cap \partial \varnothing_{P,Q} \cap \Gamma$ then $R$ and $X$ can be connected with a continuous curve in $\text{int } D_2$, while $P, Q \in \text{int } D_1$, a contradiction. Hence $D_2 \cap \partial \varnothing_{P,Q} \subset \Gamma$, and accordingly $D_1 \cap S^1 = \{P, Q\}$, and, in particular, $D_1 \cap \Gamma = \{P, Q\}$.

Assume that there is an interior point $Y$ of $\Gamma$ that belongs to, say, $D_3$. Since $P, Q \in D_2$, we may repeat the argument in the previous paragraph, replacing $D_1$ and $D_2$ by $D_2$ and $D_3$, respectively, and obtain that $D_2 \cap \Gamma = \{P, Q\}$ contradicting our assumption that there is an interior point $X \in D_2$ of $\Gamma$. Thus, $\Gamma \subset D_2$, which yields by Lemma 2.4 that $D_2 \cap S^1 = \Gamma$ and $\varnothing_{P,Q} = D_1 \cup D_2$. From this, in particular, it follows that $\text{area}(D_1) = \text{area}(D_2) = \text{area}(\varnothing_{P,Q})/2$.

Since for all values of $i$, $g_{2i}(\{P, Q\}) \subset B^2$, the definition of 1-spindle implies that $D_i \subset \varnothing_{g_{2i}(P),g_{2i}(Q)} \subset B^2$, and $g_{2i}(D_2) \setminus \Gamma \subset \text{int } \varnothing_{g_{2i}(P),g_{2i}(Q)}$ is disjoint from $S^1$. In other words, the sets $g_{2i}(\Gamma)$ cover $S^1$. Note that these arcs may intersect each other only at their endpoints, and if $|S^1 \cap g_{2i}(\Gamma)| \geq 3$, then $g_{2i}(\Gamma) \subset S^1$. Thus, $S^1$ can be decomposed into finitely many, say $k < n$ circular arcs, each of which is congruent to $\Gamma$.

Let $s = 2\pi/k$ denote the arclength of $\Gamma$. Then $ks = 2\pi$ on one hand, and

$$\frac{\pi}{n} = \frac{\text{area}(B^2)}{n} = \text{area}(D_2) = \frac{\text{area}(\varnothing_{P,Q})}{2} = \frac{s - \sin s}{4} = \frac{2\pi - \sin 2\pi}{4}$$

on the other hand. Thus, we have $\sin \frac{2\pi}{k} = \pi(\frac{2}{k} - \frac{4}{n})$. The left-hand side is an algebraic number (see, e.g. [18, Theorem 2.1]), from which $\frac{2}{k} = \frac{4}{n}$ follows, hence
\[
\sin \frac{2\pi}{k} = 0, \text{ implying that } k \text{ is a divisor of } 2, \text{ contradicting our assumption that } \Gamma \text{ is shorter than a half-circle.}
\]

**Remark 2.7.** Since \( S_i \subset \partial \text{conv} D_i \), it follows that for all values of \( i, j \), we have \( g_{ij}(S_i) \subset \partial \text{conv} D_j \).

**Remark 2.8.** For any values of \( i, j, k \), the arcs \( g_{ik}(S_i) \) and \( g_{jk}(S_j) \) share at most some of their endpoints, or they coincide.

**Proof.** Observe that since for any \( i, S_i \) is contained in the convex hull of \( D_i \), if the arcs \( g_{ik}(S_i) \) and \( g_{jk}(S_j) \) are not disjoint apart from (possibly) their endpoints, then \( g_{ik}(S_i) \cap g_{jk}(S_j) \) is a nondegenerate unit circular arc, and thus, \( g_{ik}(S_i) \cup g_{jk}(S_j) \) lies on a unit circle \( S \).

Since \( S_i = g_{ki}(g_{ik}(S_i)) \subset S^1 \), we have \( g_{ki}(S) = S^1 \). Thus, \( S_i \cup g_{ki}(g_{jk}(S_j)) \subset S^1 \cap D_i = S_i \). This implies that \( g_{jk}(S_j) \subseteq g_{ik}(S_i) \). The containment relation \( g_{ik}(S_i) \subseteq g_{jk}(S_j) \) can be obtained using a similar argument, which yields the desired equality.

**Lemma 2.9.** Let \( D_1, D_2, \ldots, D_n \) be a monohedral tiling of \( B^2 \), where \( n > 1 \). Then at least two of the arcs \( S_1, g_{21}(S_2), \ldots, g_{n1}(S_n) \) coincide.

**Proof.** Suppose for contradiction that the arcs \( S_1, g_{21}(S_2), \ldots, g_{n1}(S_n) \) are disjoint apart from possibly their endpoints. By our earlier observation these arcs are in \( \partial \text{conv} D_1 \). As the total turning angle of these \( n \) arcs is \( 2\pi \), and the total turning angle along the boundary of a convex body is also \( 2\pi \), \( \partial \text{conv} D_1 \) may only consist in excess of these arcs some segments that connect the endpoints of these arcs in a smooth way. In other words, \( \text{conv} D_1 = P + B^2 \) for some convex \( n \)-gon \( P \). This implies that the circumradius of \( D_1 \) is at least 1, with equality if and only if \( D_1 = B^2 \), a contradiction.

**Definition 2.10.** A multicurve (cf. also [11]) is a finite family of continuous simple curves, called the members of the multicurve, which are parameterized on non-degenerate closed finite intervals, and any point of the plane belongs to at most one member, or it is the endpoint of exactly two members. If \( F \) and \( G \) are multicurves, \( \bigcup F = \bigcup G \), and every member of \( F \) is the union of some members of \( G \), we say that \( G \) is a partition of \( F \).

**Definition 2.11.** Let \( F \) and \( G \) be multicurves. If there are partitions \( F' \) and \( G' \) of \( F \) and \( G \), respectively, and a bijection \( f : F' \to G' \) such that \( f(\mathcal{C}) \) is congruent to \( \mathcal{C} \) for all \( \mathcal{C} \in F' \), we say that \( F \) and \( G \) are equidecomposable.

The following lemma can be proved very similarly to the analogous statement for equidecomposability of polygons [4], thus we omit the proof.

**Lemma 2.12.** Equidecomposability is an equivalence relation on the family of multicurves in \( \mathbb{R}^2 \).
Corollary 2.13. If $F$ and $G$ are multicurves with $\bigcup F = \bigcup G$, then $F$ and $G$ are equidecomposable.

**Proof.** Clearly, it is sufficient to prove the statement for the connected components of $\bigcup F$, and by Lemma 2.12 we may assume that one of the multicurves, say $G$, is a simple continuous curve. But then $F$ is a partition of $G$, in which case the statement is obvious. □

Corollary 2.14. If $F$ and $G$ are equidecomposable, and their subfamilies $F' \subseteq F$ and $G' \subseteq G$ are equidecomposable, then $F \setminus F'$ and $G \setminus G'$ are equidecomposable.

**Proof.** By Lemma 2.12, we may assume that $\bigcup F = \bigcup G$. Without loss of generality, we may also assume that $\bigcup F$ is connected, which yields that we may regard both $F$ and $G$ as different partitions of the same simple, continuous curve. More specifically, after reparametrizing if necessary, we may assume that there is some curve $C : [a, b] \to \mathbb{R}^2$, and partitions $P_F$ and $P_G$ of $[a, b]$ such that the elements of $F$ and $G$ are the restrictions of $C$ to the subintervals of $P_F$ and $P_G$, respectively. By Corollary 2.13, a multicurve is equidecomposable with any of its partitions, and hence, we may assume that $P_F = P_G$, and there is a bijection between the elements of $F'$ and $G'$ such that the corresponding elements are congruent. Since congruence is an equivalence relation, it is clear that any such bijection can be extended to all subintervals of $P_F$, which proves the assertion. □

3. **Proof of Theorem 1.1**

First, consider a monohedral tiling of $B^2$ with the topological discs $D_1$ and $D_2$. The containment $O \in D_1 \cap D_2$ can be proved in a number of elementary ways (see, e.g. [7]); here we also show that the tiling is rotationally generated.

By Lemma 2.6, for $i = 1, 2$, $S_i = D_i \cap S^1$ is a connected arc and hence, $S_1$ or $S_2$ is an arc of length at least $\pi$. Thus, $D_1$ or $D_2$ contains a pair of antipodal points of $B^2$, which, by Lemma 2.5, implies that the tiling is rotationally generated.

From now on, we consider the case that $B^2$ is decomposed into three congruent topological discs $D_1, D_2, D_3$, and for $i = 1, 2, 3$, we set $S_i = D_i \cap S^1$. By Lemmas 2.6 and 2.5, we may assume that each tile intersects $S^1$ in a nondegenerate circle arc, which is smaller than a half-circle.

By Lemma 2.3, we have that $D_1 \cap D_2 \cap D_3$ consists of a single point $M \in \text{int} B^2$, and that for any $i \neq j$, $D_i \cap D_j$ is a simple, continuous curve connecting $M$ and a point of $S^1$.

To prove the assertion, we distinguish some cases. Before we do it, we observe that by Remark 2.8, any pair of the curves $S_1, g_{21}(S_2)$ and $g_{31}(S_3)$ intersect in at most a common endpoint, or they coincide.

**Case 1:** No pair of the arcs $S_1, g_{21}(S_2)$ and $g_{31}(S_3)$ coincide.

In this case we immediately have a contradiction by Lemma 2.9.

**Case 2:** Two of the arcs $S_1, g_{21}(S_2)$ and $g_{31}(S_3)$ coincide, the third one is different.

Using a suitable relabeling of the tiles, we may assume that $S_1 = g_{21}(S_2)$. Let the
arclength of this arc be $0 < \alpha < \pi$, and the arclength of $S_3$ be $\beta$. The equality $S_1 = g_{21}(S_2)$ implies, in particular, that $g_{21}$ is an isometry of $S^1$; or more generally that it is either the reflection about the symmetry axis $\ell$ of $S_1 \cup S_2$ or a rotation around $O$ with angle $\alpha$. We may assume without loss of generality that $\ell$ is the $y$-axis, the common point of $S_1$ and $S_2$ is $(0,1)$, and $S_1 \subset \{(x,y) : x \leq 0\}$.

Furthermore, in the proof we set $C_1 = D_1 \cap D_3$, and $C_2 = D_2 \cap D_3$.

Subcase 2.a: $g_{21}$ is the reflection about $\ell$.

If there is a point $P \in \text{int} D_1 \cap \{(x,y) : x > 0\}$, then a continuous curve $\Gamma$ in int $D_1$ connects $P$ and the midpoint of $S_1$, so $g_{12}(\Gamma)$ connects the midpoint of $S_2$ to $g_{12}(P)$ in int $D_2$. This implies that $\Gamma \cap g_{12}(\Gamma)$ is in int $D_1 \cap \text{int} D_2 = \emptyset$, which is a contradiction. Thus we have $D_1 \subset \{(x,y) : x \leq 0\}$ and also $D_2 \subset \{(x,y) : x \geq 0\}$.

Observe that $g_{13}(S_1) = g_{23}(g_{12}(S_1)) = g_{23}(S_2)$, and $D_3 = \text{cl}(B^2 \setminus (D_1 \cup D_2))$ is symmetric in $\ell$. We denote this arc of length $\alpha$ by $S = g_{13}(S_1)$. Note that by the conditions of Case 2 $S \neq S_3$, and $S \subset \partial \text{conv} D_3$ by Remark 2.7. Furthermore, $\partial \text{conv} D_3$ does not contain any arc of length $\alpha$ apart from $S$ and possibly $S_3$, as otherwise the idea of the proof of Lemma 2.9 yields a contradiction. Thus, $S$ is symmetric in the $y$-axis.

Since $D_3$ is connected, and every point of $\ell$ belongs either to $D_3$, or to both $D_1$ and $D_2$, the segment connecting the midpoint $X$ of $S$ and the midpoint $Y$ of $S_3$ belongs to $D_3$. Let the length of $XY$ be $\delta > 0$, and note that the fact $X,Y \in \partial \text{conv} D_3$ yields that the line through $XY$ intersects $D_3$ exactly in $XY$ and $XY \setminus \{X,Y\} \subset \text{int} D_3$. For $i = 1,2$, $g_{3i}(XY)$ is the segment of length $\delta$ in $B^2$, starting at the midpoint of $S_i$, and perpendicular to it. Thus, if $\delta < 1$, then $O \notin \bar{D}_i$ for any value of $i$, if $\delta > 1$, then $O \in \text{int} D_i$ for all values of $i$, and if $\delta = 1$, then $O$ is the midpoint of a unit circle arc in the boundary of each of the $D_i$s, which is a contradiction.

Subcase 2.b: $g_{21}$ is the rotation around $O$ by angle $\alpha$ in counterclockwise direction.

As $O$ is a fixed point of $g_{21}$, it follows that either $O \in D_1 \cap D_2$, or $O \notin D_1 \cup D_2$.

By the definition of tiling and our assumptions, in the first case $O \in \partial D_1 \cap \partial D_2$, and in the second case $O \in \text{int} D_3$.

First, consider the case that $O \in \partial D_1 \cap \partial D_2$.

Recall that by Lemma 2.3, $D_1 \cap D_2 \cap D_3$ is a single point $M$, and for any $i \neq j$, $D_i \cap D_j$ is a simple continuous curve connecting $M$ to a point of $S^1$. Thus, if $O = M$, then $g_{21}(D_1 \cap D_2) = D_1 \cap D_3$, and $g_{12}(D_1 \cap D_2) = D_2 \cap D_3$. Since $\partial D_1$ and $\partial D_3$ are equidecomposable, this implies that $S_1$ and $S_3$ are congruent, and hence $\alpha = 2\pi/3$. In other words, if $O = M$, then the tiling is rotationally generated. Thus, we assume that $O \notin D_3$, which by the compactness of $D_3$ yields the existence of a small closed circular disc $B$ centered at $O$ such that $B \cap D_3 = \emptyset$.

Let $t \mapsto \mathcal{C}(t)$ be a continuous parameterization of the curve $D_1 \cap D_2$ satisfying $O = \mathcal{C}(0)$, and let $t_+ = \sup\{t : \mathcal{C}([0,t]) \subset B\}$ and $t_- = \inf\{t : \mathcal{C}([t,0]) \subset B\}$. Then $g_{12}(\mathcal{C}(t_{\pm})) = \mathcal{C}(t_{\mp})$, which implies that $g_{12}$ is the reflection about $O$. Thus $\alpha = \pi$ and $\beta = 0$, which contradicts our assumptions.
In the remaining part of Subcase 2.b, we assume that \( O \in \text{int} \, D_3 \).

Let \( M_1 = g_{21}(M) \) and \( M_2 = g_{12}(M) \). Since \( \alpha > 0 \), we have \( M_2 \neq M \). On the other hand, we clearly have \( M_2 \in \partial D_2 \) and \( M_2 \notin S^1 \).

Let \( B \) be the circular disc in \( D_3 \) that is centered at \( O \) and is of maximum radius \( r > 0 \). Then \( B \) is tangent to at least one of the curves \( C_1 \) and \( C_2 \), say \( C_2 \) touches \( B \) in \( X_2 \in \partial B \cap C_2 \). Let \( X_1 = g_{21}(X_2) \). Then \( X_1 \in B \cap D_1 = B \cap C_1 \) clearly, hence \( X_2 \in g_{12}(C_1) \cap C_2 \neq \emptyset \). Since \( g_{12}(C_1) \) is a continuous curve in \( \partial D_2 \), connecting the intersection point of \( S_1 \) and \( S_2 \) to \( M_2 \) in \( \text{int} \, B^2 \), it follows that \( M \in g_{12}(C_1) \), that is, \( M_1 \in C_1 \), implying also \( M_2 \in C_2 \).

Thus, \( M_1 \) divides the curve \( C_1 \) into two parts: one from \( M \) to \( M_1 \), which we denote by \( C_1^M \), and the other one from \( M_1 \) to a point of \( S_1 \), which we denote by \( C_1^S \). We define the parts \( C_2^M \) and \( C_2^S \) of \( C_2 \) similarly, using \( M_2 \) in place of \( M_1 \). Furthermore, we set \( C_3^S = D_1 \cap D_2 \).

![Figure 2. \( B^2 \) is dissected into three topological discs.](image)

We clearly have \( g_{21}(C_2^M) = C_1^M \), \( g_{21}(C_2^S) = C_3^S \) and \( g_{21}(C_3^S) = C_1^S \). Observe that since \( D_1, D_2 \) and \( D_3 \) are congruent, their boundaries are equidecomposable. Furthermore, as \( C_1^S, C_2^S \), and \( C_3^S \), and also \( C_1^M \) and \( C_2^M \) are congruent, we obtain by Corollary 2.14 that \( S_1 \) and \( C_1^M \cup S_3 \) are equidecomposable. Thus we deduce that \( C_1^M \) (and also \( C_2^M \)) is a multicurve such that its every member curve is a unit circular arc, and their total length is \( \alpha - \beta \geq 0 \).

If a unit circular arc \( C \) is contained in the boundary of a tile \( D_i \), it may happen that the convex side of \( C \) belongs to \( \text{int} \, D_i \), and the concave side of \( C \) does not belong to \( D_i \). In this case we say that \( C \) is a \emph{convex circular arc} of \( D_i \), and in the opposite case that it is a \emph{concave circular arc} of \( D_i \). Clearly, if \( C \) is a unit circular arc in \( D_i \cap D_j \) for some \( i \neq j \), then it is a convex circular arc of exactly one of \( D_i \) and \( D_j \). Let \( x \) and \( y \) denote the total length of the convex and concave unit circular arcs of \( D_1 \) in \( C_1^M \). Since \( C_1^M \) and \( C_2^M \) are congruent, the total length of the convex and concave unit circular arcs of \( D_2 \) in \( C_2^M \) is also \( x \) and \( y \), respectively. Thus, the total length of the convex and concave unit circular arcs of \( D_3 \) in \( C_1^M \cup C_2^M \) is \( 2y \) and \( 2x \), respectively.
The congruence of the tiles $D_i$ and the curves $C^S_i$ for $i = 1, 2, 3$ yields that the total lengths of the convex and concave unit circular arcs of $D_1$ in $S_1 \cup C^M_1$ is equal to the total lengths of the convex and the concave unit circular arcs of $D_3$ in $S_3 \cup C^M_1 \cup C^M_2$, respectively. This equality for convex circular arcs implies that $\alpha + x = \beta + 2y$, and the equality for concave arcs implies $y = 2x$. From these equations it follows that $x = (\alpha - \beta)/3$ and $y = 2(\alpha - \beta)/3$. Thus, in particular, it follows that if $\beta = \alpha$, then $x = y = 0$ and $M = M_1 = M_2$, which yields that $\alpha = 0$, a contradiction. This means that $\beta < \alpha$.

We show that $M$ is not an interior point of a unit circular arc in $\partial D_3$ longer than $\alpha - \beta$. Suppose for contradiction that $M$ is an interior point of such a circular arc $C$. If one of $M_1$ or $M_2$, say, $M_1 \in C$, then $C^M_1 \subset C$, which yields that $C^M_2 = g_21(C^M_1)$ is also a unit circular arc, implying that $C^M_1 \cup C^M_2$ belongs to the same unit circle $\hat{S}$. Since this circle is invariant under a rotation around $O$, we have $\hat{S} = \hat{S}^1$, which contradicts our assumption that $M, M_1, M_2 \in \text{int}B^2$. Assume that $M_1, M_2 \notin C$, and let $C^1$ and $C^2$ denote $C \cap C^M_1$ and $C \cap C^M_2$, respectively. Then $g_21(C^2)$ is a unit circular arc in $C^M_1$ whose length is equal to that of $C^2$. Thus, $g_21(C^2)$ and $C^1$ intersect in a unit circular arc, which yields that $g_21(C^2) \cup C^1 = C^M_1$ is a unit circular arc, which leads to a contradiction in a similar way.

Let us say that a unit circular arc in $\partial D_i$ is maximal, if it is not a proper subset of another unit circular arc in $\partial D_i$. By Lemma 2.1, $\partial D_1$ contains finitely many, say $m \geq 1$ maximal unit circular arcs of length $\alpha$, one of which is $S_1$. Thus, $\partial D_3$ also contains $m$ maximal unit circular arcs of length $\alpha$. By the previous paragraph, any of these arcs is contained in $C^S_1 \cup C^M_1$ or in $C^S_2 \cup C^M_2$. Assume that all these arcs are contained in $C^S_1$ or in $C^S_2$. Since $C^S_1, C^S_2$ and $C^S_3$ are congruent, we have that the total number of unit circular arcs of length $\alpha$ in $S_i^S$ is equal to $m/2$. Thus, $\partial D_1$ contains $m + 1$ arcs, which is a contradiction.

Finally, consider the case that some maximal unit circular arc $S_\alpha$ of length $\alpha$ in $\partial D_3$ is not contained in $C^S_1 \cup C^S_2$. Since $\alpha > \alpha - \beta$, $M$ is not an interior point of $S_\alpha$, but $M_1$ or $M_2$ is. Without loss of generality, we may assume that $M_1$ is in the interior of $S_\alpha$. This implies that $M$ is in the interior of $g_{12}(S_\alpha) \subset C^S_3 \cup C^M_2$ (similarly as Figure 2 shows). Hence, $M$ is not an interior point of a unit circular arc in $\partial D_1$, which implies that $M_2$ is not an interior point of any unit circular arc in $\partial D_2$. On the other hand, again by Lemma 2.1, $\partial D_3$ contains $k$ maximal unit circular arcs of length $\beta$ for some $k \geq 1$, one of which is $S_3$. By our previous argument, any of these arcs is contained in one of $C^M_i$ or $C^S_i$ for some $i \in \{1, 2\}$. Let $k_M \geq 0$ and $k_S \geq 0$ denote the number of these arcs in $C^M_1$ and $C^S_1$, respectively. Then $C^M_1$ and $C^S_1$ contain exactly $k_M$ and $k_S$ of these arcs, respectively. From this it readily follows that $k = 2k_M + 2k_S + 1$. Furthermore, since $\partial D_1$ also contains $k$ maximal unit circular arcs of length $\beta$, we have $k = k_M + 2k_S$. This yields that $k_M = -1$, which is a contradiction.

**Case 3:** all of the arcs $S_1$, $g_21(S_2)$ and $g_{31}(S_3)$ coincide.

In this case $g_21$ and $g_{31}$ are either reflections about a line through $O$, or rotations
around \( O \). In particular, \( O \) is a fixed point of both of them and thus it is the unique common point \( M \) of all tiles. For any \( i \neq j \), let \( C_{ij} = D_i \cap D_j \). If both \( g_{12} \) and \( g_{13} \) are rotations around \( O \), then the tiling is clearly rotationally generated. Hence, assume that one of \( g_{12} \) and \( g_{13} \), say \( g_{12} \) is a reflection about a line \( \ell \) through \( O \). Then \( g_{12}(C_{13} \cup C_{12}) = C_{12} \cup C_{23} \) yields that \( C_{12} \) is a straight line segment in \( \ell \), which, by the congruence of the tiles implies also that \( C_{ij} \) is a segment for all \( i \neq j \). Thus, also in this case the tiling is rotationally generated, and the assertion follows.

4. Remarks and open problems

First, we observe that the quantity \( n(K) \) can be similarly defined for any \( O \)-symmetric convex body \( K \) in \( \mathbb{R}^d \) playing the role of \( B^2 \). On the other hand, Theorem 1.1 cannot be generalized for any \( O \)-symmetric convex body even in the case \( d = 2 \). Indeed, taking a parallelogram and dissecting it into three congruent parallelograms with two lines parallel to a pair of sides of the parallelogram shows that there are \( O \)-symmetric plane convex bodies \( K \) with \( n(K) = 3 \). However, it is easy to see that the following generalization of Theorem 1.1 holds.

**Theorem 4.1.** If there is a monohedral tiling of an \( O \)-symmetric, strictly convex, smooth body \( K \) in \( \mathbb{R}^2 \) with \( k \leq 3 \) topological discs, then both \( K \) and its tiling has a \( k \)-fold symmetry. In particular, for any \( O \)-symmetric, strictly convex plane body \( K \) of smooth boundary we have \( n(K) \geq 4 \).

This raises the question what happens if smoothness or the strictness of the convexity is dropped from the conditions.

Following [5], we generalize Question 1 for balls in arbitrary dimensions.

**Question 4.** Are there monohedral tilings of the closed unit ball \( B^d \) such that the center of the ball is not contained in all of the tiles? More specifically, what are the values of \( d \) for which it is possible?

We also raise the following, related problem:

**Question 5.** If \( B^2 \) has a tiling with similar copies of some topological disc \( D \), does it follow that the tiles are congruent? Does it follow that \( B^2 \) has a tiling with congruent copies of \( D \)? Do these properties hold under some additional assumption on the tiles, e.g. if they have piecewise analytic boundaries?

We should finally mention the divisibility problem, in which the topological conditions on the tiles are dropped: A subset of \( \mathbb{R}^d \) is \( m \)-divisible if it can be decomposed into \( m \in \mathbb{N} \) mutually disjoint congruent subsets. It is proved that typical convex bodies are not divisible [15], but balls are not typical in this sense, and they are \( m \)-divisible for large values of \( m \) if \( d \) is divisible by three [8] or \( d \) is even [9].
