#### Abstract

Shrub-depth and rank-depth are dense analogues of the tree-depth of a graph. It is well known that a graph has large tree-depth if and only if it has a long path as a subgraph. We prove an analogous statement for shrub-depth and rank-depth, which was conjectured by Hliněný, Kwon, Obdržálek, and Ordyniak [Tree-depth and vertex-minors, European J. Combin. 2016]. Namely, we prove that a graph has large rank-depth if and only if it has a vertex-minor isomorphic to a long path. This implies that for every integer $t$, the class of graphs with no vertex-minor isomorphic to the path on $t$ vertices has bounded shrubdepth.

[^0]
## 1 Introduction

Nešetřil and Ossona de Mendez [17] introduced the tree-depth of a graph $G$, which is defined as the minimum height of a rooted forest whose closure contains the graph $G$ as a subgraph. This concept has been proved to be very useful, in particular in the study of graph classes of bounded expansion [18. Similar to the grid theorem for tree-width of Robertson and Seymour [24], it is known that a graph has large tree-depth if and only if it has a long path as a subgraph, see [17, Proposition 6.1]. For more information on tree-depth, the readers are referred to the surveys [20, 17] by Nešetřil and Ossona de Mendez.

There have been attempts to define an analogous concept suitable for dense graphs. For tree-width, this line of research has resulted in width parameters such as clique-width [3] and rank-width [22]. In a conference paper published in 2012, Ganian, Hliněný, Nešetřil, Obdržálek, Ossona de Mendez, and Ramadurai 8 introduced the shrub-depth of a graph class, as an extension of tree-depth for dense graphs. Recently, DeVos, Kwon, and Oum [6] introduced the rank-depth of a graph as an alternative to shrubdepth and showed that shrub-depth and rank-depth are equivalent in the following sense.

Theorem 1.1 (DeVos, Kwon, and Oum [6]). A class of graphs has bounded rank-depth if and only if it has bounded shrub-depth.

Theorem 1.1 allows us to work exclusively with rank-depth going forward, and we omit the definition of shrub-depth. The definition of rankdepth is presented in Section 2,

One useful feature of rank-depth is that it does not increase under taking vertex-minors. In other words, if $H$ is a vertex-minor of $G$, then the rank-depth of $H$ is at most that of $G$. This allows us to consider obstructions for having small rank-depth in terms of vertex-minors. DeVos, Kwon, and Oum [6] showed that the rank-depth of the $n$-vertex path is larger than $\log n / \log (1+4 \log n)$ for $n \geqslant 2$ and thus graphs having a long path as a vertex-minor have large rank-depth. Hliněný, Kwon, Obdržálek, and Ordyniak [11] conjectured that the converse is also true. Their original conjecture was stated in terms of shrub-depth but is equivalent by Theorem 1.1. We prove their conjecture as follows.

Theorem 1.2. For every positive integer $t$, there exists an integer $N(t)$ such that every graph of rank-depth at least $N(t)$ contains a vertex-minor isomorphic to the path on $t$ vertices.

Courcelle and Oum [4] showed that there is a $\mathrm{CMSO}_{1}$ transduction that maps a graph to its vertex-minors. Therefore, Theorem 1.2 implies that a class $\mathcal{G}$ of graphs has bounded rank-depth if and only if for every $\mathrm{CMSO}_{1}$ transduction $\tau$, there exists an integer $t$ such that $P_{t} \notin \tau(\mathcal{G})$, which was conjectured by Ganian, Hliněný, Nešetřil, Obdržálek, and Ossona de Mendez [7].

If we apply the same proof for bipartite graphs, then we prove the following theorem on pivot-minors of graphs. Pivot-minors are more restricted in a sense that every pivot-minor of a graph is a vertex-minor but not every vertex-minor is a pivot-minor. This theorem allows us to deduce a corollary for binary matroids of large branch-depth.

Theorem 1.3. For every positive integer $t$, there exists an integer $N(t)$ such that every bipartite graph of rank-depth at least $N(t)$ contains a pivot-minor isomorphic to $P_{t}$.

The paper is organized as follows. In Section 2, we review vertex-minors and rank-depth and prove a few useful properties related to rank-depth. In Section 3, we present the proof of Theorem 1.2, In Section 4, we obtain Theorem 1.3 and discuss its consequence to binary matroids of large branchdepth. Finally, in Section 5 we conclude the paper by giving some remarks on linear $\chi$-boundedness of graphs with no $P_{t}$ vertex-minors.

## 2 Preliminaries and basic lemmas

All graphs in this paper are simple, meaning that neither loops nor parallel edges are allowed. For two sets $X$ and $Y$, we write $X \Delta Y$ for $(X \backslash Y) \cup(Y \backslash X)$.

Let $G$ be a graph. We write $V(G)$ and $E(G)$ for the vertex set and the edge set of $G$, respectively. For a vertex $v$ of $G$, we write $N_{G}(v)$ to denote the set of all neighbors of $v$ in $G$. For a vertex $v$ of $G$, let $G-v$ denote the graph obtained from $G$ by removing $v$ and all edges incident with $v$. For an edge $e$ of $G$, let $G-e$ denote the graph obtained from $G$ by removing $e$. For a vertex subset $S$ of $G$, we write $G[S]$ for the subgraph of $G$ induced by $S$. We write $\bar{G}$ for the complement of $G$; that is, $u$ and $v$ are adjacent in $G$ if and only if they are not adjacent in $\bar{G}$.

We write $A(G)$ for the adjacency matrix of $G$ over the binary field, that is, the $V(G) \times V(G)$ matrix over the binary field such that the $(x, y)$-entry is one if $x \neq y$ and $x$ is adjacent to $y$ in $G$, and zero otherwise. For an $X \times Y$ matrix $M$ and $X^{\prime} \subseteq X, Y^{\prime} \subseteq Y$, we write $M\left[X^{\prime}, Y^{\prime}\right]$ for the $X^{\prime} \times Y^{\prime}$ submatrix of $M$.

Figure 1: The graph $K_{4} \square K_{4}$.

Let $P_{n}$ denote the path on $n$ vertices, and let $K_{n}$ denote the complete graph on $n$ vertices. The radius of a tree is the minimum $r$ such that there is a node having distance at most $r$ from every node.

For two $n$-vertex graphs $G$ and $H$ with fixed orderings $\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ and $\left\{w_{1}, w_{2}, \ldots, w_{n}\right\}$ on their respective vertex sets, let $G \square H$ be the graph with vertex set $V(G) \cup V(H)$ such that $(G \square H)[V(G)]=G,(G \square$ $H)[V(H)]=H$, and for all $i, j \in\{1,2, \ldots, n\}, v_{i} w_{j} \in E(G \square H)$ if and only if $i \geqslant j$. See Figure 1 for an example. An induced subgraph isomorphic to $G \square H$ for some $G$ and $H$ is called a semi-induced half-graph in [19].

### 2.1 Vertex-minors

For a vertex $v$ of a graph $G$, local complementation at $v$ is an operation which results in a new graph $G * v$ on $V(G)$ such that

$$
E(G * v)=E(G) \Delta\left\{x y: x, y \in N_{G}(v), x \neq y\right\} .
$$

For an edge $u v$ of a graph $G$, the operation of pivoting $u v$, denoted $G \wedge u v$, is defined as $G \wedge u v:=G * u * v * u$. See Oum [21] for further background and properties of local complementation and pivoting. In particular, note that if $G$ is bipartite, then so is $G \wedge u v$.

A graph $H$ is locally equivalent to $G$ if $H$ can be obtained from $G$ by a sequence of local complementations. A graph $H$ is pivot equivalent to $G$ if $H$ can be obtained from $G$ by a sequence of pivots. A graph $H$ is a vertexminor of $G$ if $H$ is an induced subgraph of a graph that is locally equivalent to $G$. Finally, a graph $H$ is a pivot-minor of $G$ if $H$ is an induced subgraph of a graph that is pivot equivalent to $G$.

For a subset $S$ of $V(G)$, let $\rho_{G}(S)$ be the rank of the $S \times(V(G) \backslash S)$ submatrix of $A(G)$. This function is called the cut-rank function of $G$. It is easy to show that the cut-rank function is invariant under taking local complementations, again see Oum [21. Thus we have the following fact.

Lemma 2.1. If $H$ is a vertex-minor of $G$ and $X \subseteq V(G)$, then

$$
\rho_{H}(X \cap V(H)) \leqslant \rho_{G}(X) .
$$

The following lemmas will be used to find a long path.
Lemma 2.2 (Kim, Kwon, Oum, and Sivaraman [12, Lemma 5.6]). The graph $K_{n} \boxtimes \overline{K_{n}}$ has a pivot-minor isomorphic to $P_{n+1}$.

Lemma 2.3 (Kwon and Oum [14, Lemma 2.8]). The graph $\overline{K_{n}} \square \overline{K_{n}}$ has a pivot-minor isomorphic to $P_{2 n}$.

### 2.2 Rank-depth

We now review the notion of rank-depth, which was introduced by DeVos, Kwon, and Oum [6]. A decomposition of a graph $G$ is a pair $(T, \sigma)$ of a tree $T$ and a bijection $\sigma$ from $V(G)$ to the set of leaves of $T$. The radius of a decomposition $(T, \sigma)$ is the radius of the tree $T$. For a non-leaf node $v \in V(T)$, the components of the graph $T-v$ give rise to a partition $\mathcal{P}_{v}$ of $V(G)$ by $\sigma$. The width of $v$ is defined to be

$$
\max _{\mathcal{P}^{\prime} \subseteq \mathcal{P}_{v}} \rho_{G}\left(\bigcup_{X \in \mathcal{P}^{\prime}} X\right)
$$

The width of the decomposition $(T, \sigma)$ is the maximum width of a non-leaf node of $T$. We say that a decomposition $(T, \sigma)$ is a $(k, r)$-decomposition of $G$ if the width is at most $k$ and the radius is at most $r$. The rank-depth of a graph $G$ is the minimum integer $k$ such that $G$ admits a $(k, k)$-decomposition. If $|V(G)|<2$, then there is no decomposition and the rank-depth is zero. Note that every tree in a decomposition has radius at least one and therefore the rank-depth of a graph is at least one if $|V(G)| \geqslant 2$.

By Lemma 2.1, it is easy to see the following.
Lemma 2.4 (DeVos, Kwon, and Oum [6]). If $H$ is a vertex-minor of $G$, then the rank-depth of $H$ is at most the rank-depth of $G$.

The next two lemmas will serve as a base case for induction in the proof of Theorem 1.2

Lemma 2.5. Let $G$ be a graph of rank-depth $m$. Then $G$ has a connected component of rank-depth at least $m-1$.

Proof. If $m<2$, then it is trivial, as the one-vertex graph has rank-depth zero. Thus, we may assume that $m \geqslant 2$.

Suppose for contradiction that every connected component of $G$ has rank-depth at most $m-2$. Let $C_{1}, C_{2}, \ldots, C_{t}$ be the connected components of $G$. For each $i \in\{1,2, \ldots, t\}$,

- if $C_{i}$ contains at least two vertices, then we take an $(m-2, m-2)$ decomposition $\left(T_{i}, \sigma_{i}\right)$ where $r_{i}$ is a node of $T_{i}$ having distance at most $m-2$ to every node of $T_{i}$, and
- if $C_{i}$ consists of one vertex, then let $T_{i}$ be the one-node graph on $\left\{r_{i}\right\}$ and let $\sigma_{i}: V\left(C_{i}\right) \rightarrow\left\{r_{i}\right\}$ be the uniquely possible function.

We obtain a new decomposition $(T, \sigma)$ of $G$ by taking the disjoint union of $T_{i}$ 's and adding a new node $r$ and adding edges $r r_{i}$ for all $i \in\{1,2, \ldots, t\}$. For every vertex $v$ of $G$, define $\sigma(v)=\sigma_{i}(v)$ if $v$ is a vertex of $C_{i}$. Then $(T, \sigma)$ has depth at most $m-1$ and width at most $m-2$. This contradicts the assumption that $G$ has rank-depth $m$.

We conclude that $G$ has a connected component of rank-depth at least $m-1$.

The following lemma can be proven similarly to Lemma 2.5, For a graph $G$ of rank-depth $m$ and a non-empty vertex set $A$, it is easy to check that $G-A$ has rank-depth at least $m-|A|$, and by Lemma 2.5, $G-A$ has a connected component of rank-depth at least $m-|A|-1$. But, by a direct argument, we can guarantee that there is a connected component of $G-A$ of rank-depth at least $m-|A|$. We include the full proof for completeness.

Lemma 2.6. Let $G$ be a graph of rank-depth $m$ and $A$ be a non-empty proper subset of $V(G)$. Then $G-A$ has a connected component of rank-depth at least $m-|A|$.

Proof. If $|A| \geqslant m$, then any connected component has rank-depth at least zero. Thus, we may assume that $|A|<m$. This implies that $m \geqslant 2$ as $A$ is non-empty.

Suppose for contradiction that every connected component of $G-A$ has rank-depth at most $m-|A|-1$. Let $C_{1}, C_{2}, \ldots, C_{t}$ be the connected components of $G-A$. For each $i \in\{1,2, \ldots, t\}$,

- if $C_{i}$ contains at least two vertices, then we take an $(m-|A|-1, m-$ $|A|-1)$-decomposition $\left(T_{i}, \sigma_{i}\right)$ where $r_{i}$ is a node of $T_{i}$ having distance at most $m-|A|-1$ to every node of $T_{i}$, and
- if $C_{i}$ consists of one vertex, we set $T_{i}$ to be the one-node graph on $\left\{r_{i}\right\}$ and let $\sigma_{i}: V\left(C_{i}\right) \rightarrow\left\{r_{i}\right\}$ be the uniquely possible function.

We obtain a new decomposition $(T, \sigma)$ of $G$ by taking the disjoint union of $T_{i}$ 's and adding a new node $r$ and adding edges $r r_{i}$ for all $i \in\{1,2, \ldots, t\}$, and additionally appending $|A|$ leaves to $r$ and assigning each vertex of $A$ to a distinct leaf with the map $\sigma$. For every vertex $v$ of $G-A$, define $\sigma(v)=\sigma_{i}(v)$ if $v$ is a vertex of $C_{i}$. Then $(T, \sigma)$ has depth at most $m-|A|$ and width at most $m-1$. Because $|A| \geqslant 1$, this contradicts the assumption that $G$ has rank-depth $m$.

We conclude that $G-A$ has a connected component of rank-depth at least $m-|A|$.

Lemma 2.7. Let $m$ and $d$ be positive integers. Let $G$ be a graph with a vertex partition $(A, B)$ such that connected components of $G[A]$ and $G[B]$ have rank-depth at most $m$ and $\rho_{G}(A) \leqslant d$. Then $G$ has rank-depth at most $m+d+1$.

Proof. Let $C_{1}, \ldots, C_{p}$ be the connected components of $G[A]$, and $D_{1}, \ldots, D_{q}$ be the connected components of $G[B]$. For each $i \in\{1,2, \ldots, p\}$,

- if $C_{i}$ contains at least two vertices, then we take an $(m, m)$-decomposition ( $T_{i}, \sigma_{i}$ ) where $r_{i}$ is a node of $T_{i}$ having distance at most $m$ to every node of $T_{i}$, and
- if $C_{i}$ consists of one vertex, then set $T_{i}$ as the one-node graph on $\left\{r_{i}\right\}$ and $\sigma_{i}: V\left(C_{i}\right) \rightarrow\left\{r_{i}\right\}$ as the uniquely possible function.

Similarly, we define $\left(F_{j}, \mu_{j}\right)$ for each $D_{j}$ where $f_{j}$ is a node of $F_{j}$ having distance at most $m$ to every node of $F_{j}$.

Now, we obtain a new decomposition $(T, \sigma)$ of $G$ as follows. Let $T$ be the tree obtained by taking the disjoint union of all of $T_{i}$ 's and $F_{j}$ 's, adding new vertices $x$ and $y$, an edge $x y$, edges $x r_{i}$ for all $i \in\{1, \ldots, p\}$, and edges $y f_{j}$ for all $j \in\{1, \ldots, q\}$. Define $\sigma(v)=\sigma_{i}(v)$ if $v$ is a vertex of $C_{i}$, and $\sigma(v)=\mu_{j}(v)$ if $v$ is a vertex of $D_{j}$. Then $(T, \sigma)$ has depth at most $m+2$ and width at most $m+d$. Because $d \geqslant 1, G$ has rank-depth at most $\max \{m+2, m+d\} \leqslant m+d+1$.

### 2.3 Rank-width

We now review the definition of rank-width. A rank-decomposition of a graph $G$ is a pair $(T, L)$ of a tree $T$ whose vertices each have degree either
one or three, and a bijection $L$ from $V(G)$ to the set of leaves of $T$. The width of an edge $e$ of $T$ is the cut-rank in $G$ of the set of all leaves assigned to one of the components of $T-e$. The width of the rank-decomposition $(T, L)$ is the maximum width of an edge of $T$. Finally, the rank-width of $G$ is the minimum width over all rank-decompositions of $G$. Graphs with at most one vertex do not admit rank-decompositions and we define their rank-width to be zero.

## 3 The proof

We write $R(n ; k)$ to denote the minimum number $N$ such that every coloring of the edges of $K_{N}$ with $k$ colors induces a monochromatic complete subgraph on $n$ vertices. The classical theorem of Ramsey [23] implies that $R(n ; k)$ exists.

The following lemma is well known. We include its proof for the sake of completeness.

Lemma 3.1. Let $G$ be a graph of rank-width at most $q$ and let $M \subseteq V(G)$. If $|M| \geqslant 3 k+1$ for a positive integer $k$, then there is a vertex partition $(X, Y)$ of $G$ such that $\rho_{H}(X) \leqslant q$ and $\min (|M \cap X|,|M \cap Y|)>k$.

Proof. Suppose that there is no such vertex partition. Let $(T, L)$ be a rankdecomposition of width at most $q$. For each edge $u v$ of $T$, let us orient $e$ towards $v$ if the component of $T-e$ containing $u$ has at most $k$ vertices in $L(M)$. By the assumption, every edge is oriented. Since $T$ is acyclic, there is a node $w$ of $T$ such that all edges of $T$ incident with $w$ are oriented towards $w$. But this implies that $|M| \leqslant 3 k$, a contradiction.

For a path $P$ with an endpoint $x$ and a graph $H$ and a non-empty subset of vertices $S \subseteq V(H)$, we denote by $(P, x)+(H, S)$ the graph obtained from the disjoint union of $P$ and $H$ by adding all edges between $x$ and $S$. We now prove our main proposition; Theorem 1.2 will follow quickly after.

Proposition 3.2. For all positive integers $a, b, t, q$, there exists an integer $f(a, b, t, q)$ such that every graph of rank-width at most $q$ and rank-depth at least $f(a, b, t, q)$ has a vertex-minor isomorphic to either $P_{t}$ or $\left(P_{a}, x\right)+$ $(H, S)$ where $x$ is an endpoint of $P_{a}, H$ is a connected graph of rank-depth at least $b$, and $S$ is a non-empty subset of $V(H)$.
Proof. For all positive integers $b, t, q$, we set

$$
f(1, b, t, q):=b+2,
$$

Figure 2: The graph $G_{1}\left[A_{1} \cup \cdots \cup A_{r} \cup V\left(H_{r}\right)\right]$, when $r=3$ and $a=5$.
and for $a \geqslant 2$, we set

$$
\begin{aligned}
& u:=\max \left(3 \cdot\left(2^{q}-1\right)+1, t-1\right), \\
& r:=R\left(u+1 ; 2^{a-1}\right), \\
& g_{i}:= \begin{cases}b+q+2 & \text { if } i=r, \\
f\left(a-1, g_{i+1}, t, q\right) & \text { if } i \in\{0,1,2, \ldots, r-1\},\end{cases} \\
& f(a, b, t, q):=g_{0} .
\end{aligned}
$$

We prove the proposition by induction on $a$. Let $G$ be a graph whose rankdepth is at least $f(a, b, t, q)$ and rank-width is at most $q$. If $a=1$, then it has a component $G^{\prime}$ of rank-depth at least $b+1$ by Lemma 2.5. Let $v \in V\left(G^{\prime}\right)$. By Lemma 2.6, $G^{\prime}-v$ has a connected component $H$ of rank-depth at least b. So, $\left(G^{\prime}[\{v\}], v\right)+\left(H, N_{G}(v) \cap V(H)\right)$ is the second outcome.

Thus, we may assume that $a \geqslant 2$. Suppose that $G$ has no vertex-minor isomorphic to $P_{t}$. We claim that $G$ contains the second outcome.

Let $H_{0}:=G$. Observe that $H_{0}$ has rank-depth at least $f(a, b, t, q)=g_{0}$.
For $i \in\{1,2, \ldots, r\}$, we recursively find tuples $\left(A_{i}, x_{i}, H_{i}, S_{i}\right)$ from $H_{i-1}$ such that

- $A_{i}$ is isomorphic to $P_{a-1}$ and $x_{i}$ is an endpoint of $A_{i}$,
- $H_{i}$ is a connected graph of rank-depth at least $g_{i}$,
- $S_{i}$ is a non-empty subset of $V\left(H_{i}\right)$, and
- $\left(A_{i}, x_{i}\right)+\left(H_{i}, S_{i}\right)$ is a vertex-minor of $H_{i-1}$.

Let $i \in\{1,2, \ldots, r\}$ and assume that $H_{i-1}$ is a given graph of rank-depth at least $g_{i-1}$. Then by the induction hypothesis, $H_{i-1}$ has a vertex-minor $\left(A_{i}, x_{i}\right)+\left(H_{i}, S_{i}\right)$ where $A_{i}$ is isomorphic to $P_{a-1}, x_{i}$ is an endpoint of $A_{i}$,
$H_{i}$ is a connected graph of rank-depth at least $g_{i}$, and $S_{i}$ is a non-empty subset of $V\left(H_{i}\right)$. By the choice of functions $g_{0}, g_{1}, \ldots, g_{r}$, we can obtain the tuples for all $i \in\{1,2, \ldots, r\}$.

Observe that for $i<j$, no vertex in $V\left(A_{i}\right) \backslash\left\{x_{i}\right\}$ has a neighbor in $H_{i}$, and therefore, the sequence of local complementations to obtain $\left(A_{j}, x_{j}\right)+$ $\left(H_{j}, S_{j}\right)$ from $H_{j-1}$ does not change previous paths $A_{1}, \ldots, A_{j-1}$, but may change the edges between $x_{1}, x_{2}, \ldots, x_{j-1}$.

By definition, $H_{r}$ is connected and has rank-depth at least $g_{r}$. Let $G_{1}$ be the graph obtained from $G$ by following the sequence of local complementations to obtain $\left(A_{1}, x_{1}\right)+\left(H_{1}, S_{1}\right), \ldots,\left(A_{r}, x_{r}\right)+\left(H_{r}, S_{r}\right)$. See Figure 2 for a depiction. Note that $G_{1}\left[V\left(H_{i}\right) \cup\left\{x_{i}\right\}\right]$ is connected for each $i$, as $H_{i}$ is connected, $S_{i}$ is non-empty, and we apply local complementations only inside $H_{i}$ to obtain later $H_{j}$ 's.

If for some $i \in\{1,2, \ldots, r\}, N_{G_{1}}\left(x_{i}\right) \cap V\left(H_{r}\right)=\varnothing$, then by taking a shortest path from $x_{i}$ to $V\left(H_{r}\right)$ in the graph $G_{1}\left[V\left(H_{i}\right) \cup\left\{x_{i}\right\}\right]$, we can directly obtain the second outcome. So, we may assume that each of $\left\{x_{1}, x_{2}, \ldots, x_{r}\right\}$ has a neighbor in $V\left(H_{r}\right)$.

Note that for $i<j$, only the endpoint $x_{i}$ in $A_{i}$ can have a neighbor in $A_{j}$ in $G_{1}$, and therefore, there are $2^{a-1}$ possible ways of having edges between $A_{i}$ and $A_{j}$ in $G_{1}$. Since $r=R\left(u+1 ; 2^{a-1}\right)$, by applying the theorem of Ramsey, we deduce that there exists a subset $W \subseteq\{1,2, \ldots, r\}$ of size $u+1$ such that for all $i<j$ with $i, j \in W,\left\{\ell:\right.$ the $\ell$-th vertex of $A_{j}$ is adjacent to $x_{i}$ in $\left.G_{1}\right\}$ are identical.

If $x_{i}$ has a neighbor in $V\left(A_{j}-x_{j}\right)$ in $G_{1}$ for some $i<j$ with $i, j \in W$, then $G_{1}$ has $\overline{K_{u}} \square \overline{K_{u}}$ or $\overline{K_{u}} \square K_{u}$ as an induced subgraph. Since $u \geqslant$ $t-1$, by Lemmas 2.2 and $2.3, G_{1}$ contains a pivot-minor isomorphic to $P_{t}$, contradicting the assumption. So, for all $i<j$ with $i, j \in W, x_{i}$ has no neighbors in $V\left(A_{j}-x_{j}\right)$.

Note that $\left\{x_{i}: i \in W\right\}$ is an independent set or a clique in $G_{1}$. If it is an independent set, then for some $i^{\prime} \in W$, we set

- $G_{2}:=G_{1}$ and $W^{\prime}:=W \backslash\left\{i^{\prime}\right\}$.

If $\left\{x_{i}: i \in W\right\}$ is a clique, then we choose a vertex $x_{i^{\prime}}$ for some $i^{\prime} \in W$ and locally complement at $x_{i^{\prime}}$. Then $\left\{x_{i}: i \in W \backslash\left\{i^{\prime}\right\}\right\}$ becomes an independent set. We set

- $G_{2}:=G_{1} * x_{i^{\prime}}$ and $W^{\prime}:=W \backslash\left\{i^{\prime}\right\}$.

Let $M:=\left\{x_{i}: i \in W^{\prime}\right\}$ and $H:=G_{2}\left[V\left(H_{r}\right) \cup M \cup\left\{x_{i^{\prime}}\right\}\right]$.
By definition, $H$ is locally equivalent to the graph $G_{1}\left[V\left(H_{r}\right) \cup M \cup\left\{x_{i^{\prime}}\right\}\right]$. Thus, as the latter is connected, $H$ is also connected. Similarly, since $H_{r}=$
$G_{1}\left[V\left(H_{r}\right)\right]$ has rank-depth at least $g_{r}, H$ has rank-depth at least $g_{r}$. Also, note that $H$ has rank-width at most $q$ and $M$ is an independent set of size $u \geqslant 3 \cdot\left(2^{q}-1\right)+1$ in $H$. Thus, by Lemma 3.1, $H$ admits a vertex partition $(X, Y)$ such that $|M \cap X|>2^{q}-1,|M \cap Y|>2^{q}-1$, and $\rho_{H}(X) \leqslant q$.

Since $H$ has rank-depth at least $g_{r}=b+q+2$ and $\rho_{H}(X) \leqslant q$, by Lemma [2.7, $H[X]$ or $H[Y]$ has a connected component of rank-depth at least $b+1$. Without loss of generality, we assume that $H[X]$ has a connected component $Q$ of rank-depth at least $b+1$.

Now, if $M \cap Y$ has a vertex $x_{i}$ that has no neighbor in $Q$, then by taking a shortest path from $x_{i}$ to $Q$ in $H$, along with $A_{i}$, we can find the second outcome.

Thus, we may assume that in $H$, all vertices in $M \cap Y$ have a neighbor in $Q$. Since $\rho_{H}(X) \leqslant q$, there are at most $2^{q}-1$ distinct non-zero rows in the matrix $A(H)[M \cap Y, V(Q)]$. As $|M \cap Y| \geqslant 2^{q}$, by the pigeon-hole principle, $H$ has two vertices $x_{i_{1}}$ and $x_{i_{2}}$ in $M \cap Y$ for some $i_{1}, i_{2} \in W^{\prime}$ that have the same neighborhood in $Q$.

First assume that $x_{i_{1}}$ has exactly one neighbor in $Q$, say $w$. As $Q$ has rank-depth at least $b+1, Q-w$ has a connected component $Q^{\prime}$ having rank-depth at least $b$ by Lemma [2.6. Then

$$
\left(G_{2}\left[V\left(A_{i_{1}}\right) \cup\{w\}\right], w\right)+\left(Q^{\prime}, N_{G_{2}}(w) \cap V\left(Q^{\prime}\right)\right)
$$

is the required second outcome. So, we may assume that $x_{i_{1}}$ has at least two neighbors in $Q$. Let $w$ be a neighbor of $x_{i_{1}}$ in $Q$.

Since $x_{i_{1}}$ and $x_{i_{2}}$ have the same neighborhood in $Q$ and they are not adjacent, if we pivot $x_{i_{2}} w$, then the edges between $x_{i_{1}}$ and $N_{H}\left(x_{i_{1}}\right) \cap V(Q)$ are removed and $x_{i_{2}}$ becomes the unique neighbor of $x_{i_{1}}$ in $V(Q) \cup\left\{x_{i_{2}}\right\}$. Note that $G_{2}\left[V(Q) \cup\left\{x_{i_{2}}\right\}\right]$ is connected, and thus $\left(G_{2} \wedge x_{i_{2}} w\right)\left[V(Q) \cup\left\{x_{i_{2}}\right\}\right]$ is also connected. As $Q$ has rank-depth at least $b+1,\left(G_{2} \wedge x_{i_{2}} w\right)[V(Q) \cup$ $\left.\left\{x_{i_{2}}\right\}\right]-x_{i_{2}}$ has a connected component $Q^{\prime}$ that has rank-depth at least $b$. Then

$$
\left(\left(G_{2} \wedge x_{i_{2}} w\right)\left[V\left(A_{i_{1}}\right) \cup\left\{x_{i_{2}}\right\}\right], x_{i_{2}}\right)+\left(Q^{\prime}, N_{G_{2} \wedge x_{i_{2}} w}\left(x_{i_{2}}\right) \cap V\left(Q^{\prime}\right)\right)
$$

is the second outcome. This proves the proposition.
Proposition 3.2 implies the following result.
Theorem 3.3. For all positive integers $t$ and $q$, there exists an integer $F(t, q)$ such that every graph of rank-width at most $q$ and rank-depth at least $F(t, q)$ contains a vertex-minor isomorphic to $P_{t}$.

Proof. We take $F(t, q):=f(t-1,1, t, q)$ where $f$ is the function in Proposition 3.2,

A circle graph is the intersection graph of chords on a circle. It is easy to see that $P_{t}$ is a circle graph. We can derive Theorem 1.2 by taking $q=\beta\left(P_{t}\right)$ from the following recent theorem.

Theorem 3.4 (Geelen, Kwon, McCarty, and Wollan [10]). For every circle graph $H$, there exists an integer $\beta(H)$ such that every graph of rank-width more than $\beta(H)$ contains a vertex-minor isomorphic to $H$.

Theorem 1.2. For every positive integer $t$, there exists an integer $N(t)$ such that every graph of rank-depth at least $N(t)$ contains a vertex-minor isomorphic to $P_{t}$.

Proof. We take $N(t):=F\left(t, \beta\left(P_{t}\right)\right)$ where $\beta$ is the function given in Theorem 3.4 and $F$ is the function from Theorem 3.3. If a graph has rank-width more than $\beta\left(P_{t}\right)$, then by Theorem [3.4, it contains a vertex-minor isomorphic to $P_{t}$. So, we may assume that a graph has rank-width at most $\beta\left(P_{t}\right)$. Then by Theorem [3.3, it contains a vertex-minor isomorphic to $P_{t}$.

## 4 Pivot-minors

We can prove a stronger result on bipartite graphs, by slightly modifying the proof of Proposition 3.2. Suppose that a given graph $G$ is bipartite in the proof of Proposition 3.2. The only place that we have to apply local complementation instead of pivoting is when the set $\left\{x_{i}: i \in W\right\}$ is a clique, and we want to change it into an independent set. But if $G$ is bipartite, then the obtained set $\left\{x_{i}: i \in W\right\}$ has no triangle, and so it is an independent set since $|W| \geqslant 3$. Therefore, we can proceed only with pivoting. For bipartite graphs, we can use the following theorem due to Oum [21], obtained as a consequence of the grid theorem for binary matroids (9).

Theorem 4.1 (Oum [21). For every bipartite circle graph $H$, there exists an integer $\gamma(H)$ such that every bipartite graph of rank-width more than $\gamma(H)$ contains a pivot-minor isomorphic to $H$.

Thus we deduce the following theorem for bipartite graphs.
Theorem 1.3, For every positive integer $t$, there exists an integer $N(t)$ such that every bipartite graph of rank-depth at least $N(t)$ contains a pivot-minor isomorphic to $P_{t}$.

Figure 3: The fan graph $F_{5}$.

Theorem 1.3 allows us to obtain the following corollary for binary matroids, solving a special case of a conjecture of DeVos, Kwon, and Oum [6] on general matroids. We need a few terms to state the corollary. The branchdepth of a matroid is defined analogously to the definition of the rank-depth obtained by replacing the cut-rank function with the matroid connectivity function [6]. Let $F_{t}$ be the fan graph, that is the union of $P_{t}$ with one vertex adjacent to all vertices of $P_{t}$, see Figure 3. As usual, $M\left(F_{t}\right)$ denotes the cycle matroid of $F_{t}$.

Corollary 4.2. For every positive integer $t$, there exists an integer $N(t)$ such that every binary matroid of branch-depth at least $N(t)$ contains a minor isomorphic to $M\left(F_{t}\right)$.

Proof. It is known [2, 21] that the connectivity function of a binary matroid is equal to the cut-rank function of a corresponding bipartite graph, called a fundamental graph. Furthermore for two binary matroids $M$ and $N$, if $N$ is connected, and a fundamental graph of $N$ is a pivot-minor of a fundamental graph of $M$, then either $N$ or $N^{*}$ is a minor of $M$, see Oum [21, Corollary 3.6]. Since $\left(M\left(F_{t}\right)\right)^{*}$ has a minor isomorphic to $M\left(F_{t-1}\right)$, we deduce the corollary from Theorem 1.3, because the path graph $P_{2 t-1}$ is a fundamental graph of $M\left(F_{t}\right)$.

We show that the class $\left\{K_{n} \square K_{n}: n \geqslant 1\right\}$ has unbounded rank-depth, while for every positive integer $n, K_{n} \boxtimes K_{n}$ has no pivot-minor isomorphic to $P_{5}$. It implies that contrary to Theorem [1.3, the class of graphs having no $P_{n}$ pivot-minor has unbounded rank-depth for each $n \geqslant 5$.

Kwon and Oum [16, Lemma 6.5] showed that for every integer $n \geqslant 2$, $K_{n} \boxtimes K_{n}$ contains a vertex-minor isomorphic to $P_{2 n-2}$. Thus, $\left\{K_{n} \square K_{n}\right.$ : $n \geqslant 1\}$ has unbounded rank-depth.

Now, we show that for $n \geqslant 1, K_{n} \boxtimes K_{n}$ has no pivot-minor isomorphic to $P_{5}$. We prove a stronger statement that $K_{n} \boxtimes K_{n}$ has no pivot-minor isomorphic to $K_{1,3}$. Dabrowski et al. 5] characterized the class of graphs having no pivot-minor isomorphic to $K_{1,3}$ in terms of forbidden induced subgraphs. See Figure 4 for bull, $W_{4}$, and $\overline{B W_{3}}$.

Figure 4: The graphs bull, $W_{4}$, and $\overline{B W_{3}}$.

Theorem 4.3 (Dabrowski et al. [5]). A graph has a pivot-minor isomorphic to $K_{1,3}$ if and only if it has an induced subgraph isomorphic to one of $K_{1,3}$, $P_{5}$, bull, $W_{4}$, and $\overline{B W_{3}}$.

Lemma 4.4. For $n \geqslant 1, K_{n} \square K_{n}$ has no induced subgraph isomorphic to one of $K_{1,3}, P_{5}$, bull, $W_{4}$, and $\overline{B W_{3}}$.

Proof. As the maximum size of an independent set in $K_{n} \square K_{n}$ is $2, K_{n} \square K_{n}$ has no induced subgraph isomorphic to one of $K_{1,3}, P_{5}$, and bull.

Also $K_{n} \boxtimes K_{n}$ has no induced cycle of length 4 because such a cycle should contain two vertices in each $K_{n}$ but the edges between two $K_{n}$ 's have no induced matching of size 2. Therefore, it has no induced subgraph isomorphic to $W_{4}$ or $\overline{B W_{3}}$.

By Theorem4.3 and Lemma 4.4, $K_{n} \square K_{n}$ has no pivot-minor isomorphic to $K_{1,3}$, and to $P_{5}$. Thus, for all $n \geqslant 5$, the class of graphs having no $P_{n}$ pivot-minor includes $\left\{K_{n} \square K_{n}: n \geqslant 1\right\}$, which has unbounded rank-depth. It may be interesting to see whether every graph with sufficiently large rankdepth contains either $P_{n}$ or $K_{n} \square K_{n}$ as a pivot-minor. We leave it as an open question.

Question 1. Does there exist a function $f$ such that for every $n$, every graph with rank-depth at least $f(n)$ contains a pivot-minor isomorphic to $P_{n}$ or $K_{n} \square K_{n}$ ?

## 5 Concluding remarks

### 5.1 Linear $\chi$-boundedness

We define linear rank-width. For an ordering $\left(v_{1}, v_{2}, \ldots, v_{n}\right)$ of the vertex set of a graph $G$, its width is defined as the maximum of $\rho_{G}\left(\left\{v_{1}, \ldots, v_{i}\right\}\right)$ for all $i \in\{1,2, \ldots, n-1\}$, and the linear rank-width of $G$ is defined as the minimum width of all orderings of $G$. If $|V(G)|<2$, then the linear rank-width of $G$ is defined as 0 .

Graphs of bounded rank-depth have bounded linear rank-width, which was already known through the notions of shrub-depth and linear cliquewidth [7]. Kwon and Oum [15] proved it directly as follows.

Proposition 5.1 (Kwon and Oum [15]). Every graph of rank-depth $k$ has linear rank-width at most $k^{2}$.

We write $\chi(G)$ to denote the chromatic number of $G$ and $\omega(G)$ to denote the maximum size of a clique of $G$. A class $\mathcal{C}$ of graphs is $\chi$-bounded if there is a function $f$ such that $\chi(H) \leqslant f(\omega(H))$ for all induced subgraphs $H$ of a graph in $\mathcal{C}$. In addition, if $f$ can be taken as a polynomial function, then $\mathcal{C}$ is polynomially $\chi$-bounded. If $f$ can be taken as a linear function, then $\mathcal{C}$ is linearly $\chi$-bounded.

Proposition 5.2 (Nešetřil, Ossona de Mendez, Rabinovich, and Siebertz [19]). For every positive integer $r$, there exists an integer $c(r)$ such that for every graph $G$ of linear rank-width at most $r$,

$$
\chi(G) \leqslant c(r) \omega(G)
$$

By combining Proposition 5.1 and Proposition 5.2, we can prove the following, which answers a previous question by Kim, Kwon, Oum, and Sivaraman [12].

Theorem 5.3. For every positive integer $t$, the class of graphs with no vertex-minor isomorphic to $P_{t}$ is linearly $\chi$-bounded.

We remark that there is an alternative way to prove Theorem 5.3 without using linear rank-width. First, DeVos, Kwon, and Oum [6, Lemma 4.10] showed that if a graph has rank-depth $k$, then it has an $(a, k)$-shrubbery where

$$
a=(1+o(1)) 2^{\left(2^{2 k+1}\left(2^{2 k+2}-1\right)+1\right) k / 2} .
$$

(Please see [6] for the definition of an $(a, k)$-shrubbery.) Lemma 2.16 of Nešetřil, Ossona de Mendez, Rabinovich, and Siebertz [19] states that every class of bounded shrub-depth can be partitioned into bounded number of vertex-disjoint induced subgraphs, each of which is a cograph. Its (short and easy) proof shows that a graph with an ( $a, k)$-shrubbery can be partitioned into at most $a$ vertex-disjoint induced subgraphs, each of which is a cograph. Since cographs are perfect, we deduce that if $G$ has rank-depth at most $k$, then $\chi(G) \leqslant \omega(G)(1+o(1)) 2^{\left(2^{2 k+1}\left(2^{2 k+2}-1\right)+1\right) k / 2}$.

Figure 5: Obstructions for being a vertex-minor of a path.

### 5.2 When does the class of $\mathcal{H}$-vertex-minor-free graphs have bounded rank-depth?

For a set $\mathcal{H}$ of graphs, we say that $G$ is $\mathcal{H}$-minor-free if $G$ has no minor isomorphic to a graph in $\mathcal{H}$, and $G$ is $\mathcal{H}$-vertex-minor-free if $G$ has no vertexminor isomorphic to a graph in $\mathcal{H}$. Robertson and Seymour [24] showed that $\mathcal{H}$-minor-free graphs have bounded tree-width if and only if $\mathcal{H}$ contains a planar graph. As an analogue, Geelen, Kwon, McCarty, and Wollan 10 showed that $\mathcal{H}$-vertex-minor-free graphs have bounded rank-width if and only if $\mathcal{H}$ contains a circle graph. Interestingly, Theorem 1.2 allows us to characterize the classes $\mathcal{H}$ such that $\mathcal{H}$-vertex-minor-free graphs have bounded rank-depth. This is due to the following theorem; the equivalence between (a) and (b) was shown by Kwon and Oum 13 and the equivalence between (a) and (c) was shown by Adler, Farley, and Proskurowski [1].

Theorem 5.4 (Kwon and Oum [13]; Adler, Farley, and Proskurowski [1). Let $H$ be a graph. The following are equivalent.
(a) H has linear rank-width at most one.
(b) $H$ is a vertex-minor of a path.
(c) $H$ has no vertex-minor isomorphic to $C_{5}, N$, or $Q$ in Figure 5 .

We define linear rank-width in the next subsection. Here, we only need the fact that linear rank-width does not increase when we take vertex-minors and that paths have linear rank-width 1 and arbitrary large rank-depth to deduce the following corollary from Theorems 5.4 and 1.2 .

Corollary 5.5. Let $\mathcal{H}$ be a set of graphs. Then the following are equivalent.
(a) The class of $\mathcal{H}$-vertex-minor-free graphs has bounded rank-depth.
(b) $\mathcal{H}$ contains a graph of linear rank-width at most one.
(c) $\mathcal{H}$ contains a graph with no vertex-minor isomorphic to $C_{5}, N$, or $Q$.

Acknowledgement. The authors would like to thank anonymous reviewers for their helpful suggestions.
