(Dated: January 17, 2020)

We propose a scheme for the construction of linear-response functions of an interacting electronic system via quantum phase estimation and statistical sampling on a quantum computer. By using the unitary decomposition of electronic operators for avoiding the difficulty due to their nonunitarity, we provide the circuits equipped with ancillae for probabilistic preparation of qubit states on which the necessary nonunitary operators have acted. We perform simulations of such construction of the charge and spin response functions and photoabsorption cross sections for C$_2$ and N$_2$ molecules by comparing with the results from full configuration-interaction calculations. It is found that the accurate detection of subtle structures coming from the weak poles in the response functions requires a large number of measurements.

I. INTRODUCTION

Since the information carrier of a programmable quantum computer is a set of qubits that exploits the principle of superposition, essentially parallel algorithms can exist and perform computation for classically formidable problems. Quantum chemistry is believed to be one of the most suitable research fields for quantum computation since its problem setting is quantum mechanical by definition. Indeed, a quantum computer can treat a many-electron state composed of lots of Slater determinants as it is in a sense that the electronic state is encoded as a superposition of qubit states via an appropriately chosen map such as the Jordan–Wigner (JW) transformations.

The quantity which a quantum chemistry calculation is asked to first provide is the total energy of a target system. One of the most widespread methods for obtaining the total energy is the variational quantum eigensolver (VQE), in which a trial many-electron state is prepared via a parametrized quantum circuit. The parameters are optimized iteratively with the aid of a classical computer aiming at the ground state. This approach was first realized by using a quantum photonic device, after which the realizations by superconducting and ion trap quantum computers have been reported. There exist algorithms for obtaining the energy spectra of excited states.

Not only academic interest but also industrial demands for accurate explanations and predictions of material properties make it an urgent task to develop methodologies on quantum computers for various electronic properties other than energy levels. The one-particle Green’s functions (GFs) are important in correlated electronic systems since they are often used in explanation of spectra measured in photoemission and its inverse experiments. Recently we proposed a method for the GFs by focusing on noisy intermediate-scale quantum (NISQ) devices.

The charge and spin response functions, formulated in the linear-response theory, describe the leading contributions to the electric and magnetic excitations when perturbation fields are applied to a target system. Since the response functions are the fundamental building blocks in constructing the elaborated methods for correlated electrons such as GW theory, the accurate calculation of them is needed. In addition, there exist response functions directly related to measurable quantities such as dielectric constants, electric conductivities, and magnetic susceptibilities.

Given the recent rapid development of fabrication techniques for quantum hardware and the growing demands for quantum computation in material science, it is worth making tools for analyses on correlation effects. In this study, we propose a scheme for the construction of the response functions of an interacting electronic system via statistical sampling on a quantum computer. For examining the validity of our scheme, we perform simulations of such construction of the response functions of diatomic molecules by referring to the full configuration-interaction (FCI) results.

This paper is organized as follows. In Section II, we explain the basic ideas and our scheme in detail by providing the quantum circuits for obtaining the response functions via statistical sampling. In Section III, we describe the computational details for our simulations on a classical computer. In Section IV, we show the simulation results for C$_2$ and N$_2$ molecules. In Section V, we provide the conclusions.

II. METHODS

A. Circuit for a linear combination of unitaries

The calculation of a physical quantities of interest quite often involves the evaluation of matrix elements of various electronic operators. Such an operator is, however,
FIG. 1. Circuit $C_{O}$ for the probabilistic preparation of a state on which a linear combination $O$ of $2^{n}$ unitaries have acted. $H$ in the circuit represents the Hadamard gate. The desired state is prepared according to a measurement outcome of $n$ ancillary qubits. This circuit contains $C^{(n)}$ as a partial circuit defined in Fig. 2.

not necessarily unitary and it prohibits one from implementing it straightforwardly as logic gates for qubits. We describe a workaround for this difficulty by providing a circuit for probabilistic state preparation.

For $2^{n}$ unitaries $U_{k}$, where $k$ is a bit string of length $n$, we want to apply an arbitrary linear combination of them

$$O = c_{0...00}U_{0...00} + c_{0...01}U_{0...01} + \cdots + c_{1...11}U_{1...11}$$

(1)

to an input register $|\psi\rangle$. We can assume that all the coefficients $c$ are real and $c_{0...00} = 1$ without loss of generality. We construct a circuit $C_{O}$ equipped with $n$ ancillary qubits, as depicted in Fig. 1, containing a partial circuit $C^{(n)}$ defined recursively in Fig. 2. If the measurement outcome for the ancillae is $|0\rangle^{\otimes n}$, the state of whole system collapses to $|0\rangle^{\otimes n} \otimes O|\psi\rangle$ up to a normalization constant. The proof of this fact is provided in Appendix A.

The state preparation techniques for the response functions described below are special cases of the one introduced above.

B. Definitions for linear responses

1. Linear-response functions

We work with the $n_{\text{ orbs}}$ orthonormalized spatial one-electron orbitals for each spin direction in a target $N$-electron system, which we assume is in the many-electron ground state $|\Psi_{gs}\rangle$ at zero temperature. The formalism described below can be easily extended to a system with multiple ground states and/or a nonzero temperature.

The response functions in terms of Hermitian operators $O$ and $O'$ in time domain is defined as

$$\chi_{OO'}(t, t') \equiv -i\theta(t - t') \langle [O(t), O'(t')],$$

(2)

where $O(t)$ is the operator in the Heisenberg picture and the expectation value is for the ground state. We assume that the system has been in the equilibrium when the perturbation is turned on. Since the response function defined in eq. (2) depends on time only via $t - t'$ in this case, its expression in frequency domain is written as

$$\chi_{OO'}(\omega) = R_{OO'}(\omega + i\delta) + R_{OO'}(-\omega - i\delta)$$

(3)

for a real frequency $\omega$.

$$R_{OO'}(z) \equiv \sum_{\lambda} \frac{L_{\lambda}O_{OO'}}{z - (E_{\lambda} - E_{gs}^{N})}$$

(4)

is the Lehmann summation over the energy eigenstates for a complex frequency $z$. $E_{gs}^{N}$ is the ground-state energy and $E_{\lambda}$ is the energy eigenvalue of the $\lambda$th excited state $|\Psi_{\lambda}\rangle$.

$$L_{\lambda}O_{OO'} \equiv \langle \Psi_{gs}|O|\Psi_{\lambda}\rangle \langle \Psi_{\lambda}|O'|\Psi_{gs}\rangle$$

(5)

is the transition matrix element, which satisfies clearly $L_{\lambda}O_{OO'} = (L_{\lambda}O_{OO'})^*$.

The positive infinitesimal constant $\delta$ appears in eq. (3) due to the retarded nature of the response function, rendering all the poles immediately below the real axis. It is clear that the real part of $\chi_{OO'}(\omega)$ is even with respect to $\omega$, while the imaginary part is odd.

2. Charge and spin responses

By using the creation $a_{p\sigma}^{+}$ and annihilation $a_{p\sigma}$ operators for the $p$th spatial orbital of $\sigma$ spin $|\sigma_{p}\rangle$ ($\sigma = \alpha, \beta$), the electron number operator is given by $n_{p\sigma} = a_{p\sigma}^{+}a_{p\sigma}$. The spin operator is given by $S_{p} = \sum_{\sigma, \sigma'} a_{p\sigma}^{+}(\sigma^{1}_{\sigma\sigma'}/2)a_{p\sigma'}$, where $\sigma^{1}$ is the Pauli matrix for the electronic state.

The orbital-wise response functions involving the charge and spin of the individual spin orbitals are obtained by putting $O_{pn} = \sum_{\sigma} n_{p\sigma}$ and $O_{pj} \equiv s_{pj}$ ($j = x, y, z$), respectively, into eq. (4). To rewrite the expression for transition matrix elements in eq. (5) into a more tractable form, we define the charge-change transition matrix element

$$N_{\lambda p\sigma, p'\sigma'} \equiv \langle \Psi_{gs}|n_{p\sigma}|\Psi_{\lambda}\rangle \langle \Psi_{\lambda}|n_{p'\sigma'}|\Psi_{gs}\rangle$$

(6)

for the $\lambda$th energy eigenstate $|\Psi_{\lambda}\rangle$ of the $N$-electron states. We define similarly the spin-spin one

$$S_{\lambda p j, p' j'} \equiv \langle \Psi_{gs}|s_{pj}|\Psi_{\lambda}\rangle \langle \Psi_{\lambda}|s_{p'j'}|\Psi_{gs}\rangle$$

(7)

for $j, j' = x, y, z$ and the spin-change one

$$M_{\lambda p j, p' j'} \equiv \langle \Psi_{gs}|s_{pj}|\Psi_{\lambda}\rangle \langle \Psi_{\lambda}|n_{p'\sigma'}|\Psi_{gs}\rangle = M'_{\lambda p j, p' j'}.$$ 

(8)

From these matrix elements, we define the following Hermitian matrices $L_{\lambda}$:

$$L_{\lambda_{pn}, p' n} \equiv \sum_{\sigma, \sigma'} N_{\lambda p\sigma, p'\sigma'},$$

(9)

$$L_{\lambda p j, p' j'} \equiv S_{\lambda p j, p' j'},$$

(10)

$$L_{\lambda p j, p' n} \equiv \sum_{\sigma} M_{\lambda p j, p' \sigma},$$

(11)

which are used for eq. (5).
cross section have to obtain the transition matrix elementsronic operators of a target system to the qubit ones such
as the one-electron orbitals. Our scheme is actually appl-
ica to such a generic case for O and O′, for which we
have to obtain the transition matrix elements
\[ B_{\lambda m_1 m_2 m_3 m_4} = \langle \Psi_{gs} | a^\dagger_{m_1} a_{m_2} | \Psi_{\lambda} \rangle \langle \Psi_{\lambda} | a^\dagger_{m_3} a_{m_4} | \Psi_{gs} \rangle, \]
(13)
which satisfy clearly \( B_{\lambda m_1 m_2 m_3 m_4} = (B_{\lambda m_4 m_3 m_2 m_1})^* \).
From them, we sum up the contributions to eq. (5) as
\[ L_{\lambda} O O' = \sum_{m_1, m_2, m_3, m_4} O_{m_1 m_2} O'_{m_3 m_4} B_{\lambda m_1 m_2 m_3 m_4}. \]
(14)
We calculate the electric polarizabilities of molecules in the present study as examples for the generic scheme. The contribution from electrons to the electric dipole of a molecule is \( d = -\sum_{m, m'} d_{mm'} a^\dagger_m a_{m'} \), where the negative sign on the right-hand side comes from the electron charge. \( d_{mm'} = \langle \phi_m | r | \phi_{m'} \rangle \) is the matrix element of position operator. The linear electric polarizability tensor \( \alpha_{jj'} (j, j' = x, y, z) \) is defined as the first derivative of the expected electric dipole with respect to an external electric field, obtained via the response function as \( \alpha_{jj'} (\omega) = -\chi_{jj'} (\omega) \), from which the photoabsorption cross section[28] is given by
\[ \sigma (\omega) = \frac{4\pi}{c} \omega \text{Im} \text{Tr} \, \alpha (\omega). \]
(15)
This cross section is a measurable quantity in optical absorption experiments.

4. Unitary decomposition of electronic operators

Although there are alternatives for mapping the electronic operators of a target system to the qubit ones such
while the hole number operator is written as

\[ \tilde{n}_{\rho \sigma} = 1 - n_{\rho \sigma} = \frac{U_{\rho \sigma}^\dagger U_{\rho \sigma}^\dagger + U_{\rho \sigma} U_{\rho \sigma}^\dagger - U_{\rho \sigma}^\dagger U_{\rho \sigma}^\dagger}{4}. \] (19)

We construct a circuit \( C_{\rho \sigma} \) equipped with two ancillary qubits \( |q_0^A\rangle \) and \( |q_0^B\rangle \) by implementing the controlled operations of \( U_{\rho \sigma} \), as depicted in Fig. 3. The whole system consists of the ancillae and an arbitrary input register \( |\psi\rangle \). Its state changes by undergoing the circuit as

\[ |\psi\rangle \rightarrow |0\rangle \otimes |1\rangle \otimes \tilde{n}_{\rho \sigma} |\psi\rangle + |1\rangle \otimes |0\rangle \otimes n_{\rho \sigma} |\psi\rangle \equiv |\Phi_{\rho \sigma}\rangle, \] (20)

since \((a_{\rho \sigma}^\dagger)^2\) and \(a_{\rho \sigma}^2\) vanish due to the Fermi statistics.

The projective measurement \( |0\rangle \otimes |q\rangle \langle q| \otimes I (q = 0, 1) \) on \( |q_0^A\rangle \) is represented by the two operators \( P_q = I \otimes |q\rangle \langle q| \otimes I (q = 0, 1) \). The state of the whole system collapses immediately after the measurement as follows:

\[ |\Phi_{\rho \sigma}\rangle |0\rangle \text{ observed } \rightarrow |1\rangle \otimes |0\rangle \otimes \frac{n_{\rho \sigma}}{\sqrt{\tilde{n}_{\rho \sigma}}} |\psi\rangle \]
prob. \( \|n_{\rho \sigma} |\psi\rangle\|^2 \equiv P_{\rho \sigma} \), (21)

\[ |\Phi_{\rho \sigma}\rangle |1\rangle \text{ observed } \rightarrow |0\rangle \otimes |1\rangle \otimes \frac{\tilde{n}_{\rho \sigma}}{\sqrt{\tilde{n}_{\rho \sigma}}} |\psi\rangle \]
prob. \( \|\tilde{n}_{\rho \sigma} |\psi\rangle\|^2 \equiv \tilde{P}_{\rho \sigma} \). (22)

2. Circuits for off-diagonal components

For mutually different combinations \((\rho, \sigma)\) and \((\rho', \sigma')\) of spatial orbitals and spins, we define the four non-Hermitian auxiliary operators

\[ n_{\rho \sigma, \rho' \sigma'}^\pm = n_{\rho \sigma} \pm \frac{e^{\pm i\pi/4} n_{\rho' \sigma'}}{2} \] (23)

and

\[ \tilde{n}_{\rho \sigma, \rho' \sigma'}^\pm = \tilde{n}_{\rho \sigma} \pm \frac{e^{\pm i\pi/4} \tilde{n}_{\rho' \sigma'}}{2}. \] (24)

Unnormalized auxiliary states \( |\Psi_{\rho \sigma, \rho' \sigma'}^{\pm}\rangle \equiv |\tilde{n}_{\rho \sigma, \rho' \sigma'}^\pm\rangle \) have overlaps \( T_{\lambda \rho \sigma, \rho' \sigma'} \equiv \langle \Psi_{\lambda \rho \sigma, \rho' \sigma'}^{\pm} | \Psi_{\rho \sigma, \rho' \sigma'}^{\pm} \rangle \) with the energy eigenstates, from which the charge-charge transition matrix elements in eq. (6) can be calculated as

\[ N_{\lambda \rho \sigma, \rho' \sigma'} = e^{-i\pi/4} (T_{\lambda \rho \sigma, \rho' \sigma'} + T_{\lambda \rho \sigma, \rho' \sigma'}^\dagger) + e^{i\pi/4} (T_{\lambda \rho \sigma, \rho' \sigma'} - T_{\lambda \rho \sigma, \rho' \sigma'}^\dagger). \] (25)

We construct a circuit \( C_{\rho \sigma, \rho' \sigma'} \) equipped with three ancillary qubits by using the controlled operations of the partial circuits \( U_{\rho \sigma}^\dagger \) and \( U_{\rho' \sigma'}^\dagger \), as depicted in Fig. 3, as depicted in Fig. 4. The whole system consists of the ancillae and an arbitrary input register \( |\psi\rangle \). Its state changes by undergoing the circuit as

\[ |q_2^A = 0\rangle \otimes |q_1^B = 0\rangle \otimes |q_0^A = 0\rangle \otimes |\psi\rangle \]
\[ \rightarrow |0\rangle \otimes |1\rangle \otimes \frac{n_{\rho \sigma}}{\sqrt{\tilde{n}_{\rho \sigma}}} |\psi\rangle + |1\rangle \otimes |0\rangle \otimes n_{\rho \sigma} |\psi\rangle \equiv |\Phi_{\rho \sigma, \rho' \sigma'}^{\pm}\rangle \] (26)

The projective measurement on \( |q_2^A\rangle \) and \( |q_1^A\rangle \) is represented by the four operators \( P_{qq'} = |q\rangle \langle q| \otimes |q'\rangle \langle q'| \otimes I \otimes I (q, q' = 0, 1) \). The two outcomes among the possible four are of interest, immediately after which the whole system collapses as follows:

\[ |\Phi_{\rho \sigma, \rho' \sigma'}^{\pm}\rangle |0\rangle |1\rangle \text{ observed } \rightarrow |0\rangle \otimes |1\rangle \otimes |0\rangle \otimes \frac{n_{\rho \sigma}}{\sqrt{\tilde{n}_{\rho \sigma}}} |\psi\rangle \]
prob. \( \|n_{\rho \sigma}^+ |\psi\rangle\|^2 \equiv P_{\rho \sigma, \rho' \sigma'}^+ \), (27)

\[ |\Phi_{\rho \sigma, \rho' \sigma'}^{\pm}\rangle |1\rangle |1\rangle \text{ observed } \rightarrow |1\rangle \otimes |1\rangle \otimes |0\rangle \otimes \frac{\tilde{n}_{\rho \sigma}}{\sqrt{\tilde{n}_{\rho \sigma}}} |\psi\rangle \]
prob. \( \|\tilde{n}_{\rho \sigma} |\psi\rangle\|^2 \equiv \tilde{P}_{\rho \sigma, \rho' \sigma'}^- \). (28)
3. Transition matrices via statistical sampling

Given the result of a measurement on the ancillary bits for a diagonal or an off-diagonal component, we have the register $|\tilde{\psi}\rangle$ different from the input $N$-electron state. Then we perform QPE for the Hamiltonian $H$ by inputting $|\tilde{\psi}\rangle$ to obtain one of the energy eigenvalues in the Hilbert subspace for the $N$-electron states. A QPE experiment inevitably suffers from probabilistic errors that depend on the number of qubits and the various parameters for the Suzuki–Trotter decomposition of $H$. We assume for simplicity, however, that the QPE procedure is realized on a quantum computer with ideal precision [19]. We will thus find the estimated value to be $E_N^A$ with a probability $|\langle \Phi_A |\tilde{\psi}\rangle|^2$.

If we input $|\Psi_{\text{gs}}\rangle$ to the diagonal circuit $C_{\text{pA}}$ in Fig. 3 and observe the ancillary bit $|q_A^0\rangle = 0$ for QPE, the energy eigenvalue $E_N^A$ will be obtained with a probability [see eq. (21)]

$$
\left|\langle \Psi_A | \frac{n_{p\sigma}}{\sqrt{P_{p\sigma}}} | \Psi_{\text{gs}}\rangle\right|^2 = \frac{1}{P_{p\sigma}} N_{\lambda p\sigma, p\sigma}.
$$

(29)

This means that we can get the diagonal components of transition matrices $N_{\lambda}$ via statistical sampling for a fixed combination of $p$ and $\sigma$.

If we input $|\Psi_{\text{gs}}\rangle$ to the off-diagonal circuit $C_{\text{pA, p'B'}}$ in Fig. 4 and observe the ancillary bits $|q_2^A = 0\rangle \otimes |q_1^0 = 1\rangle$ or $|q_2^A = 1\rangle \otimes |q_1^1 = 1\rangle$ for QPE, the energy eigenvalue $E_N^{A,j}$ will be obtained with probabilities [see eqs. (27) and (28)]

$$
\left|\langle \Psi_A | \frac{n_{p\sigma, p'\sigma'}}{\sqrt{P_{p\sigma, p'\sigma'}}} | \Psi_{\text{gs}}\rangle\right|^2 = \frac{1}{P_{p\sigma, p'\sigma'}} T_{\lambda p\sigma, p'\sigma'}^{+}.
$$

(30)

This means that we can get the off-diagonal components of $N_{\lambda}$ from eq. (25) via statistical sampling for a fixed combination of $p, p', \sigma$, and $\sigma'$.

D. Spin-spin responses

Let us next consider the determination of the spin-spin transition matrix elements $S_{\lambda p j, p' j'}$ for $j, j' = x, y$. Those involving the $z$ components of spins can be calculated from $N_{\lambda}$ by using the relation $s_{pz} = (n_{p\alpha} - n_{p\beta})/2$.

1. Circuits for diagonal components

From the unitary operators in eqs. (16) and (17) for a combination of a spatial orbital $p$ and a spin $\sigma$, we define the following four unitary operators: $U^{(p)}_{0z} \equiv U_{0p\alpha} U_{1p\beta}$, $U^{(p)}_{1x} \equiv -U_{1p\alpha} U_{0p\beta}$, $U^{(p)}_{0y} \equiv -i U_{0p\alpha} U_{0p\beta}$, and $U^{(p)}_{1y} \equiv i U_{0p\alpha} U_{1p\beta}$.

![FIG. 5. Spin-spin diagonal circuit $C_{pj}$ ($j = x, y$) for probabilistic preparation of $s_{pj}|\psi\rangle$ and $\tilde{s}_{pj}|\psi\rangle$ from an arbitrary input state $|\psi\rangle$ and an ancillary qubit. We define the partial circuit $U^{(p)}_j$ by enclosing it with dashed lines.]

$U^{(p)}_j = i U_{1p \sigma} U_{1p \beta}$. With them, the spin operators for the $x$ and $y$ directions are written as

$$
s_{pj} = \frac{U^{(p)}_{pj} + U^{(p)}_{j'}}{4},
$$

(31)

for $j = x, y$. We define

$$
\tilde{s}_{pj} = \frac{U^{(p)}_{pj} - U^{(p)}_{j'}}{4},
$$

(32)

for later convenience.

We construct a circuit $C_{pj}$ equipped with an ancillary qubit by implementing the controlled operations of $U^{(p)}_j$ and $U^{(p)}_{j'}$, as depicted in Fig. 5. The whole system consists of the ancilla and an arbitrary input register $|\psi\rangle$. Its state changes by undergoing the circuit as

$$
|q_A^0\rangle \otimes |\psi\rangle \rightarrow |0\rangle \otimes 2s_{pj}|\psi\rangle + |1\rangle \otimes 2\tilde{s}_{pj}|\psi\rangle \equiv |\Phi_{pj}\rangle.
$$

(33)

The projective measurement on $|q_A^0\rangle$ is represented by the two operators $P_q = |q\rangle \langle q| \otimes I (q = 0, 1)$. The state of the whole system collapses immediately after the measurement as follows:

$$
|\Phi_{pj}\rangle \rightarrow^\text{observed} |0\rangle \otimes 2s_{pj} \sqrt{P_{pj}} |\psi\rangle,
$$

prob. $\|2s_{pj}|\psi\rangle|^2 \equiv P_{pj}$,

$$
|\Phi_{pj}\rangle \rightarrow^\text{observed} |1\rangle \otimes 2\tilde{s}_{pj} \sqrt{P_{pj}} |\psi\rangle,
$$

prob. $\|2\tilde{s}_{pj}|\psi\rangle|^2 \equiv P_{pj}$.

(34)

(35)

2. Circuits for off-diagonal components

For mutually different combinations $(p, j)$ and $(p', j')$ of spatial orbitals and spin components $j, j' = x, y$, we define the four non-Hermitian auxiliary operators

$$
s_{pj, p' j'}^{+} = \frac{s_{pj} \pm e^{i\pi/4} s_{pj j'}}{2},
$$

(36)

and

$$
\tilde{s}_{pj, p' j'}^{+} = \frac{\tilde{s}_{pj} \pm e^{i\pi/4} \tilde{s}_{pj j'}}{2}.
$$

(37)
Unnormalized auxiliary states $|\Phi_{p_j,p_j'}^{\pm}\rangle \equiv s_{p_j,p_j'}^\pm |\Psi_{gs}\rangle$ can have overlaps $T_{\lambda p_j,p_j'}^{\pm} \equiv |\langle \Psi_{\lambda} | \Psi_{p_j,p_j'}^{\pm}\rangle|^2$ with the energy eigenstates, from which the spin-spin transition matrix elements in eq. (7) can be calculated as

$$S_{\lambda p_j,p_j'} = e^{-i\pi/4} (T_{\lambda p_j,p_j'}^+ - T_{\lambda p_j,p_j'}^-) + e^{i\pi/4} (T_{\lambda p_j,p_j'}^- - T_{\lambda p_j,p_j'}^+) \tag{38}$$

We construct a circuit $C_{p_j,p_j'}$ equipped with two ancillary qubits by using the controlled operations of the partial circuits $U^{(p)}_{1}$ and $U^{(\beta)}_{1}$, defined in Fig. 5, as depicted in Fig. 6. The whole system consists of the ancillae and an arbitrary input register $|\psi\rangle$. Its state changes by undergoing the circuit as

$$|q^A_1 = 0\rangle \otimes |q^A_0 = 0\rangle \otimes |\psi\rangle \rightarrow |0\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^+ |\psi\rangle + |1\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^- |\psi\rangle + |1\rangle \otimes |1\rangle \otimes 2\tilde{s}_{p_j,p_j'}^- |\psi\rangle \equiv |\Phi_{p_j,p_j'}^{\pm}\rangle. \tag{39}$$

The projective measurement on $|q^A_1\rangle$ and $|q^A_0\rangle$ is represented by the four operators $P_{qq'} = |q\rangle\langle q| \otimes |q'\rangle\langle q'| \otimes I (q,q' = 0, 1)$. The two outcomes among the possible four are of our interest, immediately after which the whole system collapses as follows:

$$|\Phi_{p_j,p_j'}^{\pm}\rangle \otimes |0\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^+ |\psi\rangle \rightarrow |0\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^+ |\psi\rangle \equiv P_{p_j,p_j'}^{+} |\psi\rangle, \tag{40}$$

$$|\Phi_{p_j,p_j'}^{\pm}\rangle \otimes |1\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^- |\psi\rangle \rightarrow |1\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^- |\psi\rangle \equiv P_{p_j,p_j'}^{-} |\psi\rangle. \tag{41}$$

3. Transition matrices via statistical sampling

We can get the transition matrices $S_{\lambda}$ via statistical sampling similarly to the charge-charge ones. If we input $|\Psi_{gs}\rangle$ to the diagonal circuit $C_{pj}$ in Fig. 5 followed by a measurement and QPE for $H$, the energy eigenvalue $E_{\lambda}$ will be obtained with a probability $\langle \Psi_{\lambda} | \Psi_{pj}^{+}\rangle^2$. If we use the off-diagonal circuit $C_{pj,p_j'}$ in Fig. 6, on the other hand, the energy eigenvalue $E_{\lambda}$ will be obtained with probabilities $4T_{\lambda pj,p_j'}^{\pm}$ depending on the measurement outcome. [See eqs. (40) and (41)]

The off-diagonal components of transition matrices are then calculated from eq. (38).

E. Spin-charge responses

Having found ways to determine the charge-charge and spin-spin contributions, let us consider the determination of the spin-charge transition matrices $M_{\lambda}$.

1. Circuits for off-diagonal components

For combinations $(p, j)$ and $(p', \sigma')$ of spatial orbitals and spin components $j = x, y$ with $\sigma' = \alpha, \beta$, we define the two non-Hermitian auxiliary operators

$$u_{p_j,p_j',\sigma'}^{\pm} = s_{p_j,p_j'} \pm e^{\pm i\pi/4} |n_{p_j,p_j'}^{\sigma'}/2\rangle \langle n_{p_j,p_j'}^{\sigma'}| \equiv P_{p_j,p_j'} |\Psi_{gs}\rangle. \tag{42}$$

Unnormalized auxiliary states $|\Psi_{p_j,p_j'}^{\pm}\rangle \equiv u_{p_j,p_j',\alpha}^\pm |\Psi_{gs}\rangle$ can have overlaps $T_{\lambda p_j,p_j'}^{\pm} \equiv |\langle \Psi_{\lambda} | \Psi_{p_j,p_j'}^{\pm}\rangle|^2$ with the energy eigenstates, from which the spin-charge transition matrix elements in eq. (8) can be calculated as

$$M_{\lambda p_j,p_j'} = e^{-i\pi/4} (T_{\lambda p_j,p_j'}^+ - T_{\lambda p_j,p_j'}^-) + e^{i\pi/4} (T_{\lambda p_j,p_j'}^- - T_{\lambda p_j,p_j'}^+) \equiv \sqrt{2S_{\lambda p_j,p_j'} - N_{\lambda p_j,p_j'}}. \tag{43}$$

We construct a circuit $C_{p_j,p_j',\sigma'}$ equipped with three ancillary qubits by using the controlled operations of the partial circuits $U^{(p)}_{1}$ in Fig. 5 and $U^{(\beta)}_{1}$ in Fig. 3, as depicted in Fig. 7. The whole system consists of the ancillae and an arbitrary input register $|\psi\rangle$. Its state changes by undergoing the circuit as

$$|q^A_1 = 0\rangle \otimes |q^A_0 = 0\rangle \otimes |\psi\rangle \rightarrow |0\rangle \otimes |0\rangle \otimes 2s_{p_j,p_j'}^+ |\psi\rangle + |1\rangle \otimes |0\rangle \otimes 2\tilde{s}_{p_j,p_j'}^- |\psi\rangle + |0\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes |1\rangle \otimes \frac{e^{\pm i\pi/4} n_{p_j,p_j'}^{\sigma'}}{2} |\psi\rangle + |1\rangle \otimes |0\rangle \otimes |0\rangle \otimes (s_{p_j} - e^{\pm i\pi/4} n_{p_j,p_j'}^{\sigma'}) |\psi\rangle \equiv |\Phi_{p_j,p_j'}^{\pm}\rangle \tag{44}$$

The projective measurement on $|q^A_1\rangle$ and $|q^A_0\rangle$ is represented by the four operators $P_{qq'} = |q\rangle\langle q| \otimes I \otimes |q'\rangle\langle q'| \otimes I (q,q' = 0, 1)$. Only one of the four possible outcomes is of our interest, immediately after which the whole system
collapses as follows:
\[
|\Phi^{\pm}_{p_j,p';\sigma'}\rangle \langle \Phi^{\pm}_{p_j,p';\sigma'}| \rightarrow \frac{u^{\pm}_{p_j,p';\sigma'}}{\sqrt{\rho^{\pm}_{p_j,p';\sigma'}}}|\psi\rangle
\]
\[
\text{prob. } \left| u^{\pm}_{p_j,p';\sigma'} |\psi\rangle \right|^2 \equiv \rho^{\pm}_{p_j,p';\sigma'}. (45)
\]

2. Transition matrices via statistical sampling

We can get the transition matrices \(M_{\lambda}\) via statistical sampling similarly to the charge-charge and spin-spin ones. If we input \(|\Psi_{gs}\rangle\) to the off-diagonal circuit \(C_{p_j,p';\sigma'}^{\pm}\) in Fig. 7 followed by a measurement and QPE for \(H\), the energy eigenvalue \(E_{\lambda}\) will be obtained with a probability \(T_{\lambda}^{\pm}_{p_j,p';\sigma'}\). [See eq. (45)] The off-diagonal components of transition matrices are then calculated from eq. (43).

We provide the pseudocodes in Appendix B for the calculation procedures of response functions explained above.

F. Generic cases

Here we describe briefly the scheme for the response function involving generic one-body operators given as eq. (12).

1. Circuits for diagonal components

For a combination of spin orbitals \(m_1\) and \(m_2\), we define the four unitary operators \(U^{(m_1,m_2)}_{\kappa,\kappa'}\equiv U_{\kappa m_1}U_{\kappa' m_2}\) \((\kappa,\kappa'=0,1)\). We construct a circuit \(C_{m_1,m_2}\) equipped with two ancillary qubits by implementing the controlled operations for an arbitrary input register \(|\psi\rangle\), as depicted in Fig. 8. It is easily confirmed that the whole state changes by undergoing the circuit as
\[
|q_0^{A} = 0 \rangle \otimes |q_0^{A} = 0 \rangle \otimes |\psi\rangle
\]
\[
\rightarrow |1 \rangle \otimes |0 \rangle \otimes a_{m_1}^{\dagger} a_{m_2}^{\dagger} |\psi\rangle + \text{(other terms)} \quad (46)
\]

When the target ground state is input, the projective measurement on the two ancillae leads to the probabilistic preparation of \(a_{m_1}^{\dagger} a_{m_2}^{\dagger} |\Psi_{gs}\rangle\), for which the subsequent QPE process gives the “diagonal” matrix element \(B_{m_1,m_2,m_3,m_4}\) [see eq. (13)] via statistical sampling.

The charge-charge diagonal circuit \(C_{p\sigma}\) in Fig. 3 is a special case of the generic circuit described here.

2. Circuits for off-diagonal components

For mutually different combinations \((m_1,m_2)\) and \((m_3,m_4)\) of spin orbitals, we define the two non-Hermitian auxiliary operators
\[
f_{m_1,m_2,m_3,m_4}^{\pm} \equiv \frac{a_{m_1}^{\dagger} a_{m_2}^{\dagger} \pm e^{i\pi/4} a_{m_3}^{\dagger} a_{m_4}^{\dagger}}{2}. \quad (47)
\]

Unnormalized auxiliary states \(|\Psi^{\pm}_{m_1,m_2,m_3,m_4}\rangle = f_{m_1,m_2,m_3,m_4}^{\pm} |\Psi_{gs}\rangle\) can have overlaps \(T_{\lambda}^{m_1,m_2,m_3,m_4} = |\langle \Psi_{\lambda} | \Psi^{\pm}_{m_1,m_2,m_3,m_4}\rangle |^2\) with the energy eigenstates, from which the “off-diagonal” matrix element is calculated as
\[
B_{m_1,m_2,m_3,m_4} = e^{-i\pi/4} (T_{\lambda}^{m_1,m_2,m_3,m_4} - T_{\lambda}^{m_1,m_2,m_3,m_4})
\]
\[
+ e^{i\pi/4} (T_{\lambda}^{m_1,m_2,m_3,m_4} - T_{\lambda}^{m_1,m_2,m_3,m_4}). \quad (48)
\]

We construct a circuit \(C_{m_1,m_2,m_3,m_4}\) equipped with three ancillary qubits by using the controlled operations of the partial circuits defined in Fig. 8, for an arbitrary input register \(|\psi\rangle\). It is easily confirmed that the whole state changes by undergoing the circuit as
\[
|q_0^{A} = 0 \rangle \otimes |q_0^{A} = 0 \rangle \otimes |\psi\rangle
\]
\[
\rightarrow |0 \rangle \otimes |1 \rangle \otimes |0 \rangle \otimes f_{m_2,m_3,m_4}^{\pm} |\psi\rangle 
\]
\[
+ |1 \rangle \otimes |1 \rangle \otimes |0 \rangle \otimes f_{m_1,m_3,m_4}^{\pm} |\psi\rangle + \text{(other terms)}. \quad (49)
\]

When the target ground state is input, the projective measurement on the three ancillae leads to the probabilistic preparation of \(a_{m_1}^{\dagger} a_{m_2}^{\dagger} |\Psi_{gs}\rangle\). This circuit and the similarly constructed \(C_{m_3,m_4,m_1,m_2}\) allows one to calculate \(B_{m_1,m_2,m_3,m_4}\) from eq. (48) via statistical sampling. After obtaining the necessary matrix elements, they are put into eq. (14) to calculate the Lehmann summation.

The charge-charge off-diagonal circuit \(C_{p\sigma}\) in Fig. 4 is a special case of the generic circuit described here.

III. COMPUTATIONAL DETAILS

We adopted STO-6G basis sets as the Cartesian Gaussian-type basis functions[30] for all the elements in our quantum chemistry calculations. The two-electron integrals between the atomic orbitals (AOs) were calculated efficiently.[31] We first performed restricted Hartree-Fock (RHF) calculations to get the orthonormalized molecular orbitals (MOs) in the target systems.
and calculated the two-electron integrals between them, from which we constructed the second-quantized electronic Hamiltonians.

In the FCI calculations for the large target Hilbert subspaces, we performed exact diagonalization of the electronic (not in qubit representation) Hamiltonians by using the Arnoldi method.\[32\] We can take the z axis as the quantization axis for spins without loss of generality since our calculations are nonrelativistic.

We calculated the FCI response functions simply by substituting the necessary quantities into eq. (3). For the simulations of response functions from statistical sampling, we generated random numbers according to the matrix elements between the FCI energy eigenstates to mimic the measurements on ancillae and the ideal QPE procedures. We set \( \delta \) in eq. (3) to 0.01 a.u. throughout the present study.

IV. RESULTS AND DISCUSSION

A. C\(_2\) molecule

We used the experimental bond length of 1.242 Å\[33\] for a C\(_2\) molecule in the RHF calculation and obtained the total energy \( E_{\text{RHF}} = -2045.2939 \text{ eV} \). This system contains six electrons per spin direction which occupy the lowest six MOs, as shown in Fig. 10(a). We found via the subsequent FCI calculation with \( E_{\text{FCI}} = -2052.6918 \text{ eV} \) that the major electronic configuration in the nondegenerate many-electron ground state, denoted by \( X^1\Sigma^+_g \) in spectroscopic notation, is the same as in the RHF solution. The ground state was found via the exact diagonalization of the Hilbert subspace for \( n_\sigma = n_\beta = 6 \), from which we obtained the lowest 2000 among the 44100 energy eigenvalues.

We calculated the response functions \( \chi_{\text{FCI}} \) exact within the FCI solution, from which the components \( \chi_{\text{FCI}}^{1\pi n,1\pi n} \) and \( \chi_{\text{FCI}}^{1\pi \sigma,3\sigma z} \) are plotted in Fig. 11. We also performed simulations of statistical sampling for the construction of response function \( \chi_{\text{FCI-stat}} \) based on our scheme and plotted those for \( N_{\text{meas}} = 10000 \) and 40000. It is seen that \( \chi_{\text{FCI}}^{1\pi n,1\pi n} \) in Fig. 11(a), which involves only the HOMO, is well reproduced by \( \chi_{\text{FCI-stat}}^{1\pi n,1\pi n} \) with \( N_{\text{meas}} = 10000 \). On the other hand, \( \chi_{\text{FCI-stat}}^{1\pi \sigma,3\sigma z} \) in Fig. 11(b) is not accurately reproduced by \( \chi_{\text{FCI-stat}}^{1\pi n,1\pi n} \) with \( N_{\text{meas}} = 10000 \). These results mean that the response involving a weak excitation channel requires a large number of measurements for its accurate reproduction, just like the situation for the GFs.\[19\]

We calculated the photoabsorption cross section \( \sigma_{\text{FCI}} \) from the FCI solution, as shown in Fig. 12. By simulating the process for a generic one-body operator to obtain
the matrix elements in eq. (13), we also calculated the cross section $\sigma_{\text{FCI-\text{stat}}}^{\text{FCI}}$ for $N_{\text{meas}} = 5000$ and 40000 and plotted it in the figure. It is seen that those from sampling can take negative values despite the original definition in eq. (15), which is ensured to be nonnegative. It is due to our naïve implementation of eq. (48) by using random numbers without considering any symmetry. The major peaks in $\sigma_{\text{FCI}}^{\text{FCI}}$ were well reproduced by $\sigma_{\text{FCI-\text{stat}}}^{\text{FCI}}$ with the smaller $N_{\text{meas}}$, while the detailed structure between them required the larger $N_{\text{meas}}$ for the accurate reproduction. Since symmetry-adapted construction of transition matrix elements should reduce the necessary total number of measurements and physically appropriate results, such techniques will be useful as well as in VQE calculations.\cite{cite35}

B. $\text{N}_2$ molecule

We used the experimental bond length of 1.098 Å\cite{cite36} for an $\text{N}_2$ molecule in the RHF calculation and obtained the total energy $E_{\text{RHF}} = -2953.5952$ eV. This system contains seven electrons per spin direction which occupy the lowest seven MOs, as shown in Fig. 10(b). We found via the subsequent FCI calculation with $E_{\text{FCI}} = -2957.9124$ eV that the major electronic configuration in the nondegenerate many-electron ground state is $X^1\Sigma_g^+$ \cite{cite34}, the same as in the RHF solution. The ground state was found via the exact diagonalization of the Hilbert subspace for $n_\pi = n_\sigma = 7$, from which we obtained the lowest 2000 among the 14400 energy eigenvalues.

We calculated the response functions from the FCI solution, from which the components $\chi_{3\sigma n,3\pi n}^{\text{FCI}}$ and $\chi_{3\pi n,1\pi^* n}^{\text{FCI}}$ are plotted in Fig. 13. We also performed simulations for the construction of $\chi_{3\sigma n,3\pi n}^{\text{FCI}}$ and plotted those for $N_{\text{meas}} = 10000$ and 40000. It is seen that $\chi_{3\sigma n,3\pi n}^{\text{FCI}}$ in Fig. 13(a), which involves only the HOMO, is not well reproduced by $\chi_{3\sigma n,3\pi n}^{\text{FCI-\text{stat}}}$ with $N_{\text{meas}} = 10000$, in contrast to the C$_2$ molecule case. Since the strength of $\chi_{3\pi n,1\pi^* n}^{\text{FCI}}$ in Fig. 13(b) is similar to that of $\chi_{3\sigma n,3\sigma n}^{\text{FCI}}$, $N_{\text{meas}} = 10000$ is not sufficient for the accurate reproduction of correct values as well. We found that $\chi_{3\pi z,1\pi^* z}^{\text{FCI}}$ (not shown) is much weaker and even $N_{\text{meas}} = 40000$ is insufficient for obtaining good $\chi_{3\pi z,1\pi^* z}^{\text{FCI-\text{stat}}}$.

We calculated the photoabsorption cross section $\sigma_{\text{FCI}}^{\text{FCI}}$ from the FCI solution, as shown in Fig. 14. Those from simulations of measurements $\sigma_{\text{FCI-\text{stat}}}^{\text{FCI}}$ for $N_{\text{meas}} = 5000$
and 40000 are also shown in the figure.

V. CONCLUSIONS

We proposed a scheme for the construction of linear-response functions of an interacting electronic system via QPE and statistical sampling on a quantum computer. By using the unitary decomposition of electronic operators for avoiding the difficulty due to their nonunitarity, we provided the circuits equipped with at most three ancillae for probabilistic preparation of qubit states on which the necessary nonunitary operators have acted. We performed simulations of such construction of the response functions for $C_2$ and $N_2$ molecules by comparing with the accurate ones based on the FCI calculations. It was found that the accurate detection of subtle structures coming from the weak poles in the response functions requires a large number of measurements.

Since the unitary decomposition of electronic operators is applicable regardless of the adopted qubit representation, an electronic state on which an arbitrary product of the creation and annihilation operators has acted can be prepared at least probabilistically. The approach described in this study thus enables one to access not only the response functions and GFs but also various physical quantities on a quantum computer. Invention and enrichment of tools for such properties will enhance the practical use of quantum computers for material simulations.

Appendix A: Proof for a generic probabilistic state preparation

1. Proof

Here we provide the proof for the validity of circuit \( C_O \) in Fig. 1 for probabilistic state preparation. \( C_O \) is characterized by the \( 2^n - 1 \) parameters, \( \theta^{(n)}, \theta^{(n-1)}, \theta^{(n-1)}, \ldots, \theta^{(2)} \). An arbitrary input state \( |\psi\rangle \) and the linear combination \( O \) of unitaries in eq. (1) \( C_O |\psi\rangle \) up to a normalization constant can be prepared by setting the parameters to appropriate values, as demonstrated below.

We use the notation \( |\Phi_n\rangle = |0\rangle \otimes |\psi\rangle \), \( H_n = H \otimes I \), and \( R_q(-\theta)|q\rangle = |q, \theta\rangle \) for \( q = 0, 1 \). The action of circuit on the initial state \( |\Phi_n\rangle \) can be tracked by referring to the recursive definition in Fig. 2. Specifically, we find

\[
C^{(n)} H_n |\Phi_n\rangle = \frac{1}{\sqrt{2^n}} \otimes C^{(n-1)} H_{n-1} |\Phi_{n-1}\rangle + \frac{1}{\sqrt{2^n}} \otimes C^{(n-1)} H_{n-1} |\Phi_{n-1}\rangle
\]

\[
= \frac{1}{\sqrt{2^n}} \otimes \left[ \begin{array}{c} |0, 0\rangle \otimes |0, 0\rangle \otimes |0, 0\rangle \otimes \cdots \otimes |1, 1\rangle \otimes U_{1\ldots 1} |\psi\rangle + \cdots \\
+ \frac{1}{\sqrt{2^n}} \otimes \left[ \begin{array}{c} |0, 0\rangle \otimes |0, 0\rangle \otimes |0, 0\rangle \otimes \cdots \otimes |1, 1\rangle \otimes U_{1\ldots 1} |\psi\rangle + \cdots \\
\end{array} \right] \right]
\]

(A1)

For each bit string \( k \) of length \( n \), \( U_k \) appears only once on the right-hand side of eq. (A1). If the outcome of a projective measurement on the \( n \) ancillae is \( |0\rangle \otimes \ldots \otimes |0\rangle \), the whole state collapses immediately after the measurement as follows:

\[
C^{(n)} H_n |\Phi_n\rangle |0\rangle \otimes \ldots \otimes |0\rangle \otimes \frac{1}{2^n/2} \left[ \begin{array}{c} \cos \theta^{(n)} \cos \theta^{(n-2)} \ldots \cos \theta^{(2)} U_{0\ldots 0} |\psi\rangle + \cdots \\
+ \cos \theta^{(n)} \cos \theta^{(n-2)} \ldots \cos \theta^{(2)} \sin \theta^{(1)} U_{0\ldots 0} |\psi\rangle + \cdots \\
\vdots \\
+ \sin \theta^{(n)} \sin \theta^{(n-2)} \ldots \sin \theta^{(2)} \sin \theta^{(1)} U_{1\ldots 1} |\psi\rangle + \cdots \\
\end{array} \right]
\]

(A2)

We derived the expression above by using \( \tan \theta = \cos \theta \) and \( \tan \theta = \sin \theta \). In order for the resultant state to be proportional to \( O |\psi\rangle \), we first determine the \( 2^{n-1} \) parameters \( \theta^{(0)}_{0\ldots 0}, \ldots, \theta^{(0)}_{1\ldots 1} \) (each having a bit string of length \( n - 1 \)) such that

\[
\tan \theta^{(1)}_{0\ldots 0} = \frac{c^{(0)}_{0\ldots 01}}{c^{(0)}_{0\ldots 00}}, \tan \theta^{(1)}_{0\ldots 1} = \frac{c^{(0)}_{0\ldots 11}}{c^{(0)}_{0\ldots 10}}, \ldots, \tan \theta^{(1)}_{1\ldots 1} = \frac{c^{(1)}_{1\ldots 11}}{c^{(1)}_{1\ldots 10}}.
\]

(A3)

Next we determine the \( 2^{n-2} \) parameters \( \theta^{(2)}_{0\ldots 0}, \ldots, \theta^{(2)}_{1\ldots 1} \) (each having a bit string of length \( n - 2 \)) such that

\[
\frac{\cos \theta^{(2)}_{0\ldots 0}}{\cos \theta^{(2)}_{0\ldots 00}} \tan \theta^{(2)}_{0\ldots 0} = \frac{c^{(2)}_{0\ldots 010}}{c^{(2)}_{0\ldots 000}}, \frac{\cos \theta^{(2)}_{0\ldots 1}}{\cos \theta^{(2)}_{0\ldots 10}} \tan \theta^{(2)}_{0\ldots 0} = \frac{c^{(2)}_{0\ldots 110}}{c^{(2)}_{0\ldots 100}}, \ldots, \frac{\cos \theta^{(2)}_{1\ldots 1}}{\cos \theta^{(2)}_{1\ldots 10}} \tan \theta^{(2)}_{0\ldots 0} = \frac{c^{(1)}_{1\ldots 110}}{c^{(1)}_{1\ldots 100}}.
\]

(A4)

All the remaining parameters can also be determined in this way, so that the circuit \( C_O \) allows one to prepare the desired state probabilistically.
An example for the determination of parameters for $C_2$ with $n=2$ is provided here. The circuit is parametrized by $\theta_0^{(1)}, \theta_1^{(1)},$ and $\theta^{(2)}$, as depicted in Fig. 15. The whole state immediately before a measurement is

$$\mathcal{C}(2) H_2 |\Phi_2\rangle = |0\rangle \otimes \frac{1}{2} \left[ \cos\theta^{(2)} \cos\theta_0^{(1)} U_{00} + \cos\theta^{(2)} \sin\theta_0^{(1)} U_{01} + \sin\theta^{(2)} \cos\theta_1^{(1)} U_{10} + \sin\theta^{(2)} \sin\theta_1^{(1)} U_{11} \right] |\psi\rangle + \text{(terms involving other ancillary states).}$$  \hspace{1em} (A5)

The probabilistic state preparation is possible by setting the three parameters in the manner described above. $\theta_0^{(1)}$ and $\theta_1^{(1)}$ are determined by the conditions

$$\tan \theta_0^{(1)} = \frac{c_{01}}{c_{00}}, \quad \tan \theta_1^{(1)} = \frac{c_{11}}{c_{10}},$$  \hspace{1em} (A6)

from which $\theta^{(2)}$ is determined by the condition

$$\frac{\cos \theta_1^{(1)}}{\cos \theta_0^{(1)}} \tan \theta^{(2)} = \frac{c_{10}}{c_{00}}.$$  \hspace{1em} (A7)

**Appendix B: Pseudocodes**

Here we provide the pseudocodes for the calculation of response functions proposed in the present study. We assume that all the energy eigenvalues of $N$-electron states have been obtained before entering the main procedure given just below.

1. **Main procedure**

Here is the main procedure. It calls directly or indirectly all the other procedures provided in this Appendix.
Procedure 1 Calculation of charge and spin response functions via statistical sampling

Input:
Hamiltonian \( \mathcal{H} \), number of spatial orbitals \( n_{\text{orbs}} \), \( N \)-electron ground state \( |\Psi_{gs}\rangle \) with its energy \( E_{gs}^{N} \), energy eigenvalues \( E_{\lambda}^{N} \), real frequency \( \omega \), small positive constant \( \delta \), number of measurements \( N_{\text{meas}} \) for each component

Output:
Response functions \( \chi(\omega) \)

1. function CALCRESPFuncs(\( \mathcal{H}, n_{\text{orbs}}, |\Psi_{gs}\rangle, E_{gs}^{N}, E_{\lambda}^{N}, \omega, \delta, N_{\text{meas}} \)
   2. for \( \lambda \)
      3. \( \lambda_{\pm} := \pm(\omega + i\delta) - (E_{\lambda}^{N} - E_{gs}^{N}) \)
      4. \( \chi_{\text{tmp}} := 0 \)
      5. for \( p = 1, \ldots, n_{\text{orbs}} \)
         6. for \( \sigma = \alpha, \beta \)
            7. \( N_{\sigma,\sigma'} := \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, \sigma, N_{\text{meas}}) \)
            8. for \( \lambda \)
               9. \( \chi_{\text{tmp}} += N_{\lambda,\sigma,\sigma'} \times \lambda_{\pm}(1 + \psi_{\lambda,\sigma,\sigma'}^{N} + \psi_{\lambda,\sigma,\sigma'}^{N} / \lambda_{\pm}) \)
               10. for \( j, j' = x, y \)
                   11. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                   12. for \( \sigma, \sigma' = \alpha, \beta \)
                       13. if \( p = p' \) or \( p = p' \) and \( \sigma = \beta \) and \( \sigma' = \alpha \) then
                           14. \( \chi_{\text{tmp}} += N_{\lambda,\sigma,\sigma'} \times \lambda_{\pm}(1 + \psi_{\lambda,\sigma,\sigma'}^{N} + \psi_{\lambda,\sigma,\sigma'}^{N} / \lambda_{\pm}) \)
                           15. for \( j, j' = x, y \)
                               16. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                               17. for \( \lambda \)
                                   18. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                   19. for \( \sigma, \sigma' = \alpha, \beta \)
                                       20. if \( p = p' \) or \( p = p' \) and \( j = y \) and \( j' = x \) then
                                           21. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                           22. for \( \lambda \)
                                               23. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                               24. for \( \sigma, \sigma' = \alpha, \beta \)
                                                   25. if \( p = p' \) or \( p = p' \) and \( j = y \) and \( j' = x \) then
                                                       26. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                       27. for \( \lambda \)
                                                           28. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                           29. for \( \sigma, \sigma' = \alpha, \beta \)
                                                               30. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                               31. for \( \lambda \)
                                                                   32. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                                   33. for \( \sigma, \sigma' = \alpha, \beta \)
                                                                       34. if \( p = p' \) or \( p = p' \) and \( j = y \) and \( j' = x \) then
                                                                           35. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                                           36. for \( \lambda \)
                                                                               37. \( \chi_{\text{tmp}} += \text{AMPLSCHEDDIAG}(\mathcal{H}, |\Psi_{gs}\rangle, E_{\lambda}^{N}, p, j, j', N_{\text{meas}}) \)
                                                                               38. return \( \chi \)

2. Charge-charge contributions

The following procedures calculate the matrix elements in the manner described in Subsection IIC.
a. Diagonal components

**Procedure 2** Calculation of diagonal components of transition matrices

1: function AmplsChargeDiag($\mathcal{H}, |\Psi_{gs}\rangle, E_N, p, \sigma, N_{\text{meas}}$)
2: \(N_{\text{par,par}} := 0\)
3: for \(m = 1, \ldots, N_{\text{meas}}\)
4: Input \(|\Psi_{gs}\rangle\) to \(C_{\text{par}}\) and measure the ancilla \(|q_0\rangle\)
5: if \(|q_0\rangle \equiv |0\rangle\) then
6: \(E := \text{QPE}(|\Psi\rangle, \mathcal{H})\), Find \(E\) among \(\{E_N^\lambda\}_\lambda\)
7: \(N_{\text{par,par}} += 1\)
8: \(N_{\text{par,par}} *= 1/N_{\text{meas}}\)
9: return \(N_{\text{par,par}}\)

b. Off-diagonal components

**Procedure 3** Calculation of off-diagonal components of transition matrices

1: function AmplsChargeOffDiag($\mathcal{H}, |\Psi_{gs}\rangle, E_N, p, p', \sigma, \sigma', N_{\text{meas}}$)
2: \(T_{\pm p\sigma,p'\sigma'} := \text{AmplsChargeAux}($\mathcal{H}, |\Psi_{gs}\rangle, E_N, p, p', \sigma, \sigma', N_{\text{meas}}$)\)
3: \(T_{\pm p'\sigma',p\sigma} := \text{AmplsChargeAux}($\mathcal{H}, |\Psi_{gs}\rangle, E_N, p', p, \sigma, \sigma', N_{\text{meas}}$)\)
4: for \(\lambda\)
5: \(N_{\lambda p\sigma,p'\sigma'} := e^{-i\pi/4}(T_{\lambda p\sigma,p'\sigma'}^- - T_{\lambda p\sigma,p'\sigma'}^+) + e^{i\pi/4}(T_{\lambda p\sigma,p'\sigma'}^- + T_{\lambda p\sigma,p'\sigma'}^+)\)
6: return \(N_{\lambda p\sigma,p'\sigma'}\)

**Procedure 4** Calculation of transition amplitudes for auxiliary states

1: function AmplsChargeAux($\mathcal{H}, |\Psi_{gs}^N\rangle, E_N, p, p', \sigma, \sigma', N_{\text{meas}}$)
2: \(T_{\pm p\sigma,p'\sigma'} := 0\)
3: for \(m = 1, \ldots, N_{\text{meas}}\)
4: Input \(|\Psi_{gs}\rangle\) to \(C_{p\sigma,p'\sigma'}\) and measure the ancilla \(|q_2^\lambda\rangle\) and \(|q_1^\lambda\rangle\)
5: if \(|q_2^\lambda\rangle \otimes |q_1^\lambda\rangle \equiv |0\rangle \otimes |1\rangle\) then
6: \(E := \text{QPE}(|\Psi\rangle, \mathcal{H})\), Find \(E\) among \(\{E_N^\lambda\}_\lambda\)
7: \(T_{\lambda p\sigma,p'\sigma'}^- += 1\)
8: else if \(|q_2^\lambda\rangle \otimes |q_1^\lambda\rangle \equiv |1\rangle \otimes |1\rangle\) then
9: \(E := \text{QPE}(|\Psi\rangle, \mathcal{H})\), Find \(E\) among \(\{E_N^\lambda\}_\lambda\)
10: \(T_{\lambda p\sigma,p'\sigma'}^- += 1\)
11: \(T_{\pm p\sigma,p'\sigma'} *= 1/N_{\text{meas}}\)
12: return \(T_{\pm p\sigma,p'\sigma'}\)

3. Spin-spin contributions

The following procedures calculate the matrix elements in the manner described in Subsection IID.
Procedure 5 Calculation of diagonal components of transition matrices

1: function AmplsSpinDiag(ℋ, ⟨Ψgs⟩, E^N, p, j, N_{meas})
2: S_{pj,pj} := 0
3: for m = 1, ..., N_{meas} do
4:   Input |Ψgs⟩ to C_{pj} and measure the ancilla |q^λ⟩
5:   if |q^λ⟩ ⊥ |q^0⟩ then
6:     E := QPE(⟨Ψ⟩, ℋ), Find E among {E^N_λ} \( \lambda \) \( \lambda \)
7:     S_{λpj,pj} += 1
8: S_{pj,pj} *= (4N_{meas})^{-1}
9: return S_{pj,pj}

Procedure 6 Calculation of off-diagonal components of transition matrices

1: function AmplsSpinOffDiag(ℋ, ⟨Ψgs⟩, E^N, p, p', j, j', N_{meas})
2: T^±_{pj,p'j'} := AmplsSpinAux(ℋ, ⟨Ψgs⟩, E^N, p, p', j, j', N_{meas})
3: T^±_{pj,j'} := AmplsSpinAux(ℋ, ⟨Ψgs⟩, E^N, p, j, j', N_{meas})
4: for λ do
5:   S_{λpj,p'j'} := e^{-iπ/4}(T^+_{λpj,p'j'} - T^-_{λpj,p'j'}) + e^{iπ/4}(T^+_{λpj,p'j'} - T^-_{λpj,p'j'}) \( \text{See eq. (38)} \)
6: return S_{pj,p'j'}

Procedure 7 Calculation of transition amplitudes for auxiliary states

1: function AmplsSpinAux(ℋ, ⟨Ψgs⟩, E^N, p, p', j, j', N_{meas})
2: T^±_{pj,p'j'} := 0
3: for m = 1, ..., N_{meas} do
4:   Input |Ψgs⟩ to C_{pj,p'j'} and measure the ancilla |q^λ⟩ and |q^0⟩
5:   if |q^λ⟩ ⊥ |q^0⟩ then
6:     E := QPE(⟨Ψ⟩, ℋ), Find E among {E^N_λ} \( \lambda \)
7:     T^±_{λpj,p'j'} += 1
8: else if |q^λ⟩ ⊥ |q^0⟩ then
9:     E := QPE(⟨Ψ⟩, ℋ), Find E among {E^N_λ} \( \lambda \)
10: T^±_{λpj,p'j'} += 1
11: T^±_{pj,p'j'} *= (4N_{meas})^{-1}
12: return T^±_{pj,p'j'}

4. Spin-charge contributions

The following procedures calculate the matrix elements in the manner described in Subsection II E.
Procedure 9: Calculation of transition amplitudes for auxiliary states

1. function AmplsSpinChargeAux($\mathcal{H}, |\Psi_{gs}\rangle, E^N, \nu, p, p', j, j', N_{meas}$)
2. $T_{p,j,p',j'}^\nu := 0$
3. for $m = 1, \ldots, N_{meas}$
4. Input $|\Psi_{gs}\rangle$ to $C_{p,j,p',j'}^\nu$, and measure the ancillae $|q_{\nu}^{A}\rangle$ and $|q_{\nu}^{B}\rangle$
5. if $|q_{\nu}^{A}\rangle \otimes |q_{\nu}^{B}\rangle = |0\rangle \otimes |0\rangle$ then
6. $E := \text{QPE}(\Psi, \mathcal{H})$, Find $E$ among $\{E^N\}_\lambda$
7. $T_{p,j,p',j'}^\nu + = 1$
8. $T_{p,j,p',j'}^\nu * = 1/N_{meas}$
9. return $T_{p,j,p',j'}^\nu$
